The sample slots of a Constant Tone Extension shall be numbered from 1 to S.

A_0, A_1, etc. shall be the identifiers of the different antennae in the switching pattern; A_0 shall be the antenna used during the reference period.

Given the IQ samples *I*(*n*) and *Q*(*n*) from sample slot *n*, the phase $\phi(n)$ equals $Arg(I(n) + iQ(n))$.

For $2 < n \leq S$, the relative phase $\theta(n)$ equals

$$principal\left(\phi(n) - 2\phi(n-1) + \phi(n-2)\right)$$

For each antenna A_m except A_0, the set of relative phase values for A_m is:

$$RP(m) = \{\theta(n) | 2 < n \leq S, A_m \text{ used in sample slot n}\}$$

and the mean of the relative phase values is:

$$MRP(m) = Arg\left(\sum_{\theta \in RP(m)} e^{i\theta}\right)$$

For $2 < n < S$, the reference phase deviation $\psi(n)$ equals

$$principal\left(\phi(n+1) - 3\phi(n-1) + 2\phi(n-2)\right)$$

The set of reference phase deviation values is:

$$RPD = \{\psi(n) | 2 < n < S, A_0 \text{ not used in sample slot n}\}$$

and its mean is:

$$MRPD = Arg\left(\sum_{\psi \in RPD} e^{i\psi}\right)$$

If a sample slot *n* has $I(n) = Q(n) = 0$ or has no valid sample available, then $\phi(n)$ and any value derived from it shall be considered undefined. Such undefined values shall be excluded from the sets *RP*(*m*) and *RPD*.

5.2.2 Requirements

For each antenna A_m used in the switching pattern except A_0, the results of the summations in the formulae for *MRP*(*m*) and *MRPD* shall be non-zero.

For each antenna A_m used in the switching pattern except A_0, 95% of the values *v* in the set *RP*(*m*) shall meet –0.52 ≤ *principal* (*v* – *MRP*(*m*)) ≤0.52.

The condition –1.125 ≤ *MRPD* ≤ 1.125 shall be true.

5.2.3 Test switching pattern

When testing the receiver characteristics, the switching patterns specified in Table 5.2 shall be used by an AoD transmitter or an AoA receiver. The antennae A_0, A_1, etc. shall be chosen by the implementation and shall all be different.

Note: A_0 is the antenna used during the reference period.

Number of antennae	Test switching pattern
2	A_0, A_1, A_0, A_0
3	$A_0, A_1, A_0, A_0, A_0, A_2, A_0, A_0$
4 or more	$A_0, A_1, A_0, A_0, A_0, A_2, A_0, A_0, A_0, A_3, A_0, A_0$

Table 5.2: Test switching patterns

5.3 Antenna Switching for Channel Sounding

A device supporting CS that supports an antenna array consisting of two or more antennae may switch between the antennae during the phase measurement period in each CS step that includes CS tone exchanges.

An antenna path is the combination of a given antenna selected by the initiator and a given antenna selected by the reflector, which is further described in [Vol 6] Part H, Section 4.7. The number of antenna paths is designated N_AP, whose value shall be set to a minimum of 1 and a maximum of 4.

Antenna paths are identified using indices AP1, AP2, AP3, AP4, with the maximum index dependent on the value of N_AP selected. Each antenna path is identified using

the colon separated nomenclature of "device A:device B" antenna numbering. Most antenna configurations described below are 1:X or X:1 configurations, where X is in the set of 1 to 4. In these configurations, antenna path AP1 is assigned to the 1:1 antenna combination, AP2 is assigned to the 1:2 or 2:1 combination, AP3 is assigned to the 1:3 or 3:1 combination, and AP4 is assigned to the 1:4 or 4:1 combination. The exception is the 2:2 configuration, where AP1 is assigned to 1:1, AP2 is assigned to 1:2, AP3 is assigned to 2:1 and AP4 is assigned to 2:2.

CS supports four groups of antenna configurations, which are identified by antenna configuration index (ACI) values:

- 1:1 configuration, where both devices A and B support only 1 antenna each
- 1:N_AP configuration, where device A supports 1 antenna, device B supports N_AP antennae, and N_AP is a value in the 2 to 4 range
- N_AP:1 configuration, where device A supports N_AP antennae, device B supports 1 antenna, and N_AP is a value in the 2 to 4 range
- 2:2 configuration, where device A supports 2 antennae, device B supports 2 antennae, and N_AP = 4

There are a total of eight possible combinations of these configurations, as shown in Table 5.3.

Antenna Configuration Index (ACI)	Total Number of Paths	Number of Device A Antennae	Number of Device B Antennae	Configuration
0	1	1	1	1:1
1	2	2	1	N_AP:1
2	3	3	1	N_AP:1
3	4	4	1	N_AP:1
4	2	1	2	1:N_AP
5	3	1	3	1:N_AP
6	4	1	4	1:N_AP
7	4	2	2	2:2

Table 5.3: Supported antenna path configurations for CS

6 PHASE MEASUREMENTS

6.1 Reference receiver for phase-based ranging

The reference down-conversion for the CS tone for step $k = M + 1, \ldots, M + K$, is defined at the antenna of the device as

$$\hat{x}\left(k, p, t\right) = LPF\left[x\left(p, t\right)e^{-j2\pi f_E[k]t}\right]$$

where $x(p,t)$ is the signal at the antenna of the device used in phase measurement period p as defined in Appendix B, $f_E[k]$ is the expected transmit frequency as defined in Section 3.5.2, and LPF is a low-pass filter that removes the high frequency components.

Define the transmission observation window as

$$\mathrm{TxWin}\left[k, p\right] = \left[t_{CT,1}^{TX}[k, p], t_{CT,2}^{TX}\left[k, p\right]\right]$$

Denote the expected start and end times of the CS tone to be received by a device for the kth step in phase measurement period p as $t_{CT,1}^{RX}[k, p]$ and $t_{CT,2}^{RX}[k, p]$, respectively, if a received CS tone exists within that step and phase measurement period. Within this phase measurement period, the time $t = 0$ corresponds to the start of the first transmission within a CS subevent.

The receive observation window is defined as

$$\mathrm{RxWin}\left[k, p\right] = \left[t_{CT,1}^{RX}[k, p], t_{CT,2}^{RX}\left[k, p\right]\right]$$

6.2 Phase measurement accuracy

The observed average transmitted phase for step k, phase measurement period p, is defined as

$$\overline{\Phi_{TX}}\left[k, p\right] = \angle\frac{1}{t_{CT,2}^{TX}[k, p] - t_{CT,1}^{TX}[k, p]}\int_{\mathrm{TxWin}[k]}\hat{x}\left(k, p, t\right)\,\mathrm{dt}$$

The observed average received phase for step k, phase measurement period p, is defined as

$$\overline{\Phi_{RX}}\left[k, p\right] = \angle\frac{1}{t_{CT,2}^{RX}[k, p] - t_{CT,1}^{RX}[k, p]}\int_{\mathrm{RxWin}[k]}\hat{x}\left(k, p, t\right)\,\mathrm{dt}$$

The internal phase offset for step k as described in Section 6.1 is defined as

$$\theta_C[k,p] = principal\left(\overline{\Phi_{TX}}[k,p] - \overline{\Phi_{RX}}[k,p]\right) + \angle PCT[k,p], \quad k = \mathrm{M}+1,\ldots,\mathrm{K}$$

where *principal*(·) is defined in Section 5.2.1 and *PCT*[*k*, *p*] is the phase correction terms for step *k*, phase measurement period *p*, provided by the device.

Denote $\theta_{C,UW}[k,p]$ as the phase-unwrapped version of $\theta_C[k,p]$.

Denote $\alpha[p]f_E[k] + \beta[p]$ as the solution to the linear regression of the set of points defined by ($f_E[k]$, $\theta_{C,UW}[k,p]$). Values of $\theta_{C,UW}[k,p]$, where the quality indication term for the phase measurement provided by the device is not the highest quality the device supports (see [Vol 6] Part H, Section 4.6), are not used in the calculation of the linear regression.

For any subevent where

- a CS tone is exchanged at least once for all CS channels,
- the transmit signal satisfies the conditions for frequency offset described in Section 3.5.2, and
- the receiver input level is -70 dBm,

the solution to the linear regression shall satisfy

$$|\alpha[p]| < 2\pi \times 1.7\text{ns}$$

for 95% of subevents, and

$$|principal(\alpha[p]f_E[k] + \beta[p] - \theta_{C,UW}[k,p])| < 0.28\text{ rad}$$

for 95% of the values of $\theta_C[k,p]$ within a subevent.

6.3 Frequency actuation error correction

If the initiator or reflector is aware of any local frequency actuation error (LFAE), then it shall also compensate for the phase rotation caused by the LFAE. The requirement for this compensation is applicable to both phase measurements over CS tones (see [Vol 6] Part H, Section 4.6), as well as over the sounding sequence payload of the CS_SYNC (see [Vol 6] Part H, Section 3.3.1).

For CS tones the time period over which this compensation occurs is between reception and transmission of the center of the CS tone at the antenna port, T_PM_CENTER_DELTA. For CS step mode-2, T_PM_CENTER_DELTA is specified in [Vol 6] Part H, Section 4.3.3. For CS step mode-3, T_PM_CENTER_DELTA is specified in [Vol 6] Part H, Section 4.3.4. The LFAE represents the frequency offset between the generated frequency and the expected frequency (see Section 3.5.2). In

the absence of any circuit propagation delays or synchronization errors, this correction can be nominally expressed as

$$\angle PCT' = \angle PCT - 2\pi \Delta f_k \times T\_PM\_CENTER\_DELTA$$

where Δf_k represents the frequency actuation error (in Hertz) for that local device at frequency k and the terms in parentheses represent the nominal time separation between the centers of the device's transmitted and received CS tones. Devices should modify this equation as necessary to account for any known circuit delays or synchronization errors impacting this correction.

Similarly, these corrections are also applied to the sounding sequence CS_SYNC field when phase information is extracted. The period over which this compensation occurs is between the reception and transmission of the center of the sounding sequence field at the antenna port, T_SY_CENTER_DELTA. For CS step mode-1, T_SY_CENTER_DELTA is specified in [Vol 6] Part H, Section 4.3.2. For CS step mode-3, T_SY_CENTER_DELTA is specified in [Vol 6] Part H, Section 4.3.4. The LFAE represents the frequency offset between the generated frequency and the expected frequency (see Section 3.5.2). In the absence of any circuit propagation delays or synchronization errors, this correction can be nominally expressed as

$$\angle SS\_PCT' = \angle SS\_PCT - 2\pi \Delta f_k \times T\_SY\_CENTER\_DELTA$$

where Δf_k represents the frequency actuation error (in Hertz) for that local device at frequency k and the terms in parentheses represent the nominal time separation between the centers of the device's transmitted and received sounding sequence fields. Devices should modify this equation as necessary to account for any known circuit delays or synchronization errors impacting this correction.

6.4 Phase measurement timing

The PCT value is measured during the tone's phase measurement period of length T_PM as shown in Figure 6.1. If there is no antenna switching, the phase measurement period of the tone represents the entire tone. If the measurement involves antenna switching, then the phase measurement period of the tone represents the time between antenna switch periods. In addition, a 1 µs tone measurement exclusion period is defined for the receiver (see [Vol 6] Part H, Section 4.6) to compensate for device clock drift, which might introduce some ambiguity as to the precise location of the beginning and end of the phase measurement period. The valid region of the tone is the time between the exclusion periods.

A frequency actuation error will cause the phase of this tone to increase or decrease linearly during a tone. The PCT term should represent the phase measured in the center of the valid region of the tone so that the corrected PCT term described in Section 6.3 can be used to compensate for the local frequency actuation error (LFAE).

A device should not compensate for any residual frequency error it observes during the phase measurement period except its own LFAE.

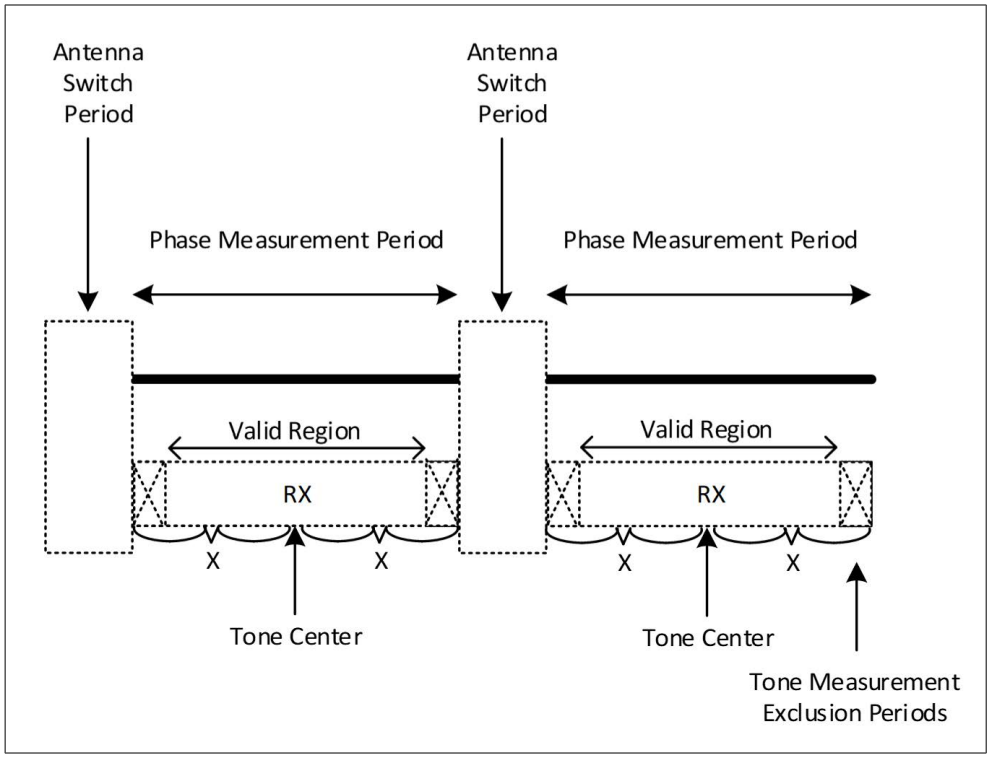

Figure 6.1: Definition of the center of the valid region of the CS tone and CS tone center

In addition to the phase, the amplitude of the PCT is used to convey the measured signal amplitude as described in [Vol 6] Part H, Section 4.6. Any frequency offset caused by a frequency actuation error should not impact the measured amplitude.

Appendix A Test Conditions

A.1 Normal operating conditions

A.1.1 Normal temperature and air humidity

The normal operating temperature shall be declared by the product manufacturer. The nominal test temperature shall be within ±10°C of the normal operating temperature.

A.1.2 Nominal supply voltage

The nominal test voltage for the equipment under normal test conditions shall be the nominal supply voltage as declared by the product manufacturer.

Appendix B Example test equipment setup for Channel Sounding receiver and transmitter

Figure B.1 shows a block diagram of components used to verify CS phase-based and round-trip time reporting accuracy. The vector signal generator represents the reference transmitter and transmits CS tones and packets toward the IUT (Implementation Under Test). The IUT transmits CS tones and packets toward the reference receiver represented by the vector signal analyzer. The vector signal generator and the vector signal analyzer are synchronized with the timing cadence of the CS procedure as described in [Vol 6] Part H, Section 4.5. In Figure B.1, x(t) represents the capture by the vector signal analyzer of the RF signal for each CS step. This capture should be continuous and should include the TX packet from the vector signal generator and the TX packet from the IUT.

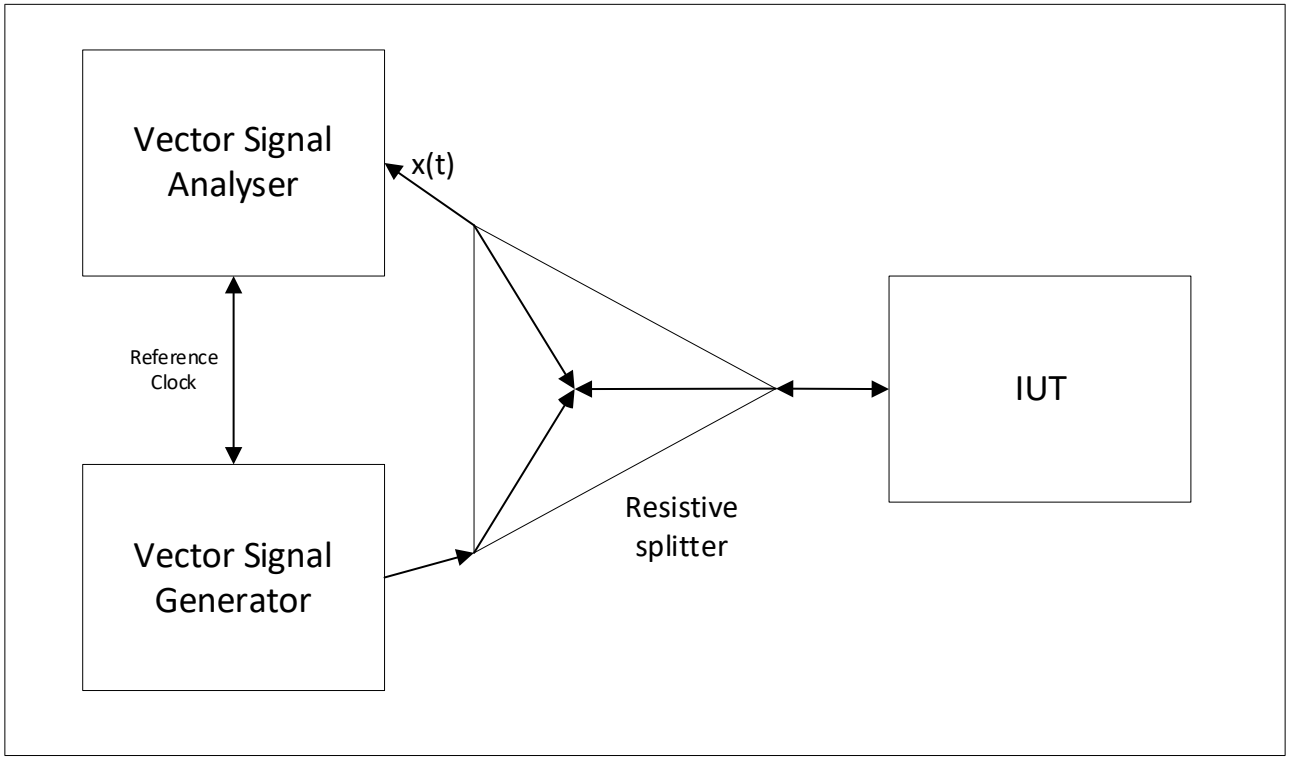

Figure B.1: Channel Sounding reference block diagram

Low Energy Controller
Part B

LINK LAYER SPECIFICATION

This Part describes the Bluetooth Low Energy Link Layer.

CONTENTS

1 GENERAL DESCRIPTION

1.1 Link Layer states

The operation of the Link Layer can be described in terms of a state machine with the following states:

- Standby State
- Advertising State
- Scanning State
- Initiating State
- Connection State
- Synchronization State
- Isochronous Broadcasting State

The Link Layer state machine allows only one state to be active at a time. The Link Layer shall have at least one Link Layer state machine that supports one of Advertising state or Scanning state. The Link Layer may have multiple instances of the Link Layer state machine.

The Link Layer in the Standby state does not transmit or receive any packets. The Standby state can be entered from any other state.

The Link Layer in the Advertising state will be transmitting advertising physical channel packets and possibly listening to and responding to responses triggered by these advertising physical channel packets. A device in the Advertising state is known as an advertiser. The Advertising state can be entered from the Standby state.

The Link Layer in the Scanning state will be listening for advertising physical channel packets from devices that are advertising. A device in the Scanning state is known as a scanner. The Scanning state can be entered from the Standby state.

The Link Layer in the Initiating state will be listening for advertising physical channel packets from a specific device(s) and responding to these packets to initiate a connection with another device. A device in the Initiating state is known as an initiator. The Initiating state can be entered from the Standby state.

The Connection state can be entered either from the Initiating state or the Advertising state. A device in the Connection state is known as being in a connection.

Within the Connection state, two roles are defined:

- Central Role
- Peripheral Role

When entered from the Initiating state, the Connection state shall be in the Central Role. When entered from the Advertising state, the Connection state shall be in the Peripheral Role.

The Link Layer in the Central Role will communicate with a device in the Peripheral Role and defines the timings of transmissions.

The Link Layer in the Peripheral Role will communicate with a single device in the Central Role.

The Link Layer in the Synchronization State will be listening for periodic physical channel packets forming a specific periodic advertising train, coming from a specified device that is transmitting periodic advertising. The Synchronization State can be entered from the Standby State. While in this State, the Host may direct the Link Layer to listen for isochronous data packets coming from a specified device that is transmitting a Broadcast Isochronous Group (BIG). A device that is in the Synchronization State and is receiving isochronous data packets is referred as a Synchronized Receiver.

The Link Layer in the Isochronous Broadcasting State will transmit isochronous data packets on an isochronous physical channel. The Isochronous Broadcasting State can be entered from the Standby State. A device that is in the Isochronous Broadcasting State is referred as an Isochronous Broadcaster.

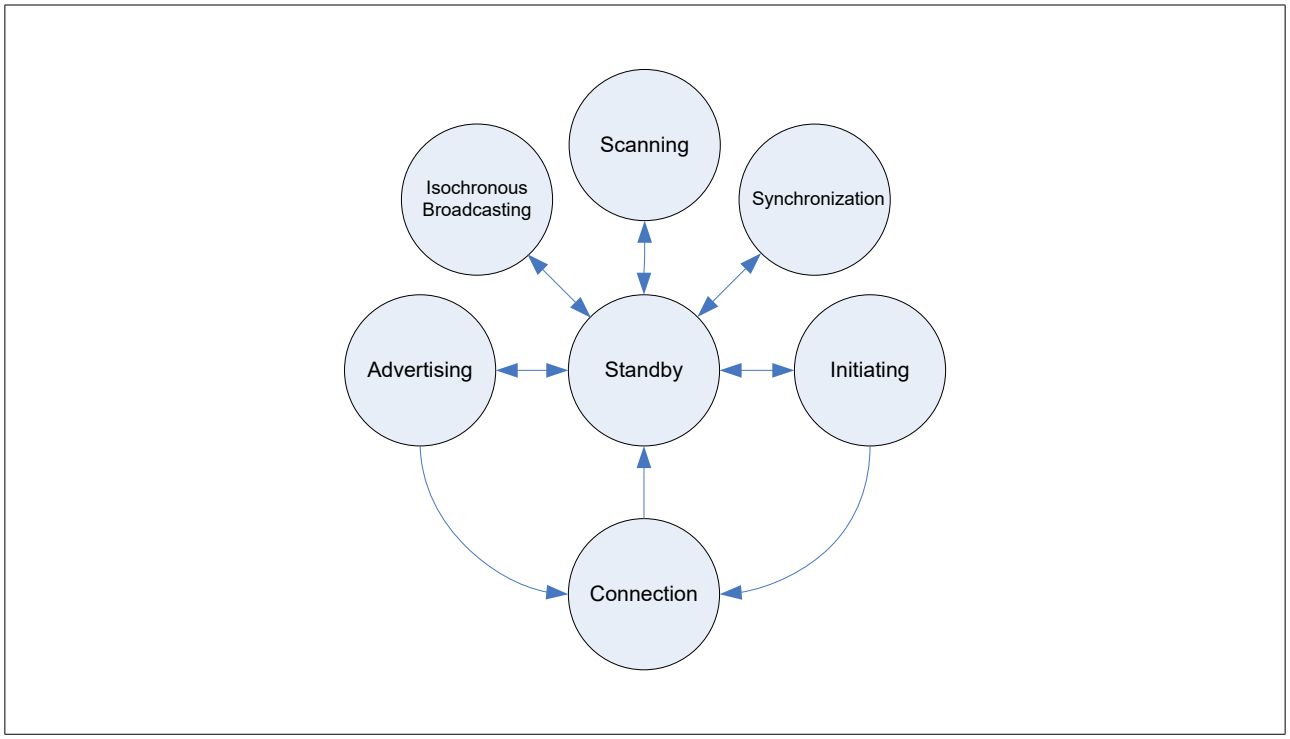

Figure 1.1: State diagram of the Link Layer state machine

1.1.1 Permitted state and role combinations

The Link Layer may optionally support multiple state machines. If it does support multiple state machines, then any combination of states and roles may be supported. In particular, subject to the requirements in Section 4.5, the Link Layer may be in the Connection State multiple times with any mix of Central Role and Peripheral Role.

Note: A device supporting scanning for periodic advertising (see Section 4.4.3.4) must support at least two state machines.

A Link Layer implementation is not required to support all the possible state combinations that are allowed by the specification. However, if it supports a state or state combination given in the "combination A" column of Table 1.1, it shall also support the corresponding state or state combination in the "combination B" column.

Combination A	Combination B
Initiating plus any combination C of other states	Connection (Central role) plus the same combination C
Connection (Central role) plus Initiating plus any combination C of other states	Connection (Central role) to more than one device in the Peripheral role plus the same combination C

Combination A	Combination B
A connectable Advertising state plus any combination C of other states	Connection (Peripheral role) plus the same combination C
Connection (Peripheral role) plus a connectable Advertising state plus any combination C of other states	Connection (Peripheral role) to more than one device in the Central role plus the same combination C

Table 1.1: Requirements on supported states and state combinations

In each case, the combination of other states C may be empty. In the last two rows, "other states" includes other connectable Advertising states.

1.1.2 Devices supporting only some states

Devices supporting only some Link Layer states or only one of the two roles within the Connection state are not required to support features (including supporting particular PDUs, procedures, data lengths, or HCI commands or particular features of an HCI command) that are only used by a state or mode that the device does not support.

1.2 Bit ordering

The bit ordering when defining fields within the packet or Protocol Data Unit (PDU) in the Link Layer specification follows the little-endian format. The following rules apply:

- The Least Significant Bit (LSB) corresponds to b_0
- The LSB is the first bit sent over the air
- In illustrations, the LSB is shown on the left side

Furthermore, data fields defined in the Link Layer, such as the PDU header fields, shall be transmitted with the LSB first. For instance, a 3-bit parameter X=3 is sent as:

$$b_0 b_1 b_2 = 110$$

Over the air, 1 is sent first, 1 is sent next, and 0 is sent last. This is shown as 110 in the specification.

Binary field values specified in the specification that follow the format 0b10101010 (e.g., the advertising physical channel Access Address in Section 2.1.2) are written with the MSB to the left.

Multi-octet fields, with the exception of the Cyclic Redundancy Check (CRC) and the Message Integrity Check (MIC), shall be transmitted with the least significant octet first. Each octet within multi-octet fields, with the exception of the CRC (see Section 3.1.1), shall be transmitted in LSB first order. For example, the 48-bit addresses in the

advertising physical channel PDUs shall be transmitted with the least significant octet first, followed by the remainder of the five octets in increasing order.

Multi-octet field values specified in the specification (e.g. the CRC initial value in Section 2.3.3.1) are written with the most significant octet to the left; for example in 0x112233445566, the octet 0x11 is the most significant octet.

Where a packet or PDU is shown in a figure as containing more than one field, the fields shall be transmitted in the order shown in the figure, leftmost first.

1.3 Device address

Devices are identified using a device address and an address type; the address type indicates either a public device address or a random device address. A public device address and a random device address are both 48 bits in length.

A device shall use at least one type of device address and may use both. The device may be addressed by any device address that it uses.

A device's Identity Address is a Public Device Address or Random Static Device Address that it uses in packets it transmits. If a device is using Resolvable Private Addresses, it shall also have an Identity Address.

Whenever two device addresses are compared, the comparison shall include the device address type (i.e. if the two addresses have different types, they are different even if the two 48-bit addresses are the same).

1.3.1 Public device address

The public device address shall be created in accordance with [Vol 2] Part B, Section 1.2, with the exception that the restriction on LAP values does not apply unless the public device address will also be used as a BD_ADDR for a BR/EDR Controller.

1.3.2 Random device address

The random device address may be of either of the following:

- Static address
- Private address.

The specific sub-type is indicated by the two most significant bits of the random device address as shown in Table 1.2.

Address [47:46]	Sub-Type
0b00	Non-resolvable private address
0b01	Resolvable private address
0b10	Reserved for future use
0b11	Static device address

Table 1.2: Sub-types of random device addresses

The term random device address refers to both static and private address types.

The transmission of a random device address is optional. A device shall accept the reception of a random device address from a remote device.

1.3.2.1 Static device address

A static address is a 48-bit randomly generated address and shall meet the following requirements:

- At least one bit of the random part of the address shall be 0
- At least one bit of the random part of the address shall be 1

The format of a static address is shown in Figure 1.2.

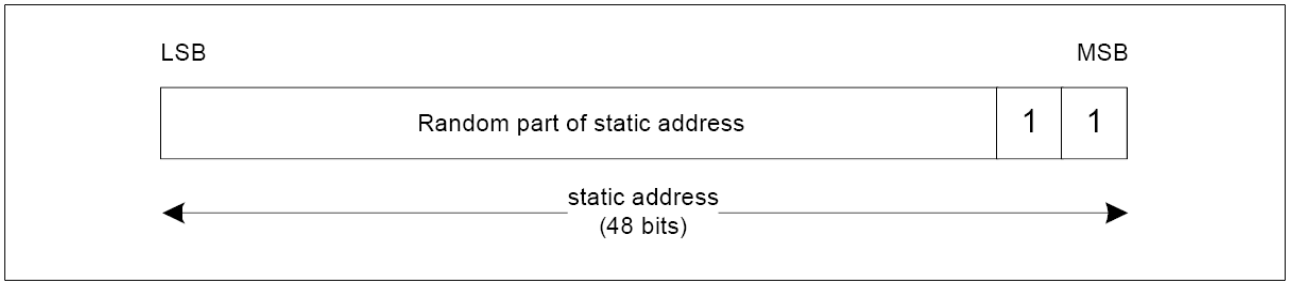

Figure 1.2: Format of static address

A device may choose to initialize its static address to a new value after each power cycle. A device shall not change its static address value once initialized until the device is power cycled.

Note: If the static address of a device is changed, then the address stored in peer devices will not be valid and the ability to reconnect using the old address will be lost.

1.3.2.2 Private device address generation

The private address may be of either of the following two sub-types:

- Non-resolvable private address
- Resolvable private address

To generate a non-resolvable address, the device shall generate a 48-bit address with the following requirements:

- At least one bit of the random part of the address shall be 1
- At least one bit of the random part of the address shall be 0
- The address shall not be equal to the public address

The format of a non-resolvable private address is shown in Figure 1.3.

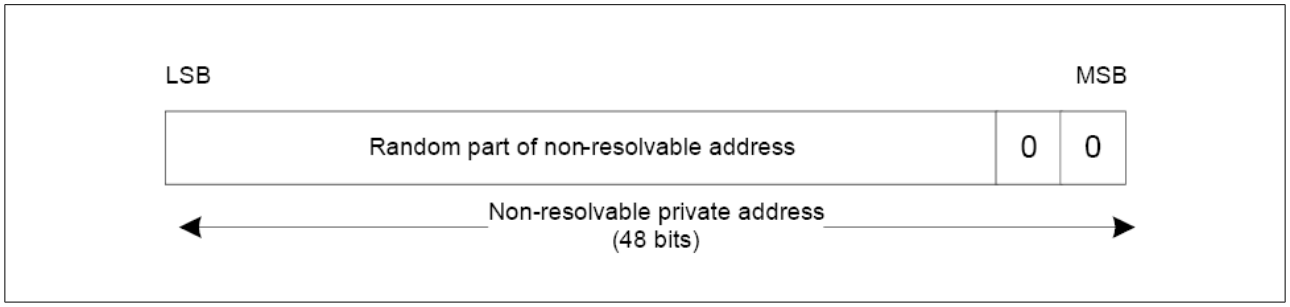

Figure 1.3: Format of non-resolvable private address

To generate a resolvable private address, the device must have either the Local Identity Resolving Key (IRK) or the Peer Identity Resolving Key (IRK). The resolvable private address shall be generated with the IRK and a randomly generated 24-bit number. The random number is known as *prand* and shall meet the following requirements:

- At least one bit of the random part of *prand* shall be 0
- At least one bit of the random part of *prand* shall be 1

The format of the resolvable private address is shown in Figure 1.4.

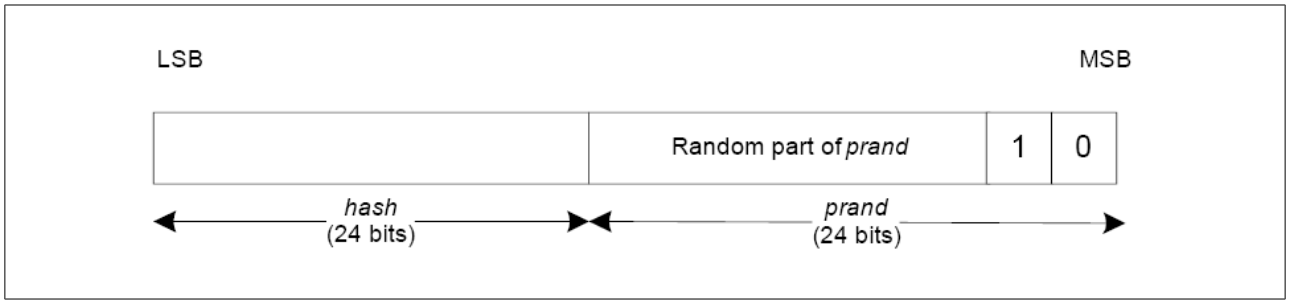

Figure 1.4: Format of resolvable private address

The hash is generated using the random address function *ah* defined in [Vol 3] Part H, Section 2.2.2 with the input parameter *k* set to the device's IRK and the input parameter *r* set to *prand*.

hash = *ah*(IRK, *prand*)

The *prand* and *hash* are concatenated to generate the random address in the following manner:

randomAddress = *prand* || *hash*

The least significant octet of *hash* becomes the least significant octet of *randomAddress* and the most significant octet of *prand* becomes the most significant octet of *randomAddress*.

1.3.2.3 Private device address resolution

A resolvable private address may be resolved if the corresponding device's IRK is available using this procedure. If a resolvable private address is resolved, the device can associate this address with the peer device.

The resolvable private address (*RPA*) is divided into a 24-bit random part (*prand*) and a 24-bit hash part (*hash*). The least significant octet of the *RPA* becomes the least significant octet of *hash* and the most significant octet of *RPA* becomes the most significant octet of *prand*. A *localHash* value is then generated using the random address hash function *ah* defined in [Vol 3] Part H, Section 2.2.2 with the input parameter *k* set to IRK of the known device and the input parameter *r* set to the *prand* value extracted from the *RPA*.

localHash = *ah*(IRK, *prand*)

The *localHash* value is then compared with the *hash* value extracted from *RPA*. If the *localHash* value matches the extracted *hash* value, then the identity of the peer device has been resolved.

If a device has more than one stored IRK, the device repeats the above procedure for each stored IRK to determine if the received resolvable private address is associated

with a stored IRK, until either address resolution is successful for one of the IRKs or all have been tried.

Note: A device that cannot resolve a private address within T_IFS_150 may respond on the reception of the next event.

A non-resolvable private address cannot be resolved.

1.4 Physical channel

As specified in [Vol 6] Part A, Section 2, 40 RF channels are defined in the 2.4 GHz ISM band. These RF channels are divided into 3 RF channels known as the "primary advertising channels", used for initial advertising and all legacy advertising activities, and 37 RF channels known as the "general-purpose channels", used for the majority of communications. Each of these RF channels is allocated a unique channel index (see Section 1.4.1).

These two groups of RF channels are used in four LE physical channels: advertising, periodic, isochronous, and data. The advertising physical channel uses both groups for discovering devices, initiating a connection, and broadcasting data; within this, the primary advertising channels form the primary advertising physical channel and the general-purpose channels form the secondary advertising physical channel. The remaining physical channels only use the general-purpose channels.

Two devices that wish to communicate use a shared physical channel. To achieve this, their transceivers must be tuned to the same RF channel at the same time.

Given that the number of RF channels is limited, and that many Bluetooth devices may be operating independently within the same spatial and temporal area, there is a strong likelihood of two independent Bluetooth devices having their transceivers tuned to the same RF channel, resulting in a physical channel collision. To mitigate the unwanted effects of this collision, each transmission on a physical channel starts with an Access Address that is used as a correlation code by devices tuned to the physical channel. This Access Address is a property of the physical channel. The Access Address is present at the start of every transmitted packet.

The Link Layer uses one physical channel at a given time.

Whenever the Link Layer is synchronized to the timing, frequency, and Access Address of a physical channel, it is said to be 'connected' on the data physical channel or ‘synchronized’ to the periodic physical channel or isochronous physical channel (whether or not it is actively involved in communications over the channel).

1.4.1 Physical channel indices

Table 1.3 shows the mapping from RF Channel to Physical Channel Index and RF Channel group. A '●' in Table 1.3 indicates the RF channel and index are part of the specified channel group; a blank cell indicates that they are not part of that group.

RF Channel (Center Frequency)	Physical Channel Index	RF Channel Group	
		Primary Advertising	General purpose
2402 MHz	37	●	
2404 MHz	0		●
2406 MHz	1		●
...	...	...	...
2424 MHz	10		●
2426 MHz	38	●	
2428 MHz	11		●
2430 MHz	12		●
...	...	...	...
2478 MHz	36		●
2480 MHz	39	●	

Table 1.3: Mapping of RF channel to physical channel index and RF channel group

2 AIR INTERFACE PACKETS

LE devices shall use the packets as defined in the following sections. There are two basic formats: one for the LE Uncoded PHYs, described in Section 2.1, and one for the LE Coded PHY, described in Section 2.2.

Additional packet formats specific to Channel Sounding are defined in [Vol 6] Part H, Section 2.

2.1 Packet format for the LE Uncoded PHYs

The following packet format is defined for the LE Uncoded PHYs (LE 1M and LE 2M) and is used for packets on all physical channels.

This packet format is shown in Figure 2.1. Each packet consists of four mandatory fields and one optional field. The mandatory fields are Preamble, Access Address, PDU, and CRC. The optional field is Constant Tone Extension.

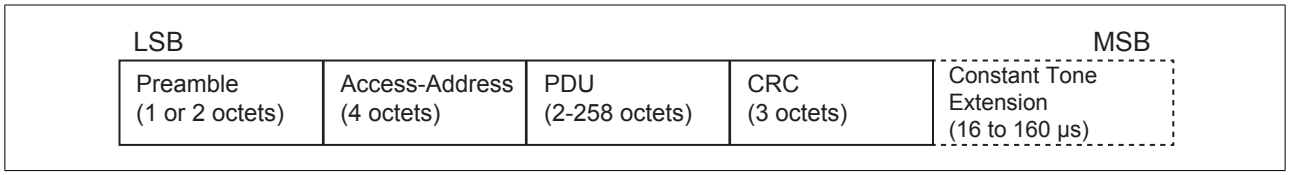

Figure 2.1: Link Layer packet format for the LE Uncoded PHYs

The preamble is 1 octet when transmitting or receiving on the LE 1M PHY and 2 octets when transmitting or receiving on the LE 2M PHY. The Access Address is 4 octets. The PDU range is from 2 to 258 octets. The CRC is 3 octets.

The Preamble is transmitted first, followed by the Access Address, PDU, CRC, and Constant Tone Extension (if present) in that order. The entire packet is transmitted at the same symbol rate (either 1 Msym/s or 2 Msym/s modulation).

Packets (not including the Constant Tone Extension) take between 44 and 2128 µs to transmit.

When the Constant Tone Extension is present, the Constant Tone Extension duration is between 16 and 160 µs, as shown in Figure 2.1.

2.1.1 Preamble

All Link Layer packets have a preamble which is used in the receiver to perform frequency synchronization, symbol timing estimation, and Automatic Gain Control training. The preamble is a fixed sequence of alternating 0 and 1 bits. For packets

transmitted on the LE 1M PHY, the preamble is 8 bits; for packets transmitted on the LE 2M PHY, the preamble is 16 bits. The first bit of the preamble (in transmission order) shall be the same as the LSB of the Access Address. The preamble is shown in Figure 2.2.

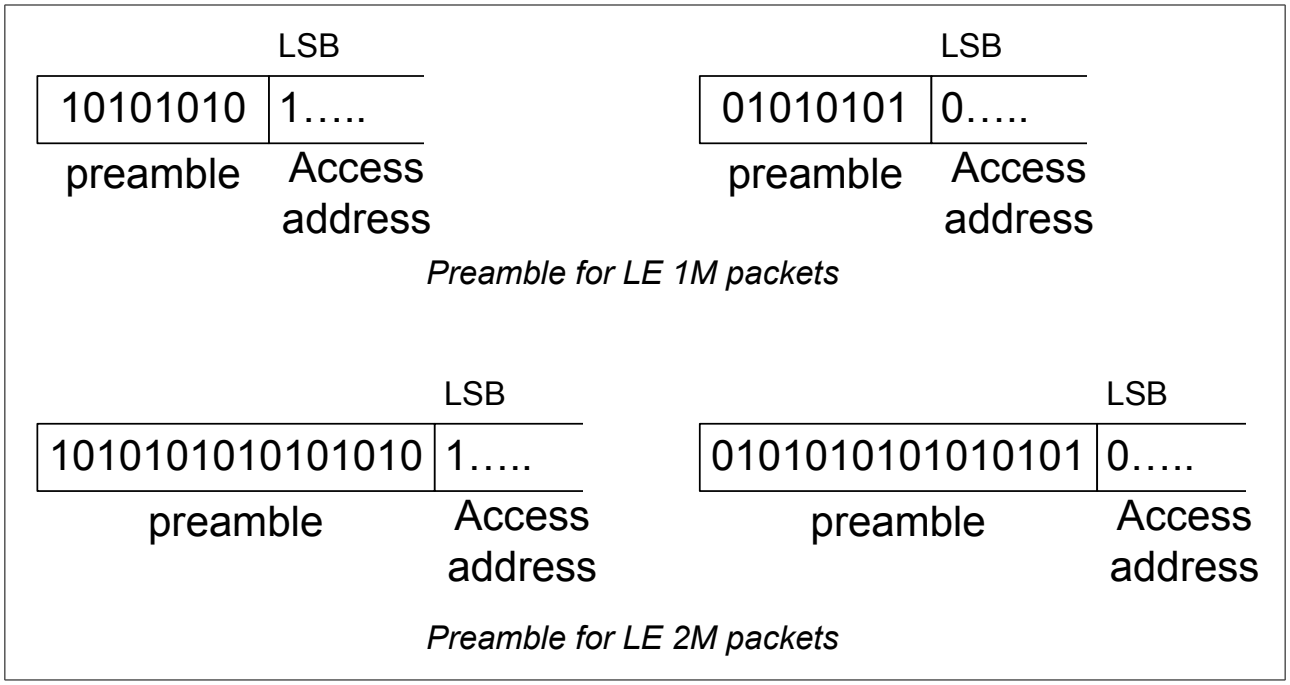

Figure 2.2: Preamble

2.1.2 Access Address

All AUX_SYNC_IND, AUX_CHAIN_IND, AUX_SYNC_SUBEVENT_IND, AUX_CONNECT_REQ, and AUX_CONNECT_RSP PDUs sent on a periodic advertising train shall use the Access Address (AA) value set in the SyncInfo field (see Section 2.3.4.6) contained in the AUX_ADV_IND PDU that describes the train. All AUX_SYNC_SUBEVENT_RSP PDUs sent on a periodic advertising with responses train shall use the Access Address value set in the Periodic Advertising Response Timing Information (see Section 1.24 of [1]) contained in the AUX_ADV_IND PDU that describes the train. For a given periodic advertising with responses train, the AA value of the AUX_SYNC_SUBEVENT_RSP PDUs shall be different from the AA value of the AUX_SYNC_SUBEVENT_IND PDUs.

The Access Address for all other advertising physical channel packets shall be 0b10001110_10001001_10111110_11010110 (0x8E89BED6).

It is intended that each Link Layer connection between any two devices, each BIS, and each periodic advertising train has a different Access Address.

The Link Layer in the Initiating state shall generate a new Access Address for each initiating PDU it sends (see Section 2.3.3.1). The Link Layer in the Advertising state shall generate a new Access Address each time that it enables a periodic advertising train and, for periodic advertising with responses, a second Access Address for the responses. The first address is sent in the SyncInfo field (see Section 2.3.4.6) of PDUs referring to that periodic advertising train and the second in the Periodic Advertising Response Timing Information (see Section 1.24 of [1]) for the train.

The Link Layer in the Central Role in the Connected State shall generate a new Access Address for each Connected Isochronous Stream (CIS) it creates. The address is sent in the Link Layer Control PDU that is used to create the CIS (see Section 2.4.2.31).

The Access Address shall be a 32-bit value. Each time it needs a new Access Address (except for a Broadcast Isochronous Stream (BIS)), the Link Layer shall generate a new random value.

Each Access Address shall meet the following requirements:

- It shall not be the Access Address for any existing ACL connection or CIS on this device.
- It shall not be the Access Address for any enabled periodic advertising train.
- It shall not be the Access Address for any existing BIS on this device.
- It shall not be the Access Address for any existing BIG Control logical link on this device.
- If it is the Access Address for a new CIS, it shall differ by more than one bit from any other Access Address being used on the same device.
- It shall have no more than six consecutive zeros or ones.
- It shall not be the advertising physical channel packets' Access Address.
- It shall not be a sequence that differs from the advertising physical channel packets' Access Address by only one bit.
- It shall not have all four octets equal.
- It shall have no more than 24 transitions.
- It shall have a minimum of two transitions in the most significant six bits.

The Link Layer in the Isochronous Broadcasting State shall generate a new Seed Access Address (SAA) for each BIG. The Access Addresses for the constituent BIS(es) are derived from the SAA. The SAA shall be a random number that meets the following requirements:

$$SAA_{19} = SAA_{15}$$
$$SAA_{22} = SAA_{16} \neq SAA_{15}$$

SAA_{25} = 0
SAA_{23} = 1

For any pair of BIGs transmitted by the same device, the SAA_{15-0} values shall differ in at least two bits.

The Access Address for each BIS and for the BIG Control logical link (see Section 4.4.6.7) in a BIG shall be derived from the SAA for that BIG.

For each BIS logical transport, the Access Address shall be equal to the SAA bit-wise XORed with a diversifier word (DW) for that logical transport derived from a Diversifier (D) as follows:

D = ((35 × n) + 42) *mod* 128 where n is the BIS_Number, or 0 for the BIG Control logical link
DW = 0b$D_0D_0D_0D_0D_0D_0D_1D_6$_$D_10D_5D_40D_3D_20$_00000000_00000000

For example, if n=1, D=77=0b01001101 and DW = 0xFD060000.

The seed for the random number generator shall be from a physical source of entropy and should have at least 20 bits of entropy.

If the random number and, in the case of an SAA, the derived Access Addresses for the BIS and the BIG Control logical link do not meet the above requirements, new random numbers shall be generated until the requirements are met.

On an implementation that also supports the LE Coded PHY (see Section 2.2), the Access Address shall also meet the following requirements:

- It shall have at least three ones in the least significant 8 bits.
- It shall have no more than eleven transitions in the least significant 16 bits.

2.1.3 PDU

The preamble and Access Address are followed by a PDU. When a packet is transmitted on either the primary or secondary advertising physical channel or the periodic physical channel, the PDU shall be the Advertising Physical Channel PDU as defined in Section 2.3. When a packet is transmitted on the data physical channel, the PDU shall be the Data Physical Channel PDU as defined in Section 2.4. When a packet is transmitted on the isochronous physical channel, the PDU shall be one of the Isochronous Physical Channel PDUs as defined in Section 2.6.

2.1.4 CRC

The PDU is followed by a 24-bit CRC. It shall be calculated over the PDU. The CRC polynomial is defined in Section 3.1.1.

2.1.5 Constant Tone Extension

The CRC is followed by an optional Constant Tone Extension, which consists of a constantly modulated series of unwhitened 1s. The Constant Tone Extension is not included in CRC or MIC calculations. The Constant Tone Extension field shall not be present in a packet sent on the isochronous physical channel. The Constant Tone Extension is discussed further in Section 2.5.

2.2 Packet format for the LE Coded PHY

The following packet format is defined for the LE Coded PHY and is used for packets on all physical channels. This packet format is shown in Figure 2.3.

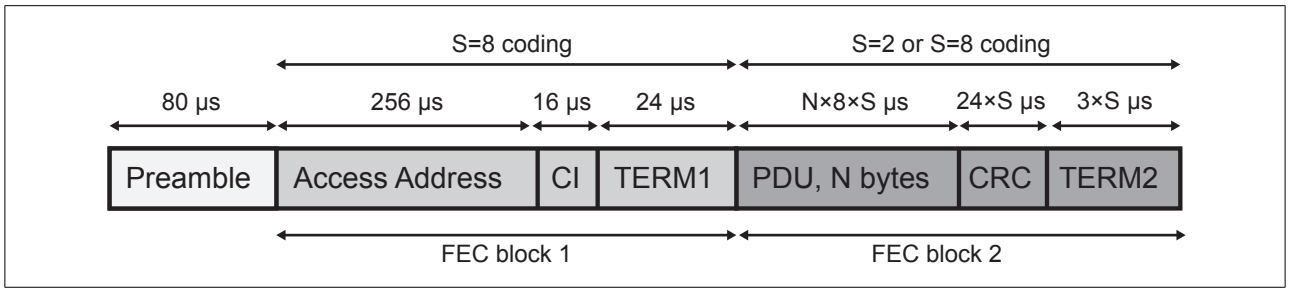

Figure 2.3: Link Layer packet format for the LE Coded PHY

Each packet consists of the Preamble, FEC block 1, and FEC block 2.

The Preamble is not coded.

The FEC block 1 consists of three fields: Access Address, Coding Indicator (CI), and TERM1. These shall use the S=8 coding scheme as defined in Section 3.3.1.

The CI determines which coding scheme is used for FEC block 2.

The FEC block 2 consists of three fields: PDU, CRC, and TERM2. These shall use either the S=2 or S=8 coding scheme as defined in Section 3.3, depending on the value of the CI.

The entire packet is transmitted with 1 Msym/s modulation.

Table 2.1 captures the size and duration of the data packet fields.

	Fields						
	Preamble	**Access Address**	**CI**	**TERM1**	**PDU**	**CRC**	**TERM2**
Number of Bits	Uncoded	32	2	3	16 – 2056	24	3
Duration when using S=8 coding (µs)	80	256	16	24	128 – 16448	192	24
Duration when using S=2 coding (µs)	80	256	16	24	32 – 4112	48	6

Table 2.1: LE Coded PHY field sizes and durations in microseconds

Packets take between 462 and 17040 µs to transmit.

Note: There is no Constant Tone Extension on the LE Coded PHY.

2.2.1 Preamble

The Preamble is 80 symbols in length and consists of 10 repetitions of the symbol pattern '00111100' (in transmission order).

2.2.2 Access Address

The Access Address is specified in Section 2.1.2.

2.2.3 Coding Indicator

The Coding Indicator (CI) consists of two bits as defined in Table 2.2.

CI	**Meaning**
0b00	FEC Block 2 coded using S=8
0b01	FEC Block 2 coded using S=2
All other values	Reserved for future use

Table 2.2: Meaning of CI

2.2.4 PDU

When a packet is transmitted on either the primary or secondary advertising physical channel or the periodic physical channel, the PDU shall be the Advertising Physical Channel PDU as defined in Section 2.3. When a packet is transmitted on the data physical channel, the PDU shall be the Data Physical Channel PDU as defined in Section 2.4. When a packet is transmitted on the isochronous physical channel, the PDU shall be one of the Isochronous Physical Channel PDUs as defined in Section 2.6.

2.2.5 CRC

The CRC is 24 bits in length and the value is calculated over all the PDU bits. The CRC generator polynomial is defined in Section 3.1.1.

2.2.6 TERM1 and TERM2

There is a terminator at the end of each FEC block referred to as TERM1 and TERM2. Each terminator is 3 bits long and forms the termination sequence defined in Section 3.3.1.

2.3 Advertising physical channel PDU

Note: Despite the name, the advertising physical channel PDU is also used on the periodic physical channel.

The advertising physical channel PDU has a 16-bit Header field and a variable size Payload field. Its format is as shown in Figure 2.4. The 16-bit Header field of the advertising physical channel PDU is as shown in Figure 2.5.

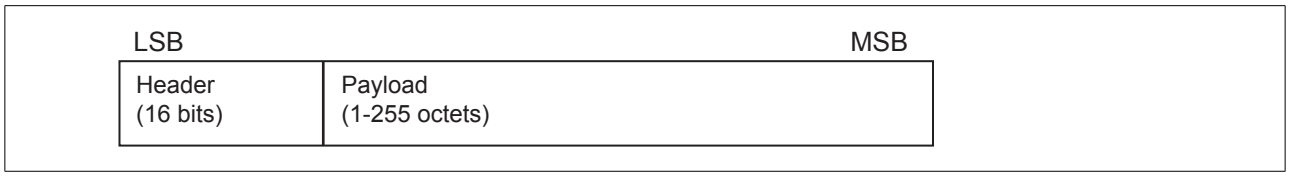

Figure 2.4: Advertising physical channel PDU

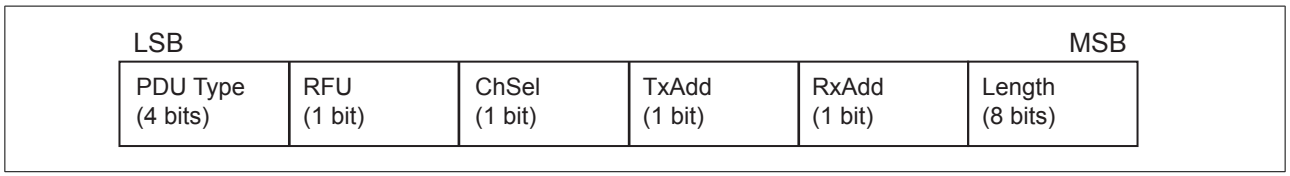

Figure 2.5: Advertising physical channel PDU header

The PDU Type field of the advertising physical channel PDU that is contained in the Header field indicates the PDU type as defined in Table 2.3, which also shows which channel and which PHYs the packet may appear on. A '●' in Table 2.3 indicates that the PDU may appear on that PHY; a blank cell indicates that the PDU shall not appear on that PHY.

PDU Type	PDU Name	Physical Channel	Permitted PHYs		
			LE 1M	LE 2M	LE Coded
0b0000	ADV_IND	Primary Advertising	•		
0b0001	ADV_DIRECT_IND	Primary Advertising	•		
0b0010	ADV_NONCONN_IND	Primary Advertising	•		
0b0011	SCAN_REQ	Primary Advertising	•		
	AUX_SCAN_REQ	Secondary Advertising	•	•	•
0b0100	SCAN_RSP	Primary Advertising	•		
0b0101	CONNECT_IND	Primary Advertising	•		
	AUX_CONNECT_REQ	Secondary Advertising	•	•	•
0b0110	ADV_SCAN_IND	Primary Advertising	•		
0b0111	ADV_EXT_IND	Primary Advertising	•		•
	AUX_ADV_IND	Secondary Advertising	•	•	•
	AUX_SCAN_RSP	Secondary Advertising	•	•	•
	AUX_SYNC_IND	Periodic	•	•	•
	AUX_CHAIN_IND	Secondary Advertising and Periodic	•	•	•
	AUX_SYNC_SUBEVENT_-IND	Periodic	•	•	•
	AUX_SYNC_SUBEVENT_-RSP	Periodic	•	•	•
0b1000	AUX_CONNECT_RSP	Secondary Advertising	•	•	•
0b1001	ADV_DECISION_IND	Primary Advertising	•		•
All other values	Reserved for future use				

Table 2.3: Advertising physical channel PDU header's PDU Type field encoding

The ChSel, TxAdd and RxAdd fields of the advertising physical channel PDU that are contained in the Header field contain information specific to the PDU type defined for each advertising physical channel PDU separately. If the ChSel, TxAdd or RxAdd fields are not defined as used in a given PDU then they shall be considered reserved for future use.

The Length field of the advertising physical channel PDU Header field indicates the length of the Payload field in octets. The valid range of the Length field shall be 1 to 255 octets.

The Payload fields in the advertising physical channel PDUs are specific to the PDU Type and are defined in Section 2.3.1 to Section 2.3.4. The PDU Types marked as Reserved for future use shall not be sent and shall be ignored upon receipt.

Within advertising physical channel PDUs, advertising data or scan response data from the Host may be included in the Payload field in some PDU Types. The format of this data is defined in [Vol 3] Part C, Section 11.

Some advertising physical channel PDUs contain an AuxPtr field (see Section 2.3.4.5) which points to a packet containing another advertising physical channel PDU. In this case, the second packet and PDU are the *auxiliary packet* and *auxiliary PDU* of the original PDU, which in turn is the *superior packet* and *superior PDU* of the second one.

Note: A PDU can only have one auxiliary PDU but more than one superior PDU.

Given a packet, its *subordinate set* consists of its auxiliary packet, if any, and the subordinate set of the auxiliary packet. A packet without an AuxPtr field has an empty subordinate set.

2.3.1 Advertising PDUs

The following advertising physical channel PDU Types are called advertising PDUs:

- ADV_IND
- ADV_DIRECT_IND
- ADV_NONCONN_IND
- ADV_SCAN_IND
- ADV_EXT_IND
- ADV_DECISION_IND
- AUX_ADV_IND
- AUX_SYNC_IND
- AUX_CHAIN_IND
- AUX_SYNC_SUBEVENT_IND
- AUX_SYNC_SUBEVENT_RSP

These PDUs are sent by the Link Layer in the Advertising state and received by a Link Layer in the Scanning state or Initiating state. The ADV_IND, ADV_DIRECT_IND, ADV_NONCONN_IND, and ADV_SCAN_IND PDUs are called “legacy advertising PDUs”. The ADV_EXT_IND, ADV_DECISION_IND, AUX_ADV_IND, AUX_SYNC_IND, AUX_CHAIN_IND, AUX_SYNC_SUBEVENT_IND, and AUX_SYNC_SUBEVENT_RSP PDUs are called “extended advertising PDUs”. The ADV_DECISION_IND PDU is also

called a “decision PDU”. Advertising events using legacy advertising PDUs are called “legacy advertising events”.

2.3.1.1 ADV_IND

The Payload field of the ADV_IND PDU is shown in Figure 2.6. The PDU shall be used in connectable and scannable undirected advertising events. The TxAdd in the advertising physical channel PDU Header field indicates whether the advertiser’s address in the AdvA field is public (TxAdd = 0) or random (TxAdd = 1). The ChSel field in the advertising physical channel PDU Header field shall be set to 1 if the advertiser supports the LE Channel Selection Algorithm #2 feature (see Section 4.5.8.3).

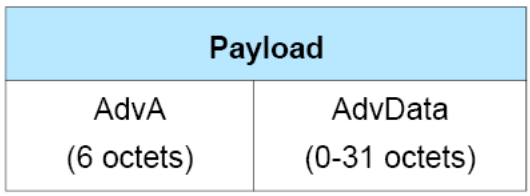

Figure 2.6: ADV_IND PDU payload

The AdvA field shall contain the advertiser’s public or random device address as indicated by TxAdd. The AdvData field, if not empty, shall contain Advertising Data from the advertiser’s Host.

2.3.1.2 ADV_DIRECT_IND

The Payload field of the ADV_DIRECT_IND PDU is shown in Figure 2.7. The PDU shall only be used in connectable directed advertising events. The TxAdd in the advertising physical channel PDU Header field indicates whether the advertiser’s address in the AdvA field is public (TxAdd = 0) or random (TxAdd = 1). The RxAdd in the advertising physical channel PDU Header field indicates whether the target’s address in the TargetA field is public (RxAdd = 0) or random (RxAdd = 1). The ChSel field in the advertising physical channel PDU Header field shall be set to 1 if the advertiser supports the LE Channel Selection Algorithm #2 feature (see Section 4.5.8.3).

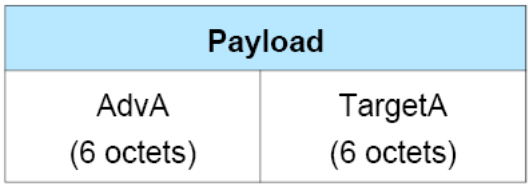

Figure 2.7: ADV_DIRECT_IND PDU Payload

The AdvA field shall contain the advertiser’s public or random device address as indicated by TxAdd. The TargetA field is the address of the device to which this PDU is addressed. The TargetA field shall contain the target’s public or random device address as indicated by RxAdd.

Note: This packet does not contain any Host data.

2.3.1.3 ADV_NONCONN_IND

The Payload field of the ADV_NONCONN_IND PDU is shown in Figure 2.8. The PDU shall only be used in non-connectable and non-scannable undirected advertising events. The TxAdd in the advertising physical channel PDU Header field indicates whether the advertiser's address in the AdvA field is public (TxAdd = 0) or random (TxAdd = 1).

Payload	
AdvA (6 octets)	AdvData (0-31 octets)

Figure 2.8: ADV_NONCONN_IND PDU Payload

The AdvA field shall contain the advertiser's public or random device address as indicated by TxAdd. The AdvData field, if not empty, shall contain Advertising Data from the advertiser's Host.

2.3.1.4 ADV_SCAN_IND

The Payload field of the ADV_SCAN_IND PDU is shown in Figure 2.9. The PDU shall only be used in scannable undirected advertising events. The TxAdd in the advertising physical channel PDU Header field indicates whether the advertiser's address in the AdvA field is public (TxAdd = 0) or random (TxAdd = 1).

Payload	
AdvA (6 octets)	AdvData (0-31 octets)

Figure 2.9: ADV_SCAN_IND PDU Payload

The AdvA field shall contain the advertiser's public or random device address as indicated by TxAdd. The AdvData field, if not empty, shall contain Advertising Data from the advertiser's Host.

2.3.1.5 ADV_EXT_IND

The ADV_EXT_IND PDU uses the Common Extended Advertising Payload Format described in Section 2.3.4. The PDU may be used in the advertising events indicated by the AdvMode field value. An advertising event using an ADV_EXT_IND PDU is directed

if, and only if, either the TargetA field is present or the AuxPtr field is present and points to a PDU where the TargetA field is present.

The Common Extended Advertising Payload Format fields permitted in the ADV_EXT_IND PDU are shown in Table 2.4.

		Common Extended Advertising Payload Format fields								
Event Type	**Adv Mode**	**AdvA**	**TargetA**	**CTE Info**	**ADI**	**Aux Ptr**	**Sync Info**	**Tx Power**	**ACAD**	**Adv Data**
Non-Connectable and Non-Scannable Undirected without auxiliary packet	0b00	M	X	X	X	X	X	O	X	X
Non-Connectable and Non-Scannable Undirected with auxiliary packet	0b00	C.1	X	X	M	M	X	C.1	X	X
Non-Connectable and Non-Scannable Directed without auxiliary packet	0b00	M	M	X	X	X	X	O	X	X
Non-Connectable and Non-Scannable Directed with auxiliary packet	0b00	C.1	C.1	X	M	M	X	C.1	X	X
Connectable Undirected	0b01	X	X	X	M	M	X	C.1	X	X

		Common Extended Advertising Payload Format fields								
Event Type	**Adv Mode**	**AdvA**	**TargetA**	**CTE Info**	**ADI**	**Aux Ptr**	**Sync Info**	**Tx Power**	**ACAD**	**Adv Data**
Connecta-ble Direc-ted	0b01	X	X	X	M	M	X	C.1	X	X
Scannable Undirec-ted	0b10	X	X	X	M	M	X	C.1	X	X
Scannable Directed	0b10	X	X	X	M	M	X	C.1	X	X
RFU	0b11									
C.1: This field is optional on the LE 1M PHY and reserved for future use on the LE Coded PHY.										

Table 2.4: Common Extended Advertising Payload Format fields permitted in the ADV_EXT_IND PDU

For the non-connectable and non-scannable directed and non-connectable and non-scannable undirected event types without ACAD or AdvData, the Controller can choose whether or not to use an auxiliary packet. See Section 4.4.2.6 and Section 4.4.2.9.

Fields reserved for future use shall not be present when the packet is sent and shall be ignored when received.

Any auxiliary packet shall be an AUX_ADV_IND packet.

2.3.1.6 AUX_ADV_IND

The AUX_ADV_IND PDU uses the Common Extended Advertising Payload Format described in Section 2.3.4. The PDU may be used in the advertising events indicated by the AdvMode field value.

The AdvMode field indicates the type of advertising event the AUX_ADV_IND packet is being used for and shall have the same value as the field in the superior PDU of this PDU.

The Common Extended Advertising Payload Format fields permitted in the AUX_ADV_IND PDU are shown in Table 2.5.

The PHY used for the AUX_ADV_IND shall be specified in the AuxPtr field of the superior PDU. The PHY specified in any AuxPtr field in an AUX_ADV_IND PDU shall be the same as the PHY the PDU was sent on.

If this PDU and its superior PDU both have an ADI field, the values in these fields shall be the same.

Note: The ADI field can be used to detect collisions.

Any auxiliary PDU shall be an AUX_CHAIN_IND PDU.

The SyncInfo field, when present, shall point to an AUX_SYNC_IND PDU.

		Common Extended Advertising Payload Format fields								
Adv Mode	**Event Type**	**AdvA**	**TargetA**	**CTE Info**	**ADI**	**Aux Ptr**	**Sync Info**	**Tx Power**	**ACAD**	**Adv Data**
0b00	Non-Connectable and Non-Scannable Undirected	C.1	X	X	M	O	O	O	O	O
0b00	Non-Connectable and Non-Scannable Directed	C.1	C.2	X	M	O	O	O	O	O
0b01	Connectable Undirected	C.2	X	X	M	X	X	O	O	O
0b01	Connectable Directed	M	M	X	M	X	X	O	O	O
0b10	Scannable Undirected	C.2	X	X	M	X	X	O	O	X
0b10	Scannable Directed	M	M	X	M	X	X	O	O	X
0b11	RFU									

C.1: This field is optional if the corresponding field in the superior PDU of this PDU is not present, otherwise it is reserved for future use.

C.2: This field is mandatory if the corresponding field in the superior PDU of this PDU is not present, otherwise it is reserved for future use.

Table 2.5: Common Extended Advertising Payload Format fields permitted in the AUX_ADV_IND PDU

2.3.1.7 AUX_SYNC_IND

The AUX_SYNC_IND PDU uses the Common Extended Advertising Payload Format described in Section 2.3.4. The PDU is used in periodic advertising.

The AdvMode field shall be set to 0b00.

The Common Extended Advertising Payload Format fields permitted in the AUX_SYNC_IND PDU are shown in Table 2.6.

The PHY used for the AUX_SYNC_IND PDU shall be that specified in Section 4.4.2.12.

Any auxiliary PDU shall be an AUX_CHAIN_IND PDU.

The Advertising SID subfield of the ADI field shall have the same value as that in the superior PDU of this PDU.

		Common Extended Advertising Payload Format fields								
Adv Mode	**Event Type**	**AdvA**	**TargetA**	**CTE Info**	**ADI**	**Aux Ptr**	**Sync Info**	**Tx Power**	**ACAD**	**Adv Data**
0b00	Non-Connectable and Non-Scannable Undirected	X	X	O	O	O	X	O	O	O
0b01 to 0b11	RFU									

Table 2.6: Common Extended Advertising Payload Format fields permitted in the AUX_SYNC_IND PDU

2.3.1.8 AUX_CHAIN_IND

The AUX_CHAIN_IND PDU uses the Common Extended Advertising Payload Format described in Section 2.3.4. The PDU is used to hold additional AdvData. Its superior PDU is an AUX_ADV_IND, AUX_SYNC_IND, AUX_SCAN_RSP or another AUX_CHAIN_IND PDU.

The AdvMode field shall be set to 0b00.

The Common Extended Advertising Payload Format fields permitted in the AUX_CHAIN_IND PDU are shown in Table 2.7.

The PHY used for the AUX_CHAIN_IND PDU shall be the same as the PHY used for its superior PDU.

The ADI field, when present, shall have the same value as the field in the superior PDU.

Note: The ADI field can be used to detect collisions.

Any auxiliary PDU shall be another AUX_CHAIN_IND PDU.

		Common Extended Advertising Payload Format fields								
Adv Mode	**Event Type**	**AdvA**	**TargetA**	**CTE Info**	**ADI**	**Aux Ptr**	**Sync Info**	**Tx Power**	**ACAD**	**Adv Data**
0b00	Chained data	X	X	C.2	C.1	O	X	O	X	O
0b01 to 0b11	RFU									

C.1: This field is mandatory if the corresponding field in the superior PDU of this PDU is present, otherwise it is reserved for future use.

C.2: This field is optional if the corresponding field in the superior PDU of this PDU is present, otherwise it is reserved for future use.

Table 2.7: Common Extended Advertising Payload Format fields permitted in the AUX_CHAIN_IND PDU

2.3.1.9 AUX_SYNC_SUBEVENT_IND

The AUX_SYNC_SUBEVENT_IND PDU uses the Common Extended Advertising Payload Format described in Section 2.3.4. This PDU is used in PAwR.

The AdvMode field shall be set to 0x00.

The Common Extended Advertising Payload Format fields permitted in the AUX_SYNC_SUBEVENT_IND PDU are shown in Table 2.8.

The PHY used for the AUX_SYNC_SUBEVENT_IND shall be that specified in Section 4.4.2.12.

The Advertising SID subfield of the ADI field shall have the same value as that in the superior PDU of this PDU.

		Common Extended Advertising Payload Format fields								
Adv Mode	**Event Type**	**AdvA**	**TargetA**	**CTE Info**	**ADI**	**Aux Ptr**	**Sync Info**	**Tx Power**	**ACAD**	**Adv Data**
0b00	Sube-vent Indica-tion	X	X	O	O	X	X	O	O	O
0b01 to 0b11	RFU									

Table 2.8: Common Extended Advertising Payload Format fields permitted in the AUX_SYNC_SUBEVENT_IND PDU

2.3.1.10 AUX_SYNC_SUBEVENT_RSP

The AUX_SYNC_SUBEVENT_RSP PDU uses the Common Extended Advertising Payload Format described in Section 2.3.4. This PDU is used in PAwR.

The AdvMode field shall be set to 0x00.

The Common Extended Advertising Payload Format fields permitted in the AUX_SYNC_SUBEVENT_RSP PDU are shown in Table 2.9.

The PHY used for the AUX_SYNC_SUBEVENT_RSP shall be that specified in Section 4.4.2.12.

		Common Extended Advertising Payload Format fields								
Adv Mode	**Event Type**	**AdvA**	**TargetA**	**CTE Info**	**ADI**	**Aux Ptr**	**Sync Info**	**Tx Power**	**ACAD**	**Adv Data**
0b00	Sube-vent Re-sponse	O	X	O	X	X	X	O	O	O
0b01 to 0b11	RFU									

Table 2.9: Common Extended Advertising Payload Format fields permitted in the AUX_SYNC_SUBEVENT_RSP PDU

2.3.1.11 ADV_DECISION_IND

The Payload field of the ADV_DECISION_IND PDU is shown in Figure 2.10. The PDU may be used in the undirected advertising events indicated by the AdvMode field value.

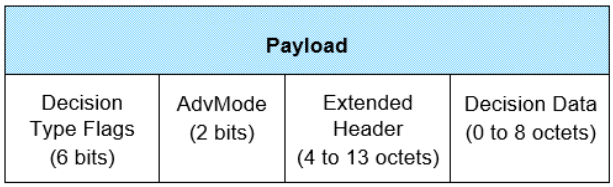

Figure 2.10: ADV_DECISION_IND payload

The Extended Header field is the same as the Extended Header field of the Common Extended Advertising Payload Format (see Section 2.3.4); the fields permitted in the ADV_DECISION_IND PDU are shown in Table 2.10.

		Common Extended Advertising Payload Format Extended Header fields							
Adv Mode	**Event Type**	**AdvA**	**TargetA**	**CTEInfo**	**ADI**	**AuxPtr**	**SyncInfo**	**TxPower**	**ACAD**
0b00	Non-Connectable and Non-Scannable Undirected	O	X	X	O	M	X	C.1	X
0b01	Connectable Undirected	O	X	X	O	M	X	C.1	X
0b10	Scannable Undirected	O	X	X	O	M	X	C.1	X
0b11	RFU								
C.1: This field is optional on the LE 1M PHY and reserved for future use on the LE Coded PHY.									

Table 2.10: Common Extended Advertising Payload Format fields permitted in the ADV_DECISION_IND PDU

The format of the Decision Data field is shown in Figure 2.11:

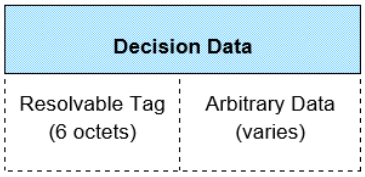

Figure 2.11: Decision Data format

The Decision Type Flags bit field definitions are listed in Table 2.11.

Bit number	Subfield
0	Resolvable Tag
All other bits	Reserved for future use

Table 2.11: Decision Type Flags field interpretation

If a bit in the Decision Type Flags field is set to 1, then the corresponding subfield of Decision Data shall be present; otherwise, the corresponding subfield shall not be present. Therefore, the Decision Data field must be long enough to hold all the subfields indicated in the Decision Type Flags field. Any octets of the Decision Data following these subfields form the Arbitrary Data subfield.

A Resolvable Tag shall have the format shown in Figure 2.12.

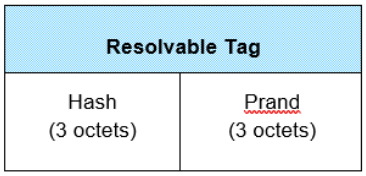

Figure 2.12: Resolvable Tag format

A Resolvable Tag is said to resolve against a key provided by the Host if the Hash field equals the value *ah*(*key, prand*), where *prand* is the value of the Prand field and *ah* is the function defined in [Vol 3] Part H, Section 2.2.2.

The auxiliary PDU shall be an AUX_ADV_IND PDU.

2.3.2 Scanning PDUs

The following advertising physical channel PDU types are called scanning PDUs.

- SCAN_REQ
- SCAN_RSP
- AUX_SCAN_REQ
- AUX_SCAN_RSP

The SCAN_REQ and AUX_SCAN_REQ PDUs are called scan request PDUs. The SCAN_RSP and AUX_SCAN_RSP PDUs are called scan response PDUs.

Where these PDUs are used to reply to a scannable advertisement, the PHY used for them shall be the same as the PHY used for the PDU that they reply to.

2.3.2.1 SCAN_REQ and AUX_SCAN_REQ

The Payload field of the SCAN_REQ and AUX_SCAN_REQ PDUs is shown in Figure 2.13. The TxAdd in the advertising physical channel PDU Header field indicates whether the scanner's address in the ScanA field is public (TxAdd = 0) or random (TxAdd = 1). The RxAdd in the advertising physical channel PDU Header field indicates whether the advertiser's address in the AdvA field is public (RxAdd = 0) or random (RxAdd = 1).

Payload	
ScanA (6 octets)	AdvA (6 octets)

Figure 2.13: SCAN_REQ and AUX_SCAN_REQ PDU Payload

The ScanA field shall contain the scanner's public or random device address as indicated by TxAdd. The AdvA field is the address of the device to which this PDU is addressed. The AdvA field shall contain the advertiser's public or random device address as indicated by RxAdd.

Note: These PDUs do not contain any Host Data.

2.3.2.2 SCAN_RSP

The Payload field of the SCAN_RSP PDU is shown in Figure 2.14. The TxAdd in the advertising physical channel PDU Header field indicates whether the advertiser's address in the AdvA field is public (TxAdd = 0) or random (TxAdd = 1). The Length field indicates the size of the Payload field (AdvA and ScanRspData) in octets.

Payload	
AdvA (6 octets)	ScanRspData (0-31 octets)

Figure 2.14: SCAN_RSP PDU Payload

The AdvA field shall contain the advertiser's public or random device address as indicated by TxAdd. The ScanRspData field may contain any data from the advertiser's Host.

2.3.2.3 AUX_SCAN_RSP

The AUX_SCAN_RSP PDU uses the Common Extended Advertising Payload Format described in Section 2.3.4.

The AdvMode field shall be set to 0b00.

The Common Extended Advertising Payload Format fields permitted in the AUX_SCAN_RSP PDU are shown in Table 2.12.

The ADI field, if present, shall have the same value as the field in the AUX_ADV_IND PDU that the scanner responded to.

Note: The ADI field can be used to detect collisions.

Any auxiliary PDU shall be an AUX_CHAIN_IND PDU.

		Common Extended Advertising Payload Format fields								
Adv Mode	**Event Type**	**AdvA**	**TargetA**	**CTE Info**	**ADI**	**Aux Ptr**	**Sync Info**	**Tx Power**	**ACAD**	**Adv Data**
0b00	Scan re-sponse	M	X	X	O	O	X	O	O	M
0b01 to 0b11	RFU									

Table 2.12: Common Extended Advertising Payload Format fields permitted in the AUX_SCAN_RSP PDU

2.3.3 Initiating PDUs

The following advertising physical channel PDU Types are called initiating PDUs:

- CONNECT_IND
- AUX_CONNECT_REQ
- AUX_CONNECT_RSP

The CONNECT_IND and the AUX_CONNECT_REQ PDUs are sent by the Link Layer in the Initiating state and received by the Link Layer in the Advertising state. The AUX_CONNECT_RSP PDU is sent by the Link Layer in the Advertising state and received by the Link Layer in the Initiating state.

The PHY used for these PDUs shall be the same as the PHY used for the PDU that they reply to.

2.3.3.1 CONNECT_IND and AUX_CONNECT_REQ

The Payload field of the CONNECT_IND and AUX_CONNECT_REQ PDUs is shown in Figure 2.15. TxAdd in the advertising physical channel PDU Header field indicates

whether the address in the InitA field is public (TxAdd = 0) or random (TxAdd = 1). The RxAdd in the advertising physical channel PDU Header field indicates whether the address in the AdvA field is public (RxAdd = 0) or random (RxAdd = 1).

The ChSel field in the CONNECT_IND PDU Header field shall be set to 1 if both the initiator and advertiser support the LE Channel Selection Algorithm #2 feature (see Section 4.5.8.3). If the initiator supports the LE Channel Selection Algorithm #2 feature but the advertiser does not, the initiator may set the ChSel field to 0 or 1. The ChSel field in the CONNECT_IND PDU Header field shall be set to 0 if the initiator does not support the LE Channel Algorithm #2 feature. The ChSel field in the AUX_CONNECT_REQ PDU Header field is reserved for future use.

Payload		
InitA (6 octets)	AdvA (6 octets)	LLData (22 octets)

Figure 2.15: CONNECT_IND and AUX_CONNECT_REQ PDU Payload

The InitA field shall contain the Initiator's public or random device address as indicated by TxAdd. The AdvA field shall contain the advertiser's public or random device address as indicated by RxAdd.

The format of the LLData field is shown in Figure 2.16.

LLData									
AA (4 octets)	CRCInit (3 octets)	WinSize (1 octet)	WinOffset (2 octets)	Interval (2 octets)	Latency (2 octets)	Timeout (2 octets)	ChM (5 octets)	Hop (5 bits)	SCA (3 bits)

Figure 2.16: LLData field structure in CONNECT_IND and AUX_CONNECT_REQ PDU's Payload

The AA field shall contain the ACL connection's Access Address determined by the Link Layer following the rules specified in Section 2.1.2.

The CRCInit field shall contain the initialization value for the CRC calculation for the ACL connection, as defined in Section 3.1.1. It shall be a random value, generated by the Link Layer. The seed for the random number generator shall be from a physical source of entropy and should have at least 20 bits of entropy.

The WinSize field shall be set to indicate the *transmitWindowSize* value, as defined in Section 4.5.3 in the following manner:

transmitWindowSize = WinSize × 1.25 ms.

The WinOffset field shall be set to indicate the *transmitWindowOffset* value, as defined in Section 4.5.3 in the following manner:

transmitWindowOffset = WinOffset × 1.25 ms.

The Interval field shall be set to indicate the *connInterval* as defined in Section 4.5.1 in the following manner:

connInterval = Interval × 1.25 ms.

The Latency field shall be set to indicate the *connPeripheralLatency* value, as defined in Section 4.5.1 in the following manner:

connPeripheralLatency = Latency.

The Timeout field shall be set to indicate the *connSupervisionTimeout* value, as defined in Section 4.5.2, in the following manner:

connSupervisionTimeout = Timeout × 10 ms.

The ChM field shall contain the channel map indicating *Used* and *Unused* data channels. Every channel is represented with a bit positioned as per the data channel index as defined in Section 1.4.1. The LSB represents data channel index 0 and the bit in position 36 represents data channel index 36. A bit value of 0 indicates that the channel is *Unused*. A bit value of 1 indicates that the channel is *Used*. The bits in positions 37, 38 and 39 are reserved for future use.

Note: When mapping from RF channels to data channel index, there is a gap where advertising channel index 38 is placed.

The Hop field shall be set to indicate the *hopIncrement* used in the data channel selection algorithm as defined in Section 4.5.8.2. It shall have a random value in the range 5 to 16.

The SCA field shall be set to indicate the *centralSCA* used to determine the Central's worst case sleep clock accuracy as defined in Section 4.2.2. The value of the SCA field shall be set as defined in Table 2.13.

SCA	*centralSCA or peripheralSCA*
0	251 ppm to 500 ppm
1	151 ppm to 250 ppm
2	101 ppm to 150 ppm
3	76 ppm to 100 ppm
4	51 ppm to 75 ppm

SCA	*centralSCA or peripheralSCA*
5	31 ppm to 50 ppm
6	21 ppm to 30 ppm
7	0 ppm to 20 ppm

Table 2.13: SCA field encoding

2.3.3.2 AUX_CONNECT_RSP

The AUX_CONNECT_RSP PDU uses the Common Extended Advertising Payload Format described in Section 2.3.4.

The AdvMode field shall be set to 0b00.

The Common Extended Advertising Payload Format fields permitted in the AUX_CONNECT_RSP PDU are shown in Table 2.14.

		Common Extended Advertising Payload Format fields								
Adv Mode	**Event Type**	**AdvA**	**TargetA**	**CTE Info**	**ADI**	**Aux Ptr**	**Sync Info**	**Tx Power**	**ACAD**	**Adv Data**
0b00	Connection response	M	M	X	X	X	X	X	X	X
0b01 to 0b11	RFU									

Table 2.14: Common Extended Advertising Payload Format fields permitted in the AUX_CONNECT_RSP PDU

2.3.4 Common Extended Advertising Payload Format

The following extended Advertising Physical Channel PDUs share the same Advertising Physical Channel PDU payload format, referred to in the specification as the “Common Extended Advertising Payload Format”:

- ADV_EXT_IND
- AUX_ADV_IND
- AUX_SCAN_RSP
- AUX_SYNC_IND
- AUX_CHAIN_IND

- AUX_CONNECT_RSP
- AUX_SYNC_SUBEVENT_IND
- AUX_SYNC_SUBEVENT_RSP

The common extended advertising payload format is shown in Figure 2.17.

Payload			
Extended Header Length (6 bits)	AdvMode (2 bits)	Extended Header (0 - 63 octets)	AdvData (0 - 254 octets)

Figure 2.17: Common Extended Advertising Payload Format

The Extended Header Length field contains a value between 0 and 63 and indicates the size of the variable length Extended Header field.

The AdvMode field indicates the mode of the advertisement. The value of the AdvMode field shall be set as defined in Table 2.15.

Value	Mode	
0b00	Non-connectable	Non-scannable
0b01	Connectable	Non-scannable
0b10	Non-connectable	Scannable
0b11	Reserved for future use	

Table 2.15: AdvMode field encoding

AdvData, if present, shall contain advertising data from the advertiser's Host. The maximum size of AdvData depends on the size of the Extended Header field. The size of the AdvData can be calculated by subtracting the length of the Extended Header field plus one octet from the Length field specified in the Advertising physical channel PDU Header field.

The Extended Header field is a variable length header that is present if, and only if, the Extended Header Length field is non-zero. The format of the Extended Header field is shown in Figure 2.18.

Extended Header								
Extended Header Flags (1 octet)	AdvA (6 octets)	TargetA (6 octets)	CTEInfo (1 octet)	AdvData Info (ADI) (2 octets)	AuxPtr (3 octets)	SyncInfo (18 octets)	TxPower (1 octet)	ACAD (varies)

Figure 2.18: Extended Header

The Extended Header Flags bit field definitions are shown in Table 2.16.

Bit	Extended Header
0	AdvA
1	TargetA
2	CTEInfo
3	AdvDataInfo (ADI)
4	AuxPtr
5	SyncInfo
6	TxPower
7	Reserved for future use

Table 2.16: Extended Header Flags

If a flag bit is set to 1, the corresponding Extended Header field is present; otherwise, the corresponding Extended Header field is not present. The Extended Header fields that are present are always in the same order as the flags in the Extended Header flags (i.e., the AdvA field is first if present, then the TargetA field if present, etc.).

Whether an Extended Header flag and corresponding Extended Header field is mandatory, optional, or reserved for future use is dependent on the Advertising Physical Channel PDU in which the extended header is used.

2.3.4.1 AdvA field

When present, the AdvA field is six octets with the format shown in Figure 2.19.

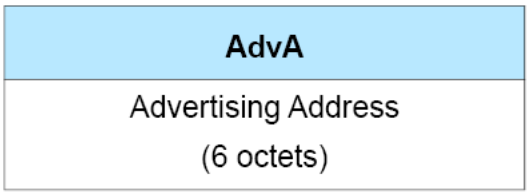

Figure 2.19: AdvA field

The Advertising Address field contains the advertiser's device address. If the AdvA field is present, TxAdd in the advertising physical channel PDU Header field indicates whether this address is public (TxAdd = 0) or random (TxAdd = 1).

2.3.4.2 TargetA field

When present, the TargetA field is six octets with the format shown in Figure 2.20.

TargetA
Target Address (6 octets)

Figure 2.20: TargetA field

The Target Address field contains the scanner's or initiator's device address to which the advertisement is directed. If the TargetA field is present, RxAdd in the advertising physical channel PDU Header field indicates whether this address is public (RxAdd = 0) or random (RxAdd = 1).

2.3.4.3 CTEInfo field

The presence of the CTEInfo field indicates that the packet includes a Constant Tone Extension. The CTEInfo field is defined in Section 2.5.2.

2.3.4.4 AdvDataInfo field

When present, the AdvDataInfo (ADI) field is two octets with the format shown in Figure 2.21.

AdvDataInfo	
Advertising Data ID (DID) (12 bits)	Advertising Set ID (SID) (4 bits)

Figure 2.21: AdvDataInfo field

The Advertising Set ID (SID) is set by the advertiser's Host to identify an advertising set transmitted by this device.

The Advertising Data ID (DID) is set by the advertiser to indicate to the scanner whether it can assume that the data contents in the AdvData are a duplicate of the previous AdvData sent in an earlier packet.

2.3.4.5 AuxPtr field

When present, the AuxPtr field is three octets with the format shown in Figure 2.22.

AuxPtr				
Channel Index (6 bits)	CA (1 bit)	Offset Units (1 bit)	AUX Offset (13 bits)	AUX PHY (3 bits)

Figure 2.22: AuxPtr field

The presence of the AuxPtr field indicates that some or all of the advertisement data is in a subsequent auxiliary packet. The contents of the AuxPtr field describe this packet.

The Channel Index field contains the general-purpose channel index (see Section 1.4.1) used to transmit the auxiliary packet.

The Offset Units field indicates the units used by the Aux Offset Field. The value of the Offset Units field shall be set as defined in Table 2.17.

Value	Units
0	30 µs
1	300 µs

Table 2.17: Offset Units field encoding

The Aux Offset field contains the time from a reference point to the approximate start of the auxiliary packet, where the reference point is the start of the packet containing the AuxPtr field. The value of the AUX Offset field is in the unit of time indicated by the Offset Units field; the offset is determined by multiplying the value by the unit. The Aux Offset shall be at least the length of the packet plus T_MAFS (see Section 4.1.2). The Offset Units field shall be set to 0 if the Aux Offset is less than 245,700 µs.The auxiliary packet shall not start any earlier than the Aux Offset after the reference point and shall start no later than the Aux Offset plus one Offset Unit after the reference point. This allows the Link Layer to round the Aux Offset to the Offset Unit.

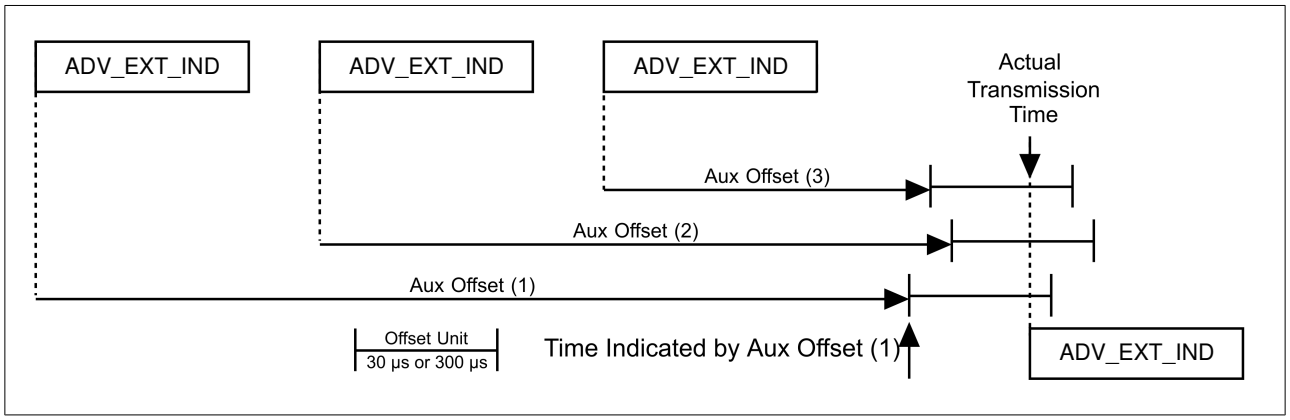

Figure 2.23: Aux Offset transmission window

The Aux PHY field indicates the PHY used to transmit the auxiliary packet. The value of the Aux PHY field shall be set as defined in Table 2.18.

Value	PHY used
0b000	LE 1M
0b001	LE 2M
0b010	LE Coded
0b011 – 0b111	Reserved for future use

Table 2.18: Aux PHY field encoding

The CA field contains the clock accuracy of the advertiser that will be used between the packet containing this data and the auxiliary packet. The value of the CA field shall be set as defined in Table 2.19.

CA Value	Advertiser's Clock Accuracy
0	51 ppm to 500 ppm
1	0 ppm to 50 ppm

Table 2.19: Clock Accuracy field encoding

An AuxPtr field with an Aux Offset of zero is permitted and indicates that no auxiliary packet will be transmitted but the Host advertising data in the current PDU is incomplete (see Section 2.3.4.9); it shall be treated as equivalent to one referring to an AUX_CHAIN_IND PDU that is never received. The remaining fields shall contain valid values.

2.3.4.6 SyncInfo field

When present, the SyncInfo field is 18 octets with the format shown in Figure 2.24.

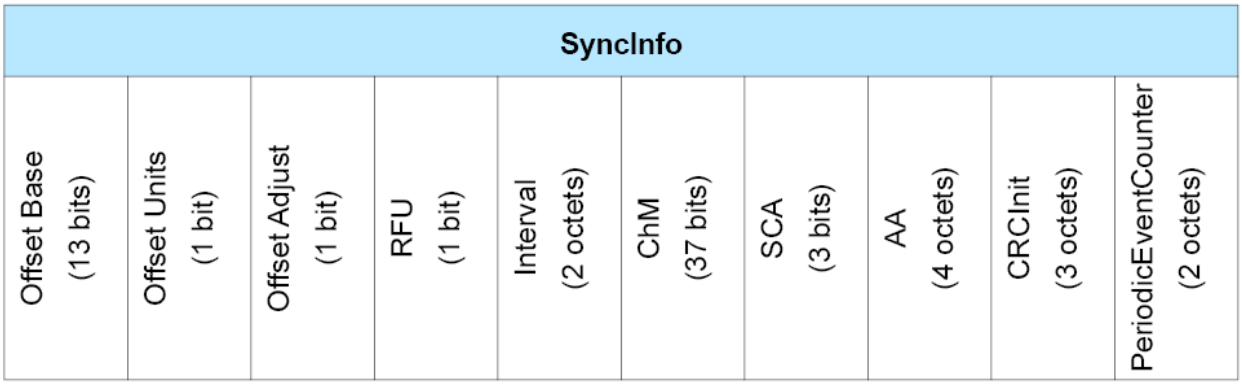

Figure 2.24: SyncInfo field

The presence of the SyncInfo field indicates the presence of a periodic advertising train (using AUX_SYNC_IND PDUs or AUX_SYNC_SUBEVENT_IND PDUs). The contents of the SyncInfo field describe this periodic advertising train.

The Offset Units field indicates the units used by the Offset Base field. The value of the Offset Units field shall be set as defined in Table 2.20.

Value	Units
0	30 µs
1	300 µs

Table 2.20: Offset Units field encoding

The SyncInfo field can appear in an advertising PDU or in an LL_PERIODIC_SYNC_IND PDU or LL_PERIODIC_SYNC_WR_IND PDU (see Section 2.4.2.27 and Section 2.4.2.40).

The syncPacketWindowOffset value is the time from a reference point to the start of the AUX_SYNC_IND or the AUX_SYNC_SUBEVENT_IND of subevent 0 packet that this SyncInfo field describes. If the SyncInfo appears in an advertising PDU, the reference point is the start of the packet containing it. If it appears in an LL_PERIODIC_SYNC_IND PDU or an LL_PERIODIC_SYNC_WR_IND PDU, the reference point is specified by that PDU. The value of syncPacketWindowOffset is determined by multiplying the value of the Offset Base field by the unit of time indicated by the Offset Units field and then, if the Offset Adjust field is set to 1, adding 2.4576 seconds. The Offset Units field shall be set to 0 if syncPacketWindowOffset is less than 245,700 µs. The Offset Adjust field shall be set to 0 if the Offset Units field is set to 0 or if the SyncInfo field appears within an advertising PDU. As illustrated in Figure 2.25, the packet containing the AUX_SYNC_IND PDU or AUX_SYNC_SUBEVENT_IND PDU shall not start any earlier than syncPacketWindowOffset after the reference point and shall start no later than syncPacketWindowOffset plus one Offset unit after the reference point. This allows the Link Layer to round syncPacketWindowOffset to the Offset Unit.

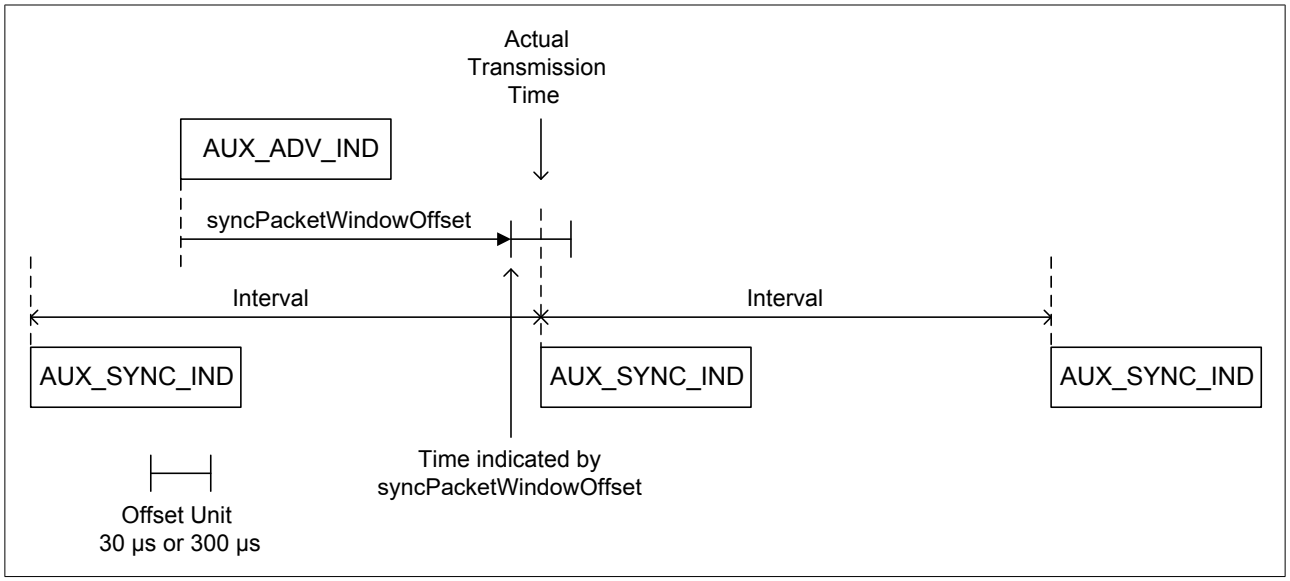

Figure 2.25: Transmission window represented by syncPacketWindowOffset

A value of 0 for syncPacketWindowOffset indicates that the time to the next AUX_SYNC_IND or AUX_SYNC_SUBEVENT_IND packet is greater than can be represented.

The Interval field contains the time, in 1.25 ms units, from the start of one packet of the periodic advertising train to the start of the next packet. The value shall not be less than 6 (7.5 ms).

The ChM field contains the channel map indicating *Used* and *Unused* RF channels on the periodic physical channel. Every channel is represented with a bit positioned as per the channel index as defined in Section 1.4.1. The LSB represents channel index 0 and the bit in position 36 represents channel index 36. A bit value of 0 indicates that the channel is *Unused*. A bit value of 1 indicates that the channel is *Used*.

The AA, CRCInit, and SCA fields have the same meaning as the corresponding fields in the CONNECT_IND PDU (see Section 2.3.3.1).

The PeriodicEventCounter field contains the value of *paEventCounter* (see Section 4.4.2.1) that applies to the AUX_SYNC_IND or AUX_SYNC_SUBEVENT_IND packet that this SyncInfo field describes.

2.3.4.7 TxPower field

When present, the TxPower is one octet with the format shown in Figure 2.26.

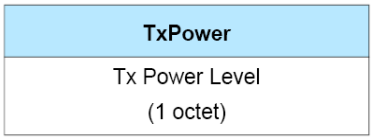

Figure 2.26: TxPower field

The Tx Power Level field is the same value defined for the Tx Power Advertising Data type defined in Section 1.5 of [1].

If the Host instructs the Controller to include the TxPower field in an advertisement, then it shall be included in the AUX_ADV_IND PDU if the extended advertising event contains one and in all the ADV_EXT_IND PDUs otherwise. Any AUX_CHAIN_IND PDUs should not contain a TxPower field. If the Host instructs the Controller to include the TxPower field in a periodic advertisement, then it shall be included in the AUX_SYNC_IND, AUX_SYNC_SUBEVENT_IND, or AUX_SYNC_SUBEVENT_RSP PDUs but not in any AUX_CHAIN_IND PDUs.

2.3.4.8 ACAD field

The remainder of the Extended Header field forms the Additional Controller Advertising Data (ACAD) field. The length of this field is the Extended Header field length minus the sum of the size of the Extended Header flags (1 octet) and those fields indicated by the flags as present. ACAD cannot be fragmented across multiple advertising physical channel PDUs; it shall always fit inside a single advertising physical channel PDU.

The ACAD field, if present, shall hold data from the advertiser's Controller or intended to be used by the recipient's Controller. It uses the format described in [Vol 3] Part C, Section 11.

The ACAD type formats and meanings are defined in Section 1 of [1]. The ACAD type identifier values are defined in Assigned Numbers.

2.3.4.9 Host Advertising Data

The portion of the PDU after the Extended Header field forms the AdvData field. The length of this field is specified in Section 2.3.4.

The AdvData field, if present, shall hold data from the advertiser's Host in the format described in [Vol 3] Part C, Section 11. If the Host does not provide any data, the AdvData field shall be omitted but, for all other purposes in this Part, this shall be treated as if the Host had provided data.

The Controller may support fragmentation of Host Advertising Data. The total amount of Host Advertising Data before fragmentation shall not exceed 1650 octets. When the Link Layer fragments the Host advertising data, the number of fragments and the size

of each fragment are chosen by the Controller. The Controller should minimize the number of fragments to ensure more reliability in delivering the entire Host advertising data. The Host may indicate a preference whether the Controller should fragment the Host advertising data, but the Controller may ignore the preference. If the amount of advertising or scan response data to be sent in an extended advertising or scanning PDU plus the Extended Header Length, AdvMode, and Extended Header fields exceed the maximum Advertising Physical Channel PDU Payload field (255 octets), the Link Layer shall fragment the Host advertising data.

The Link Layer shall place the multiple fragments in the AdvData field of different PDUs. When Host advertising data is fragmented the first fragment shall be placed in the AUX_ADV_IND, AUX_SYNC_IND or AUX_SCAN_RSP PDU while subsequent fragments shall be placed in AUX_CHAIN_IND PDUs. Each AUX_CHAIN_IND PDU is the auxiliary PDU of the PDU containing the previous fragment; AUX_CHAIN_IND PDUs not containing AdvData shall not have an auxiliary PDU containing AdvData.

If the Link Layer has fragmented the Host advertising data but is subsequently unable to transmit all the fragments, the last fragment that it is able to transmit should contain an AuxPtr field with an Aux Offset of zero so that scanners are aware that the data has been truncated.

2.4 Data Physical Channel PDU

The Data Physical Channel PDU has a 16 or 24 bit Header field, a variable size Payload field, and may include a Message Integrity Check (MIC) field.

The Data Physical Channel PDU is as shown in Figure 2.27.

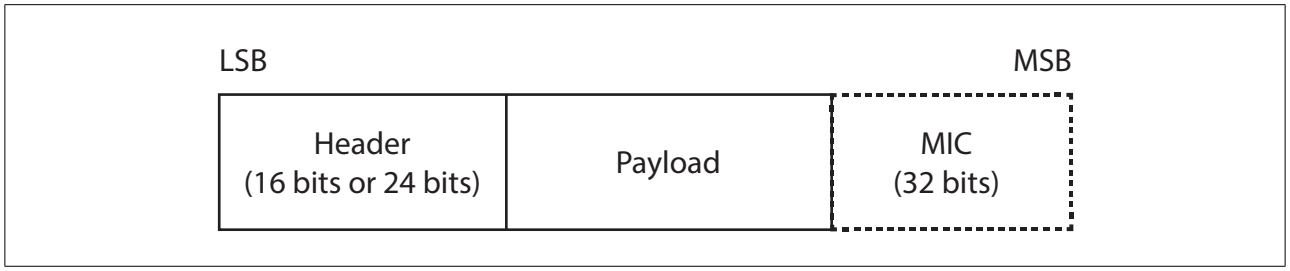

Figure 2.27: Data Physical Channel PDU

The Header field of the Data Physical Channel PDU is as shown in Figure 2.28.

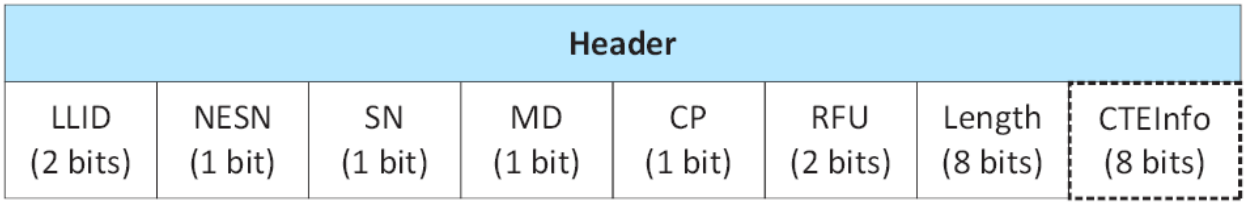

Figure 2.28: Data Physical Channel PDU header

The 16 or 24 bit Header field consists of 6 or 7 fields that are specified in Table 2.21.

The MIC field shall be included in all PDUs containing a non-zero length Payload field that are sent on an encrypted ACL connection. The MIC shall be calculated as specified in [Vol 6] Part E, Section 1. The MIC field shall not be included in any PDU that is sent on an unencrypted ACL connection or that has a zero-length Payload field.

The Payload field format depends on the LLID field of the Header field. If the LLID field is 0b01 or 0b10, the Data Physical Channel PDU Payload field contains an LL Data PDU as defined in Section 2.4.1. If the LLID field is 0b11 then the Data Physical Channel PDU Payload field contains an LL Control PDU as defined in Section 2.4.2.

The NESN bit of the Header field is defined in Section 4.5.9.

The SN bit of the Header field is defined in Section 4.5.9.

The MD bit of the Header field is defined in Section 4.5.6.

The CTEInfo Present (CP) field of the Header field indicates whether the Data Physical Channel PDU Header field has a CTEInfo field and therefore whether the data physical channel packet has a Constant Tone Extension. If the CP field is 0, then no CTEInfo field is present in the Data Channel PDU Header field and there is no Constant Tone Extension in the data physical channel packet. If the CP field is 1, then the CTEInfo field in the Data Physical Channel PDU Header field is present and the data physical channel packet includes a Constant Tone Extension.

The Length field of the Header field indicates the length of the Payload field and MIC if included. The Length field has the range 0 to 255 octets. The Payload field shall be less than or equal to 251 octets in length. The MIC is 4 octets in length.

The CTEInfo field of the Header field is present if indicated in the CP field. The CTEInfo field is defined in Section 2.5.2. The CTEInfo field can be present in the Header field of any Data Physical Channel PDU. However, the Link Layer shall not transmit a Data Physical Channel PDU containing a CTEInfo field unless it has determined that the peer device supports the Receiving Constant Tone Extensions feature (see Section 4.6.22).

Note: A Controller that transmits a PDU containing a CTEInfo field will not necessarily be able to receive one and vice-versa.

In this version of the specification, the only way to request a remote device to send a packet containing the CTEInfo field is via the Constant Tone Extension Request procedure.

Field name	Description
LLID	The LLID indicates whether the packet is an LL Data PDU or an LL Control PDU. 0b00 = Reserved for future use 0b01 = LL Data PDU: Continuation fragment of an L2CAP message, or an Empty PDU. 0b10 = LL Data PDU: Start of an L2CAP message or a complete L2CAP message with no fragmentation. 0b11 = LL Control PDU
NESN	Next Expected Sequence Number
SN	Sequence Number
MD	More Data
CP	CTEInfo Present
Length	The Length field indicates the size, in octets, of the Payload field and MIC, if included.
CTEInfo	The CTEInfo field indicates the type and length of the Constant Tone Extension.

Table 2.21: Data Physical Channel PDU Header field

2.4.1 LL Data PDU

An LL Data PDU is a Data Channel PDU that is used to send L2CAP data. The LLID field in the Header field shall be set to either 0b01 or 0b10.

An LL Data PDU with the LLID field in the Header field set to 0b01, and the Length field set to 0b00000000, is known as an Empty PDU. The Central's Link Layer may send an Empty PDU to the Peripheral to allow the Peripheral to respond with any Data Physical Channel PDU, including an Empty PDU.

An LL Data PDU with the LLID field in the Header set to 0b10 shall not have the Length field set to 0 and should not have it set to less than 4.

Note: If the Link Layer receives an HCI ACL Data Packet with Data_Total_Length equal to 0b00000000 and Packet_Boundary_Flag set to 0b00 (i.e., a start fragment), then the Link Layer cannot simply transmit the fragment over the air but, as this section requires, must instead combine it with one or more of the following continuation fragments to form a PDU with LLID set to 0b10 and non-zero length.

2.4.2 LL Control PDU

An LL Control PDU is a Data Physical Channel PDU that is used to control the Link Layer connection.

The Payload field of the LL Control PDU is shown in Figure 2.29.

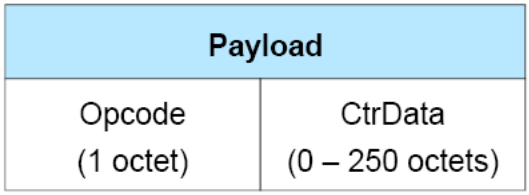

Figure 2.29: LL Control PDU Payload

An LL Control PDU shall not have the Length field set to 0b00000000.

The Opcode field identifies different types of LL Control PDU, as defined in Table 2.22.

The CtrData field in the LL Control PDU is specified by the Opcode field and is defined in the following subsections.

Where the description of a field within the CtrData field gives a range of valid values or other restrictions on a value (e.g. that field X is less than field Y), all other values shall be reserved for future use. The range may be directly specified in the relevant subsection for the LL Control PDU or indirectly, possibly in a section referenced by that subsection (e.g. the range of the WinSize field in Section 2.4.2.1 is derived from the range of the *transmitWindowSize* value specified in Section 4.5.3).

If no range is specified for a field, then all values for that field are valid.

Except where explicitly stated otherwise, all fields within the CtrData field in an LL Control PDU that hold an integer shall be interpreted as unsigned.

0x2F	LL_CS_CAPABILITIES_RSP
0x30	LL_CS_CONFIG_REQ
0x31	LL_CS_CONFIG_RSP
0x32	LL_CS_REQ
0x33	LL_CS_RSP
0x34	LL_CS_IND
0x35	LL_CS_TERMINATE_REQ
0x36	LL_CS_FAE_REQ
0x37	LL_CS_FAE_RSP
0x38	LL_CS_CHANNEL_MAP_IND
0x39	LL_CS_SEC_REQ
0x3A	LL_CS_TERMINATE_RSP
0x3B	LL_FRAME_SPACE_REQ
0x3C	LL_FRAME_SPACE_RSP
0xF0 to 0xFB	Reserved for specification development purposes
All other values	Reserved for future use

Table 2.22: LL Control PDU opcodes

If an LL Control PDU is received that is not supported or reserved for future use, the Link Layer shall respond with an LL_UNKNOWN_RSP PDU. The UnknownType field of the LL_UNKNOWN_RSP PDU shall be set to the value of the Opcode in the received PDU.

If an LL Control PDU is received with the wrong length or with invalid CtrData fields, the Link Layer may continue with the relevant Link Layer procedure with an implementation-specific interpretation of the data (e.g., if the PDU is too long it can ignore the extra data; if a field is out of range it can use the nearest permitted value). If it does not continue the procedure, it shall respond with an LL_UNKNOWN_RSP PDU or, if the relevant procedure allows it, an LL_REJECT_IND or LL_REJECT_EXT_IND PDU. The UnknownType field of the LL_UNKNOWN_RSP PDU or the RejectOpcode field of the LL_REJECT_EXT_IND PDU shall be set to the value of the Opcode in the received PDU.

2.4.2.1 LL_CONNECTION_UPDATE_IND

The format of the CtrData field is as shown in Figure 2.30.

CtrData					
WinSize (1 octet)	WinOffset (2 octets)	Interval (2 octets)	Latency (2 octets)	Timeout (2 octets)	Instant (2 octets)

Figure 2.30: CtrData field of the LL_CONNECTION_UPDATE_IND PDU

The WinSize field shall be set to indicate the *transmitWindowSize* value, as defined in Section 4.5.3 in the following manner:

transmitWindowSize = WinSize × 1.25 ms.

The WinOffset field shall be set to indicate the *transmitWindowOffset value,* as defined in Section 4.5.3, in the following manner:

transmitWindowOffset = WinOffset × 1.25 ms.

The Interval field shall be set to indicate the *connInterval* value, as defined in Section 4.5.1, in the following manner:

connInterval = Interval × 1.25 ms.

The Latency field shall be set to indicate the *connPeripheralLatency* value, as defined by Section 4.5.1, in the following manner:

connPeripheralLatency = Latency.

The Timeout field shall be set to indicate the *connSupervisionTimeout* value, as defined by Section 4.5.2, in the following manner:

connSupervisionTimeout = Timeout × 10 ms.

The Instant field shall be set to indicate the instant described in Section 5.1.1.

2.4.2.2 LL_CHANNEL_MAP_IND

The format of the CtrData field is shown in Figure 2.31.

CtrData	
ChM (5 octets)	Instant (2 octets)

Figure 2.31: CtrData field of the LL_CHANNEL_MAP_IND PDU

The ChM field shall contain the channel map indicating *Used* and *Unused* data channels. Every channel is represented with a bit positioned as per the data channel index defined by Section 1.4.1. The format of this field is identical to the ChM field in the CONNECT_IND PDU (see Section 2.3.3.1).

The Instant field shall be set to indicate the instant described in Section 5.1.2.

2.4.2.3 LL_TERMINATE_IND

The format of the CtrData field is shown in Figure 2.32.

CtrData
ErrorCode (1 octet)

Figure 2.32: CtrData field of the LL_TERMINATE_IND PDU

The ErrorCode field shall be set to inform the remote device why the connection is about to be terminated. See [Vol 1] Part F, Controller Error Codes for details.

2.4.2.4 LL_ENC_REQ

The format of the CtrData field is shown in Figure 2.33.

CtrData			
Rand (8 octets)	EDIV (2 octets)	SKD_C (8 octets)	IV_C (4 octets)

Figure 2.33: CtrData field of the LL_ENC_REQ PDU

The Rand field shall contain a random number that is provided by the Host and used with EDIV (see [Vol 3] Part H, Section 2.4.4).

The EDIV field shall contain the encrypted diversifier.

The SKD_C field shall contain the Central's portion of the session key diversifier.

The IV_C field shall contain the Central's portion of the initialization vector.

2.4.2.5 LL_ENC_RSP

The format of the CtrData field is shown in Figure 2.34.

CtrData	
SKD_P (8 octets)	IV_P (4 octets)

Figure 2.34: CtrData field of the LL_ENC_ RSP PDU

The SKD_P field shall contain the Peripheral's portion of the session key diversifier.

The IV_P field shall contain the Peripheral's portion of the initialization vector.

2.4.2.6 LL_START_ENC_REQ

The LL_START_ENC_REQ PDU does not have a CtrData field.

2.4.2.7 LL_START_ENC_RSP

The LL_START_ENC_RSP PDU does not have a CtrData field.

2.4.2.8 LL_UNKNOWN_RSP

The format of the CtrData field is shown in Figure 2.35.

CtrData
UnknownType (1 octet)

Figure 2.35: CtrData field of the LL_UNKNOWN_RSP PDU

UnknownType shall contain the Opcode field value of the received LL Control PDU.

2.4.2.9 LL_FEATURE_REQ

The format of the CtrData field is shown in Figure 2.36.

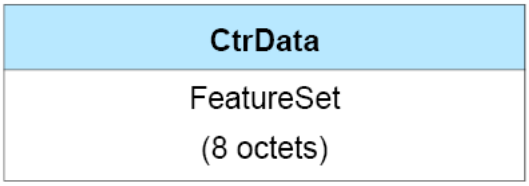

Figure 2.36: CtrData field of the LL_FEATURE_REQ PDU

FeatureSet shall contain the set of features supported by the Central's Link Layer as specified in Section 4.6.

2.4.2.10 LL_FEATURE_RSP

The format of the CtrData field is shown in Figure 2.37.

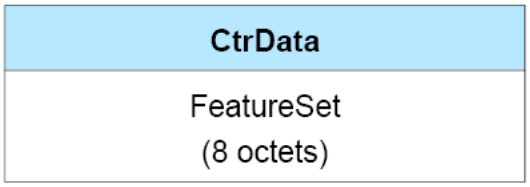

Figure 2.37: CtrData field of the LL_FEATURE_RSP PDU

FeatureSet[0] shall contain a set of features supported by the Link Layers of both the Central and Peripheral.

FeatureSet[1-7] shall contain a set of features supported by the Link Layer that transmits this PDU.

See Section 4.6 for the list of features.

2.4.2.11 LL_PAUSE_ENC_REQ

The LL_PAUSE_ENC_REQ packet does not have a CtrData field.

2.4.2.12 LL_PAUSE_ENC_RSP

The LL_PAUSE_ENC_RSP packet does not have a CtrData field.

2.4.2.13 LL_VERSION_IND

The format of the CtrData field is shown in Figure 2.38.

CtrData		
Version (1 octet)	Company_Identifier (2 octets)	Subversion (2 octets)

Figure 2.38: CtrData field of the LL_VERSION_IND PDU

Version field shall contain the version of the Bluetooth Link Layer specification supported by the Controller (see Assigned Numbers).

Company_Identifier field shall contain the company identifier of the manufacturer of the Bluetooth Controller (see Assigned Numbers).

Subversion field shall contain a unique value for each implementation or revision of an implementation of the Bluetooth Controller.

Note: A given value of Version does not indicate that the device supports all the features in the corresponding version of the specification; the relevant feature bits (see Section 4.6) should be checked instead.

Note: A larger value for Version does not necessarily indicate a higher version of the specification.

2.4.2.14 LL_REJECT_IND

The format of the CtrData field is shown in Figure 2.39.

CtrData
ErrorCode (1 octet)

Figure 2.39: CtrData field of the LL_ REJECT_IND

ErrorCode shall contain the reason a request was rejected; see [Vol 1] Part F, Controller Error Codes.

2.4.2.15 LL_PERIPHERAL_FEATURE_REQ

The format of the CtrData field is shown in Figure 2.40.

CtrData
FeatureSet (8 octets)

Figure 2.40: CtrData field of the LL_PERIPHERAL_FEATURE_REQ PDU

FeatureSet shall contain the set of features supported by the Peripheral's Link Layer as specified in Section 4.6.

2.4.2.16 LL_CONNECTION_PARAM_REQ

The format of the CtrData field is shown in Figure 2.41.

CtrData					
Interval_Min (2 octets)	Interval_Max (2 octets)	Latency (2 octets)	Timeout (2 octets)	PreferredPeriodicity (1 octet)	ReferenceConnEventCount (2 octets)

CtrData (continued)					
Offset0 (2 octets)	Offset1 (2 octets)	Offset2 (2 octets)	Offset3 (2 octets)	Offset4 (2 octets)	Offset5 (2 octets)

Figure 2.41: CtrData field of the LL_CONNECTION_PARAM_REQ PDU

The Interval_Min field shall be set to indicate the minimum value of *connInterval*, as defined in Section 4.5.1, in the following manner:

connInterval = Interval_Min × 1.25 ms.

The Interval_Max field shall be set to indicate the maximum value of *connInterval*, as defined in Section 4.5.1, in the following manner:

connInterval = Interval_Max × 1.25 ms.

The value shall not be less than the value of Interval_Min.

The Latency field shall be set to indicate the *connPeripheralLatency* value, as defined by Section 4.5.1, in the following manner:

connPeripheralLatency = Latency.

The Timeout field shall be set to indicate the *connSupervisionTimeout* value, as defined by Section 4.5.2, in the following manner:

connSupervisionTimeout = Timeout × 10 ms.

The PreferredPeriodicity field shall be set to indicate a value the *connInterval* is preferred to be a multiple of. PreferredPeriodicity is in units of 1.25 ms. E.g. if the PreferredPeriodicity is set to 100, it implies that *connInterval* is preferred to be any multiple of 125 ms. A value of zero means no preference. The PreferredPeriodicity shall be less than or equal to Interval_Max.

The ReferenceConnEventCount field shall be set to indicate the value of the *connEventCounter* relative to which all the valid Offset0 to Offset5 fields have been calculated.

Note: The ReferenceConnEventCount field is independent of the Instant field in the LL_CONNECTION_UPDATE_IND PDU.

The Offset0, Offset1, Offset2, Offset3, Offset4, and Offset5 fields shall be set to indicate the possible values of the position of the anchor points of the LE connection with the updated connection parameters relative to the ReferenceConnEventCount. The Offset0 to Offset5 fields are in units of 1.25 ms and are in decreasing order of preference; that is, Offset0 is the most preferred value, followed by Offset1, and so on. Offset0 to Offset5 shall be less than Interval_Max. A value of 0xFFFF means not valid. Valid Offset0 to Offset5 fields shall contain unique values. Valid fields shall always be before invalid fields.

2.4.2.17 LL_CONNECTION_PARAM_RSP

The format of the LL_CONNECTION_PARAM_RSP PDU is identical to the format of the LL_CONNECTION_PARAM_REQ PDU (see Section 2.4.2.16).

2.4.2.18 LL_REJECT_EXT_IND

The format of the CtrData field is shown in Figure 2.42.

CtrData	
RejectOpcode (1 octet)	ErrorCode (1 octet)

Figure 2.42: CtrData field of the LL_REJECT_EXT_IND PDU

RejectOpcode shall contain the Opcode field value of the LL Control PDU being rejected.

ErrorCode shall contain the reason the LL Control PDU was being rejected. See [Vol 1] Part F, Controller Error Codes for a list of error codes and descriptions.

This PDU shall be issued only when the remote Link Layer supports the Extended Reject Indication Link Layer feature (Section 4.6). Otherwise, the LL_REJECT_IND PDU (Section 2.4.2.14) shall be issued instead.

2.4.2.19 LL_PING_REQ

The LL_PING_REQ PDU does not have a CtrData field.

2.4.2.20 LL_PING_RSP

The LL_PING_RSP PDU does not have a CtrData field.

2.4.2.21 LL_LENGTH_REQ and LL_LENGTH_RSP

The format of the CtrData field for both the LL_LENGTH_REQ and LL_LENGTH_RSP PDUs is shown in Figure 2.43.

CtrData			
MaxRxOctets (2 octets)	MaxRxTime (2 octets)	MaxTxOctets (2 octets)	MaxTxTime (2 octets)

Figure 2.43: CtrData field of the LL_LENGTH_REQ and LL_LENGTH_RSP PDUs

MaxRxOctets shall be set to the sender's *connMaxRxOctets* value, as defined in Section 4.5.10. The MaxRxOctets field shall have a value not less than 27 octets.

MaxRxTime shall be set to the sender's *connMaxRxTime* value, as defined in Section 4.5.10. The MaxRxTime field shall have a value not less than 328 µs.

MaxTxOctets shall be set to the sender's *connMaxTxOctets* value, as defined in Section 4.5.10. The MaxTxOctets field shall have a value not less than 27 octets.

MaxTxTime shall be set to the sender's *connMaxTxTime* value, as defined in Section 4.5.10. The MaxTxTime field shall have a value not less than 328 µs.

2.4.2.22 LL_PHY_REQ and LL_PHY_RSP

The format of the CtrData field for both the LL_PHY_REQ and LL_PHY_RSP PDUs is shown in Figure 2.44.

CtrData	
TX_PHYS (1 octet)	RX_PHYS (1 octet)

Figure 2.44: CtrData field of the LL_PHY_REQ and LL_PHY_RSP PDUs

TX_PHYS shall be set to indicate the transmitter PHYs that the sender prefers to use.

RX_PHYS shall be set to indicate the receiver PHYs that the sender prefers to use.

These fields each consist of 8 bits; at least one bit in each field shall be set to 1. The bits that are set indicate which PHY or PHYs the sender prefers to use.

Bit number	Meaning
0	LE 1M PHY
1	LE 2M PHY
2	LE Coded PHY
All other bits	Reserved for future use

Table 2.23: PHY field bit meanings

2.4.2.23 LL_PHY_UPDATE_IND

The format of the CtrData field is shown in Figure 2.45.

CtrData		
PHY_C_TO_P (1 octet)	PHY_P_TO_C (1 octet)	Instant (2 octets)

Figure 2.45: CtrData field of the LL_PHY_UPDATE_IND PDU

PHY_C_TO_P shall be set to indicate the PHY that shall be used for packets sent from the Central to the Peripheral. PHY_P_TO_C shall be set to indicate the PHY that shall be used for packets sent from the Peripheral to the Central. These fields each consist of 8 bits. If a PHY is changing, the bit corresponding to the new PHY (as specified in Table 2.23) shall be set to 1 and the remaining bits to 0; if a PHY is remaining unchanged, then the corresponding field shall be set to the value 0.

Instant shall be set to indicate the instant described in Section 5.1.10.

If both the PHY_C_TO_P and PHY_P_TO_C fields are zero then there is no Instant and the Instant field is reserved for future use.

2.4.2.24 LL_MIN_USED_CHANNELS_IND

The format of the CtrData field is as shown in Figure 2.46.

CtrData	
PHYS (1 octet)	MinUsedChannels (1 octet)

Figure 2.46: CtrData field of the LL_MIN_USED_CHANNELS_IND PDU

The PHYS field shall be set to the PHY(s) for which the Peripheral has a minimum number of used channels requirement. The PHYS field consists of 8 bits as specified in Table 2.23. At least one bit in the field shall be set to 1.

The MinUsedChannels field contains the minimum number of channels to be used on the specified PHY. The MinUsedChannels field shall have a value in the range 2 to 37.

2.4.2.25 LL_CTE_REQ

The format of the CtrData field is shown in Figure 2.47.

CtrData		
MinCTELenReq (5 bits)	RFU (1 bit)	CTETypeReq (2 bits)

Figure 2.47: CtrData field of the LL_CTE_REQ PDU

MinCTELenReq shall contain the minimum length of the Constant Tone Extension (see Section 2.5.1) requested from the remote device, in 8 µs units. The value of the field shall be in the range 2 to 20.

CTETypeReq shall contain the type of the Constant Tone Extension requested from the remote device as specified in Table 2.24.

Value	Meaning
0	AoA Constant Tone Extension
1	AoD Constant Tone Extension with 1 µs slots
2	AoD Constant Tone Extension with 2 µs slots
3	Reserved for future use

Table 2.24: CTETypeReq field bit meanings

2.4.2.26 LL_CTE_RSP

The LL_CTE_RSP PDU does not have a CtrData field.

2.4.2.27 LL_PERIODIC_SYNC_IND

The format of the CtrData field is shown in Figure 2.48. This field is also embedded in the LL_PERIODIC_SYNC_WR_IND PDU (see Section 2.4.2.40).

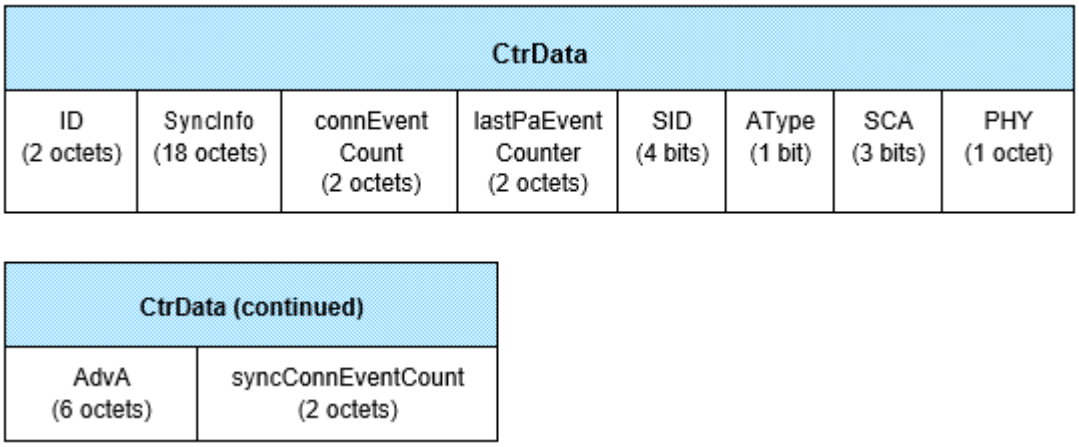

Figure 2.48: CtrData field of the LL_PERIODIC_SYNC_IND PDU

ID shall be set to an identifier provided by the Host. This is for use by higher-level protocols and its value is not specified or used by this specification.

SyncInfo has the meaning and format specified in Section 2.3.4.6, except that the reference point for syncPacketWindowOffset is the anchor point of the nearest connection event with the counter value specified in the connEventCount field and a zero offset does not have a special meaning.

connEventCount shall be set to a connection event counter value that meets the requirement currEvent - 2^{14} < connEventCount < currEvent + 2^{14} (*mod* 65536), where currEvent is the counter value for the connection event when the LL_PERIODIC_SYNC_IND PDU is being transmitted (or retransmitted).

In an LL_PERIODIC_SYNC_IND PDU, lastPaEventCounter shall be set to the paEventCounter applying to the AUX_SYNC_IND PDU used to determine the contents of the SyncInfo; the device sending this PDU shall have actually transmitted or received the AUX_SYNC_IND PDU.

When embedded in an LL_PERIODIC_SYNC_WR_IND PDU, lastPaEventCounter shall be set to the paEventCounter applying to the AUX_SYNC_SUBEVENT_IND PDU in subevent 0 used to determine the contents of the SyncInfo; the device sending the

LL_PERIODIC_SYNC_WR_IND PDU shall have actually transmitted or received an AUX_SYNC_SUBEVENT_IND PDU in a subevent of that periodic advertising event.

The lastPaEventCounter field and the PeriodicEventCounter field of the SyncInfo shall be equal, shall have a difference of 1 (*mod* 65536), or shall represent times not more than 5 seconds apart.

SID shall be set to the Advertising SID subfield of the advertising set pointing to the periodic advertising.

AType shall be 0 if the AdvA field holds a public address and 1 if it holds a random address.

SCA shall be set to indicate the sleep clock accuracy of the device sending this PDU. The value shall be represented in the same way as in the CONNECT_IND PDU (see Section 2.3.3.1).

PHY shall be set to indicate the PHY used by the periodic advertising. The bit corresponding to the PHY (as specified in Table 2.23) shall be set to 1 and the remaining bits to 0.

If the advertiser's address in the advertising set pointing to the periodic advertising is a resolvable private address, AdvA shall be set to any resolvable private address that was generated using the same IRK. Otherwise, AdvA shall be set to the advertiser's address in the advertising set.

syncConnEventCount shall be set to the connection event counter for the connection event that the sending device used in determining the contents of this PDU. This shall be a connection event where the sending device received a packet from the device it will send the LL_PERIODIC_SYNC_IND PDU to and, if the sending device is the Peripheral on the piconet containing those two devices, it used the received packet to synchronize its anchor point (see Section 4.5.7). This means that the connection must be established before this PDU can be transmitted.

2.4.2.28 LL_CLOCK_ACCURACY_REQ and LL_CLOCK_ACCURACY_RSP

The format of the CtrData field is shown in Figure 2.49.

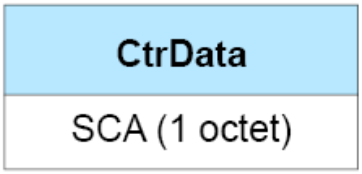

Figure 2.49: CtrData field of the LL_CLOCK_ACCURACY_REQ and LL_CLOCK_ACCURACY_RSP PDUs

The SCA field shall indicate the current *centralSCA* (if the PDU is sent by the Central) or *peripheralSCA* (if the PDU is sent by the Peripheral) used to determine the worst case sleep clock accuracy of the sending device as defined in Section 4.2.2. The format of this field is identical to the SCA field in the CONNECT_IND PDU (see Section 2.3.3.1).

2.4.2.29 LL_CIS_REQ

The format of the CtrData field is shown in Figure 2.50.

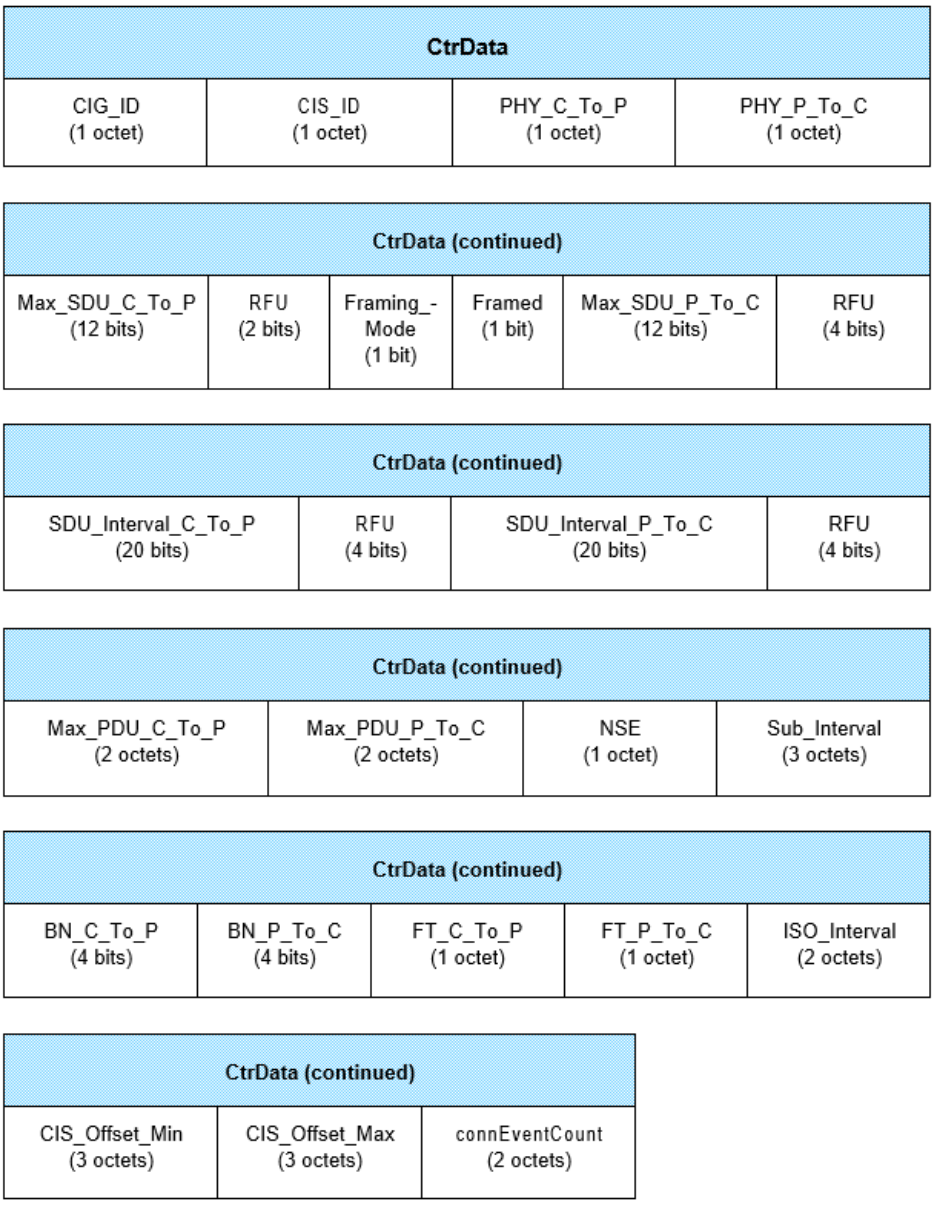

Figure 2.50: CtrData field of the LL_CIS_REQ PDU

CIG_ID shall be set to the CIG identifier as defined in Section 4.5.14.

CIS_ID shall be set to the CIS identifier as defined in Section 4.5.13.1

PHY_C_To_P shall be set to indicate the PHY that shall be used from the Central to the Peripheral, as defined in Table 2.23. Exactly 1 bit shall be set.

PHY_P_To_C shall be set to indicate the PHY that shall be used from the Peripheral to the Central, as defined in Table 2.23. Exactly 1 bit shall be set.

Max_SDU_C_To_P shall be set to the maximum size of an SDU, in octets, from the Central's Host.

Framed shall be set to 0 for unframed Data PDUs and 1 for framed Data PDUs.

For framed Data PDUs, Framing_Mode shall be set to 0 if Segmentable mode is being used and to 1 if Unsegmented mode is being used. For unframed Data PDUs, Framing_Mode is RFU.

Max_SDU_P_To_C shall be set to the maximum size of an SDU, in octets, from the Peripheral's Host.

SDU_Interval_C_To_P shall be set to the time, in microseconds, between two consecutive SDUs from the Central's Host. The value shall be between 255 and 1048575.

SDU_Interval_P_To_C shall be set to the time, in microseconds, between two consecutive SDUs from the Peripheral's Host. The value shall be between 255 and 1048575.

Max_PDU_C_To_P shall be set to the maximum Payload field size, in octets, from the Central to the Peripheral. The value shall be between 0 and 251 octets. This field shall be set to 0 if and only if BN_C_To_P is set to 0.

Max_PDU_P_To_C shall be set to the maximum Payload field size, in octets, from the Peripheral to the Central. The value shall be between 0 and 251 octets. This field shall be set to 0 if and only if BN_P_To_C is set to 0.

NSE shall be set to the maximum number of subevents in each CIS event. The value shall be between 1 and 31.

Sub_Interval shall be set to the time, in microseconds, between the start of a subevent and the start of the next subevent for that CIS in the same CIS event. The value shall be set to 0 if the NSE field is set to 1; otherwise the value shall be at least 400 µs and shall be less than ISO_Interval.

BN_C_To_P shall be set to the BN parameter value used from the Central to Peripheral, as defined in Section 4.5.13.2. The value shall be between 0 and 15.

BN_P_To_C shall be set to the BN parameter value used from the Peripheral to Central, as defined in Section 4.5.13.2. The value shall be between 0 and 15.

FT_C_To_P shall be set to the FT parameter value used from the Central to the Peripheral, as defined in Section 4.5.13.2. The value shall be between 1 and 255.

FT_P_To_C shall be set to the FT parameter value used from the Peripheral to the Central, as defined in Section 4.5.13.2. The value shall be between 1 and 255.

ISO_Interval shall be set to the time between two consecutive CIS anchor points in units of 1.25 ms. The value shall be between 4 and 3200 (i.e. 5 ms to 4 s).

CIS_Offset_Min shall be set to the proposed minimum time, in microseconds, between the ACL anchor point of the connection event with the connection event counter equal to *connEventCount* and the first CIS anchor point. The value shall be at least 500 µs.

CIS_Offset_Max shall be set to the proposed maximum time, in microseconds, between the ACL anchor point of the connection event with the connection event counter equal to *connEventCount* and the first CIS anchor point. The value shall be greater than or equal to CIS_Offset_Min and less than connInterval. CIS_Offset_Max should be less than (connInterval – ((NSE – 1) × Sub_Interval + MPT_C + T_IFS_CIS + MPT_P + T_MSS_CIS)), where MPT_C and MPT_P are defined in Section 4.5.13.1. For the first CIS in a CIG it should be less than (connInterval – (CIG_Sync_Delay + T_MSS_CIS)).

connEventCount shall be set to a connection event counter value that meets the requirement currEvent – 2^{14} < *connEventCount* < currEvent + 2^{14} (*mod* 65536), where *currEvent* is the counter value for the connection event where the PDU containing this field is being transmitted or retransmitted. *connEventCount* should be set to a value greater than *currEvent* of the event in which the LL_CIS_REQ PDU is first transmitted.

2.4.2.30 LL_CIS_RSP

The format of the CtrData field is shown in Figure 2.51.

CtrData		
CIS_Offset_Min (3 octets)	CIS_Offset_Max (3 octets)	connEventCount (2 octets)

Figure 2.51: CtrData field of the LL_CIS_RSP PDU

Each field has the same meaning as the field with the same name in the LL_CIS_REQ PDU.

2.4.2.31 LL_CIS_IND

The format of the CtrData field is shown in Figure 2.52.

CtrData				
AA (4 octets)	CIS_Offset (3 octets)	CIG_Sync_Delay (3 octets)	CIS_Sync_Delay (3 octets)	connEventCount (2 octets)

Figure 2.52: CtrData field of the LL_CIS_IND PDU

AA shall be set to the Access Address of the CIS, generated by the Link Layer following the rules specified in Section 2.1.2.

CIS_Offset shall be set to the time, in microseconds, from the ACL anchor point of the connection event that is referenced by *connEventCount* to the first CIS anchor point.

CIG_Sync_Delay shall be set to the value of CIG_Sync_Delay, as defined in Section 4.5.14.1, in microseconds.

CIS_Sync_Delay shall be set to the value of CIS_Sync_Delay, as defined in Section 4.5.14.1, in microseconds.

connEventCount shall be set to a connection event counter value that meets the requirement $currEvent - 2^{14} < connEventCount < currEvent + 2^{14}$ (*mod* 65536), where *currEvent* is the ACL connection event counter value for the connection event where the LL_CIS_IND PDU is being transmitted. *connEventCount* should be set to a value greater than *currEvent* of the event in which the LL_CIS_IND PDU is first transmitted.

2.4.2.32 LL_CIS_TERMINATE_IND

The format of the CtrData field is shown in Figure 2.53.

CtrData		
CIG_ID (1 octet)	CIS_ID (1 octet)	ErrorCode (1 octet)

Figure 2.53: CtrData field of the LL_CIS_TERMINATE_IND PDU

CIG_ID shall be set to the identifier of the CIG containing the CIS being terminated.

CIS_ID shall be set to the identifier of the CIS being terminated.

ErrorCode shall be set to inform the peer why the CIS is about to be terminated (see [Vol 1] Part F, Controller Error Codes for a list of error codes and descriptions).

2.4.2.33 LL_POWER_CONTROL_REQ

The format of the CtrData field is shown in Figure 2.54.

CtrData		
PHY (1 octet)	Delta (1 octet)	TxPower (1 octet)

Figure 2.54: CtrData field of the LL_POWER_CONTROL_REQ PDU

PHY shall be set to indicate the PHY for which the request is being made. The bit corresponding to the PHY (as specified in Table 2.25) shall be set to 1 and the remaining bits to 0.

Bit number	Meaning
0	LE 1M PHY
1	LE 2M PHY
2	LE Coded PHY with S=8 data coding
3	LE Coded PHY with S=2 data coding
All other bits	Reserved for future use

Table 2.25: PHY field bit meanings

Delta shall be set to the requested change in the recipient's transmit power level, in dB, for the PHY indicated. The value is a signed integer: a positive value indicates a request to increase the transmit power level, a negative value indicates a request to decrease it, and zero indicates that no change is being requested. A value of 0x7F indicates a request to increase to the maximum power level.

TxPower shall be set to the sender's transmit power level for the PHY indicated. The value is in dBm, represented as a signed integer. When set to 127, it indicates that the value is unavailable. It shall not be set to 126.

2.4.2.34 LL_POWER_CONTROL_RSP

The format of the CtrData field is shown in Figure 2.55.

CtrData					
Min (1 bit)	Max (1 bit)	RFU (6 bits)	Delta (1 octet)	TxPower (1 octet)	APR (1 octet)

Figure 2.55: CtrData field of the LL_POWER_CONTROL_RSP PDU

Min shall be set if the sender is currently at the minimum supported power level.

Max shall be set if the sender is currently at the maximum supported power level.

Note: if Min and Max are both set then the sender has a single fixed transmit power level.

Delta shall be set to the actual change in the sender's transmit power level, in dB, that the sender has made for the PHY requested. The value is a signed integer, with a positive value indicating a power increase, and a negative value indicating a power decrease. Zero indicates that there was no change.

TxPower shall be set to the sender's transmit power level for the PHY requested. The value is in dBm, represented as a signed integer. When set to 127, it indicates that the value is unavailable. When set to 126, it indicates that the sender is not currently managing power for the requested PHY; in this case all other fields shall be ignored.

APR (Acceptable Power Reduction) shall be set to the maximum decrease in radiative transmit power level of the peer device in dB, for the PHY requested, that is acceptable to the device sending this PDU. When set to 0xFF, it indicates that the sender is unable to determine a value.

2.4.2.35 LL_POWER_CHANGE_IND

The format of the CtrData field is shown in Figure 2.56.

CtrData					
PHY (1 octet)	Min (1 bit)	Max (1 bit)	RFU (6 bits)	Delta (1 octet)	TxPower (1 octet)

Figure 2.56: CtrData field of the LL_POWER_CHANGE_IND PDU

PHY shall be set to indicate the PHY(s) for which the power level has changed, using the values listed in Table 2.25. The PHY field may have more than one bit set if the other fields have the same values for the PHYs being reported.

Min shall be set if the sender is currently at the minimum supported power level.

Max shall be set if the sender is currently at the maximum supported power level.

Note: if Min and Max are both set then the sender has a single fixed transmit power level.

Delta shall be set to the change in the sender's transmit power level, if any, for the PHY(s) indicated. The value is a signed integer in dB, with a positive value indicating a power increase, and a negative value indicating a power decrease. Zero indicates that there was no change.

TxPower shall be set to the sender's transmit power level for the PHY(s) indicated. The value is in dBm, represented as a signed integer. When set to 127, it indicates that the value is unavailable. When set to 126, it indicates that the sender has stopped managing power for the indicated PHY(s); in this case all other fields shall be ignored.

2.4.2.36 LL_SUBRATE_REQ

The format of the CtrData field is shown in Figure 2.57.

CtrData				
SubrateFactorMin (2 octets)	SubrateFactor-Max (2 octets)	Max_Latency (2 octets)	Continuation-Number (2 octets)	Timeout (2 octets)

Figure 2.57: CtrData field of the LL_SUBRATE_REQ PDU

The SubrateFactorMin field shall be set to the minimum requested *connSubrateFactor*, as defined in Section 4.5.1.

The SubrateFactorMax field shall be set to the maximum requested *connSubrateFactor*, as defined in Section 4.5.1.

The Max_Latency field shall be set to the maximum requested *connPeripheralLatency*, as defined in Section 4.5.1, in subrated events. The same maximum shall apply irrespective of the subrating factor actually chosen. The value of SubrateFactorMax × (Max_Latency + 1) shall be less than or equal to than 500.

The ContinuationNumber field shall be set to the minimum requested *connContinuationNumber*, as defined in Section 4.5.1.

The Timeout field shall be set to indicate the requested *connSupervisionTimeout* value, as defined in Section 4.5.2, in the following manner:

connSupervisionTimeout = Timeout × 10 ms.

2.4.2.37 LL_SUBRATE_IND

The format of the CtrData field is shown in Figure 2.58.

CtrData				
SubrateFactor (2 octets)	SubrateBaseEvent (2 octets)	Latency (2 octets)	Continuation-Number (2 octets)	Timeout (2 octets)

Figure 2.58: CtrData field of the LL_SUBRATE_IND PDU

The SubrateFactor field shall be set to the new *connSubrateFactor*, as defined in Section 4.5.1, to be used on the connection.

The SubrateBaseEvent field shall be set to the new *connSubrateBaseEvent,* as defined in Section 4.5.1, to be used on the connection.

The Latency field shall be set to the new *connPeripheralLatency* in subrated events, as defined in Section 4.5.1, to be used on the connection.

The ContinuationNumber field shall be set to the new *connContinuationNumber*, as defined in Section 4.5.1, to be used on the connection.

The Timeout field shall be set to indicate the new *connSupervisionTimeout* value, as defined in Section 4.5.2, in the following manner:

connSupervisionTimeout = Timeout × 10 ms.

2.4.2.38 LL_CHANNEL_REPORTING_IND

The format of the CtrData field is shown in Figure 2.59.

CtrData		
Enable (1 octet)	Min_Spacing (1 octet)	Max_Delay (1 octet)

Figure 2.59: CtrData field of the LL_CHANNEL_REPORTING_IND

Enable shall be set to indicate whether channel classification reporting needs to be enabled or disabled as specified in Table 2.26.

Value	Meaning
0x00	Disable channel classification reporting
0x01	Enable channel classification reporting
All other values	Reserved for future use

Table 2.26: Enable field values

Min_Spacing shall be set to indicate, in units of 200 ms, the minimum amount of time from the last LL_CHANNEL_STATUS_IND PDU that was sent before the next LL_CHANNEL_STATUS_IND PDU may be sent. The value shall be between 5 (1 second) and 150 (30 seconds).

Max_Delay shall be set to indicate, in units of 200 ms, the maximum amount of time between the change in the channel classification being detected by a Peripheral and its generation of an LL_CHANNEL_STATUS_IND PDU. The value shall be between 5 (1 second) and 150 (30 seconds). Max_Delay shall be greater than or equal to Min_Spacing.

2.4.2.39 LL_CHANNEL_STATUS_IND

The format of the CtrData field is shown in Figure 2.60.

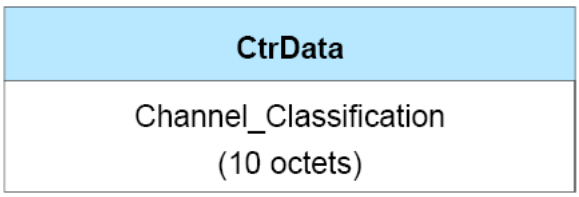

Figure 2.60: CtrData field of the LL_CHANNEL_STATUS_IND

Channel_Classification has the type uint2[37]. The n^{th} (numbering from 0) element defines the classification of data channel index n. The value of each element indicates:

- 0 = *unknown*
- 1 = *good*
- 2 = reserved for future use
- 3 = *bad*

2.4.2.40 LL_PERIODIC_SYNC_WR_IND

The format of the CtrData field is shown in Figure 2.61.

CtrData					
CtrData of LL_PERIODIC_SYNC_-IND (34 octets)	RspAA (4 octets)	numSub-events (1 octet)	sub-event-Interval (1 octet)	response-SlotDelay (1 octet)	response-SlotSpacing (1 octet)

Figure 2.61: CtrData field of the LL_PERIODIC_SYNC_WR_IND PDU

The CtrData of LL_PERIODIC_SYNC_IND field has the meaning and format specified in Section 2.4.2.27.

The RspAA field shall be set to the Access Address to be used by the device when it transmits a response packet to the periodic advertiser.

The numSubevents field shall be set to the number of subevents.

The subeventInterval field shall be set to the time, in 1.25 ms units, from the start of one subevent to the start of the next subevent.

The responseSlotDelay field shall be set to the time, in 1.25 ms units, from the start of one subevent to the first response slot.

responseSlotSpacing shall be set to the time, in 0.125 ms units, from the start of one response slot to the start of the next response slot.

2.4.2.41 LL_FEATURE_EXT_REQ and LL_FEATURE_EXT_RSP

The format of the CtrData field is shown in Figure 2.62.

CtrData		
MaxPage (1 octet)	PageNumber (1 octet)	FeaturePage (24 octets)

Figure 2.62: CtrData field of the LL_FEATURE_EXT_REQ and LL_FEATURE_EXT_RSP PDUs

MaxPage shall contain the number of the highest page of the sender's FeatureSet, with certain bits set to 0 as specified in Section 4.6, containing at least one bit set to 1.

PageNumber shall contain the page number of the page stored in FeaturePage, in the range 0x01 to 0x0A.

FeaturePage shall contain the set of features in page PageNumber of the sender's FeatureSet, with certain bits set to 0, as specified in Section 4.6.

2.4.2.42 LL_CS_SEC_REQ

The format of the CtrData field is shown in Figure 2.63.

CtrData		
CS_IV_C (8 octets)	CS_IN_C (4 octets)	CS_PV_C (8 octets)

Figure 2.63: CtrData field of the LL_CS_SEC_REQ PDU

The CS_IV_C field shall contain the Central's portion of the initialization vector used for CS security.

The CS_IN_C field shall contain the Central's portion of the instantiation nonce used for CS security.

The CS_PV_C field shall contain the Central's portion of the personalization vector used for CS security.

2.4.2.43 LL_CS_SEC_RSP

The format of the CtrData field is shown in Figure 2.64.

CtrData		
CS_IV_P (8 octets)	CS_IN_P (4 octets)	CS_PV_P (8 octets)

Figure 2.64: CtrData field of the LL_CS_SEC_RSP PDU

The CS_IV_P field shall contain the Peripheral's portion of the initialization vector used for CS security.

The CS_IN_P field shall contain the Peripheral's portion of the instantiation nonce used for CS security.

The CS_PV_P field shall contain the Peripheral's portion of the personalization vector used for CS security.

2.4.2.44 LL_CS_CAPABILITIES_REQ and LL_CS_CAPABILITIES_RSP

The format of the CtrData field is shown in Figure 2.65.

CtrData						
Mode_Types (1 octet)	RTT_-Capability (1 octet)	RTT_AA_-Only_N (1 octet)	RTT_Sounding_-N (1 octet)	RTT_Random_-Sequence_N (1 octet)	NADM_Sounding_-Capability (2 octets)	NADM_Random_-Capability (2 octets)

CtrData (continued)						
CS_SYNC_-PHY_-Capability (1 octet)	Num_Ant (4 bits)	Max_Ant_-Path (4 bits)	Role (2 bits)	RFU (1 bit)	No_FAE (1 bit)	Channel Selection #3c (1 bit)

CtrData (continued)						
Sounding_-PCT_-Estimate (1 bit)	RFU (2 bits)	Num_-Configs (1 octet)	Max_-Procedures_-Supported (2 octets)	T_SW (1 octet)	T_IP1_Capability (2 octets)	T_IP2_Capability (2 octets)

CtrData (continued)			
T_FCS_-Capability (2 octets)	T_PM_-Capability (2 octets)	RFU (1 bit)	TX_SNR_-Capability (7 bits)

Figure 2.65: CtrData field of the LL_CS_CAPABILITIES_REQ PDU

The Mode_Types field is a bit field that shall be set to indicate which of the optional CS modes are supported by the Link Layer transmitting this PDU, as described in [Vol 6] Part H, Section 4.4.

Bit Number	Meaning
0	Mode-3
All other bits	Reserved for future use

Table 2.27: Mode_Types field values

A Controller that supports mode-3 shall support the following section of this document:

- Channel Sounding step mode-3 ([Vol 6] Part H, Section 4.3.4)

The RTT_Capability field shall be set to indicate which of the time-of-flight accuracy requirements described in [Vol 6] Part H, Section 3.1.2 are met by the corresponding “N” count values (e.g. RTT_AA_Only_N, RTT_Sounding_N, RTT_Random_Sequence_N) for at least one combination of a specific PHY and Payload field length by that device. If a bit is set to 1, then the corresponding “N” value reflects the 10 ns requirement for that RTT variant. If a bit is set to 0 (default), then either the corresponding “N” value reflects the 150 ns requirement for that RTT variant or that variant is not supported. The respective bits are only valid if the corresponding "N" value is not 0. If the corresponding “N” value is set to 0, then the respective bit shall be set to 0. One or more bits in this field may be set.

Bit Number	Meaning
0	0 = The value in the RTT_AA_Only_N field refers to the “N” value that meets the 150 ns accuracy requirement. 1 = The value in the RTT_AA_Only_N field refers to the “N” value that meets the 10 ns accuracy requirement.
1	0 = The value in the RTT_Sounding_N field refers to the “N” value that meets the 150 ns accuracy requirement. 1 = The value in the RTT_Sounding_N field refers to the “N” value that meets the 10 ns accuracy requirement.
2	0 = The value in the RTT_Random_Sequence_N field refers to the “N” value that meets the 150 ns accuracy requirement. 1 = The value in the RTT_Random_Sequence_N field refers to the “N” value that meets the 10 ns accuracy requirement.
All other bits	Reserved for future use

Table 2.28: RTT_Capability field values

A device that supports the RTT_Capability shall support the following section of this document:

- [Vol 6] Part H, Section 3.1

The RTT_AA_Only_N, RTT_Sounding_N, and RTT_Random_Sequence_N fields shall hold the values specified by the product manufacturer to satisfy the accuracy

requirements described in [Vol 6] Part H, Section 3.1.2. If an implementation supports optional transmit and receive PHYs as indicated by the CS_SYNC_PHY_Capability field, then the corresponding field shall be set to the highest “N” value derived when tested across all mandatory and optional PHYs. The value of RTT_AA_Only_N shall be non-zero. If an implementation does not support another RTT type, then the corresponding field shall be set to 0.

A device that supports any of the RTT types shall support the following sections of this document:

- [Vol 6] Part H, Section 2
- [Vol 6] Part H, Section 3.1

The NADM_Sounding_Capability and NADM_Random_Capability fields are bit-mapped fields that shall be set to indicate the Normalized Attack Detector Metric support described in [Vol 6] Part H, Section 3.5.1, that shall be applied by the local Controller whenever a CS_SYNC with a sounding sequence or random sequence is received, respectively. A value of 0 indicates no NADM support availability for either of the two CS_SYNC Payload field types.

Bit Number	Meaning
0	Phase-based NADM (see [Vol 6] Part H, Section 3.5.3.4)
All other bits	Reserved for future use

Table 2.29: NADM_Sounding_Capability and NADM_Random_Capability field values

A device that supports the NADM shall support the following section of this document:

- [Vol 6] Part H, Section 3.5.1

A device that supports phase-based NADM shall support the following section of this document.

- [Vol 6] Part H, Section 3.5.3.4

The CS_SYNC_PHY_Capability field is a bit-mapped field that shall be set to indicate which of the optional transmit and receive PHYs are supported by the Link Layer transmitting this PDU for CS_SYNC exchanges during mode-0, mode-1, and mode-3 steps as described in [Vol 6] Part H, Section 4.3.

Bit Number	Meaning
1	LE 2M PHY
2	LE 2M 2BT PHY
All other bits	Reserved for future use

Table 2.30: CS_SYNC_PHY field values

A device that supports the LE 2M PHY for CS_SYNC exchanges shall support the following section of this document:

- [Vol 6] Part A, Section 3.1

A device that supports the LE 2M 2BT PHY for CS_SYNC exchanges shall support the following sections of this document:

- [Vol 6] Part A, Section 3.1
- [Vol 6] Part A, Section 3.1.2

The Num_Ant field shall be set to the number of antenna elements that are available for CS tone exchanges. The Num_Ant field shall be set to a value between 1 and 4. Each antenna element reflected by this Num_Ant field is ordered by the local device from the first ordered antenna element to the Num_Ant ordered element. This ordering is implementation specific but should remain constant.

A device that supports a Num_Ant value greater than 1 shall support the following sections of this document:

- [Vol 6] Part A, Section 5.3
- [Vol 6] Part H, Section 4.7

The Max_Ant_Path field shall be set to the maximum number of antenna paths that are supported by the device for CS tone exchanges. The field shall be set to a value between 1 and 4 and shall be greater than or equal to the value set for the Num_Ant field.

A device that supports a Max_Ant_Path value greater than 1 shall support the following sections of this document:

- [Vol 6] Part A, Section 5.3
- [Vol 6] Part H, Section 4.7

The Role field shall be set to the CS role options that the Link Layer transmitting this PDU supports, as described in Section 5.1.25. At least one bit shall be set in this field.

Bit Number	Meaning
0	Initiator
1	Reflector
All other bits	Reserved for future use

Table 2.31: Role field values

A device that supports either the initiator or reflector role shall support the following section of this document:

- [Vol 6] Part H

The No_FAE bit shall be set to 1 if the transmitting device supports only an FAE of 0 (see Section 2.4.2.52, for all allowed CS channels as specified in [Vol 6] Part H, Section 1, for the device's mode-0 transmissions when in the reflector role. Otherwise, the No_FAE bit shall be set to 0.

A device shall set the No_FAE bit in accordance with the requirements described in the following sections of this document:

- Section 2.4.2.52 and
- [Vol 6] Part A, Section 3.5.1

The Channel Selection Algorithm #3c bit shall be set to 1 if Channel Selection Algorithm #3c is supported.

A device that supports Channel Selection Algorithm #3c shall support the following section of this document:

- [Vol 6] Part H, Section 4.1.4.2

The Sounding_PCT_Estimate bit shall be set to 1 if PCT estimates from a sounding sequence are supported and RTT_Sounding_N is set to a value greater than 0.

A device that supports PCT estimates from a sounding sequence shall support the following section of this document:

- [Vol 6] Part H, Section 3.3.1

The Num_Configs field shall be set to the number of independent CS configurations supported by the Link Layer transmitting this PDU for this specific ACL connection. The Num_Configs field shall be set to a value greater than 0 and less than or equal to 4.

The Max_Procedures_Supported field shall be set to the maximum possible value supported by the Link Layer transmitting this PDU for N_PROCEDURE_COUNT value

as described in Section 4.5.18.1. The Max_Procedures_Supported field shall be set to a value greater than or equal to 0, where 0 indicates the capability to run CS procedures repetitions until terminated.

The T_SW field shall be set to one of the valid values in units of microseconds, for the duration of the antenna switch period used by the local Controller, when antenna switching is performed during active transmissions as described in [Vol 6] Part H, Section 4.7.

The T_IP1_Capability field shall contain the supported optional durations for the T_IP1 parameter. Each supported duration is represented by a bit positioned according to the T_IP1 index defined in [Vol 6] Part H, Section 4.3.1. The LSB represents T_IP1 index 0, with the next adjacent bit represented by T_IP1 index 1, and so on. A bit value of 0 indicates that the specific T_IP1 duration is not supported. A bit value of 1 indicates that the specific T_IP1 duration is supported. Bit positions beyond the maximum T_IP1 index are reserved for future use.

The T_IP2_Capability field shall contain the supported optional durations for the T_IP2 parameter. Each supported duration is represented by a bit positioned according to the T_IP2 index defined in [Vol 6] Part H, Section 4.3.3. The LSB represents T_IP2 index 0, with the next adjacent bit represented by T_IP2 index 1, and so on. A bit value of 0 indicates that the specific T_IP2 duration is not supported. A bit value of 1 indicates that the specific T_IP2 duration is supported. Bit positions beyond the maximum T_IP2 index are reserved for future use.

The T_FCS_Capability field shall contain the supported optional durations for the T_FCS parameter. Each supported duration is represented by a bit positioned according to the T_FCS index defined in [Vol 6] Part H, Section 4.3. The LSB represents T_FCS index 0, with the next adjacent bit represented by T_FCS index 1, and so on. A bit value of 0 indicates that the specific T_FCS duration is not supported. A bit value of 1 indicates that the specific T_FCS duration is supported. Bit positions beyond the maximum T_FCS index are reserved for future use.

The T_PM_Capability field shall contain the supported optional durations for the T_PM parameter. Each supported duration is represented by a bit positioned according to the T_PM index defined in [Vol 6] Part H, Section 4.3.3. The LSB represents T_PM index 0, with the next adjacent bit represented by T_PM index 1, and so on. A bit value of 0 indicates that the specific T_PM duration is not supported. A bit value of 1 indicates that the specific T_PM duration is supported. Bit positions beyond the maximum T_PM index are reserved for future use.

The TX_SNR_Capability field shall contain the supported optional levels of TX SNR control for the transmission of CS_SYNC packets used in mode-1 and mode-3 steps. Each supported level is represented by a bit positioned according to the SNR Output

Index defined in [Vol 6] Part A, Section 3.1.3. The LSB represents the SNR output index 0, with the next adjacent bit represented by SNR output index 1, and so on. A bit value of 0 indicates that the specific SNR output level is not supported. A bit value of 1 indicates that the specific SNR output level is supported. Bit positions beyond the maximum SNR output index are reserved for future use.

A device that supports TX_SNR_CAPABILITY shall support the following section of this document:

- [Vol 6] Part A, Section 3.1.3

2.4.2.45 LL_CS_CONFIG_REQ

The format of the CtrData field is shown in Figure 2.66.

CtrData						
Config_ID (6 bits)	Action (2 bits)	ChM (10 octets)	ChM_Repetition (1 octet)	Main_Mode (1 octet)	Sub_Mode (1 octet)	Main_Mode_Min_-Steps (1 octet)

CtrData (continued)						
Main_Mode_-Max_Steps (1 octet)	Main_Mode_-Repetition (1 octet)	Mode_0_-Steps (1 octet)	CS_SYNC_-PHY (1 octet)	RTT_Type (4 bits)	Role (2 bits)	RFU (2 bits)

CtrData (continued)						
ChSel (4 bits)	Ch3cShape (4 bits)	Ch3cJump (1 octet)	T_IP1 (1 octet)	T_IP2 (1 octet)	T_FCS (1 octet)	T_PM (1 octet)

CtrData (continued)
RFU (1 octet)

Figure 2.66: CtrData field of the LL_CS_CONFIG_REQ PDU

The Config_ID field shall be set to the specific CS configuration ID that is being configured, as described in Section 5.1.25.

Value	Meaning
0 to 3	CS Configuration ID
All other values	Reserved for future use

Table 2.32: Config_ID values

The Action field indicates whether or not this specific configuration ID is being created or removed, as described in Section 5.1.25. If the Action field is set to removed, then all fields except for the Config_ID and the Action fields in this PDU are RFU.

Value	Meaning
0b00	Configuration is to be removed
0b01	Configuration is to be created
All other values	Reserved for future use

Table 2.33: Action field values

The ChM field contains the channel map indicating which channels shall be used and unused within the CS procedure. Every channel is represented by a bit positioned according to the CS channel index defined in [Vol 6] Part H, Section 1. The LSB represents CS channel index 0 and bit 78 represents CS channel index 78. ChM bits beyond this index range are RFU. A bit value of 1 indicates that the channel shall be used. A bit value of 0 indicates that the channel shall not be used. At least 15 channels shall be marked as used. Some channels are excluded from use in CS procedures, as described in [Vol 2] Part A, Section 2. These channels shall be marked as unused.

The value in the ChM_Repetition field shall indicate the number of times the ChM field is cycled through for non-mode-0 steps within a CS procedure. This value shall be greater than or equal to 1.

The Main_Mode and the Sub_Mode fields shall be set to indicate which CS modes are to be used within the CS procedure, as described in [Vol 6] Part H, Section 4.4.

Value	Meaning
0x01	Mode-1
0x02	Mode-2
0x03	Mode-3
0xFF	None; applies only to Sub_Mode selection and RFU for Main_Mode selection
All other values	Reserved for future use

Table 2.34: Main_Mode and Sub_Mode field values

The Main_Mode_Min_Steps and Main_Mode_Max_Steps fields shall be set to the range of Main_Mode steps to be executed before a Sub_Mode step is executed

within the CS procedure, as described in [Vol 6] Part H, Section 4.4. If the Sub_Mode field has been set to None, then these two fields shall be reserved for future use. Otherwise, Main_Mode_Min_Steps shall be greater than or equal to 1 and less than or equal to N_STEPS_MAX - 1. Main_Mode_Max_Steps shall be greater than or equal to Main_Mode_Min_Steps and less than or equal to N_STEPS_MAX - 1.

The Main_Mode_Repetition field shall be set to the number of Main_Mode steps taken from the end of the last CS subevent to be repeated at the beginning of the next CS subevent directly after the last mode-0 step of that subevent, as described in [Vol 6] Part H, Section 4.4. This field shall be set with a value from 0 to 3.

The Mode_0_Steps field shall be set to the number of mode-0 steps to be included at the beginning of each CS Subevent, as described in [Vol 6] Part H, Section 4.4. Mode_0_Steps shall be greater than or equal to 1 and less than or equal to 3.

The CS_SYNC_PHY field shall be set to the transmit and receive PHY to be used for CS_SYNC exchanges during mode-0, mode-1, and mode-3 steps, as described in [Vol 6] Part H, Section 4.3. The bit corresponding to that PHY, as specified in Table 2.35, shall be set to 1 and the remaining bits shall be set to 0.

Bit Number	Meaning
0	LE 1M PHY
1	LE 2M PHY
2	LE Coded PHY
3	LE 2M 2BT PHY
All other bits	Reserved for future use

Table 2.35: CS_SYNC_PHY field bit meanings

The RTT_Type field shall be set to indicate which RTT variant is to be used within the CS procedure, as described in [Vol 6] Part H, Section 2.

Value	Meaning
0x00	RTT CS AA-only timing
0x01	RTT with 32-bit sounding sequence
0x02	RTT with 96-bit sounding sequence
0x03	RTT with 32-bit random sequence
0x04	RTT with 64-bit random sequence
0x05	RTT with 96-bit random sequence
0x06	RTT with 128-bit random sequence
All other values	Reserved for future use

Table 2.36: RTT_Type field values

The Role field shall be set to the CS role that the Link Layer transmitting this PDU shall use, as described in Section 5.1.25.

Value	Meaning
0b00	Initiator
0b01	Reflector
All other values	Reserved for future use

Table 2.37: Role field values

The ChSel field shall be set to the channel selection algorithm to be used within the CS procedure for non-mode-0 steps, as described in [Vol 6] Part H, Section 4.1.

Value	Meaning
0b0000	Channel Selection Algorithm #3b
0b0001	Channel Selection Algorithm #3c
All other values	Reserved for future use

Table 2.38: ChSel field values

The Ch3cShape field shall be set to the selected shape to be rendered when Channel Selection Algorithm #3c is used, as described in [Vol 6] Part H, Section 4.1.4.2. The Ch3cShape field is valid only if the ChSel field has been set to Channel Selection Algorithm #3c; otherwise, the field is reserved for future use.

Value	Meaning
0x0	Hat shape
0x1	“X” shape
All other values	Reserved for future use

Table 2.39: Ch3cShape field values

The Ch3cJump field shall be set to one of the valid CSChannelJump values defined in Table 4.2 in Section 4.5.8.3.2. This field is valid only if the ChSel field has been set to Channel Selection Algorithm #3c; otherwise, the field is reserved for future use.

The T_IP1 field shall be set to the T_IP1 index as defined in [Vol 6] Part H, Section 4.3.1, which shows the selected duration of the interlude period used between CS_SYNC packets used in mode-0 and mode-1 steps.

The T_IP2 field shall be set to the T_IP2 index as defined in [Vol 6] Part H, Section 4.3.3, which shows the selected duration of the interlude period used between CS tones.

The T_FCS field shall be set to the T_FCS index as defined in Section 4.5.18.1, which shows the selected duration used for frequency changes.

The T_PM field shall be set to the T_PM index as defined in [Vol 6] Part H, Section 4.3.3, which shows the selected duration used for the phase measurement period of CS tones.

2.4.2.46 LL_CS_CONFIG_RSP

The format of the CtrData field is shown in Figure 2.67.

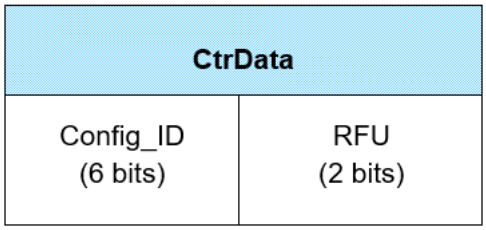

Figure 2.67: CtrData field of the LL_CS_CONFIG_RSP PDU

The Config_ID field has the same meaning as the Config_ID field in the LL_CS_CONFIG_REQ PDU (see Section 2.4.2.45).

2.4.2.47 LL_CS_REQ

The format of the CtrData field is shown in Figure 2.68.

CtrData						
Config_ID (6 bits)	RFU (2 bits)	connEventCount (2 octets)	Offset_Min (3 octets)	Offset_Max (3 octets)	Max_Procedure_Len (2 octets)	Event_Interval (2 octets)

CtrData (continued)						
Subevents_Per_Event (1 octet)	Subevent_Interval (2 octets)	Subevent_Len (3 octets)	Procedure_Interval (2 octets)	Procedure_Count (2 octets)	ACI (1 octet)	Preferred_Peer_Ant (1 octet)

CtrData (continued)			
PHY (1 octet)	Pwr_Delta (1 octet)	TX_SNR_I (4 bits)	TX_SNR_R (4 bits)

Figure 2.68: CtrData field of the LL_CS_REQ PDU

The Config_ID field shall be used to select a created CS procedure configuration parameter set, as described in Section 5.1.25.

The connEventCount field shall be set to a connection event counter value that meets the requirement $currEvent - 2^{14} < connEventCount < currEvent + 2^{14}$ (***mod*** 65536), where *currEvent* is the counter value for the connection event in which the PDU containing this field is being transmitted or retransmitted. The connEventCount field should be set to a value greater than the *currEvent* value of the event in which the LL_CS_REQ is first transmitted.

The Offset_Min field shall be set to the proposed minimum time, in microseconds, from the ACL anchor point of the connection event that is referenced by connEventCount to the start of the first CS subevent. The Offset_Min value shall be greater than or equal to 500 µs and less than 4 seconds.

The Offset_Max field shall be set to the proposed maximum time, in microseconds, between the ACL anchor point of the connection event from which the first CS step of the first CS subevent is offset. The value shall be greater than or equal to the Offset_Min value and shall be less than the LE connection interval.

The Max_Procedure_Len field shall be set to the proposed maximum extent of the entire CS procedure in units of 625 microseconds. This value is equivalent to the time

extent from the beginning of the transmission of the first CS step to the end of the transmission of the final CS step.

The Event_Interval field shall be set to time, in units of connection intervals between the start of two consecutive CS events that are offset directly from ACL anchor points as described in Section 5.1.26. This value shall be greater than or equal to 1 and less than or equal to 65535.

The Subevents_Per_Event field shall be set to indicate the number of CS subevents that are to be included in each CS event. This value shall be greater than or equal to 1 and is limited by the maximum number of subevents allowed in a CS procedure as described in Section 4.5.18.1. The use of this parameter is further described in Section 5.1.26.

The Subevent_Interval field shall be set to indicate the gap, in units of 625 microseconds, between the start of two consecutive CS subevents that are anchored starting from the same ACL anchor point. The Subevent_Interval field is valid only if Subevents_Per_Event > 1, otherwise this field shall be set to 0. This field is further defined in Section 5.1.26.

The Subevent_Len field shall be set to indicate the maximum duration of each CS subevent in microseconds and shall be greater than or equal to 1250 microseconds and less than 4 seconds. The Subevent_Len is further defined in Section 5.1.26.

The Procedure_Interval field shall be set to indicate the time in units of connection intervals between the start of consecutive CS procedures. The Procedure_Interval field shall be set to a value from 0 to 65535. This value shall be set to 0 if the procedure is only to be run once.

The Procedure_Count field shall be set to indicate the number of consecutive CS procedures to invoke. The Procedure_Count field shall be set to a value from 0 to 65535. A value of 0 indicates that CS procedures shall continue to be invoked until terminated, as described in Section 5.1.27.

The ACI field shall indicate the preferred ACI to use in the CS procedure, as described in [Vol 6] Part A, Section 5.3, where device A represents the initiator.

The Preferred_Peer_Ant field is a bit-mapped field that shall indicate the preferred peer-ordered antenna elements to be used by the peer for the antenna configuration denoted by the ACI field.

Bit Number	Meaning
0	Use first ordered antenna element
1	Use second ordered antenna element

Bit Number	Meaning
2	Use third ordered antenna element
3	Use fourth ordered antenna element
All other bits	Reserved for future use

Table 2.40: Preferred_Peer_Ant field values

The PHY field shall be set to indicate the remote device's Tx PHY, to which the Pwr_Delta field in this PDU applies. The bit corresponding to that PHY as specified in Table 2.25 shall be set to 1 and the remaining bits shall be set to 0.

The Pwr_Delta field shall represent the difference between the remote device's transmit power level for the CS tones and CS_SYNC packets, and the transmit power level for the PHY indicated by the PHY field. The value in the Pwr_Delta field is a signed integer in dB, with a positive value indicating a higher transmit power level for the CS tones and CS_SYNC packets, and a negative value indicating a lower transmit power level for the CS tones and CS_SYNC packets, compared to the transmit power level for the PHY indicated by the PHY field. A Pwr_Delta value of 0x00 indicates that the two transmit power levels are the same.

The TX_SNR_I field shall be set to indicate the SNR output index to be used by the initiator in the transmission of all CS_SYNC packets used in mode-1 and mode-3 steps, as described in [Vol 6] Part A, Section 3.1.3. This field shall be set to 0xF if SNR control is not to be used or not supported by the Channel Sounding initiator device.

The TX_SNR_R field shall be set to indicate the SNR output index to be used by the reflector in the transmission of all CS_SYNC packets used in mode-1 and mode-3 steps, as described in [Vol 6] Part A, Section 3.1.3. This field shall be set to 0xF if SNR control is not to be used or not supported by the Channel Sounding reflector device.

2.4.2.48 LL_CS_RSP

The format of the CtrData field is shown in Figure 2.69.

CtrData						
Config_ID (6 bits)	RFU (2 bits)	connEventCount (2 octets)	Offset_Min (3 octets)	Offset_Max (3 octets)	Event_Interval (2 octets)	Subevents_Per_-Event (1 octet)

CtrData (continued)					
Subevent_Interval (2 octets)	Subevent_Len (3 octets)	ACI (1 octet)	PHY (1 octet)	Pwr_Delta (1 octet)	RFU (1 octet)

Figure 2.69: CtrData field of the LL_CS_RSP PDU

The LL_CS_RSP CtrData fields have the same meaning as the fields in the LL_CS_REQ PDU CtrData field. The values of each field are selected as described in Section 5.1.26.

2.4.2.49 LL_CS_IND

The format of the CtrData field is shown in Figure 2.70.

CtrData						
Config_ID (6 bits)	RFU (2 bits)	connEventCount (2 octets)	Offset (3 octets)	Event_Interval (2 octets)	Subevents_Per_-Event (1 octet)	Subevent_Interval (2 octets)

CtrData (continued)				
Subevent_Len (3 octets)	ACI (1 octet)	PHY (1 octet)	Pwr_Delta (1 octet)	RFU (1 octet)

Figure 2.70: CtrData field of the LL_CS_IND PDU

The Config_ID, Event_Interval, Subevents_Per_Event, Subevent_Interval, Subevent_Len, ACI, PHY, and Pwr_Delta fields have the same meaning as the fields in the LL_CS_REQ PDU CtrData field.

The connEventCount field shall be set to a connection event counter value that meets the requirement $currEvent - 2^{14} < connEventCount < currEvent + 2^{14}$ (*mod* 65536),

where *currEvent* is the counter value for the connection event in which the PDU containing this field is being transmitted or retransmitted. The *connEventCount* value should be set to a value greater than the *currEvent* value of the event in which the LL_CS_IND is first transmitted.

The Offset field shall be set to the time, in microseconds, from the ACL anchor point of the connection event that is referenced by connEventCount to the start of the first CS subevent.

2.4.2.50 LL_CS_TERMINATE_REQ and LL_CS_TERMINATE_RSP

The format of the CtrData field is shown in Figure 2.71.

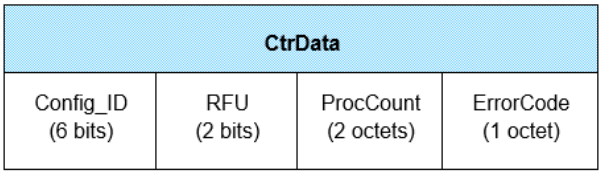

Figure 2.71: CtrData field of the LL_CS_TERMINATE_REQ and LL_CS_TERMINATE_RSP PDU

The Config_ID field shall be used to identify the CS procedure configuration parameter that was used to start the CS procedure repeat that is to be terminated.

The ProcCount field shall be set to the value of CSProcCount at the time this PDU is transmitted.

The ErrorCode field shall be set to inform the peer why the CS procedure repeat is about to be terminated (see [Vol 1] Part F, Controller Error Codes for a list of error codes and descriptions).

2.4.2.51 LL_CS_FAE_REQ

The LL_CS_FAE_REQ PDU does not have a CtrData field.

2.4.2.52 LL_CS_FAE_RSP

The format of the CtrData field is shown in Figure 2.72.

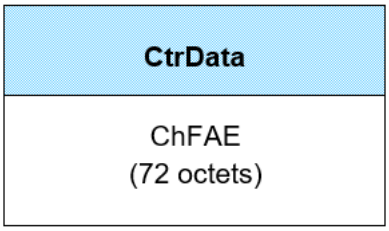

Figure 2.72: CtrData field of the LL_CS_FAE_RSP PDU

The ChFAE field contains the per-channel mode-0 FAE table of the local Controller. Every per-channel mode-0 FAE value is represented by an 8-bit signed integer, positioned per the CS channel index table in [Vol 6] Part H, Section 1. Only the allowed channels are represented, shifted lower to fill in the indices left void by the channel indices that are not allowed. Each FAE value spans the [-4, +3.96875] ppm range, with a resolution of 0.03125 ppm. A value of -128 then represents -4 ppm and a value of 127 represents 3.96875 ppm. Each FAE value is multiplied by 32 and then rounded to the nearest integer value within the signed integer range of [-128, 127]. A value of 0 then represents a range of -0.015625 ppm to 0.015625 ppm. The FAE is defined in [Vol 6] Part A, Section 3.5.1.

2.4.2.53 LL_CS_CHANNEL_MAP_IND

The format of the CtrData field is shown in Figure 2.73.

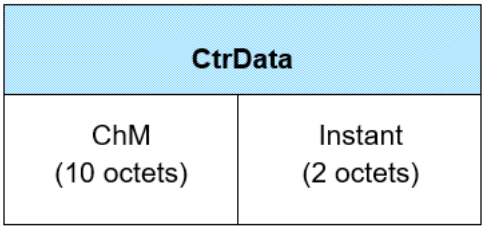

Figure 2.73: CtrData field of the LL_CS_CHANNEL_MAP_IND PDU

The ChM field contains the channel map indicating which channels shall be used and unused within the CS procedure. Every channel is represented by a bit positioned according to the CS channel index in [Vol 6] Part H, Section 1. The format of the field is identical to the ChM field in the LL_CS_CONFIG_REQ PDU (see Section 2.4.2.45).

The Instant field shall be set to a connection event counter value that meets the requirement *currEvent* - 2^{14} < *Instant* < *currEvent* + 2^{14} (*mod* 65536), where *currEvent* is the counter value for the connection event in which the PDU containing this field is being transmitted or retransmitted. The Instant field should be set to a value greater than the *currEvent* value of the event in which the LL_CS_CHANNEL_MAP_IND is first transmitted.

2.4.2.54 LL_FRAME_SPACE_REQ

The format of the CtrData field is shown in Figure 2.74.

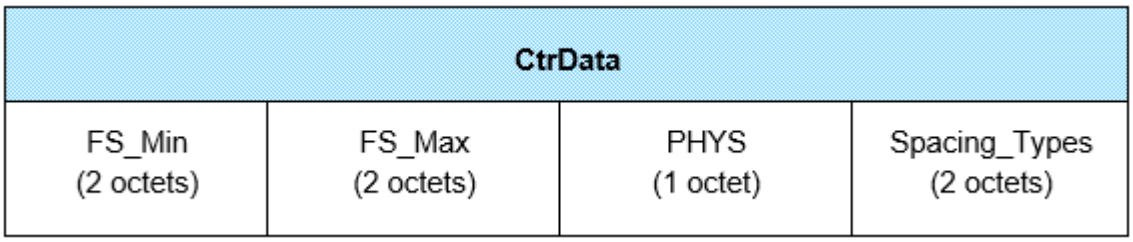

Figure 2.74: CtrData field of the LL_FRAME_SPACE_REQ

The FS_Min field shall be set to the minimum frame space value being requested by the Controller, in microseconds.

The FS_Max field shall be set to the maximum frame space value being requested by the Controller, in microseconds. The value shall be greater than or equal to FS_Min and shall not be greater than 10 ms.

The PHYS field shall be set to indicate the PHYs for which the request is being made. The bit corresponding to each PHY for which the request is being made (as specified in Table 2.23) shall be set to 1, and the remaining bits shall be set to 0. At least one bit shall be set to 1.

The Spacing_Types field shall be set to indicate the Frame Space (as defined in Section 4.1) for which the request is being made. The bit corresponding to each frame spacing type for which the request is being made (as specified in Table 2.41) shall be set to 1, and the remaining bits shall be set to 0. At least one bit shall be set to 1.

Bit number	Meaning
0	T_IFS_ACL_CP
1	T_IFS_ACL_PC
2	T_MCES
3	T_IFS_CIS
4	T_MSS_CIS
All other bits	Reserved for future use

Table 2.41: Spacing type

2.4.2.55 LL_FRAME_SPACE_RSP

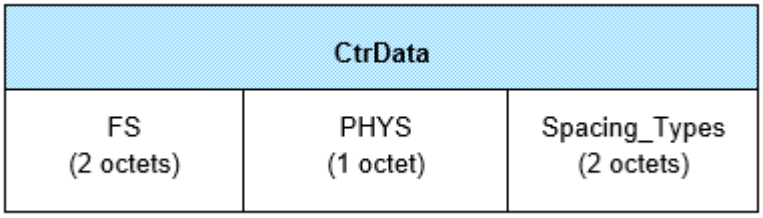

Figure 2.75: CtrData field of the LL_FRAME_SPACE_RSP

The FS field shall be set to the frame space value selected by the Controller, in microseconds.

The PHYS field indicates the PHYs for which the response is being sent. The bit corresponding to each PHY for which the response is being made (as specified in Table 2.23) shall be set to 1, and the remaining bits shall be set to 0. If all the frame space values for a PHY will remain unchanged, then the corresponding field shall be set to 0.

The Spacing_Types field indicates the spacing types for which the response is to be set. The bit corresponding to each spacing type for which the response is to be set (as specified in Table 2.41) shall be set to 1, and the remaining bits shall be set to 0. If all the frame space values for a spacing type will remain unchanged, then the corresponding field shall be set to 0.

2.5 Constant Tone Extension and IQ sampling

2.5.1 Constant Tone Extension structure and types

The Constant Tone Extension has a variable length; it shall be at least 16 µs and not greater than 160 µs. The contents are a constantly modulated series of 1s and no whitening shall be applied to them.

The first 4 µs of the Constant Tone Extension are termed the guard period and the next 8 µs are termed the reference period. After the reference period, the Constant Tone Extension consists of a sequence of alternating switch slots and sample slots, each either 1 µs or 2 µs long as specified by the Host. The 2-µs-long switch and sample slots are mandatory to support; the 1-µs-long switch and sample slots are optional to support. However, if a device supports 1-µs-long switch and sample slots, it shall support them on all supported PHYs that allow Constant Tone Extensions. The structure of the Constant Tone Extension is shown in Figure 2.76.

The Constant Tone Extension can be one of two types: AoA or AoD.

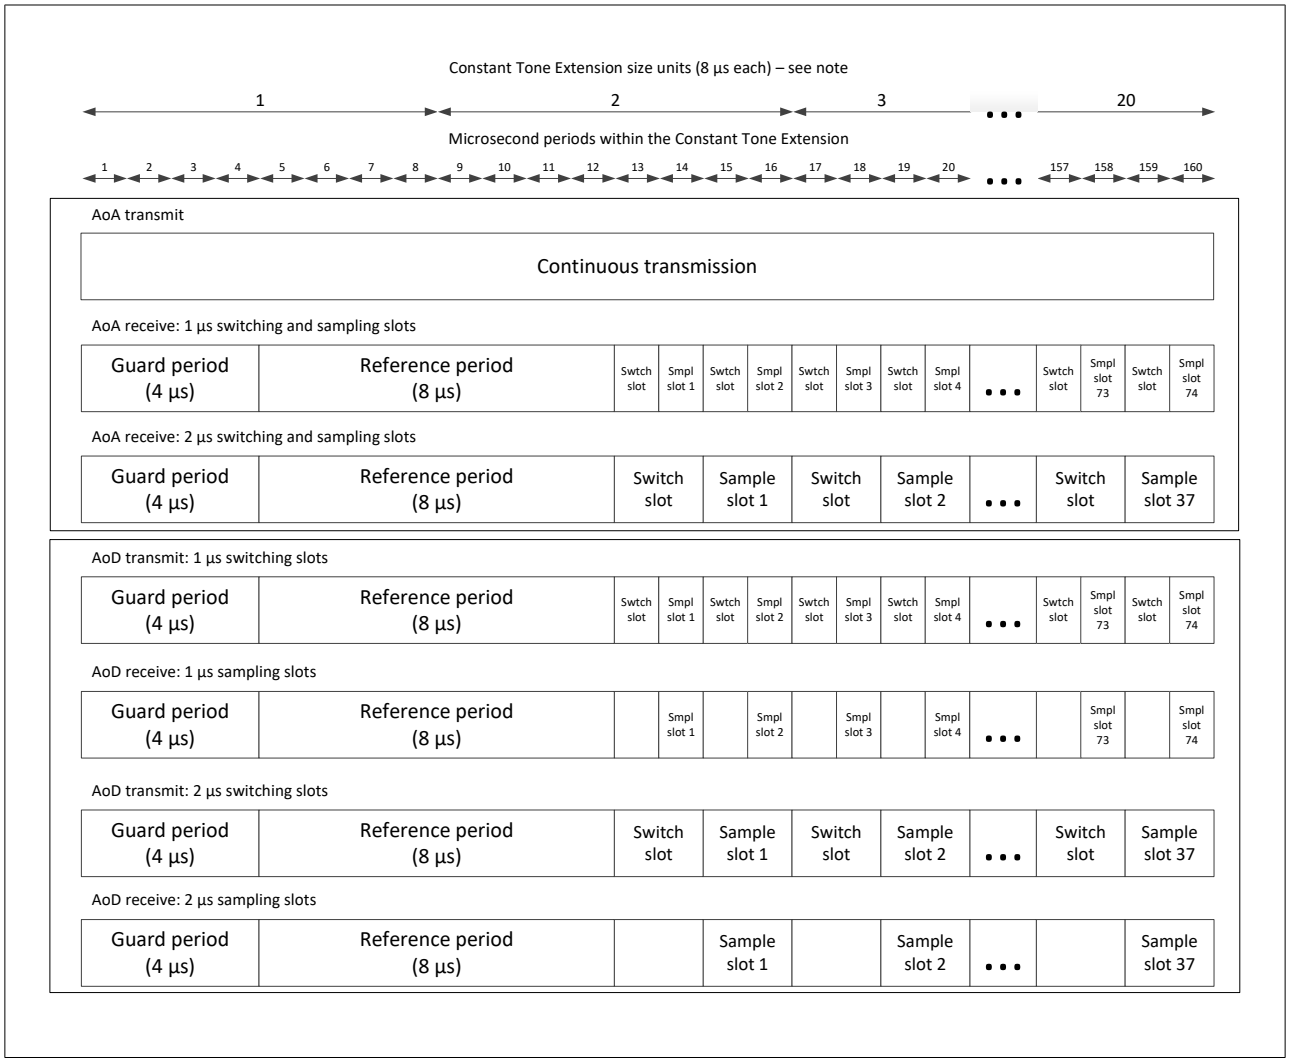

Figure 2.76: Constant Tone Extension structure

Note: See Section 2.4.2.25 for examples of the use of these units.

2.5.2 CTEInfo field

When present, the CTEInfo field is one octet with the format shown in Figure 2.77.

CTEInfo		
CTETime (5 bits)	RFU (1 bit)	CTEType (2 bits)

Figure 2.77: CTEInfo field

The presence of the CTEInfo field indicates that the packet includes a Constant Tone Extension.

The CTETime field defines the length of the Constant Tone Extension in 8 µs units. The value of the CTETime field shall be between 2 and 20; all other values are reserved for future use.

The CTEType field defines the type of the Constant Tone Extension and the duration of the switching slots. The value of the field is specified in Table 2.42 and the various possible formats are specified in Section 2.5.1.

CTEType value	Description
0	AoA Constant Tone Extension
1	AoD Constant Tone Extension with 1 µs slots
2	AoD Constant Tone Extension with 2 µs slots
3	Reserved for future use

Table 2.42: CTEType field encoding

2.5.3 Transmitting Constant Tone Extensions

When transmitting a packet that contains an AoA Constant Tone Extension, the transmitter shall not switch antennae. When transmitting a packet that contains an AoD Constant Tone Extension, the transmitter shall perform antenna switching at the rate and according to the switching pattern configured by the Host (see [Vol 6] Part A, Section 5).

A device that supports transmitting Constant Tone Extensions shall be able to transmit a Constant Tone Extension that is at least 16 µs long.

2.5.4 IQ sampling

When requested by the Host, the receiver shall perform IQ sampling when receiving a valid packet that contains a Constant Tone Extension and may perform IQ sampling when receiving a packet that contains a Constant Tone Extension but an incorrect CRC. The remainder of this section shall apply whenever the receiver performs IQ sampling on a packet.

When receiving a packet that contains an AoD Constant Tone Extension, the receiver does not need to switch antennae. When receiving a packet that contains an AoA Constant Tone Extension, the receiver shall perform antenna switching at the rate and according to the switching pattern configured by the Host (see [Vol 6] Part A, Section 5). In both cases, the receiver shall take an IQ sample each microsecond during the reference period and an IQ sample each sample slot (thus there will be 8 reference IQ samples, 1 to 37 IQ samples with 2 µs slots, and 2 to 74 IQ samples with 1 µs

slots, meaning 9 to 82 samples in total). The Controller shall report the IQ samples to the Host. The receiver shall sample the entire Constant Tone Extension, irrespective of length, unless this conflicts with other activities.

Note: In order to obtain good quality data for angle estimation, IQ samples should be taken at the same point within each IQ Sampling Window; this starts 0.125 µs after the beginning and ends 0.125 µs before the end of each microsecond period (see Figure 2.78). If 2 µs sample slots are used, the sampling should be done during the latter microsecond (see Figure 2.79).

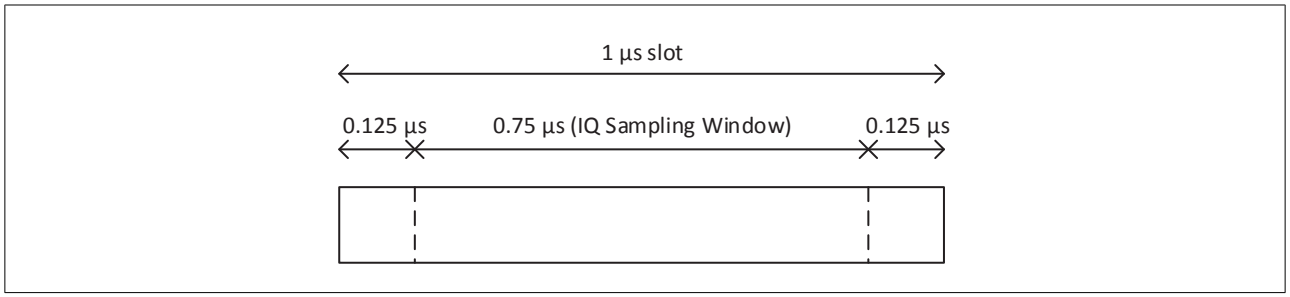

Figure 2.78: IQ Sampling Window for 1 µs sample slots

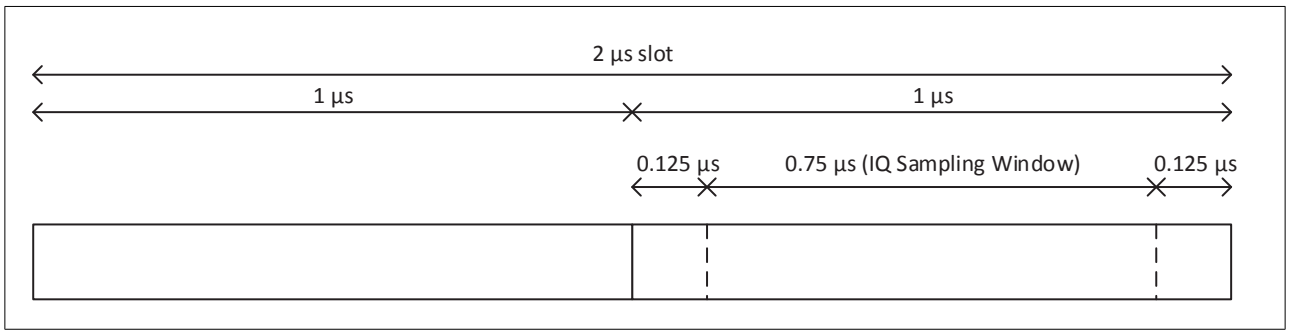

Figure 2.79: IQ Sampling Window for 2 µs sample slots

A Controller that supports IQ Sampling shall be able to measure the RSSI of received packets on any antenna used for receiving the body of the packet (in both cases excluding any Constant Tone Extension) and be able to receive and sample a Constant Tone Extension of any valid length.

If the Controller has insufficient resources to perform sampling on all Constant Tone Extensions it receives, it may stop sampling after it has reported at least one set of IQ samples to the Host. If the Controller stops sampling, it shall report this to the Host and should resume sampling at the start of the next periodic advertising event or connection event. If the required resources are not yet available, then the Controller may, but should not, report this to the Host again.

2.6 Isochronous Physical Channel PDU

The Isochronous Physical Channel PDU has a 16-bit Header field, a variable size Payload field, and may include a Message Integrity Check (MIC) field.

The Isochronous Physical Channel PDU is shown in Figure 2.80.

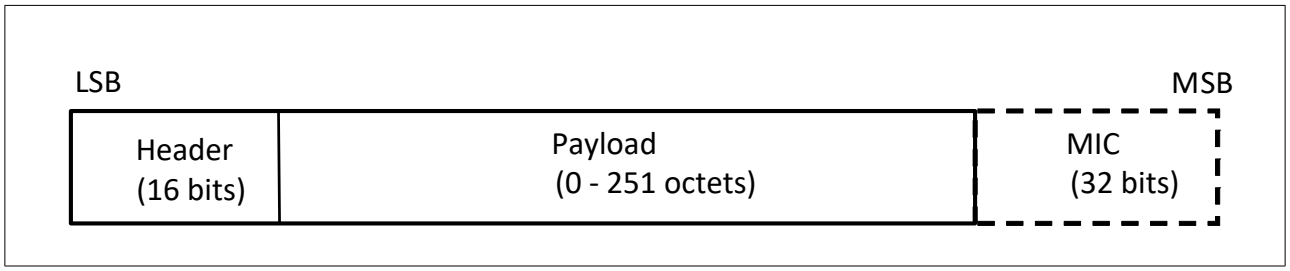

Figure 2.80: Isochronous Physical Channel PDU

The format of the Header field and the Payload field depends on the type of the Isochronous Physical Channel PDU that is being used. When used on a CIS, an Isochronous Physical Channel PDU shall be a Connected Isochronous PDU as defined in Section 2.6.1. When used on a BIS, it shall be a Broadcast Isochronous PDU as defined in Section 2.6.2.

The MIC field shall be included in all PDUs containing a non-zero length Payload field that are sent on an encrypted CIS or BIS. The MIC shall be calculated as specified in [Vol 6] Part E, Section 1. The MIC is a 4-octet field. The MIC field shall not be included in any PDU that is sent on an unencrypted CIS or BIS or that has a zero-length Payload field.

2.6.1 Connected Isochronous PDU

A Connected Isochronous PDU (CIS PDU) shall be either a CIS Data PDU or a CIS Null PDU. A CIS Data PDU is used to carry isochronous data. A CIS Null PDU is used when there is no data to be sent.

The Header field of the Connected Isochronous PDU is shown in Figure 2.81.

Header							
LLID (2 bits)	NESN (1 bit)	SN (1 bit)	CIE (1 bit)	RFU (1 bit)	NPI (1 bit)	RFU (1 bit)	Length (8 bits)

Figure 2.81: Connected Isochronous PDU Header field

The 16-bit Header field consists of the fields that are shown in Table 2.43.

- The LLID field is RFU in a CIS Null PDU.
- The Next Expected Sequence Number (NESN) field shall be set as defined in Section 4.5.9.
- The Sequence Number (SN) field shall be set as defined in Section 4.5.9 in a CIS Data PDU. This field is RFU in a CIS Null PDU.
- The Close Isochronous Event (CIE) field shall be set as defined in Section 4.5.13.4.
- The Null PDU Indicator (NPI) field shall be set for every CIS Null PDU.
- The Length field shall be set to 0 for a CIS Null PDU.

Field Name	Description
LLID	The LLID field indicates the type of content of the Payload field of the CIS Data PDU. 0b00 = Unframed CIS Data PDU; end fragment of an SDU or a complete SDU. 0b01 = Unframed CIS Data PDU; start or continuation fragment of an SDU. 0b10 = Framed CIS Data PDU. 0b11 = Reserved for future use.
NESN	Next Expected Sequence Number
SN	Sequence Number
CIE	Close Isochronous Event
NPI	The Null PDU Indicator (NPI) indicates whether the packet is a CIS Data PDU or a CIS Null PDU.
Length	The Length field indicates the size, in octets, of the Payload field and MIC, if included.

Table 2.43: Connected Isochronous PDU Header field

See [Vol 6] Part G, Section 1 for more details about fragmentation and segmentation of SDUs.

2.6.2 Broadcast Isochronous PDU

A Broadcast Isochronous PDU (BIS PDU) shall be either a BIS Data PDU or BIG Control PDU. A BIS Data PDU is used to carry isochronous data. A BIG Control PDU is used to send control information for a BIG.

The Header field of the Broadcast Isochronous PDU is shown in Figure 2.82.

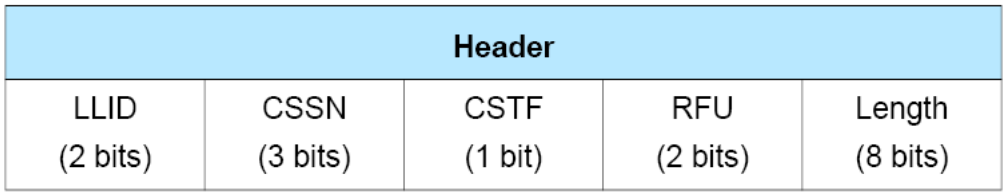

Figure 2.82: Broadcast Isochronous PDU Header field

The 16-bit Header field consists of the fields that are specified in Table 2.44.

The Control Subevent Sequence Number (CSSN) field shall be set as defined in Section 4.4.6.7.

The Control Subevent Transmission Flag (CSTF) field shall be set as defined in Section 4.4.6.7.

Field Name	Description
LLID	The LLID field indicates the type of content of the Payload field of the PDU. 0b00 = Unframed BIS Data PDU; end fragment of an SDU or a complete SDU. 0b01 = Unframed BIS Data PDU; start or continuation fragment of an SDU. 0b10 = Framed BIS Data PDU. 0b11 = BIG Control PDU.
CSSN	Control Subevent Sequence Number
CSTF	Control Subevent Transmission Flag
Length	The Length field indicates the size, in octets, of the Payload field and MIC, if included.

Table 2.44: Broadcast Isochronous PDU Header field

See [Vol 6] Part G, Section 1 for more details about fragmentation and segmentation of SDUs.

2.6.3 BIG Control PDU

A BIG Control PDU shall be used to send control information in a BIG (see Section 4.4.6.7).

The format of the Payload field in a BIG Control PDU is shown in Figure 2.83.

Payload	
Opcode (1 octet)	CtrData (0 to 250 octets)

Figure 2.83: Format of the Payload field of a BIG Control PDU

A BIG Control PDU shall not have the Length field (see Section 2.6.2) set to 0b00000000.

The Opcode field identifies different types of BIG Control PDUs, as defined in Table 2.45.

The CtrData field in the BIG Control PDU is specified by the Opcode field and is defined in the following subsections. For a given Opcode the length of the CtrData field is fixed.

Where the description of a field within the CtrData field gives a range of valid values or other restrictions on a value (e.g. that field X is less than field Y), all other values shall be reserved for future use. The range may be directly specified in the relevant subsection for the BIG Control PDU or indirectly, possibly in a section referenced by that subsection.

Except where explicitly stated otherwise, all fields within the CtrData field in a BIG Control PDU that hold an integer shall be interpreted as unsigned.

Opcode	BIG Control PDU Name
0x00	BIG_CHANNEL_MAP_IND
0x01	BIG_TERMINATE_IND
0xF8 to 0xFB	Reserved for specification development purposes
All other values	Reserved for future use

Table 2.45: BIG Control PDU opcodes

If a BIG Control PDU is received that is not supported or is reserved for future use, the Link Layer shall ignore it.

If a BIG Control PDU is received with the wrong length or with invalid CtrData fields, the Link Layer may continue with the relevant BIG Control procedure with an implementation-specific interpretation of the data (e.g., if the PDU is too long, it can ignore the extra data; if a field is out of range, it can use the nearest permitted value). If it does not continue the procedure, it shall ignore the PDU.

2.6.3.1 BIG_CHANNEL_MAP_IND

The format of the CtrData field is shown in Figure 2.84.

CtrData	
ChM (5 octets)	Instant (2 octets)

Figure 2.84: CtrData field of the BIG_CHANNEL_MAP_IND PDU

The BIG_CHANNEL_MAP_IND CtrData consists of two fields:

- The ChM field shall be set to the channel map indicating Used and Unused data channels. Every channel is represented with a bit positioned as per the channel index defined by Section 1.4.1. The format of this field is identical to the ChM field in the CONNECT_IND PDU (see Section 2.3.3.1).
- The Instant field shall be set to the value of $\text{bigEventCounter}_{15\text{-}0}$ (see Section 4.4.6.3) when the channel map takes effect.

2.6.3.2 BIG_TERMINATE_IND

The format of the CtrData field is shown in Figure 2.85.

CtrData	
Reason (1 octet)	Instant (2 octets)

Figure 2.85: CtrData field of the BIG_TERMINATE_IND PDU

The BIG_TERMINATE_IND CtrData consists of two fields:

- The Reason field shall be set to inform the Synchronized Receiver(s) why the BIG is about to be terminated. See [Vol 1] Part F, Controller Error Codes for a list of error codes and descriptions.
- The Instant field shall be set to the value of $\textit{bigEventCounter}_{15\text{-}0}$ (see Section 4.4.6.3) when the BIG will be terminated.

3 BIT STREAM PROCESSING

Bluetooth devices shall use the bit stream processing schemes as defined in the following sections.

Figure 3.1 shows the bit stream processing for PDUs on the LE Uncoded PHYs.

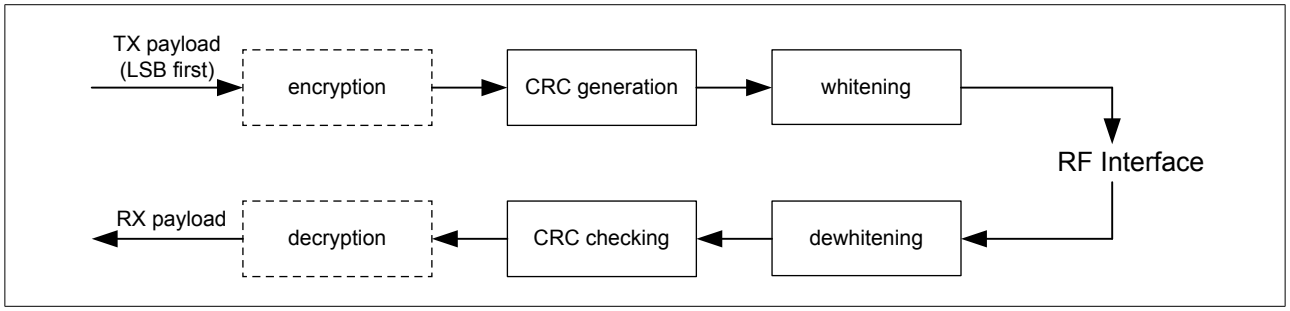

Figure 3.1: Payload bit processes for the LE Uncoded PHYs

Figure 3.2 shows the bit stream processing for PDUs on the LE Coded PHYs.

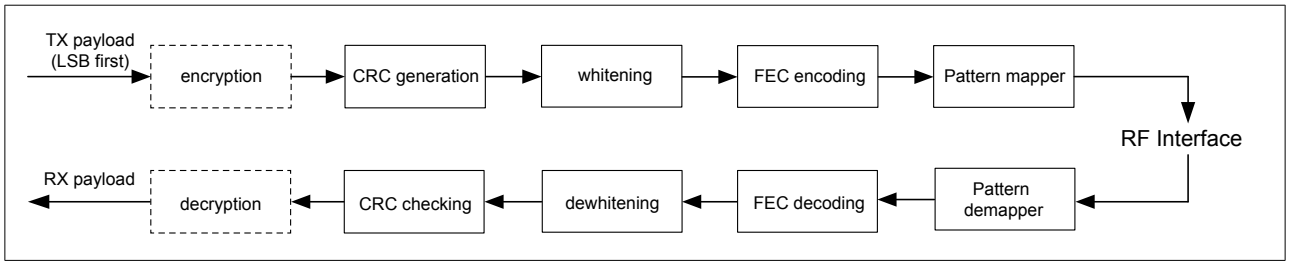

Figure 3.2: Bit stream processing for the LE Coded PHYs

3.1 Error checking

At packet reception, the Access Address shall be checked first. If the Access Address is incorrect, the packet shall be rejected, otherwise the packet shall be considered received. If the CRC is incorrect, the packet shall be rejected, otherwise the packet shall be considered successfully received and therefore valid. A packet shall only be processed if the packet is considered valid, except that the receiver may carry out IQ sampling (see Section 2.5.4) even if the CRC is incorrect. A packet with an incorrect CRC may cause a connection event to continue, as specified in Section 4.5.1.

3.1.1 CRC generation

The CRC shall be calculated on the PDU of all Link Layer packets. If the PDU is encrypted, then the CRC shall be calculated after encryption of the PDU has been performed.

The CRC polynomial is a 24-bit CRC and all bits in the PDU shall be processed in transmitted order starting from the least significant bit. The polynomial has the form of $x^{24} + x^{10} + x^9 + x^6 + x^4 + x^3 + x + 1$. For every Data Physical Channel PDU and Connected Isochronous PDU, the shift register shall be preset with the CRC initialization value set for the ACL connection and communicated in the CONNECT_IND or AUX_CONNECT_REQ PDU. For every PDU sent on a periodic advertising train (including AUX_CONNECT_REQ and AUX_CONNECT_RSP PDUs), the shift register shall be preset with the CRCInit value set in the SyncInfo field (see Section 2.3.4.6) that describes the periodic advertising train. For all other Advertising Physical Channel PDUs, the shift register shall be preset with 0x555555. For every Broadcast Isochronous PDU, the shift register shall be preset with the BaseCRCInit value from the BIGInfo data (see Section 4.4.6.11) in the most significant 2 octets and the BIS_Number for the specific BIS in the least significant octet. For BIG Control PDUs, the least significant octet shall be 0.

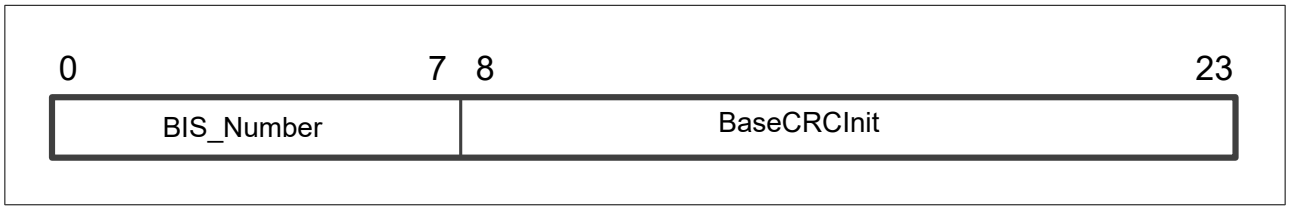

Figure 3.3: Generation of CRCInit for Broadcast Isochronous PDUs

Position 0 shall be set as the least significant bit and position 23 shall be set as the most significant bit of the initialization value. The CRC is transmitted most significant bit first, i.e. from position 23 to position 0 (see Section 1.2).

Figure 3.4 shows an example linear feedback shift register (LFSR) to generate the CRC.

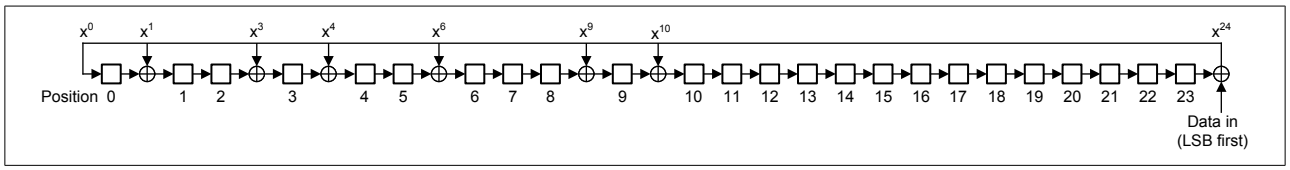

Figure 3.4: The LFSR circuit generating the CRC

3.2 Data whitening

Data whitening is used to avoid long sequences of zeros or ones, e.g., 0b0000000 or 0b1111111, in the data bit stream. Whitening shall be applied on the PDU and CRC of all Link Layer packets and is performed after the CRC generation in the transmitter. No other parts of the packets are whitened. De-whitening is performed before the CRC checking in the receiver (see Figure 3.1).

The whitener and de-whitener are defined the same way, using a 7-bit linear feedback shift register with the polynomial $x^7 + x^4 + 1$. Before whitening or de-whitening, the shift register is initialized with a sequence that is derived from the physical channel index in which the packet is transmitted in the following manner:

- Position 0 is set to one.
- Positions 1 to 6 are set to the channel index of the channel used when transmitting or receiving, from the most significant bit in position 1 to the least significant bit in position 6.

For example, if the channel index = 23 (0x17), the positions would be set as follows:

Position 0 = 1
Position 1 = 0
Position 2 = 1
Position 3 = 0
Position 4 = 1
Position 5 = 1
Position 6 = 1

Figure 3.5 shows an example linear feedback shift register (LFSR) to generate data whitening.

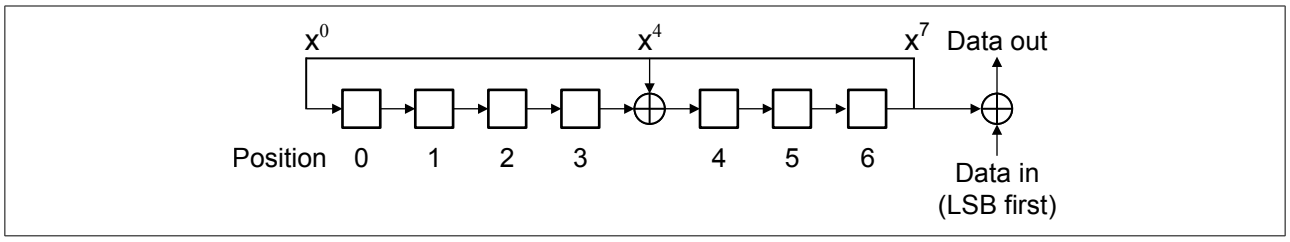

Figure 3.5: The LFSR circuit to generate data whitening

3.3 Coding

Coding only applies to the LE Coded PHY.

Coding consists of two processes. Data is first coded by the Forward Error Correction (FEC) convolutional encoder as defined in Section 3.3.1 and then spread by the pattern mapper as defined in Section 3.3.2.

3.3.1 Forward Error Correction encoder

The convolutional FEC encoder uses a non-systematic, non-recursive rate ½ code with constraint length K=4. The generator polynomials are:

$G_0(x) = 1 + x + x^2 + x^3$

$G_1(x) = 1 + x^2 + x^3$

The bit coming from generator polynomial G_0 (a_0) is transmitted first; the bit coming from generator polynomial G_1 (a_1) is transmitted second.

The initial state of the convolutional FEC encoder is set to all zeros. An input sequence of three consecutive zeros always brings the convolutional FEC encoder back to its original state. This sequence is known as the termination sequence.

Figure 3.6 illustrates operation of the convolutional FEC encoder. Squares represent bit storage operations and circles represent XOR.

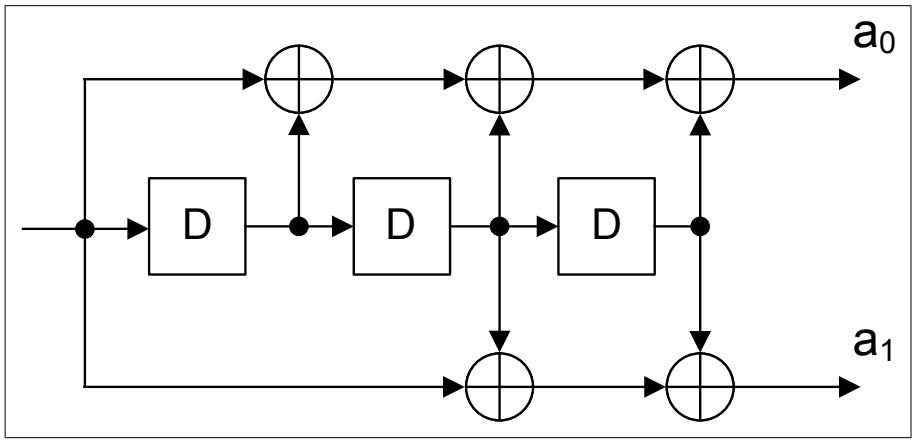

Figure 3.6: Convolutional Forward Error Correction encoder

3.3.2 Pattern mapper

The pattern mapper converts each bit from the convolutional FEC encoder into P symbols, where the value of P depends on the coding scheme in use, according to Table 3.1 (the output sequences are in transmission order):

Input bit from the convolutional FEC encoder	Output sequence when P=1 (used by S=2)	Output sequence when P=4 (used by S=8)
0	0	0011
1	1	1100

Table 3.1: Pattern mapper inputs and outputs

4 AIR INTERFACE PROTOCOL

The air interface protocol consists of the multiple access scheme, device discovery and Link Layer connection methods.

4.1 Frame Space

4.1.1 Inter Frame Space

The time interval between two consecutive packets on the same channel index is called the Inter Frame Space. It is defined as the time from the end of the last bit of the previous packet to the start of the first bit of the subsequent packet. The Inter Frame Space is designated “T_IFS” followed by a suffix to indicate its purpose. The different types of Inter Frame Space are:

- T_IFS_ACL_CP – the time between the end of a transmission by the Central and the following transmission by the Peripheral on an ACL. This value is selected based on the Peripheral’s transmission PHY (see Section 4.5.1).
- T_IFS_ACL_PC – the time between the end of a transmission by the Peripheral and the following transmission by the Central on an ACL. This value is selected based on the Central’s transmission PHY (see Section 4.5.1).
- T_IFS_CIS – the time between the end of a transmission by the Central and the following transmission by the Peripheral in a CIS sub-event. This value is selected based on the Peripheral’s transmission PHY (see Section 4.2).
- T_IFS_150 – various times that cannot be negotiated.

These values shall default to 150 µs but may be changed for a specific connection and specific PHYs on that connection, using the Frame Space Update procedure (see Section 5.1.30), except for T_IFS_150, which remains fixed.

4.1.2 Minimum AUX Frame Space

The minimum time interval between a packet containing an AuxPtr and the auxiliary packet it indicates is called the Minimum AUX Frame Space. It is defined as the minimum time from the end of the last bit of the packet containing the AuxPtr to the start of the auxiliary packet. The Minimum AUX Frame Space is designated “T_MAFS” and shall be 300 µs.

Figure 4.1 illustrates an example where the Minimum AUX Frame Space applies.

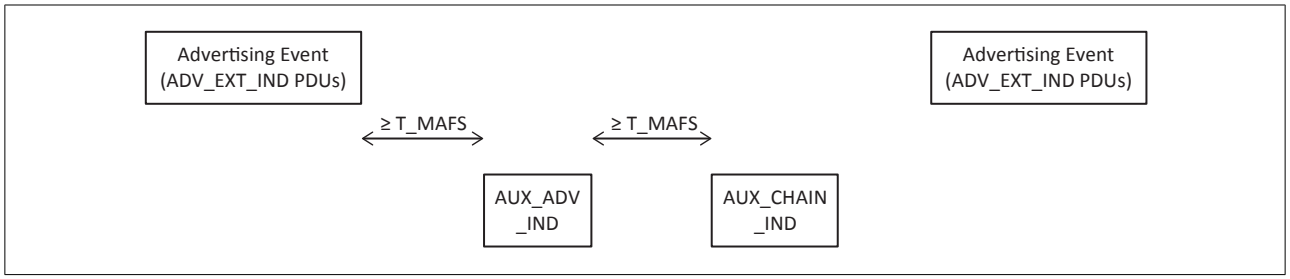

Figure 4.1: Example where the Minimum AUX Frame Space applies

4.1.3 Minimum Isochronous Channel Subevent Space

The minimum time interval between the end of the last bit of the last packet in one subevent and the start of the first bit of the first packet in the next subevent is called the Minimum Subevent Space.

The Minimum Subevent Space is designated "T_MSS_CIS" for CISes and “T_MSS_150” for BISes and shall default to 150 µs. The value of T_MSS_CIS may be changed using the Frame Space Update procedure (see Section 5.1.30). The value of T_MSS_150 cannot be changed.

Figure 4.2 illustrates an example where the Minimum Subevent Space applies in a CIS.

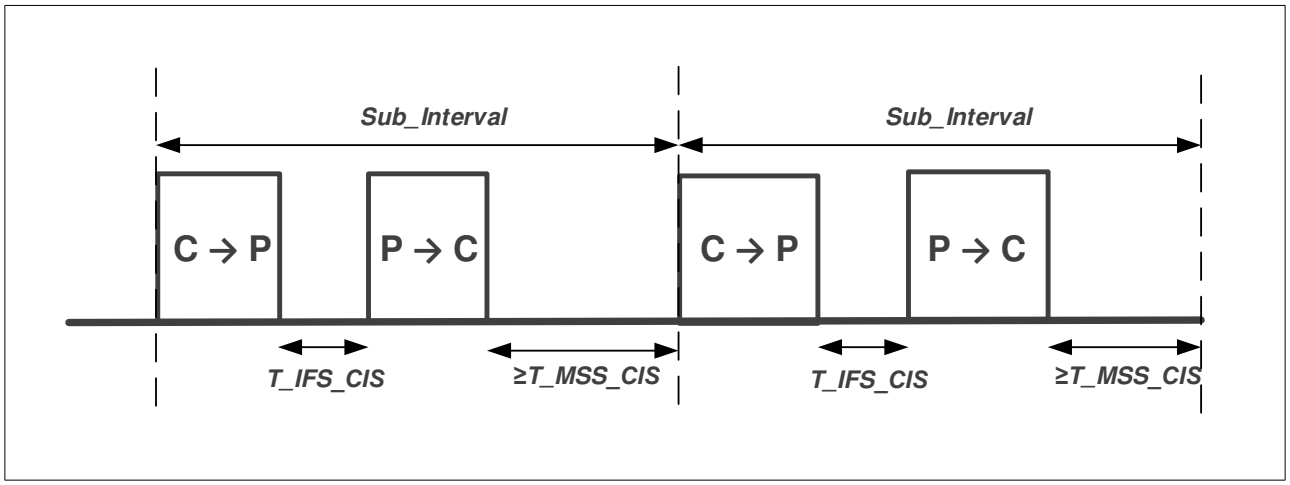

Figure 4.2: Minimum Subevent Space in a CIS

Figure 4.3 illustrates an example where the Minimum Subevent Space applies in a BIS.

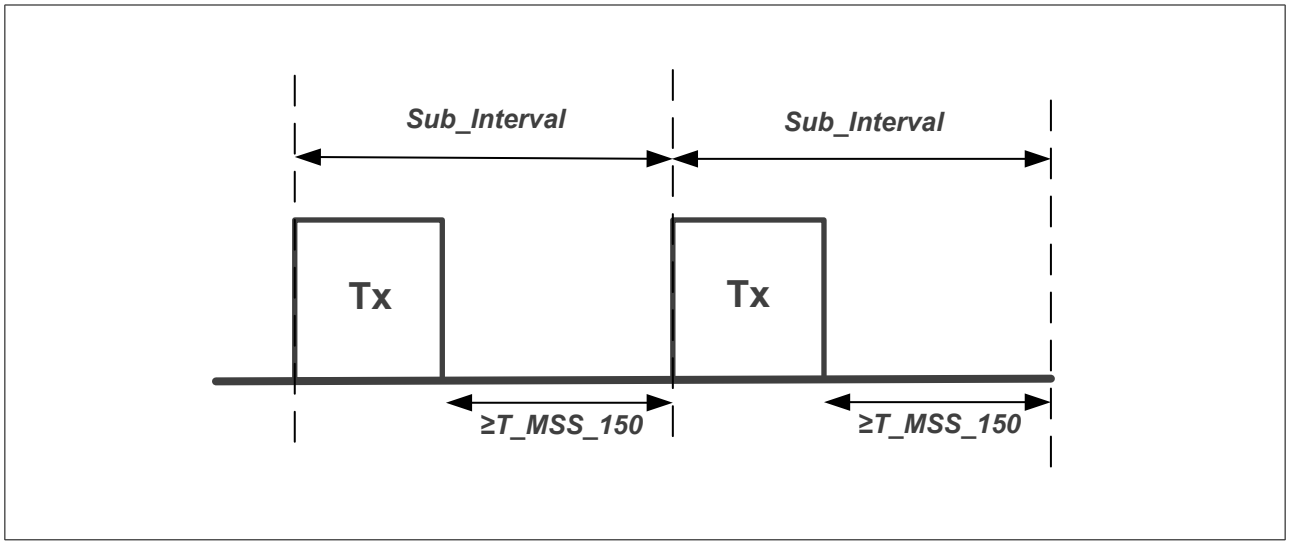

Figure 4.3: Minimum Subevent Space in a BIS

4.1.4 Minimum Channel Sounding subevent space

The minimum time interval between the end of a CS subevent and the start of the next CS subevent whose subevent length is defined by T_SUBEVENT_LEN and whose periodicity is defined by T_SUBEVENT_INTERVAL, as described in Section 4.5.18.1, is called the minimum subevent space.

The minimum subevent space is designated T_MES and shall be 150 µs.

Figure 4.4 shows an example in which the minimum subevent space applies between CS subevents.

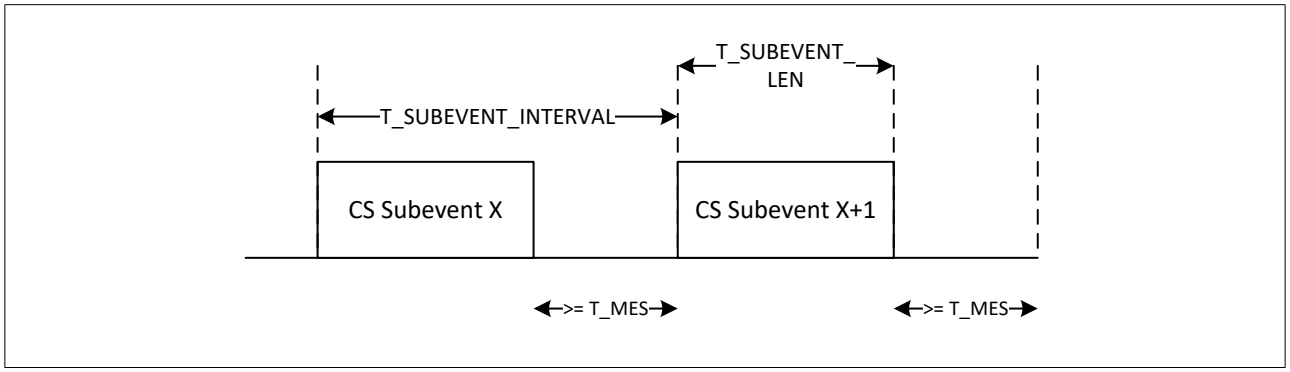

Figure 4.4: Minimum subevent spacing in a CS procedure

Similarly, T_MES shall also be the minimum time interval between the last CS subevent within a CS event and the first CS subevent of the next CS event.

4.1.5 Minimum Connection Event Spacing

The minimum time interval between the last PDU sent from the peripheral and the anchor point of the next connection event is called the Minimum Connection Event Spacing. It is defined as the minimum time from the end of the last bit of the packet sent from the Peripheral to the anchor point of the next connection event.

The Minimum Connection Event Spacing is designated “T_MCES” and shall default to 150 µs. The value of T_MCES may be changed using the Frame Space Update procedure (see Section 5.1.30).

4.2 Timing requirements

The Link Layer shall use one of two possible clock accuracies: in the circumstances described in Section 4.2.1 it shall use the active clock accuracy; otherwise it shall use the sleep clock accuracy.

The clock accuracies specified in this section apply to the time between two specific events and only apply to devices when they transmit a packet. The clock used to time packet reception may have any accuracy but the receiving device will need to allow for this. For example, if the receiving device clock has an accuracy of 2000 ppm and a maximum jitter of 45 µs, then, for an event 1 second after the last event where timings were synchronized, the device will need to start listening at least 2045 µs earlier and continue listening until at least 2045 µs later than it would otherwise have done.

An implementation may use either a single clock or several clocks. For example, one implementation could use a single clock with variable accuracy whereas a different implementation could use one clock that only runs during periods where an event timed using active clock accuracy is pending and another clock with lower accuracy that runs at all times.

4.2.1 Active clock accuracy

The average timing of packet transmission during a connection, BIG, or CIG event during active scanning, during a periodic advertising with responses subevent, and when requesting a connection is determined using the active clock accuracy, with a drift less than or equal to ±50 ppm. All instantaneous timings shall not deviate more than 2 µs from the average timing.

The average timing of CS tone transmission during a CS subevent is determined using the same active clock accuracy but using the instantaneous timing requirements specified in [Vol 6] Part H, Section 4.5.

More specifically, these requirements apply to the intervals between:

- adjacent packets in the same connection event
- packets in the same BIG or CIG event, even if they are in different BISes or CISes or in different subevents
- an advertising packet and a packet containing a SCAN_REQ, AUX_SCAN_REQ, CONNECT_IND, or AUX_CONNECT_REQ PDU
- a packet containing a SCAN_REQ and the response packet containing a SCAN_RSP PDU
- a packet containing an AUX_SCAN_REQ PDU and the response packet containing an AUX_SCAN_RSP PDU
- a packet containing an AUX_CONNECT_REQ PDU and the response packet containing an AUX_CONNECT_RSP PDU
- packets in the same periodic advertising with responses subevent
- the transmission and reception of the content of CS steps within a CS subevent.

4.2.2 Sleep clock accuracy

The average timing of all other activities is determined using the sleep clock accuracy, with a drift less than or equal to ±500 ppm. All instantaneous timings shall not deviate more than 16 µs from the average timing. The worst-case drift and instantaneous deviation of the active clock shall be less than or equal to those of the sleep clock.

In the specification, the Central's current sleep clock accuracy is referred to as *centralSCA* and the Peripheral's current sleep clock accuracy as *peripheralSCA*.

On a connection a device shall not use a sleep clock accuracy that is worse than the worst case indicated in the SCA field of the most recently sent LL_CLOCK_ACCURACY_REQ or LL_CLOCK_ACCURACY_RSP PDU. If the Link Layer has not initiated or responded to the Sleep Clock Accuracy Update procedure (see Section 5.1.14) in the current connection, the Central shall use a sleep clock accuracy that is better than or equal to the worst case indicated in the SCA field of the CONNECT_IND or AUX_CONNECT_REQ PDU used to create the connection and the Peripheral shall use a sleep clock accuracy of ±500 ppm or better.

Note: These requirements therefore apply to:

- The time between ACL anchor points (see Section 4.5.7).
- The time between CIS anchor points (see Section 4.5.14.1).
- The time between BIG anchor points (see Section 4.4.6.4).

- The time between CS subevents (see Section 4.5.18.1).
- The advertising and periodic advertising intervals and the advDelay value (see Section 4.4.2.2).
- All intervals between packets in the same extended advertising event or periodic advertising event.
- All offsets specified by the AuxPtr and SyncInfo fields of advertising PDUs.

Note: This means that a 2 s connection interval with a 500 ppm Central sleep clock accuracy will require a window widening either side of the anchor point of 1 ms plus 16 µs plus any allowance for the accuracy of the clock actually used by the Peripheral during the connection interval.

4.2.3 Range delay

Where two devices are more than a few meters apart the time taken for a signal to propagate between them will be significant compared with the Active Clock Accuracy defined in Section 4.2.1. When a device is listening for a packet that might be up to D meters away, it should listen for an extra 2D × 4 ns after the nominal latest time (e.g. T_IFS_ACL_CP + 2 µs) that the packet would have been transmitted.

(1÷c ~= 3.3 × refractive index ns/m, so 4 ns gives a conservative allowance.)

Figure 4.5 shows the range delays relative to a Central packet transmission in an ACL.

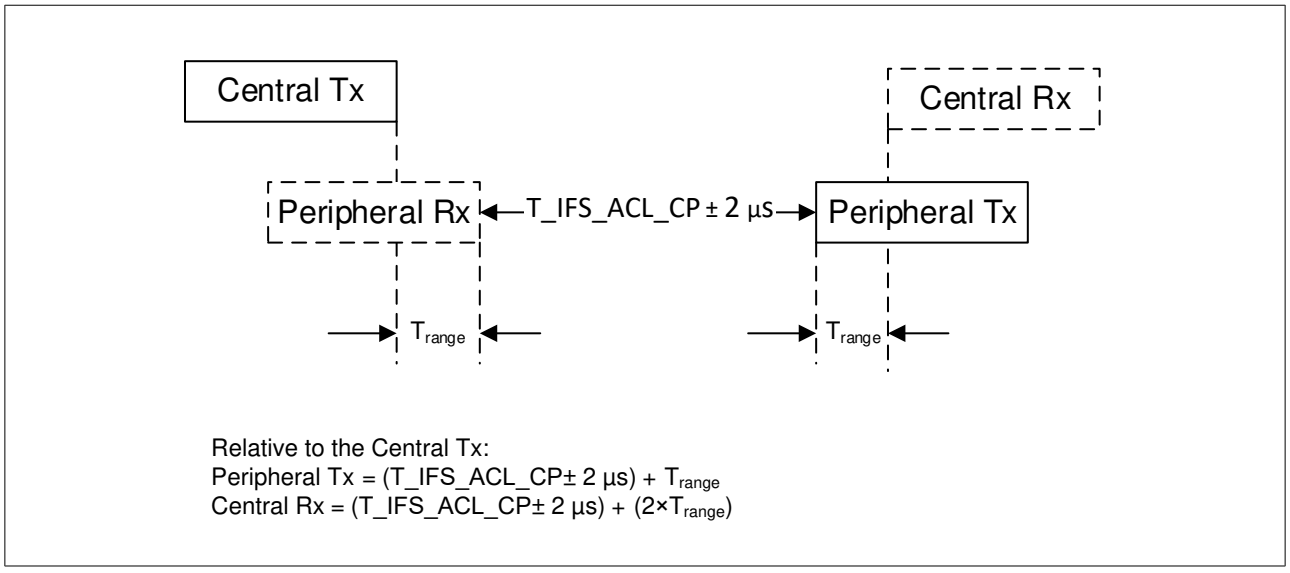

Figure 4.5: Range delays relative to a Central packet transmission in an ACL

4.2.4 Window widening

In various circumstances a Link Layer is expecting to receive a packet within a certain window (extending from *receiveWindowStart* to *receiveWindowEnd*) or at a certain time

(in which case *receiveWindowStart* and *receiveWindowEnd* are both that time) but, because of active clock accuracies (see Section 4.2.1) and sleep clock accuracies (see Section 4.2.2), there is uncertainty as to the exact timing of that window at the sending Link Layer. The recipient shall therefore adjust its listening time to allow for this uncertainty.

The increase in listening time is called the window widening. Assuming the clock inaccuracies are purely given in parts per million (ppm), it is calculated as follows:

transmitterAllowance = (*txCA* ÷ 1000000) × (*receiveWindowEnd* − *timeOfLastSync*) + J µs

where J shall be 2 when the active clock applies and 16 when the sleep clock applies and the other parameters are specified in Table 4.1.

Note: *txCA* is the clock accuracy of the transmitting Link Layer and *timeOfLastSync* is the most recent time that the receiving Link Layer was able to synchronize its clock to that of the transmitting Link Layer.

Activity	***txCA***	***timeOfLastSync***	***receiveWindowStart***	***receiveWindowEnd***
Receiving any auxiliary packet	CA field of the relevant AuxPtr field	Start of the packet containing that field	AUX Offset from the start of that packet	One Offset Unit after *receiveWindowStart*
Advertiser performing connection setup - Peripheral role	SCA field of the relevant CONNECT_IND or AUX_CONNECT_REQ PDU.	Start of the packet containing that PDU.	Start of the transmit window (see Section 4.5.3)	End of the transmit window
Peripheral performing connection parameter update	Current *centralSCA* (see Section 4.5.7)	Last ACL or CIS anchor point where a packet was received from the Central	Start of the transmit window (see Section 5.1.1 and Section 5.1.7)	End of the transmit window
Peripheral receiving the next connection event	Current *centralSCA* (see Section 4.5.7)	Last ACL or CIS anchor point where a packet was received from the Central	Time of the scheduled connection event anchor point	

Activity	***txCA***	***timeOfLastSync***	***receiveWindowStart***	***receiveWindowEnd***
Adjacent packets in the same connection event (see also Section 5.1.30.1)	50	End of the previous packet	T_IFS_ACL_CP or T_IFS_ACL_PC after timeOfLastSync	
Adjacent packets in the same CIS subevent	50	End of the previous packet	T_IFS_CIS after *timeOfLastSync*	
Synchronization state - synchronizing	SCA field of the relevant SyncInfo field	Start of the packet containing that field	syncPacketWindowOffset from the start of that packet	One Offset Unit after *receiveWindowStart*
Synchronization state - synchronized	*txCA* used while synchronizing	Start of the last packet received containing an AUX_SYNC_IND PDU	Time of the scheduled periodic advertising event	
Synchronization state - listening for subevent	txCA used while synchronizing	Start of the last packet received containing an AUX_SYNC_SUBEVENT_IND or AUX_CONNECT_REQ PDU	Time of the scheduled periodic advertising subevent	
Periodic Advertising state - listening to response slot	50	Start of the last packet transmitted containing an AUX_SYNC_SUBEVENT_IND PDU	Time of the scheduled subevent response slot	
Peripheral receiving the next CIS event	Current *centralSCA* (see Section 4.5.7)	Last ACL anchor point or the start of a CIS subevent where a packet was received from the Central	Time of the scheduled CIS subevent	
Reception of a BIS Data PDU in the first BIS event	SCA from SyncInfo	Start of the last packet received on the associated periodic advertising train	Offset in BIGInfo from the start of that packet plus any BIS_Spacing applied	One offset Unit after ReceiveWindowStart

Activity	*txCA*	*timeOfLastSync*	*receiveWindowStart*	*receiveWindowEnd*
Reception of the next BIS event	txCA used while synchronizing	Start of the last packet received in any BIS event on the same BIG	Time of the scheduled BIS subevent	
Reception of subsequent sub-events	50	Start of the last subevent where a packet was received	Time of the start of the scheduled subevent	
Peripheral as CS reflector receiving the next CS subevent	Same as current *centralSCA* (see Section 4.5.7.1)	Last ACL anchor point prior to the start of a CS event or the start of a CS subevent in which a packet was received from the initiator	Time of the scheduled CS subevent	
Central as CS reflector receiving the next CS subevent	Same as the current peripheralSCA (see Section 4.5.7.1)	Last ACL anchor point prior to the start of a CS event or the start of a CS subevent in which a packet was received from the initiator.	Time of the scheduled CS subevent	
Adjacent CS SYNCs or CS tones in the same CS subevent	50	Start of the CS subevent	Reception windows are defined in [Vol 6] Part H, Section 4.5.	

Table 4.1: Parameters for window widening

The rows relating to a Peripheral receiving a CIS event or a device receiving a BIS event only apply until a packet has been received in the event from the correct sender, regardless of a CRC match, and the timing re-synchronized. Once this has happened, the row "Reception of subsequent sub-events" applies for the rest of the event.

If the recipient has more accurate information about the transmitting Link Layer's clock, it may select a smaller value for *transmitterAllowance*.

windowWidening = transmitterAllowance + receiverAllowance

where *receiverAllowance* is the allowance made by the receiver for its own clock accuracy.

If the recipient listens for a packet, it shall listen starting at *windowWidening* before *receiveWindowStart* and until *windowWidening* after *receiveWindowEnd*.

The *windowWidening* in an ACL connection shall be smaller than ((*connInterval* ÷ 2) - T_MCES µs). If the *windowWidening* reaches ((*connInterval* ÷ 2) − T_MCES µs) in magnitude, the connection should be considered lost (see Section 4.5.12).

If the *windowWidening* for a CIS with NSE < 3 reaches ((ISO_Interval ÷ 2) − T_MSS_CIS) µs in magnitude, the Link Layer should terminate the CIS (see Section 5.1.16).

If the *windowWidening* for a BIS with NSE < 3 reaches ((ISO_Interval ÷ 2) − T_MSS_150) µs in magnitude, then the Link Layer should stop synchronization with the BIG.

If the *windowWidening* for a CIS or BIS with NSE ≥ 3 reaches Sub_Interval in magnitude, the Link Layer should terminate the CIS or stop synchronization with the BIG. The value of Sub_Interval should be chosen to ensure that this limit is not reached within 2 × ISO_Interval. For example, if *txCA* equals 150 ppm and *receiverAllowance* equals *transmitterAllowance*, the parameters should be chosen so that Sub_Interval ÷ ISO_Interval > 0.0006.

The *windowWidening* in a CS procedure shall be smaller than ((T_EVENT_INTERVAL ÷ 2) − T_MES µs). T_EVENT_INTERVAL is defined in Section 5.1.26 and T_MES is defined in Section 4.1.4. If the *windowWidening* reaches ((T_EVENT_INTERVAL ÷ 2) − T_MES µs) in magnitude, then the CS procedure should be aborted. When the CS procedure is aborted, the Host shall be notified.

4.3 Link Layer device filtering

The Link Layer may perform device filtering based on the device address of the peer device. Link Layer device filtering is used by the Link Layer to minimize the number of devices to which it responds.

A Link Layer shall support Link Layer device filtering unless it only supports the Advertising state and only supports non-connectable and non-scannable advertising.

The filter policies for the Advertising state, Scanning state, Initiating state, and Periodic Sync Establishment are independent of each other. When the Link Layer is in the Advertising state, the advertising filter policy shall be used. When the Link Layer is in the Scanning state, the scanning filter policy shall be used. When the Link Layer is in the Initiating state, the initiator filter policy shall be used. When the Link Layer is performing Periodic Sync Establishment, the periodic sync establishment filter policy shall be used. If the Link Layer does not support the Advertising state, Scanning state, Initiating state, or Periodic Sync Establishment, the corresponding filter policy is not required to be supported.

4.3.1 Filter Accept List

The set of devices that the Link Layer uses for device filtering is called the Filter Accept List.

A Filter Accept List contains a set of records used for Link Layer device filtering. A Filter Accept List record contains both the device address and the device address type (public or random). There is also a special device address type "anonymous"; an entry with this type matches all advertisements sent with no address. All Link Layers supporting Link Layer device filtering shall support a Filter Accept List capable of storing at least one record.

On reset, the Filter Accept List shall be empty.

The Filter Accept List is configured by the Host and is used by the Link Layer to filter advertisers, scanners, or initiators, but not periodic sync establishment. This allows the Host to configure the Link Layer to act on a request without awakening the Host.

All the device filter policies shall use the same Filter Accept List.

4.3.2 Advertising filter policy

The advertising filter policy determines how the advertiser’s Link Layer processes scan and/or connection requests.

When the Link Layer is using non-connectable and non-scannable directed advertising events, scannable directed advertising events, and connectable directed advertising events the advertising filter policy shall be ignored. Otherwise the Link Layer shall use one of the following advertising filter policy modes which are configured by the Host:

- The Link Layer shall process scan and connection requests from all devices (i.e. the Filter Accept List is not in use). This is the default on reset.
- The Link Layer shall process connection requests from all devices and shall only process scan requests from devices that are in the Filter Accept List.
- The Link Layer shall process scan requests from all devices and shall only process connection requests from devices that are in the Filter Accept List.
- The Link Layer shall process scan and connection requests only from devices in the Filter Accept List.

Only one advertising filter policy mode per advertising set shall be supported at a time.

4.3.3 Scanning filter policy

The scanning filter policy determines how the scanner’s Link Layer processes advertising and scan response PDUs. The Link Layer shall use one of the following

scanning filter policies as selected by the Host. Only one scanning filter policy shall be supported at a time.

There is a choice of two primary filter policies:

- Unfiltered: The Link Layer shall process all advertising and scan response PDUs (i.e., the Filter Accept List is not used). This is the default on reset.
- Filtered: The Link Layer shall process decision PDUs and their subordinate sets from all devices and other advertising PDUs and any scan response PDUs only from devices in the Filter Accept List.

In the basic scanning filter policy mode, a directed advertising PDU accepted by the primary filter policy shall nevertheless be ignored unless either:

- the TargetA field is identical to the scanner's device address, or
- the TargetA field is a resolvable private address, address resolution is enabled, and the address is resolved successfully.

Note: The scanning filter policy does not affect initiation or periodic sync establishment even though they involve scanning for advertising PDUs.

4.3.3.1 Extended scanning filter policies

If the Link Layer supports the extended scanning filter policies, then extended mode shall also be supported. This is identical to basic mode except that a directed advertising PDU accepted by the primary filter policy shall nevertheless be ignored unless either:

- the TargetA field is identical to the scanner's device address, or
- the TargetA field is a resolvable private address.

4.3.3.2 Decision scanning filter policy modes

The Link Layer shall also use one of the following filter policy modes which are configured by the Host. These only apply to advertising PDUs received on the primary advertising physical channel. They apply in addition to the primary filter policy in use.

- No decisions: The Link Layer shall ignore decision PDUs and shall process other advertising PDUs. This is the default on reset and is the only mode that shall be used if the Link Layer does not support the Decision-Based Advertising Filtering feature.
- Decisions only: The Link Layer shall only process decision PDUs and shall ignore all other advertising PDUs.
- All PDUs: The Link Layer shall process all advertising PDUs.

4.3.4 Initiator filter policy

The initiator filter policy determines how an initiator's Link Layer processes advertising PDUs. The Link Layer shall use one of the following initiator filter policy modes which are configured by the Host:

- The Link Layer shall ignore the Filter Accept List and process connectable advertising PDUs, other than decision PDUs, from a specific single device specified by the Host.
- The Link Layer shall ignore the Filter Accept List and only process connectable decision PDUs from any device.
- The Link Layer shall process connectable advertising PDUs from all devices in the Filter Accept List.
- The Link Layer shall process connectable advertising PDUs, other than decision PDUs, from all devices in the Filter Accept List.
- The Link Layer shall process connectable decision PDUs and their subordinate sets from all devices and other connectable advertising PDUs from all devices in the Filter Accept List.

If the Link Layer receives a connectable directed advertising PDU that is not allowed by the initiator filter policy, the connectable directed advertising PDU shall be ignored.

Only one initiator filter policy mode shall be supported at a time.

4.3.5 Periodic sync establishment filter policy

The periodic sync establishment filter policy determines how a scanner's Link Layer processes advertising PDUs when attempting to synchronize to a periodic advertising train. The Link Layer shall use one of the following periodic sync establishment filter policy modes which are configured by the Host:

- The Link Layer shall ignore the Periodic Advertiser List and process advertising PDUs from a specific single device specified by the Host.
- The Link Layer shall process advertising PDUs from all devices in the Periodic Advertiser List.

If the Link Layer receives an advertising PDU which contains a SyncInfo field from an advertiser that is not contained in the Periodic Advertiser List or the single address specified by the Host, or if the advertising has an Advertising SID which is not the one specified in the list entry or by the Host, the SyncInfo field shall be ignored.

Only one periodic sync establishment filter policy mode shall be supported at a time.

Synchronization to periodic advertising takes place at the same time as scanning, but the filter policies for the two activities are independent. The periodic sync establishment

filter policy, and not the scanning filter policy, shall determine which advertising PDUs are used to synchronize to a periodic advertising train (successful synchronization is then reported to the Host). If a received PDU only matches one of the two policies, it shall only be processed for the purpose that uses that policy and not for the other.

The Link Layer shall ignore the Periodic Advertiser List when synchronizing to a periodic advertising train where it received the synchronization information using the Periodic Advertising Sync Transfer procedure (see Section 5.1.13).

4.4 Non-connected states

The Host may specify which coding to use when transmitting packets on the LE Coded PHY. If it does not, then the Controller determines the coding of each packet. The coding is indicated by the CI as defined in Section 2.2.3 and may be different in each direction and in adjacent packets in a given direction.

4.4.1 Standby state

The Standby state is the default state in the Link Layer. The Link Layer shall not send or receive packets in the Standby state. The Link Layer may leave the Standby state to enter the Advertising state, Scanning state, Initiator state, Synchronization state, or Isochronous Broadcasting state.

4.4.2 Advertising state

The Link Layer shall enter the Advertising state when directed by the Host. When placed in the Advertising state, the Link Layer shall send advertising PDUs (see Section 2.3.1) in advertising events, periodic advertising events, or both.

Each advertising event is composed of one or more advertising PDUs sent on used primary advertising channel indices. The advertising event shall be closed after one advertising PDU has been sent on each of the used primary advertising channel indices (see Section 4.4.2.1). Some advertising PDUs in an advertising event may be omitted, causing the advertising event to begin late or close early, or the entire advertising event may be omitted to accommodate other functionality.

The time between two consecutive advertising events is defined in Section 4.4.2.2.

An advertising event can be one of the following types:

- a connectable and scannable undirected event
- a connectable undirected event
- a connectable directed event
- a non-connectable and non-scannable undirected event

- a non-connectable and non-scannable directed event
- a scannable undirected event
- a scannable directed event

At most one advertising PDU shall be sent on each used primary advertising channel index in an advertising event. Unless specified otherwise, the primary advertising channel indices may be utilized in any order. The order may be different in different events.

The advertising event type determines the allowable response PDUs. Table 4.2 specifies the allowable responses for each advertising event.

Connectable and scannable undirected, connectable undirected, and connectable directed events are collectively referred to as connectable events; the remaining events (non-connectable and non-scannable undirected, non-connectable and non-scannable directed, scannable undirected, and scannable directed) are collectively referred to as non-connectable events. Connectable and scannable undirected, scannable undirected, and scannable directed events are collectively referred to as scannable events; the remaining events (non-connectable and non-scannable undirected, non-connectable and non-scannable directed, connectable undirected, and connectable directed) are collectively referred to as non-scannable events.

		Allowable response PDUs			
Advertising Event Type	**Type of PDU being responded to**	**SCAN_-REQ[1]**	**CONNECT_-IND[1]**	**AUX_-SCAN_-REQ**	**AUX_-CONNECT_-REQ**
Connectable and Scannable Undirected event	ADV_IND	YES	YES	NO	NO
Connectable Undirected event	ADV_EXT_IND or ADV_DECISION_-IND	NO	NO	NO	NO
	AUX_ADV_IND	NO	NO	NO	YES
Connectable Directed event	ADV_DIRECT_IND	NO	YES[2]	NO	NO
	ADV_EXT_IND	NO	NO	NO	NO
	AUX_ADV_IND	NO	NO	NO	YES[2]
Non-Connectable and Non-Scannable Undirected event	ADV_NONCONN_-IND	NO	NO	NO	NO
	ADV_EXT_IND or ADV_DECISION_-IND	NO	NO	NO	NO

		Allowable response PDUs			
Advertising Event Type	**Type of PDU being responded to**	**SCAN_-REQ[1]**	**CONNECT_-IND[1]**	**AUX_-SCAN_-REQ**	**AUX_-CONNECT_-REQ**
	AUX_ADV_IND	NO	NO	NO	NO
Non-Connectable and Non-Scanna-ble Directed event	ADV_EXT_IND	NO	NO	NO	NO
	AUX_ADV_IND	NO	NO	NO	NO
Scannable Undir-ected event	ADV_SCAN_IND	YES	NO	NO	NO
	ADV_EXT_IND or ADV_DECISION_-IND	NO	NO	NO	NO
	AUX_ADV_IND	NO	NO	YES	NO
Scannable Directed event	ADV_EXT_IND	NO	NO	NO	NO
	AUX_ADV_IND	NO	NO	YES[3]	NO

Table 4.2: Advertising event types, PDUs used, and allowable response PDUs

[1]Not permitted on the LE Coded PHY.

[2]Initiators other than the correctly addressed initiator shall not respond.

[3]Scanners other than the correctly addressed scanner shall not respond.

If the advertiser receives a PDU for the advertising event that is not explicitly allowed it shall be ignored. If no PDU is received or the received PDU was ignored, the advertiser shall either send an advertising PDU on the next used primary advertising channel index or close the advertising event.

The Controller shall not use two different types of PDU on the primary advertising physical channel in the same advertising event. The Controller may use the ADV_DECISION_IND PDU instead of the ADV_EXT_IND PDU in any undirected advertising event.

4.4.2.1 Advertising channel index selection

Advertising events use three predefined primary advertising physical channels. Primary advertising channel indices are either used or unused.

For AUX_ADV_IND and AUX_CHAIN_IND PDUs, the secondary advertising channel index used in the Channel Index subfield of the AuxPtr field is implementation specific. It is recommended that sufficient channel diversity is used to avoid collisions.

Each periodic advertising train shall have a 16-bit event counter (*paEventCounter*). The initial value of this counter is implementation specific. The counter shall be incremented by one for each Periodic Advertising Interval (see Section 4.4.2.3), whether or not the AUX_SYNC_IND PDU is actually transmitted; the *paEventCounter* shall wrap from

0xFFFF to 0x0000. AUX_SYNC_IND PDUs shall use the Channel Selection Algorithm #2 (see Section 4.5.8.3) with this event counter.

When periodic advertising subevents are used, the train has a 7-bit value (*paSubEventCounter*). The *paSubEventCounter* is set to 0 at the start of each periodic advertising event and incremented by one for each subevent. AUX_SYNC_SUBEVENT_IND PDUs shall use the Channel Selection Algorithm #2 with the *paEventCounter* and *paSubEventCounter*.

The response slots shall use the same channel as the AUX_SYNC_SUBEVENT_IND packet.

The Link Layer shall use the primary and secondary advertising channel indices as specified by the Host, and the used primary and secondary advertising channel indices shall take effect when the Advertising state is entered. The Link Layer need not use all the secondary channels that the Host has marked as "unknown".

4.4.2.2 Advertising events

Advertising events are defined as one or more advertising PDUs sent on the primary advertising physical channel. At most one PDU shall be sent on each used advertising channel index; usually a PDU is sent on all the used advertising indices in each advertising event. The advertising event can be closed early after a CONNECT_IND is received or when a SCAN_RSP is sent.

Advertising packets sent on the secondary advertising physical channel are not part of the advertising event. Advertising events that use the ADV_EXT_IND PDU may also be part of an extended advertising event. All ADV_EXT_IND PDUs containing an AuxPtr field in the same advertising event shall point to the same AUX_ADV_IND packet.

4.4.2.2.1 Advertising interval

For all undirected advertising events or connectable directed advertising events used in a low duty cycle mode, the time between the start of two consecutive advertising events (*T_advEvent*) for the same advertising set (see Section 4.4.2.10) is computed as follows for each advertising event:

$$T\_advEvent = advInterval + advDelay$$

The advertising interval (*advInterval*) shall be an integer multiple of 0.625 ms in the range 20 ms to 10,485.759375 s.

The *advDelay* is a (pseudo-)random value with a range 0 ms to 10 ms generated by the Link Layer for each advertising event.

As illustrated in Figure 4.6, the advertising events are perturbed in time using the advDelay.

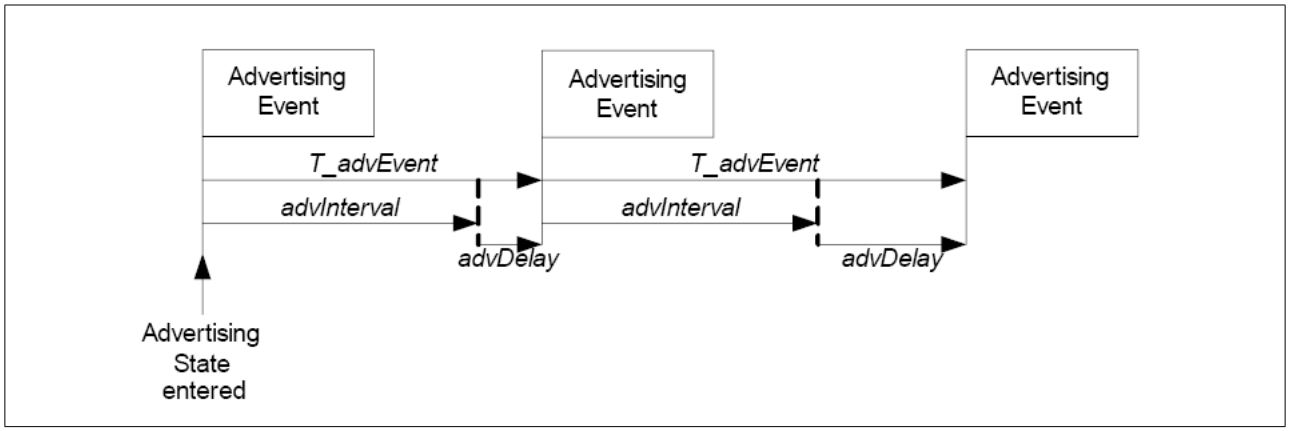

Figure 4.6: Advertising events perturbed in time using advDelay

4.4.2.2.2 Extended advertising event

An extended advertising event begins at the start of an advertising event and consists of the PDUs in that advertising event plus their subordinate sets. The extended advertising event ends with the last such PDU.

Multiple extended advertising events may overlap with each other. This can occur when ADV_EXT_IND PDUs containing an AuxPtr field in multiple advertising events point to the same AUX_ADV_IND packet, or when a different advertising event is interposed between the ADV_EXT_IND PDUs and the AUX_ADV_IND PDU.

T_advEvent, advInterval and advDelay have the same meaning as in Section 4.4.2.2.1.

Figure 4.7 illustrates an example of overlapping extended advertising events.

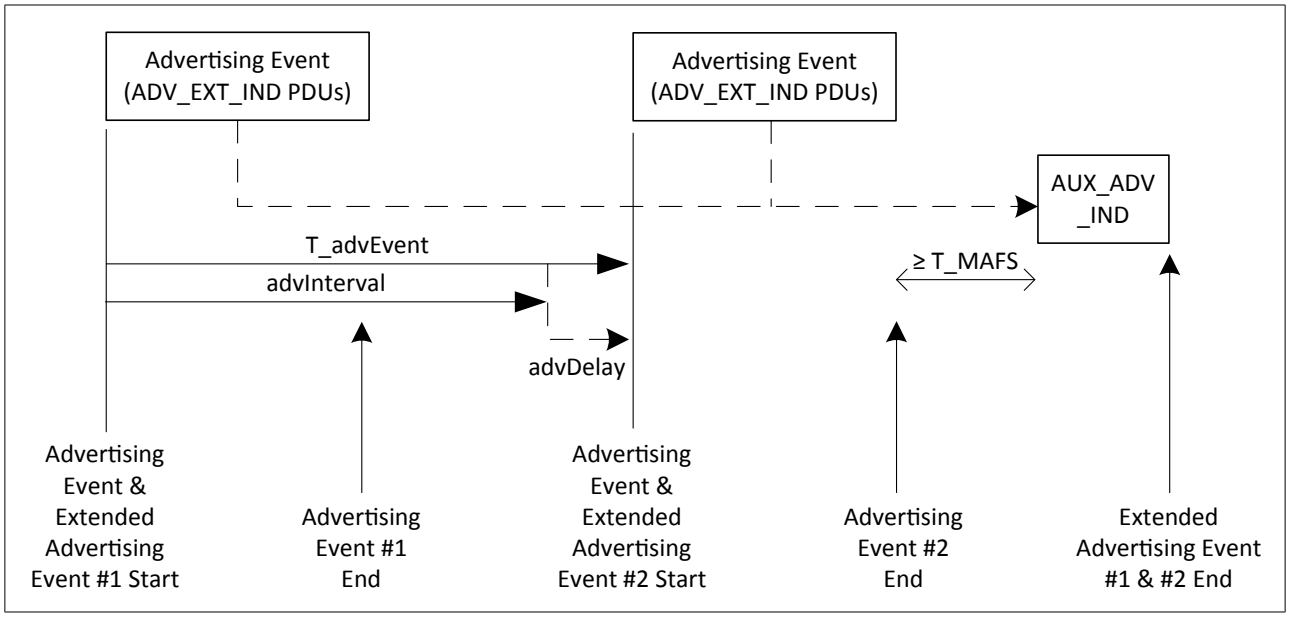

Figure 4.7: Example of overlapping extended advertising events

An auxiliary advertising segment starts with the first AUX_ADV_IND PDU in an extended advertising event and ends at the end of the extended advertising event (an auxiliary advertising segment can belong to more than one extended advertising event). Two auxiliary advertising segments for the same advertising set shall not overlap each other.

Figure 4.8 illustrates an example of auxiliary advertising segments belonging to multiple extended advertising events.

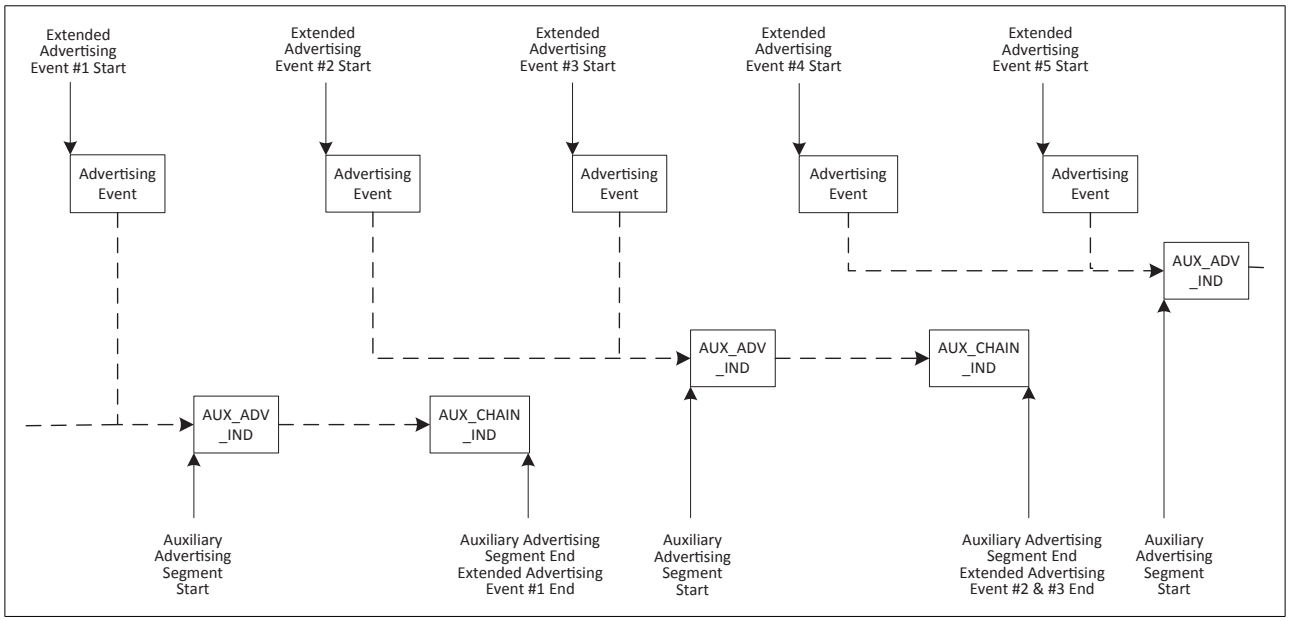

Figure 4.8: Example of auxiliary advertising segments

An advertiser should not space PDUs within the auxiliary advertising segment so that two of them would be within the same receive window. If an advertiser transmits a PDU with an AuxPtr field containing an offset of T milliseconds, then it should not start to transmit any other packet on the same RF channel as the auxiliary packet within 2.5×T microseconds of the start of the auxiliary packet of the original PDU.

4.4.2.2.3 Periodic advertising events

The Periodic Advertising Interval is the interval between the start of two scheduled AUX_SYNC_IND PDUs from the same advertising set (even if the PDUs are not transmitted for some reason). The Periodic Advertising Interval shall be an integer multiple of 1.25 ms in the range 7.5 ms to 81.91875 s.

A periodic advertising event consists of an AUX_SYNC_IND PDU and its subordinate set.

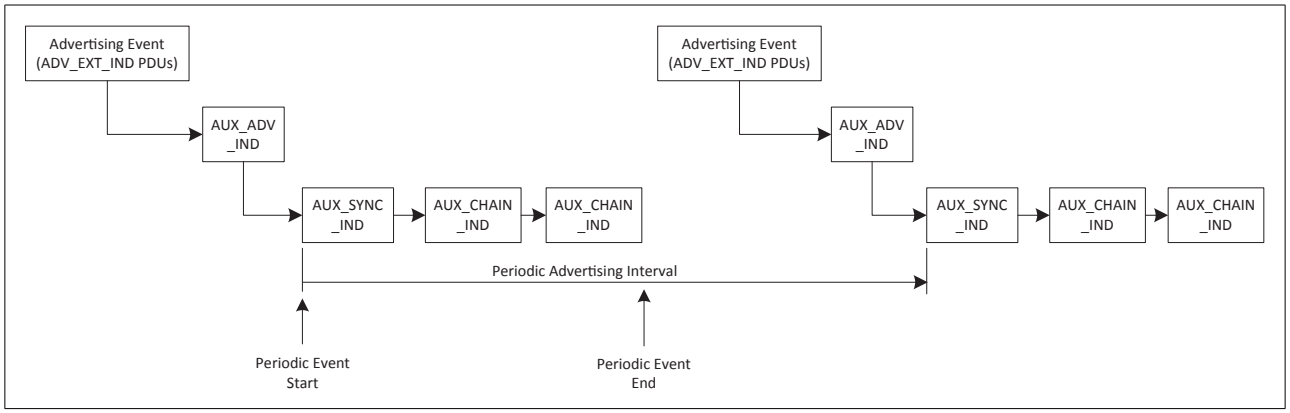

Figure 4.9: Example of periodic advertising events from the same advertising set

Two periodic advertising events for the same periodic advertising train shall not overlap each other. The periodic advertising interval shall not change while the periodic advertising is enabled.

4.4.2.2.4 Periodic advertising with responses events

A periodic advertising with responses event (PAwR event) consists of one or more subevents. Each subevent consists of an AUX_SYNC_SUBEVENT_IND PDU and one or more AUX_SYNC_SUBEVENT_RSP PDUs (see Figure 4.11).

The duration of the AUX_SYNC_SUBEVENT_IND PDU shall be smaller than Periodic Advertising Response Slot Delay minus T_IFS_150 if one or more response slots are defined and smaller than Periodic Advertising Subevent Interval minus T_IFS_150 otherwise. The duration of the AUX_SYNC_SUBEVENT_RSP PDU shall be smaller than Periodic Advertising Response Slot Spacing minus T_IFS_150. The gap between the end of one AUX_SYNC_SUBEVENT_IND

or AUX_SYNC_SUBEVENT_RSP packet and the start of the next AUX_SYNC_SUBEVENT_IND or AUX_SYNC_SUBEVENT_RSP packet shall be at least T_IFS_150.

The AUX_SYNC_SUBEVENT_RSP PDU shall be sent in response to the AUX_SYNC_SUBEVENT_IND PDU in a response slot and subevent provided by the Host. The data in the AUX_SYNC_SUBEVENT_RSP PDU shall contain the response to the data received in the AUX_SYNC_SUBEVENT_IND PDU. The Controller shall send the response no later than the Periodic Advertising Interval after the start of the received AUX_SYNC_SUBEVENT_IND PDU (therefore, if there is only one subevent in each event then the response must be sent in the same subevent).

The Periodic Advertising Interval is the interval between the start of two scheduled AUX_SYNC_SUBEVENT_IND PDUs with the same subevent number from the same advertising set (even if the PDUs are not transmitted for some reason). The Periodic Advertising Interval shall be an integer multiple of 1.25 ms in the range 7.5 ms to 81.91875 s.

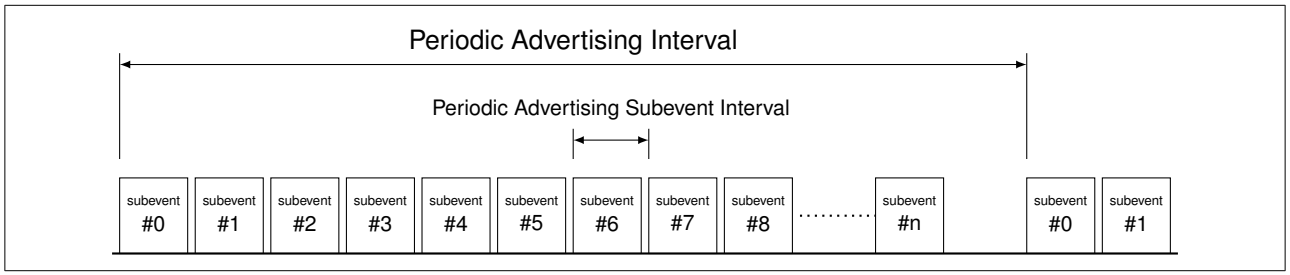

Figure 4.10: Periodic Advertising Subevents

The Periodic Advertising Subevent Interval is the interval between the start of two scheduled adjacent AUX_SYNC_SUBEVENT_IND PDUs in the same PAwR event. The Periodic Advertising Subevent Interval shall be an integer multiple of 1.25 ms in the range 7.5 ms to 318.75 ms. The subevent ends Periodic Advertising Subevent Interval after the start of the subevent. Up to 128 subevents can be used in a Periodic Advertising Interval. The subevent(s) to synchronize to is provided by the Host. If the Host has not provided the subevent(s), the Controller may synchronize with any subevent.

One or more response slots are defined when a device that is synchronized with this periodic advertising train may transmit a response packet. A synchronized device may only transmit a response packet in at most one response slot per subevent. Different synchronized devices may transmit response packets in different response slots in the same subevent. The Periodic Advertising Response Slot Delay is the interval between the start of an AUX_SYNC_SUBEVENT_IND PDU and the first response slot. The Periodic Advertising Response Slot Delay shall be an integer multiple of 1.25 ms in the range 1.25 ms to 317.5 ms. The Periodic Advertising Response Slot Spacing is

the interval between the start of two adjacent response slots in a given subevent. The Periodic Advertising Response Slot Spacing shall be an integer multiple of 0.125 ms in the range 0.25 ms to 31.875 ms and shall not be greater than (Periodic Advertising Subevent Interval − Periodic Advertising Response Slot Delay) ÷ number of response slots.

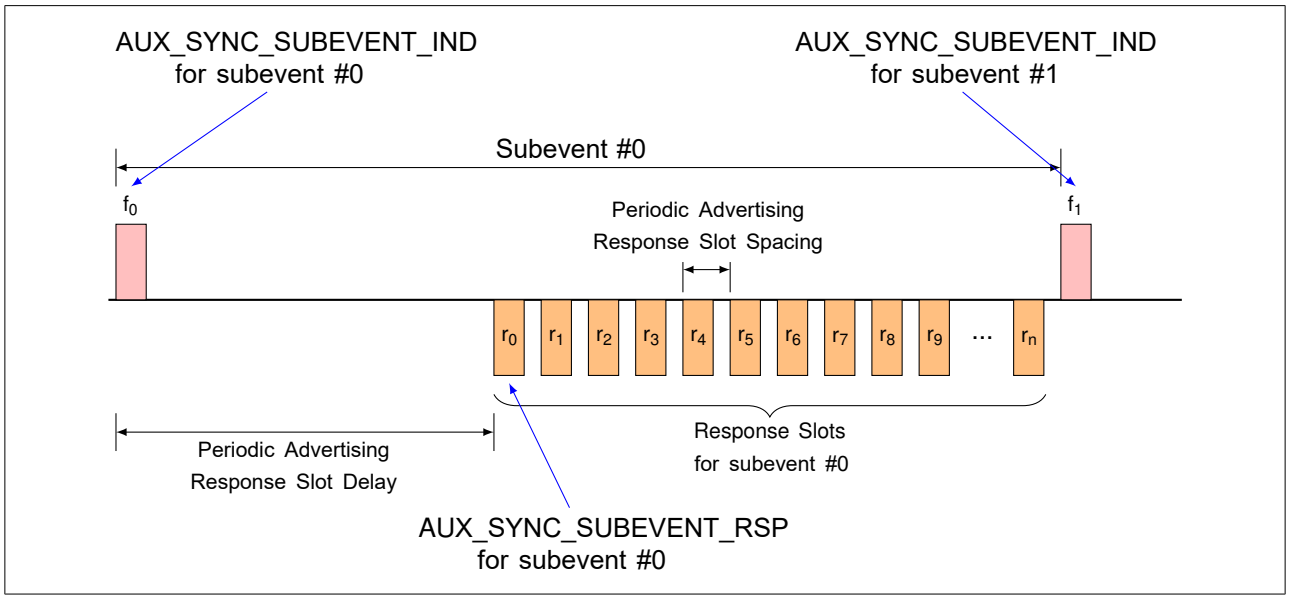

Figure 4.11: Periodic Advertising Subevent Response Slots

Two periodic advertising events for the same PAwR train shall not overlap each other. Two PAwR subevents shall not overlap each other. The Periodic Advertising Interval, Periodic Advertising Subevent Interval, Periodic Advertising Response Slot Delay, and Periodic Advertising Response Slot Interval shall not change while PAwR is enabled for that advertising set.

4.4.2.3 Connectable and scannable undirected event type

When the connectable and scannable undirected advertising event type is used, advertising indications (ADV_IND PDUs) are sent by the Link Layer.

The connectable and scannable undirected advertising event type allows a scanner or initiator to respond with either a scan request or connect request. A scanner may send a scan request (SCAN_REQ PDU) to request additional information about the advertiser. An initiator may send a connect request (CONNECT_IND PDU) to request the Link Layer to enter the Connection state.

The Link Layer shall listen on the same primary advertising channel index for requests from scanners or initiators.

If the advertiser receives a SCAN_REQ PDU that contains its device address from a scanner allowed by the advertising filter policy, it shall reply with a SCAN_RSP PDU on

the same primary advertising channel index. After the SCAN_RSP PDU is sent, or if the advertising filter policy did not allow processing the SCAN_REQ PDU, the advertiser shall either move to the next used primary advertising channel index to send another ADV_IND PDU, or close the advertising event.

If the advertiser receives a CONNECT_IND PDU that contains its device address, from an initiator allowed by the advertising filter policy, and is not already connected to the same device address, then the Link Layer shall exit the Advertising state and transition to the Connection state in the Peripheral Role as defined in Section 4.5.5. If the advertising filter policy did not allow processing the received CONNECT_IND PDU, the advertiser shall either move to the next used primary advertising channel index to send another ADV_IND PDU, or close the advertising event.

The time between the beginning of two consecutive ADV_IND PDUs within an advertising event shall be less than or equal to 10 ms. The advertising event shall be closed within the advertising interval.

An illustration of an advertising event using all the primary advertising channel indices and in which no SCAN_REQ or CONNECT_IND PDUs are received is shown in Figure 4.12.

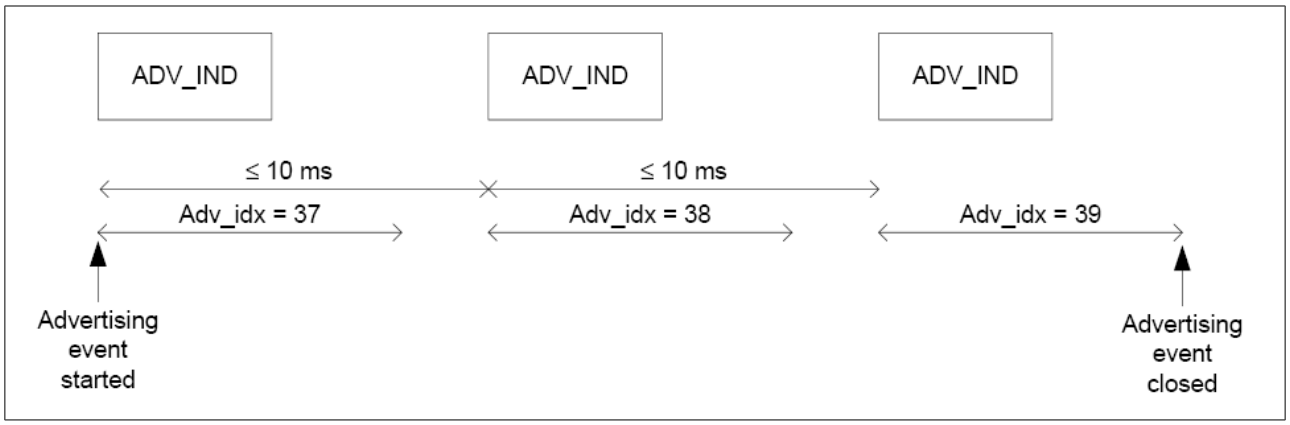

Figure 4.12: Connectable and scannable undirected advertising event with only advertising PDUs

Two illustrations of advertising events using all the primary advertising channel indices during which a SCAN_REQ PDU is received and a SCAN_RSP PDU is sent are shown in Figure 4.13 and in Figure 4.14.

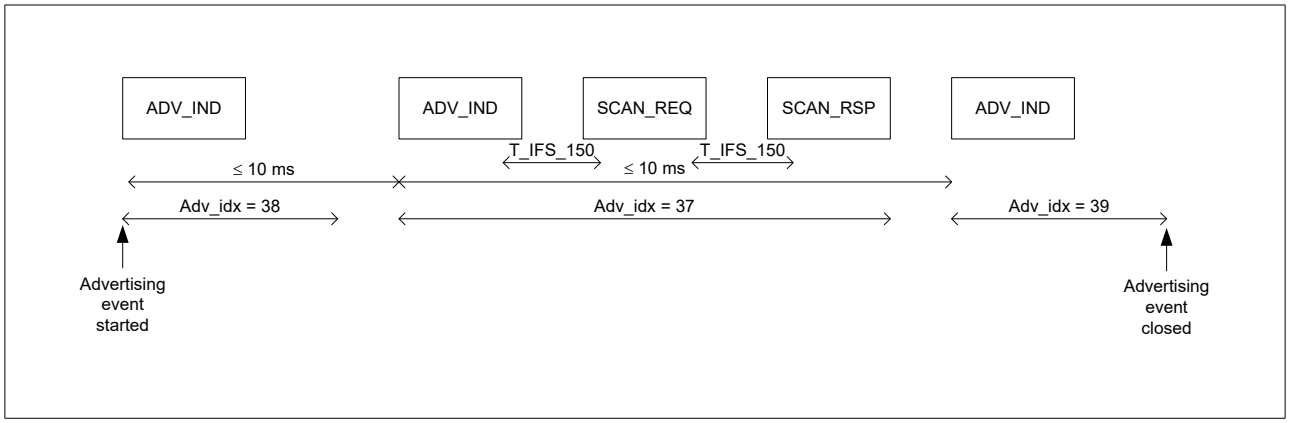

Figure 4.13: Connectable and scannable undirected advertising event with SCAN_REQ and SCAN_RSP PDUs in the middle of an advertising event

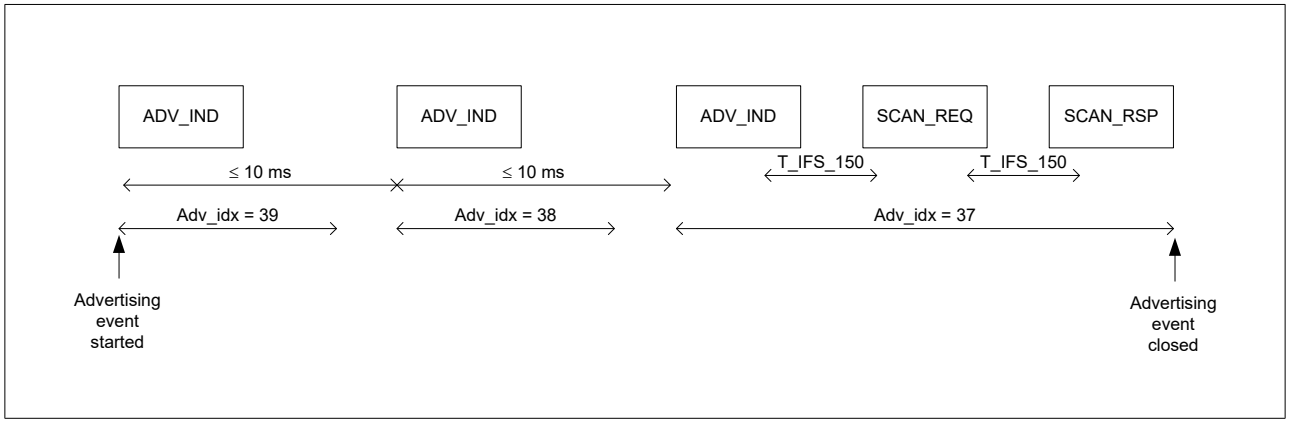

Figure 4.14: Connectable and scannable undirected advertising event with SCAN_REQ and SCAN_RSP PDUs at the end of an advertising event

Figure 4.15 illustrates an advertising event during which a CONNECT_IND PDU is received on the second primary advertising channel index.

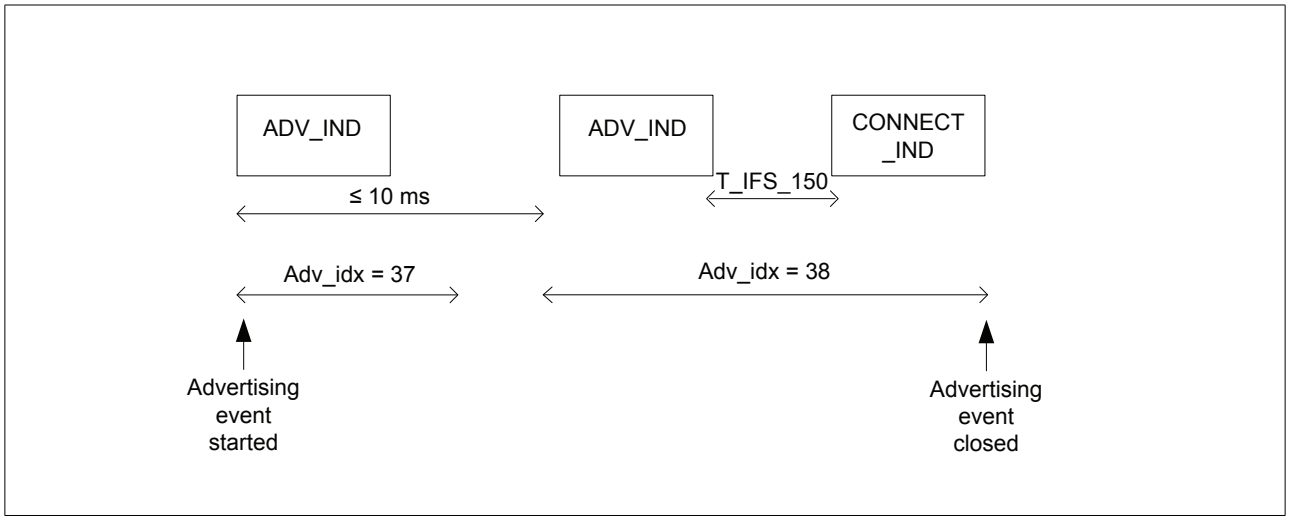

Figure 4.15: Connectable and scannable undirected advertising event when a CONNECT_IND PDU is received

If the Controller supports LL Privacy, then the requirements in Section 6.2.1 shall also be followed.

4.4.2.4 Connectable directed event type

When the connectable directed advertising event type is used, directed advertising indications are sent by the Link Layer.

The connectable directed advertising event type allows an initiator to respond so that both the advertiser and initiator will enter the Connection state.

The connectable directed advertising event type may use either the ADV_DIRECT_IND PDU (see Section 4.4.2.4.1 to Section 4.4.2.4.3) or the ADV_EXT_IND PDU (see Section 4.4.2.4.4).

If the Controller supports LL Privacy, then the requirements in Section 6.2.2 shall also be followed.

4.4.2.4.1 Connectable directed event type using ADV_DIRECT_IND

The connectable directed advertising event type using ADV_DIRECT_IND allows an initiator to respond with a connect request on the primary advertising physical channel to establish an ACL connection.

The ADV_DIRECT_IND PDU contains both the initiator's device address and the advertiser's device address. Only the addressed initiator may initiate an ACL connection with the advertiser by sending a CONNECT_IND PDU to the advertiser.

After every ADV_DIRECT_IND PDU sent by the advertiser, the advertiser shall listen for CONNECT_IND PDUs on the same primary advertising channel index. Any SCAN_REQ PDUs received shall be ignored.

If the advertiser receives a CONNECT_IND PDU that contains its device address, the initiator device address is contained in the ADV_DIRECT_IND PDU, and the advertiser is not already connected to that initiator device address, then the Link Layer shall exit the Advertising state and transition to the Connection state in the Peripheral Role as defined in Section 4.5.5.

Otherwise, the advertiser shall either move to the next used primary advertising channel index to send another ADV_DIRECT_IND PDU, or close the Advertising event.

Connectable directed advertising may be either used in a low duty cycle or high duty cycle mode; these are described in the next two sections. Low duty cycle connectable directed advertising is designed for cases where reconnection with a specific device is required, but time is not of the essence or it is not known if the Central is in range or not. High duty cycle connectable directed advertising is designed for cases in which fast ACL connection setup is essential (for example, a reconnection).

Note: High duty cycle connectable directed advertising is a power and bandwidth intensive advertising scheme that should only be used when fast connection setup is required.

4.4.2.4.2 Low duty cycle connectable directed advertising

In low duty cycle connectable directed advertising, the time between the start of two consecutive ADV_DIRECT_IND PDUs within an advertising event shall be less than or equal to 10 ms. The advertising event shall be closed within the advertising interval.

An illustration of an advertising event using all primary advertising channel indices and in which no CONNECT_IND PDUs are received is shown in Figure 4.16.

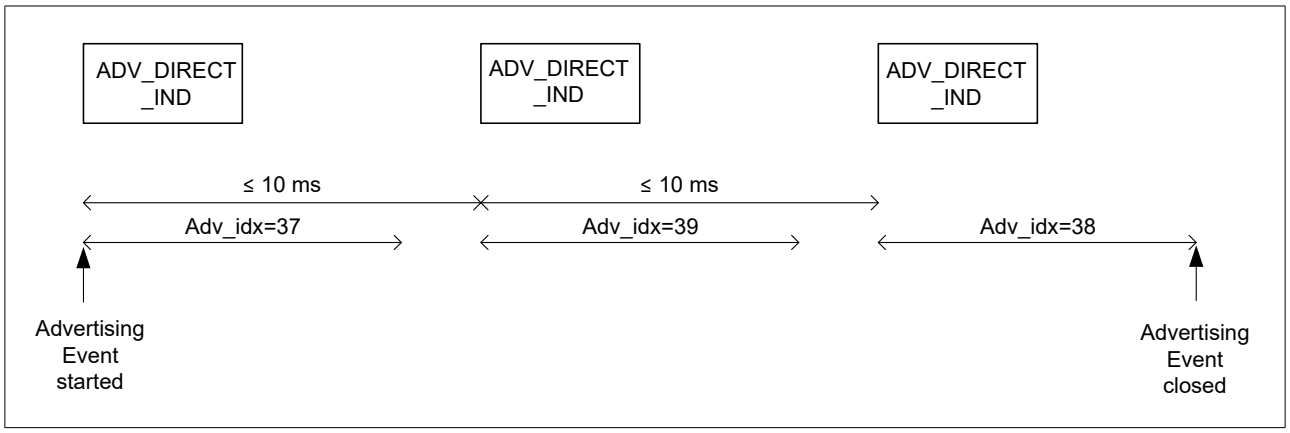

Figure 4.16: Low duty cycle connectable directed advertising event with only advertising PDUs

Figure 4.17 illustrates an advertising event using ADV_DIRECT_IND advertising PDUs during which a CONNECT_IND PDU is received on the second primary advertising channel index.

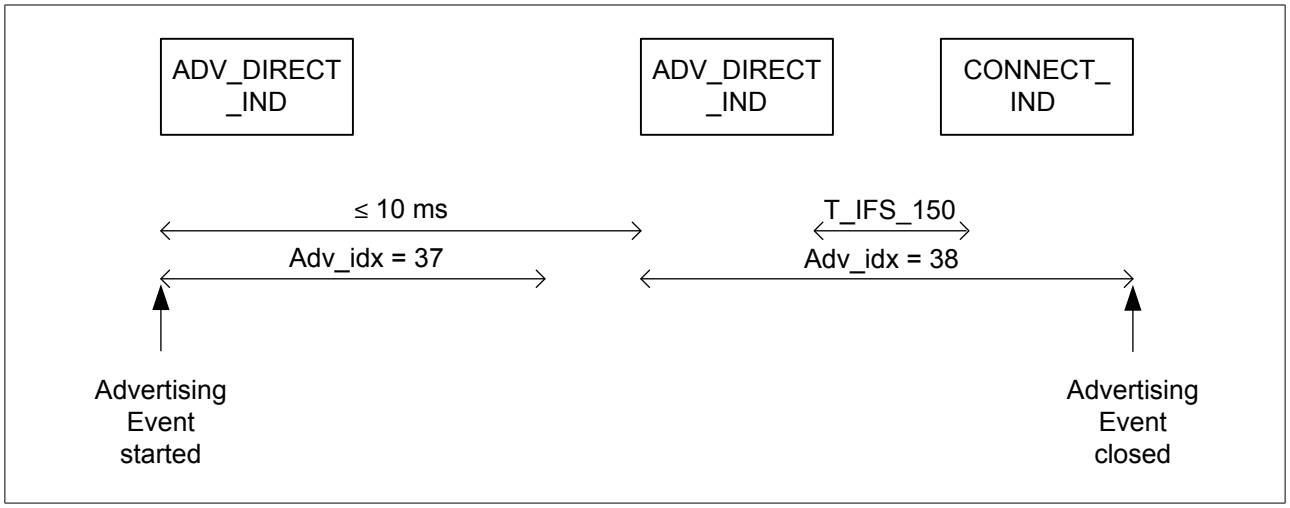

Figure 4.17: Low duty cycle connectable directed advertising event during which a CONNECT_IND PDU is received

4.4.2.4.3 High duty cycle connectable directed advertising

In high duty cycle connectable directed advertising mode, the time between the start of two consecutive ADV_DIRECT_IND PDUs sent on the same advertising channel index shall be less than or equal to 3.75 ms.

The Link Layer shall exit the Advertising state no later than 1.28 s after the Advertising state was entered.

The Link Layer shall start each advertising event with the lowest used primary advertising channel index and move sequentially through the other used primary advertising indices.

A sequence of five ADV_DIRECT_IND PDUs in two Advertising events without CONNECT_IND PDUs is shown in Figure 4.18 for the case in which all the primary advertising physical channels are used.

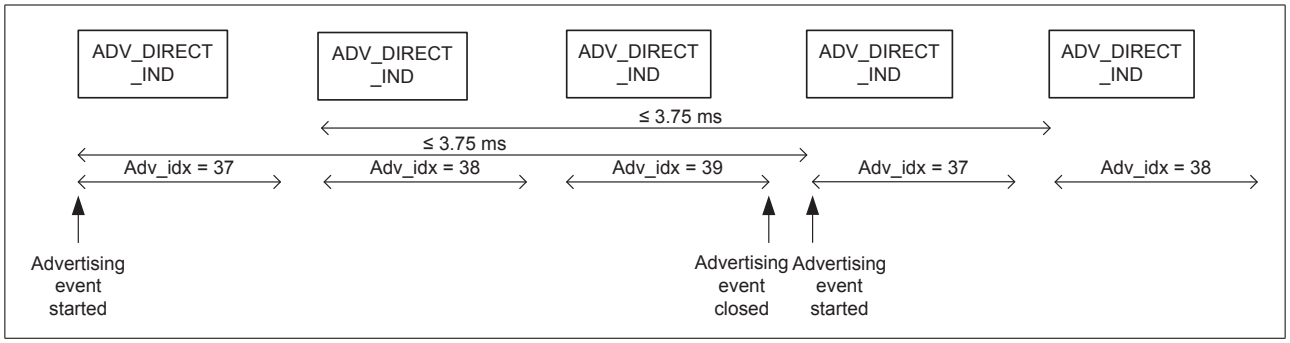

Figure 4.18: High duty cycle connectable directed advertising event with only advertising PDUs

4.4.2.4.4 Connectable directed event type using ADV_EXT_IND

The connectable directed advertising event type using ADV_EXT_IND allows an initiator to respond with a connect request on the secondary advertising physical channel to establish an ACL connection.

After every AUX_ADV_IND PDU related to this event it sends, the advertiser shall listen for AUX_CONNECT_REQ PDUs on the same secondary advertising channel index. Any AUX_SCAN_REQ PDUs received shall be ignored.

If the advertiser receives an AUX_CONNECT_REQ PDU that contains its device address, the initiator's device address was contained in the AUX_ADV_IND PDU, and the advertiser is not already connected to that initiator device address, then the advertiser shall reply with an AUX_CONNECT_RSP PDU on the same secondary advertising channel index. If the advertiser's Link Layer does not support LL Privacy, then it shall use those addresses in the AUX_CONNECT_RSP PDU. After the AUX_CONNECT_RSP PDU is sent the Link Layer shall exit the Advertising state and transition to the Connection state in the Peripheral Role as defined in Section 4.5.5. Any AUX_SCAN_REQ PDUs received on the secondary advertising physical channel shall be ignored.

The time between the start of two consecutive connectable directed ADV_EXT_IND PDUs within an advertising event shall be less than or equal to 10 ms. The advertising event shall be closed within the advertising interval.

The channel index on the secondary channel, SAdv_idx, is contained in the AuxPtr field of the ADV_EXT_IND PDU.

Figure 4.19 shows an advertising event in which no AUX_CONNECT_REQ PDU is received.

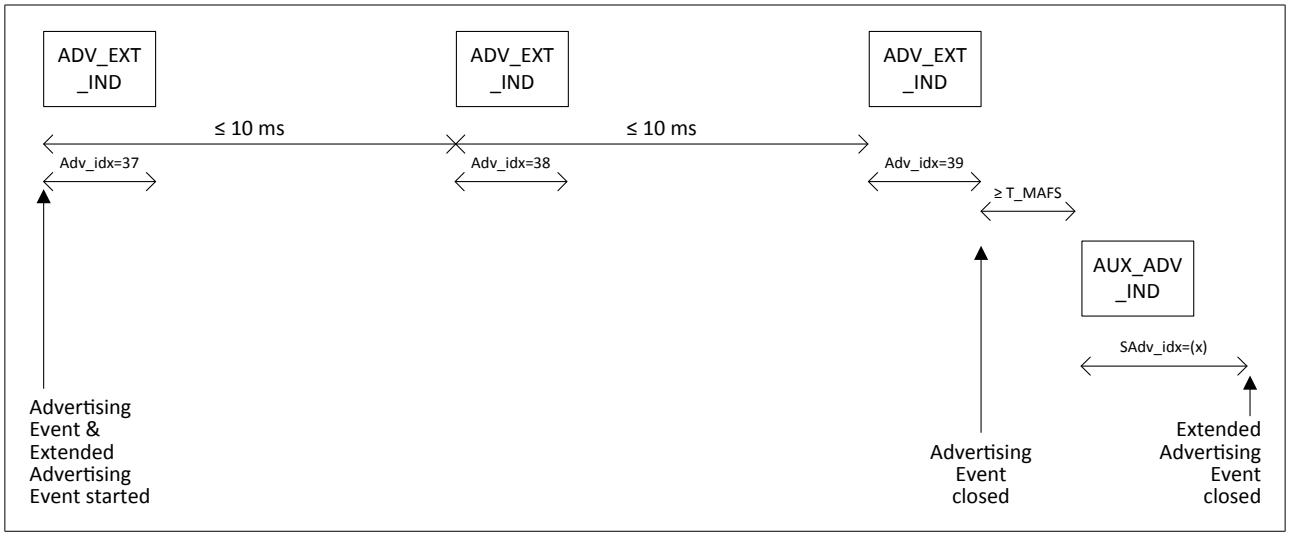

Figure 4.19: Connectable directed advertising event using the ADV_EXT_IND PDUs and AUX_ADV_IND PDU containing advertising data

Figure 4.20 illustrates an advertising event using connectable directed ADV_EXT_IND advertising PDUs during which an AUX_CONNECT_REQ PDU is received on the second secondary advertising channel index.

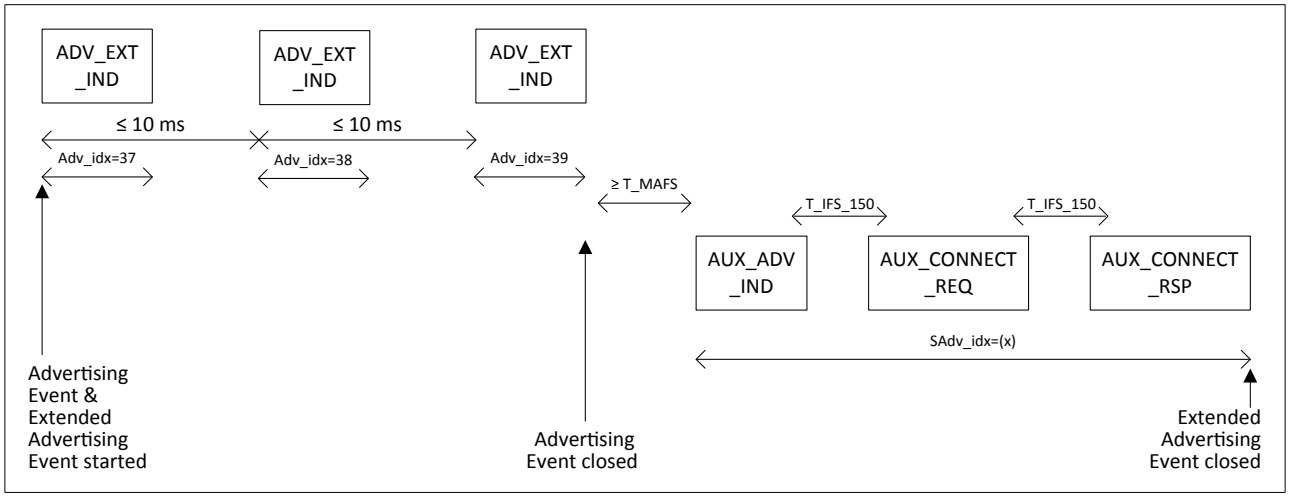

Figure 4.20: Connectable directed advertising event using ADV_EXT_IND PDUs and AUX_ADV_IND PDUs containing advertising data with an AUX_CONNECT_REQ PDU

4.4.2.5 Scannable undirected event type

When the scannable undirected advertising event type is used, scannable undirected advertising indications (ADV_SCAN_IND or scannable undirected ADV_EXT_IND or ADV_DECISION_IND PDUs) are sent by the Link Layer.

If the Controller supports LL Privacy, then the requirements in Section 6.2.3 shall also be followed.

4.4.2.5.1 Scannable undirected event type using ADV_SCAN_IND

The scannable undirected event type allows a scanner to respond with a scan request (SCAN_REQ PDU) to request additional information about the advertiser.

The Link Layer shall listen on the same primary advertising channel index for requests from scanners. Any CONNECT_IND PDUs received shall be ignored.

If the advertiser receives a SCAN_REQ PDU that contains its device address from a scanner allowed by the advertising filter policy it shall reply with a SCAN_RSP PDU on the same advertising channel index. After the SCAN_RSP PDU is sent or if the advertising filter policy did not allow processing the SCAN_REQ PDU the advertiser shall either move to the next used primary advertising channel index to send another ADV_SCAN_IND PDU, or close the advertising event.

The time between the beginning of two consecutive ADV_SCAN_IND PDUs within an advertising event shall be less than or equal to 10 ms. The advertising event shall be closed within the advertising interval.

The structure of an advertising event in which no SCAN_REQ PDU was received is shown in Figure 4.21 for the case in which all the primary advertising physical channels are used.

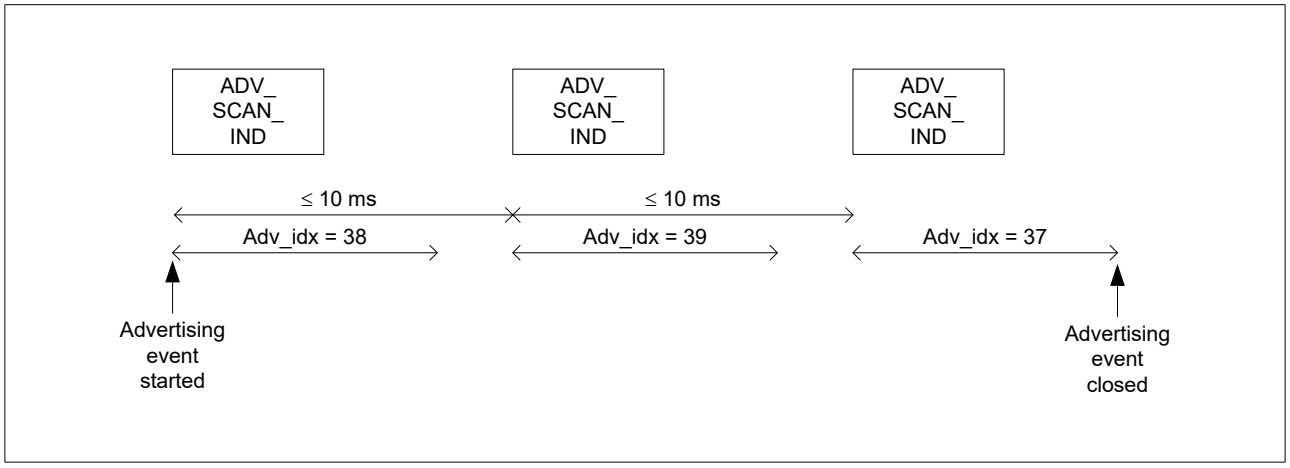

Figure 4.21: Scannable undirected advertising event with only advertising PDUs

Two example advertising events during which a SCAN_REQ PDU is received and a SCAN_RSP PDU is sent are shown in Figure 4.22 and in Figure 4.23 for the case in which all the primary advertising physical channels are used.

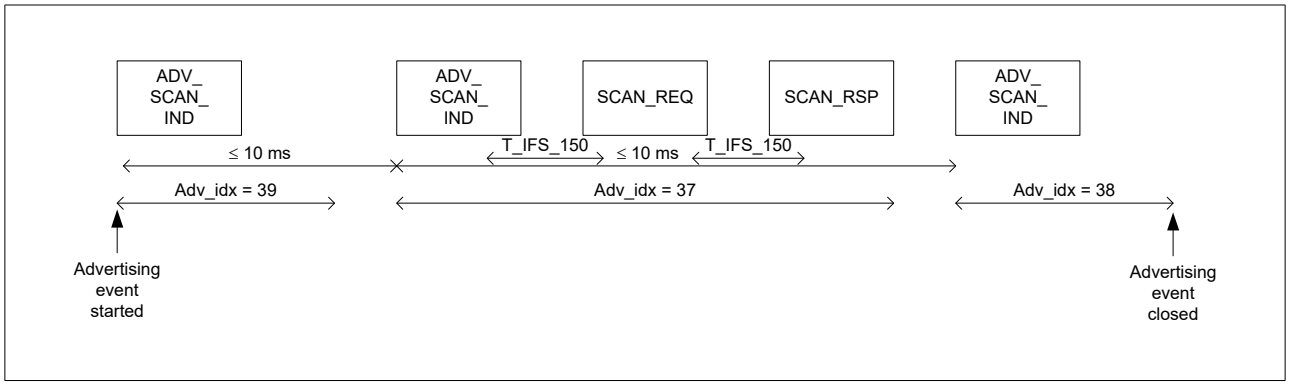

Figure 4.22: Scannable undirected advertising event with SCAN_REQ and SCAN_RSP PDUs in the middle of an advertising event

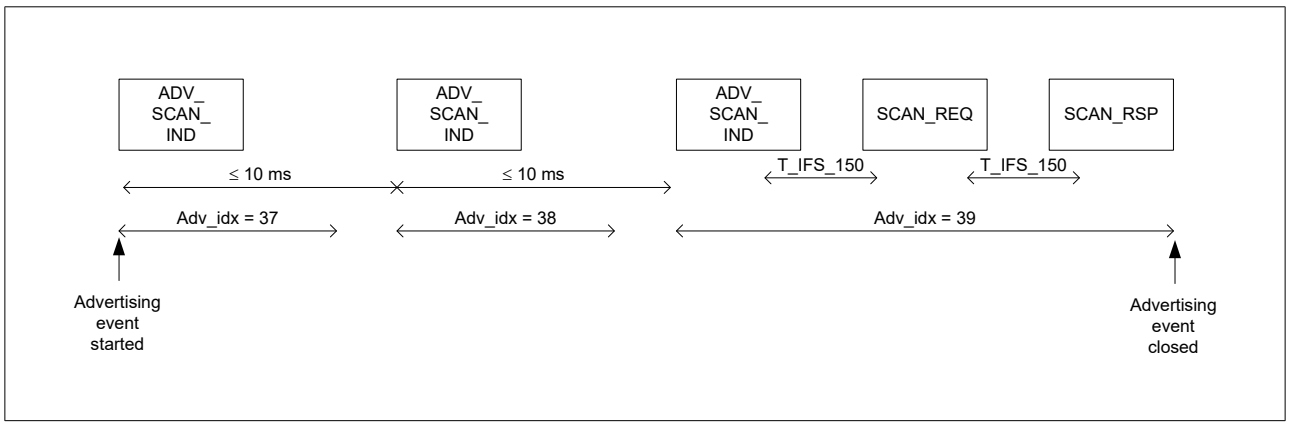

Figure 4.23: Scannable undirected advertising event with SCAN_REQ and SCAN_RSP PDUs at the end of an advertising event

4.4.2.5.2 Scannable undirected event type using ADV_EXT_IND or ADV_DECISION_IND

The scannable undirected event type using the ADV_EXT_IND or ADV_DECISION_IND PDU allows any scanner to respond with a scan request to receive scan response data on the secondary advertising physical channel.

A scanner may send a scan request using the AUX_SCAN_REQ PDU on the same secondary advertising channel index as the received AUX_ADV_IND PDU pointed to by the ADV_EXT_IND PDU.

After every AUX_ADV_IND PDU sent by the advertiser, the advertiser shall listen for AUX_SCAN_REQ PDUs on the same secondary advertising channel index from scanners. Any AUX_CONNECT_REQ PDUs received shall be ignored.

If the advertiser receives an AUX_SCAN_REQ PDU that contains its device address from a scanner allowed by the advertising filter policy, it shall reply with an AUX_SCAN_RSP PDU on the same secondary advertising channel index prior to the start of the next advertising event. After the AUX_SCAN_RSP PDU is sent, or if the

advertising filter policy prohibits processing the AUX_SCAN_REQ PDU, the advertising event shall be closed. Any AUX_CONNECT_REQ PDUs on the secondary advertising physical channel shall be ignored.

The time between the beginning of two consecutive ADV_EXT_IND or ADV_DECISION_IND PDUs within an advertising event shall be less than or equal to 10 ms. The advertising event shall be closed within the advertising interval.

Figure 4.24 shows an advertising event in which no AUX_SCAN_REQ PDU is received.

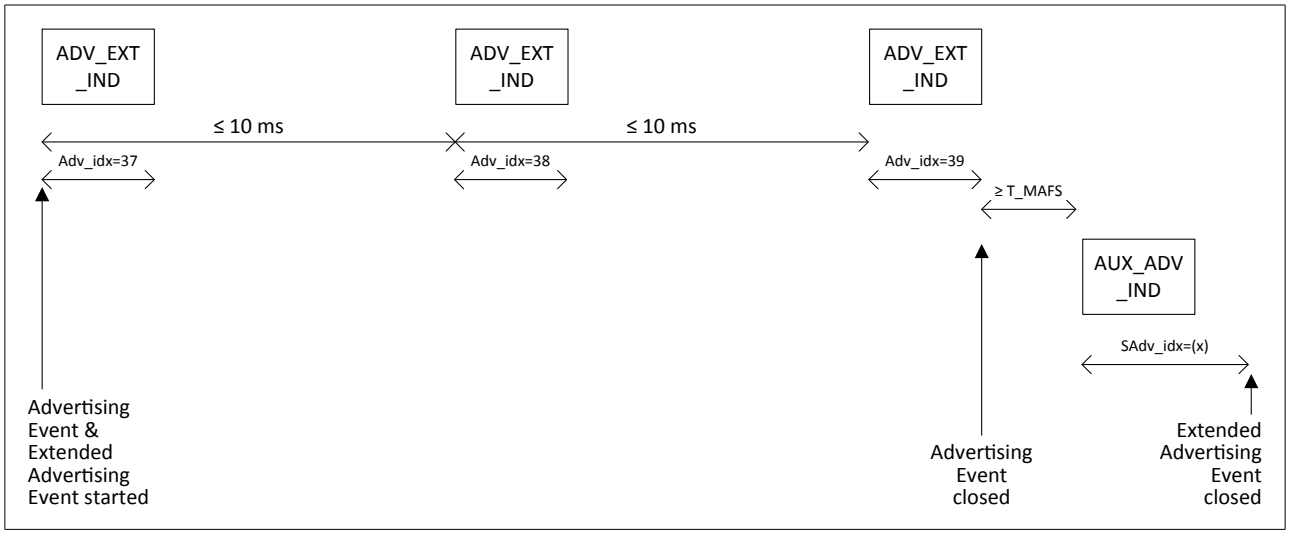

Figure 4.24: Scannable undirected advertising event using the ADV_EXT_IND PDU and AUX_ADV_IND PDUs where no scan request is received

An example advertising event during which an AUX_SCAN_REQ PDU is received and an AUX_SCAN_RSP PDU is sent on the secondary advertising physical channel is shown in Figure 4.25.

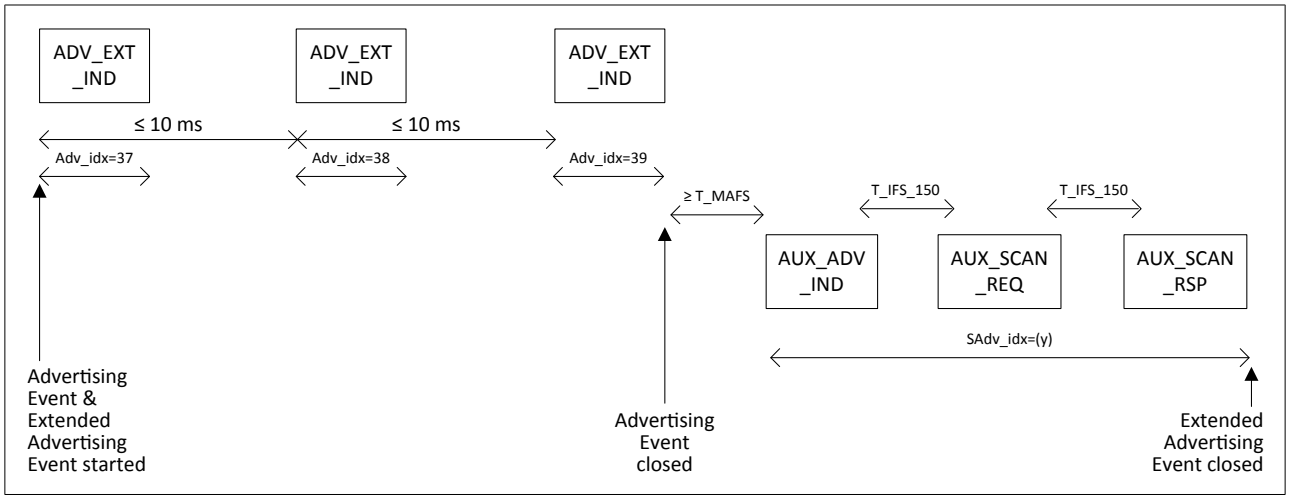

Figure 4.25: Scannable undirected advertising event with ADV_EXT_IND and AUX_ADV_IND PDUs where a scan request is received

4.4.2.6 Non-connectable and non-scannable undirected event type

When the non-connectable and non-scannable undirected advertising event type is used, non-connectable and non-scannable undirected advertising indications (ADV_NONCONN_IND or non-connectable and non-scannable undirected ADV_EXT_IND or ADV_DECISION_IND PDUs, either with or without an auxiliary AUX_ADV_IND PDU) are sent by the Link Layer.

The non-connectable and non-scannable undirected event type allows a scanner to receive information from the advertiser. This information is contained either in the ADV_NONCONN_IND PDU or in an AUX_ADV_IND PDU pointed to by the AuxPtr field of the ADV_EXT_IND or ADV_DECISION_IND PDU.

The advertiser shall either move to the next used primary advertising channel index or close the advertising event after each ADV_NONCONN_IND, ADV_EXT_IND, or ADV_DECISION_IND PDU that is sent. The Link Layer does not listen, and therefore cannot receive any requests from scanners or initiators.

The time between the beginning of two consecutive ADV_NONCONN_IND, ADV_EXT_IND, or ADV_DECISION_IND PDUs within an advertising event shall be less than or equal to 10 ms. The advertising event shall be closed within the advertising interval.

When using an ADV_EXT_IND PDU with an AUX_ADV_IND PDU, the Controller shall decide which PDU contains the AdvA field and should make this choice based on overall efficient use of the medium.

An illustration of a non-connectable and non-scannable undirected advertising event is shown in Figure 4.26 for the case in which all the primary advertising physical channels are used.

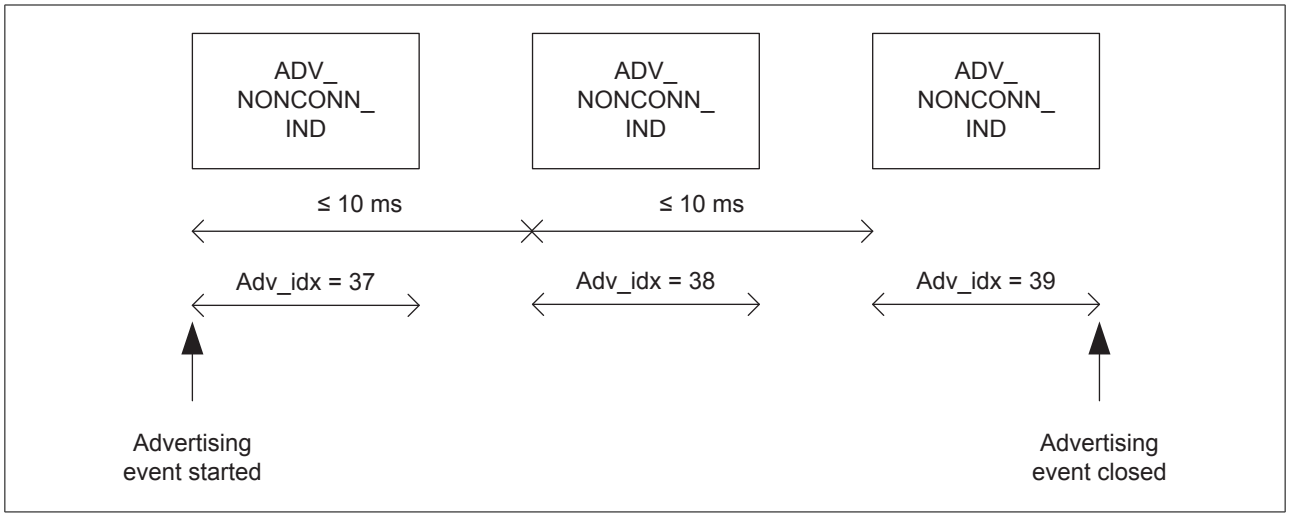

Figure 4.26: Non-connectable and non-scannable undirected advertising event using ADV_NONCONN_IND PDUs

Figure 4.27 shows an example of a non-connectable and non-scannable undirected ADV_EXT_IND PDU.

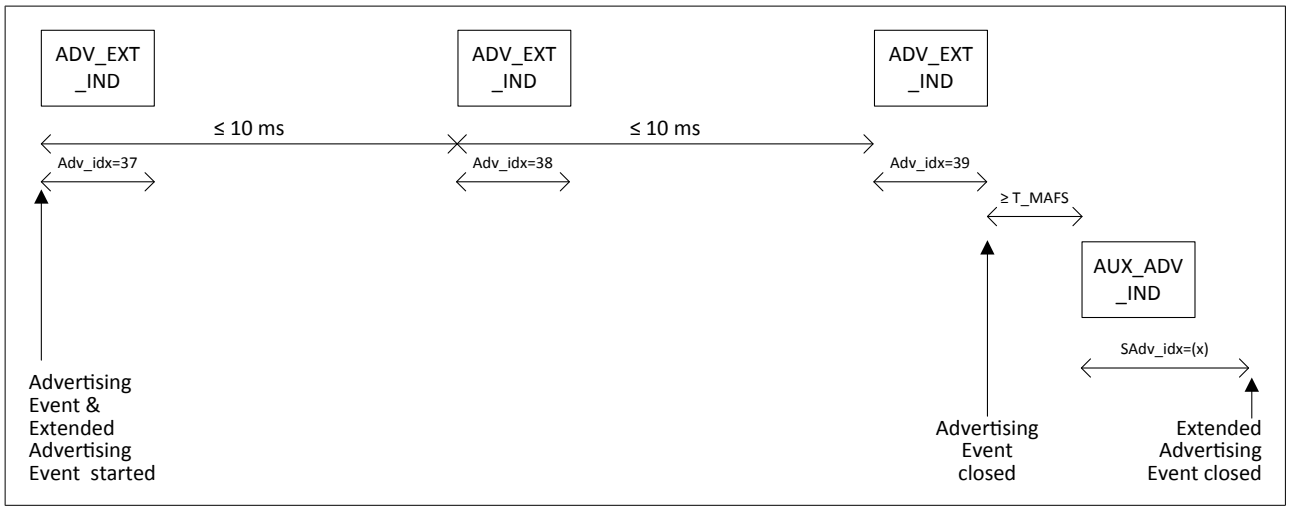

Figure 4.27: Non-connectable and non-scannable undirected advertising event using the ADV_EXT_IND PDU

Figure 4.28 shows an example of a non-connectable and non-scannable undirected ADV_EXT_IND PDU where the Host advertising data is fragmented using the AUX_CHAIN_IND PDU.

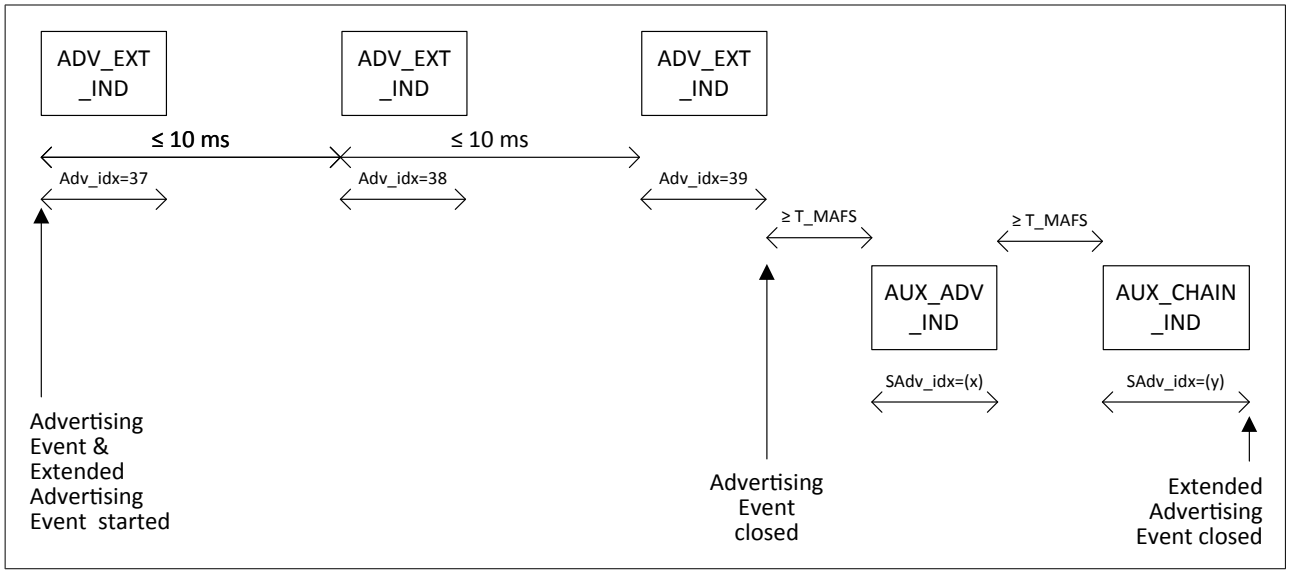

Figure 4.28: Non-connectable and non-scannable undirected advertising event using the ADV_EXT_IND PDU with fragmented Host advertising data

If the Controller supports LL Privacy, then the requirements in Section 6.2.3 shall also be followed.

4.4.2.7 Connectable undirected event type

The connectable undirected advertising event type using the ADV_EXT_IND or ADV_DECISION_IND PDU allows an initiator to respond with a connect request to establish an ACL connection on the secondary advertising physical channel.

An initiator may send a connect request using the AUX_CONNECT_REQ PDU on the same secondary advertising physical channel as the AUX_ADV_IND PDU to request the Link Layer to enter the Connection state.

After every AUX_ADV_IND PDU sent related to this event by the advertiser, the advertiser shall listen for AUX_CONNECT_REQ PDUs on the same secondary advertising channel index. Any AUX_SCAN_REQ PDUs received shall be ignored.

If the advertiser receives an AUX_CONNECT_REQ PDU that contains its device address from an initiator allowed by the advertising filter policy and if the advertiser is not already connected to that initiator device address, then it shall reply with an AUX_CONNECT_RSP PDU on the same secondary advertising channel index. After the AUX_CONNECT_RSP PDU is sent the Link Layer shall exit the Advertising state and transition to the Connection state in the Peripheral Role as defined in Section 4.5.5.

The time between the beginning of two consecutive ADV_EXT_IND or ADV_DECISION_IND PDUs within an advertising event shall be less than or equal to 10 ms. The advertising event shall be closed within the advertising interval.

Figure 4.29 shows an advertising event in which no AUX_CONNECT_REQ PDU is received.

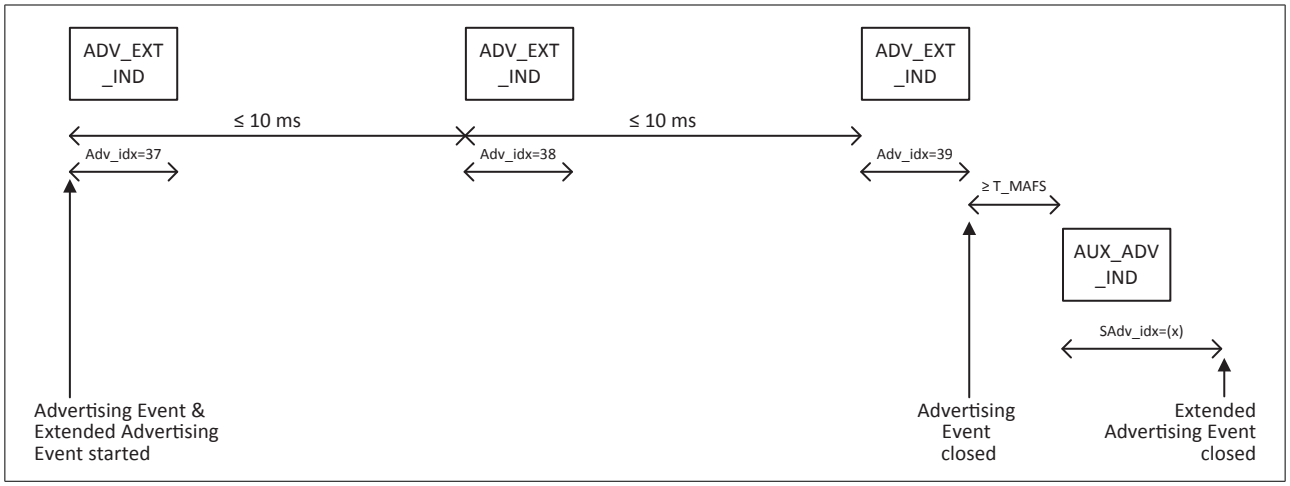

Figure 4.29: Connectable undirected advertising event using the ADV_EXT_IND PDUs and AUX_ADV_IND PDU containing advertising data

Figure 4.30 illustrates an advertising event during which an AUX_CONNECT_REQ PDU is received and an AUX_CONNECT_RSP PDU is sent on the secondary advertising channel index.

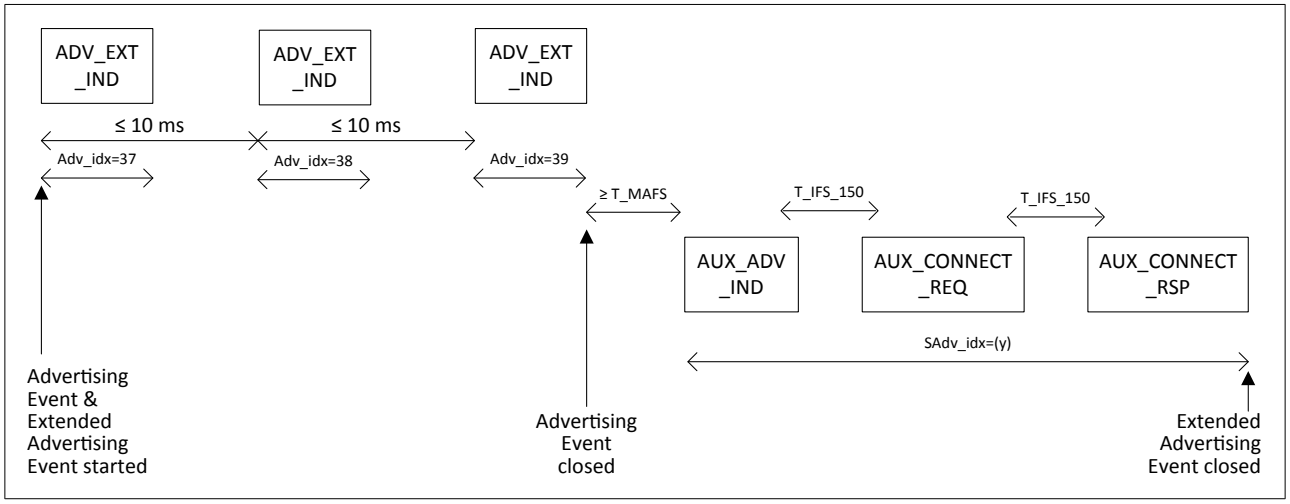

Figure 4.30: Connectable undirected advertising using ADV_EXT_IND PDUs when an AUX_CONNECT_REQ PDU is received

If the Controller supports LL Privacy, then the requirements in Section 6.2.4 shall also be followed.

4.4.2.8 Scannable directed event type

The scannable directed advertising event type using the ADV_EXT_IND PDU allows a specific scanner to respond with a scan request to receive scan response data on the secondary advertising physical channel.

After every AUX_ADV_IND PDU sent, the advertiser shall listen for an AUX_SCAN_REQ PDU on the same secondary advertising channel index from the targeted scanner.

If the advertiser receives an AUX_SCAN_REQ PDU that contains its device address and the scanner's device address is contained in the AUX_ADV_IND PDU, it shall reply with an AUX_SCAN_RSP PDU on the same secondary advertising channel index prior to the next advertising event. The AUX_SCAN_RSP PDU shall contain the scan response data. AUX_SCAN_REQ PDUs from any other scanner or any AUX_CONNECT_REQ PDUs received shall be ignored.

The time between the beginning of two consecutive ADV_EXT_IND PDUs within an advertising event shall be less than or equal to 10 ms. The advertising event shall be closed within the advertising interval.

See Section 4.4.2.5.2 for a description on how the AUX_SCAN_REQ packet is used in conjunction with the AUX_SCAN_RSP packets on the secondary advertising physical channel.

If the Controller supports LL Privacy, then the requirements in Section 6.2.5 shall also be followed.

4.4.2.9 Non-connectable and non-scannable directed event type

The non-connectable and non-scannable directed advertising event type using the ADV_EXT_IND PDU (either with or without an auxiliary AUX_ADV_IND PDU) allows an advertiser to send non-connectable and non-scannable directed ADV_EXT_IND PDUs on the primary advertising physical channel with any advertising data sent on the secondary advertising physical channel targeted for a specific scanner.

Note: The Host cannot specify which PDU contains the AdvA or TargetA field; the Controller should make this choice based on overall efficient use of the medium.

The Link Layer does not listen, and therefore cannot receive any requests from scanners or initiators.

If the Controller supports LL Privacy, then the requirements in Section 6.2.5 shall also be followed.

4.4.2.10 Advertising Sets

The advertiser's Host may instruct the Link Layer to interleave advertising events. Advertising data belonging together is called an advertising set. The Link Layer may support multiple advertising sets, with each set having different advertising parameters such as advertising PDU type, advertising interval, and PHY.

When advertising with the ADV_EXT_IND, AUX_ADV_IND, or AUX_SYNC_IND PDUs, the advertising set or group of sets is identified by the Advertising SID subfield of the ADI field. The Link Layer shall set the Advertising SID subfield as directed by the Host.

The scanner may filter advertisements based on the Advertising SID.

The advertising events for each advertising set are considered a separate instance of the Advertising State and each have their own Advertising Interval (see Section 4.4.2.2.1).

Figure 4.31 illustrates an example of advertising using multiple advertising sets.

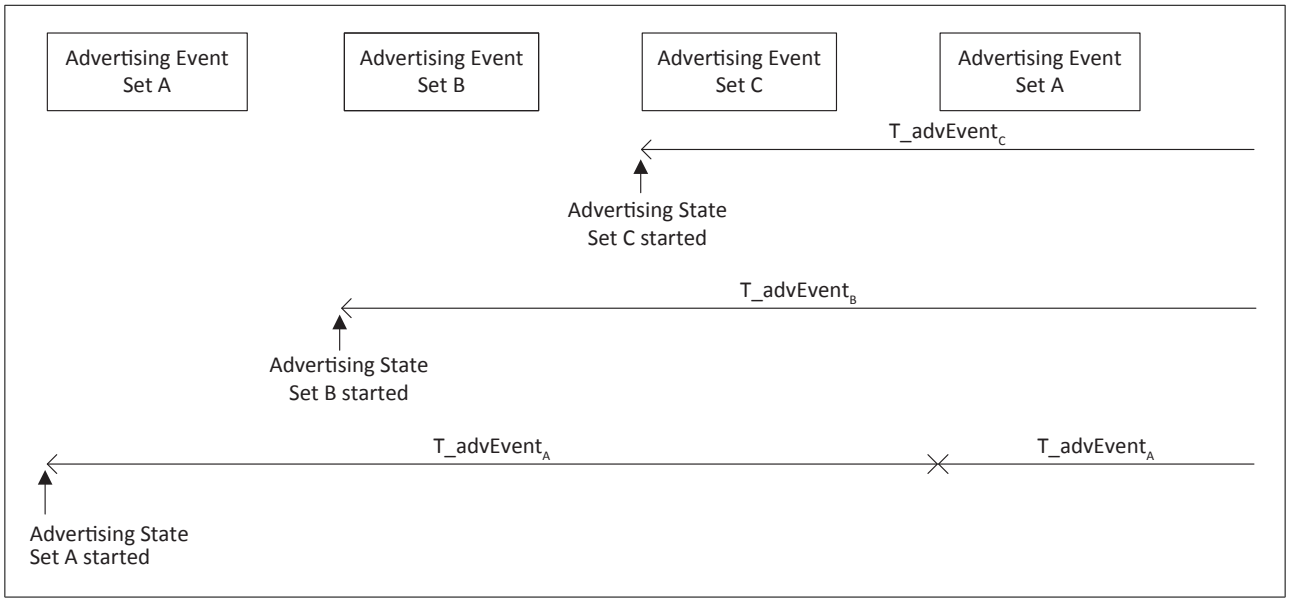

Figure 4.31: Multiple advertising sets example

On reset, all advertising sets are destroyed.

When an advertising set is created that includes advertising data, the Controller shall reserve sufficient resources to allow the set to contain at least 31 octets of advertising data. The Controller may release or reuse any unused portion of those resources at any time after the Host first specifies advertising data for that set or creates another advertising set.

When an advertising set is created that is scannable, the Controller shall reserve sufficient resources to allow the set to contain at least 31 octets of scan response data.

The Controller may release or reuse those resources if the set is made non-scannable and may release or reuse any unused portion of those resources at any time after the Host first specifies scan response data for that set or creates another advertising set.

4.4.2.11 Using AdvDataInfo (ADI)

The AdvDataInfo (ADI) field is used to identify advertising sets and duplicate AdvData in the AUX_ADV_IND, AUX_SYNC_IND, AUX_SYNC_SUBEVENT_IND, and AUX_SCAN_RSP PDUs. For scannable advertising events using the ADV_EXT_IND PDU, AdvData is not permitted in the AUX_ADV_IND PDU so the ADI only refers to the AdvData contained in the AUX_SCAN_RSP PDU. The Advertising SID is used to distinguish different advertising sets or groups of advertising sets from the same device. The advertiser may use the same Advertising SID for more than one advertising set, resulting in a group of advertising sets that cannot be distinguished by scanning devices using only the SID.

The Advertising DID for a given advertising set or periodic advertising train shall be initialized with a randomly chosen value. The advertising set and any associated periodic advertising shall have separate Advertising DIDs. Whenever the Host provides new advertising data, periodic advertising data, or scan response data for a given advertising set (whether it is the same as the previous data or not), the Advertising DID shall be updated. The new value shall be a randomly chosen value that is not the same as the most recently used value.

Note: Choosing Advertising DID field values randomly reduces the possibility of PDUs from different advertisers containing the same ADI field value.

Note: The Advertising DID is not required to change when a SyncInfo field is added to or removed from an advertising set. However, if it does not change, then scanners may fail to synchronize to periodic advertising because entries in the Advertising DID cache (see Section 4.4.3) mean they ignore the advertisements containing the SyncInfo field. Therefore, advertisers should update the Advertising DID when a periodic advertising train is enabled. Alternatively, the Host should enable periodic advertising before enabling advertising.

4.4.2.12 Periodic advertising

When advertising data is required to be sent regularly at a fixed interval, periodic advertising is used. Two forms of periodic advertising are defined: periodic advertising without responses and periodic advertising with responses.

Periodic advertising without responses consists of advertisements sent at a fixed interval with the advertisement data changing from time to time. The AUX_SYNC_IND and AUX_CHAIN_IND PDUs making up such a sequence of advertisements form a periodic advertising train.

Note: No AUX_SYNC_SUBEVENT_IND and AUX_SYNC_SUBEVENT_RSP PDUs are sent on a periodic advertising without responses train

Periodic Advertising with Responses (PAwR) consists of advertisements sent at a fixed interval with the advertisement data changing frequently, with responses being sent in response. The AUX_SYNC_SUBEVENT_IND and AUX_SYNC_SUBEVENT_RSP PDUs making up such a sequence of advertisements form a PAwR train.

Note: No AUX_SYNC_IND and AUX_CHAIN_IND PDUs are sent on a PAwR train.

The advertising set containing the Periodic Advertising is identified by the AdvDataInfo field of ADV_EXT_IND PDUs that point to AUX_ADV_IND PDUs containing the SyncInfo field. The AUX_SYNC_IND PDUs, the AUX_SYNC_SUBEVENT_IND PDUs, and the PDUs that point to them shall always be sent on the same PHY. The PHY used, the Access Address, and the CRCInit value of the AUX_SYNC_IND PDUs and the AUX_SYNC_SUBEVENT_IND PDUs for a periodic advertising train shall not change while that train is enabled. Advertising pointing to a periodic advertising train shall not be anonymous. Each time that a periodic advertising train is enabled, the Controller shall transmit at least one AUX_ADV_IND PDU pointing to the first AUX_SYNC_IND or AUX_SYNC_SUBEVENT_IND PDU of that train; after this, there is no requirement whether or when to transmit advertising PDUs pointing to the train. If the Periodic Advertising is with responses, then the ACAD field of the AUX_ADV_IND PDUs shall contain Periodic Advertising Response Timing Information (see Section 1.24 of [1]).

Note: The SyncInfo field is only allowed in non-scannable and non-connectable advertisements.

4.4.2.12.1 Trains without responses

When periodic advertising without responses takes place, the advertiser shall send AUX_SYNC_IND PDUs at regular intervals (the periodic advertising interval - see Section 4.4.2.2.3), which are described in the SyncInfo field of AUX_ADV_IND PDUs.

The Host may send periodic advertising data to the Link Layer. This advertising data is placed by the Link Layer in the periodic AUX_SYNC_IND PDUs and their subordinate sets. The Link Layer shall repeat the last advertising data sent by the Host until it receives new advertising data. The AUX_SYNC_IND PDUs are continuously sent out until the Host directs the Link Layer to terminate the periodic advertising train. When including the ADI field is enabled by the Host and where the periodic advertising data is not changed for every periodic advertising event, the Controller should include the ADI field in the AUX_SYNC_IND PDU.

Packets in a periodic advertising train may include a Constant Tone Extension. The Host may enable this before the periodic advertising train starts or may enable or

disable inclusion of the Constant Tone Extension while the periodic advertising is in progress.

When an advertising set is first configured for periodic advertising, the Controller shall either reserve sufficient resources to allow the set to contain at least 31 octets of advertising data or else shall not allow periodic advertising on that advertising set. The Controller may release or reuse any unused portion of those resources at any time after the Host first specifies periodic advertising data for that set or creates another advertising set.

Figure 4.32 illustrates an example of periodic advertising.

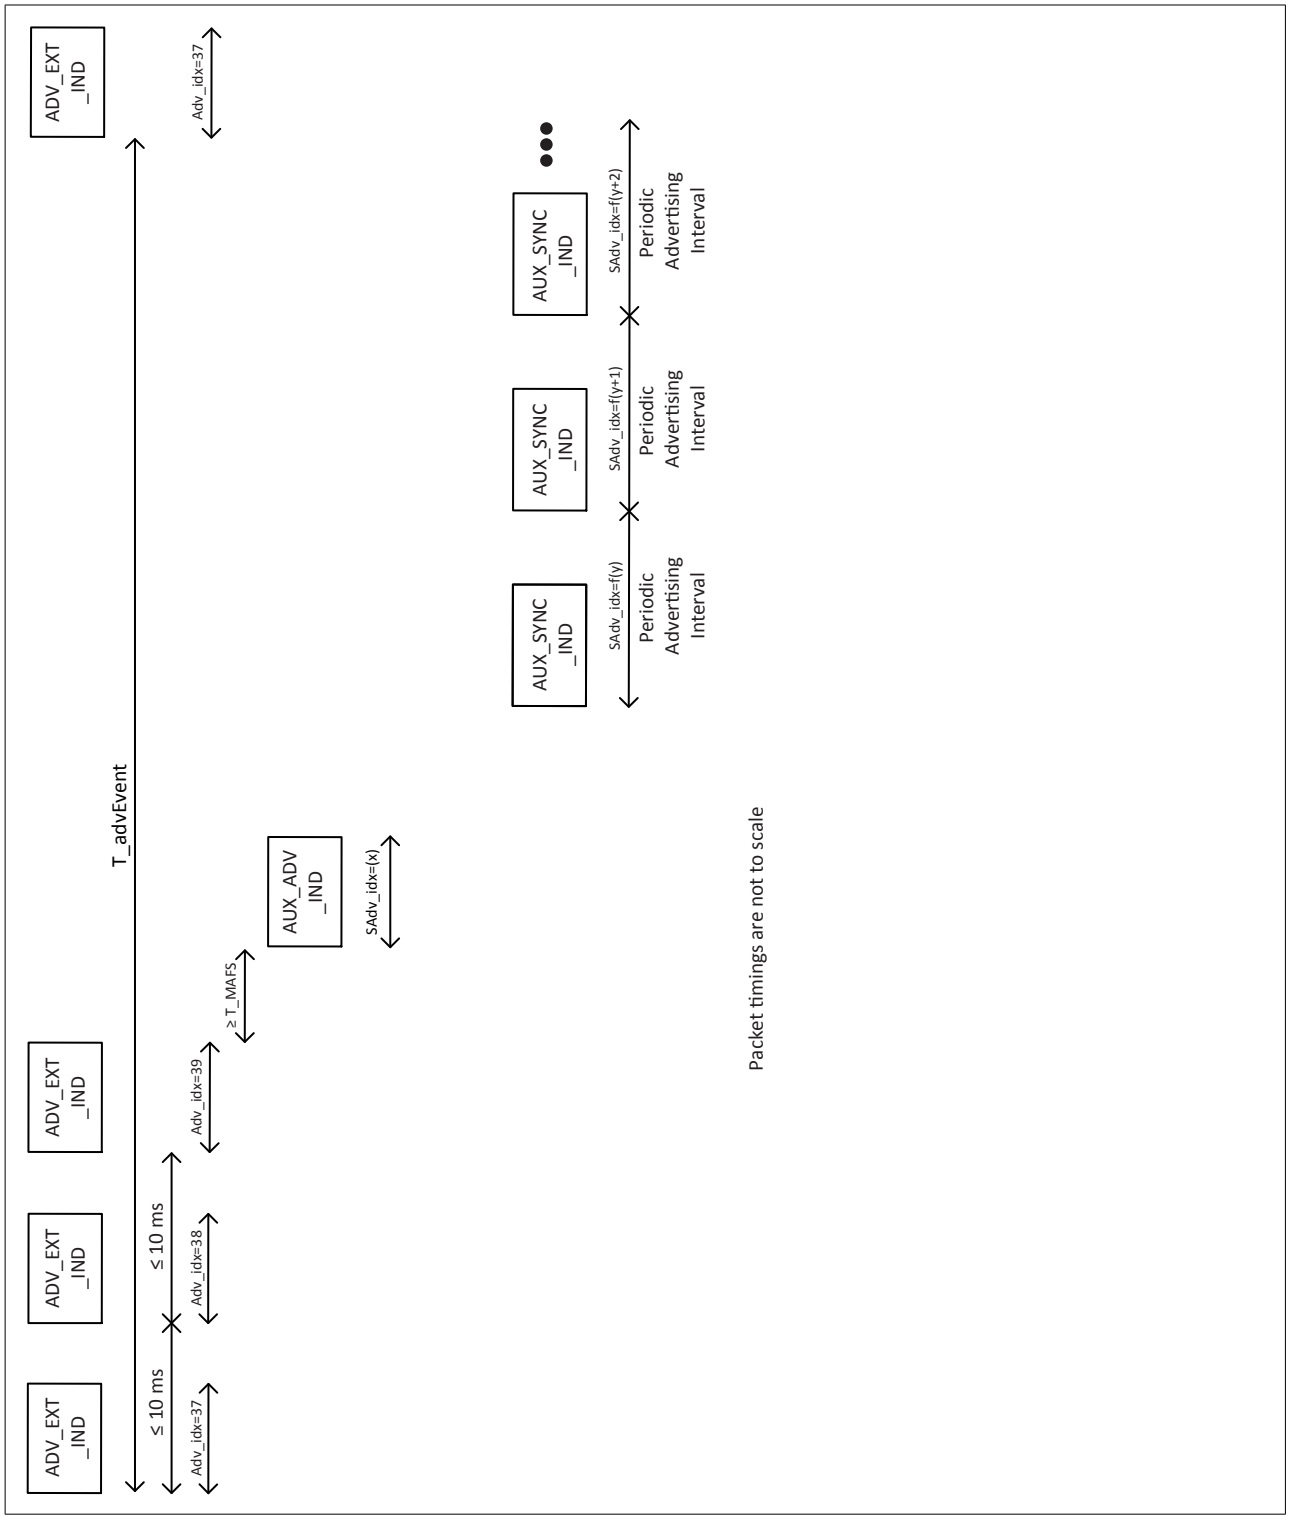

Figure 4.32: Example of periodic advertising without responses

4.4.2.12.2 Trains with responses

When PAwR takes place, the advertiser shall send AUX_SYNC_SUBEVENT_IND PDUs at regular intervals defined by the periodic advertising interval and the periodic advertising subevent interval (see Section 4.4.2.2.4). The PHY used and the CRCInit value of the AUX_SYNC_SUBEVENT_IND and AUX_SYNC_SUBEVENT_RSP PDUs for a periodic advertising train shall not change while that train is enabled. The Access Address value of the AUX_SYNC_SUBEVENT_IND shall not change while that train is enabled. The Access Address value of the AUX_SYNC_SUBEVENT_RSP shall be set by each synchronized device to the RspAA.

The Host may send periodic advertising data to the Link Layer. This advertising data is placed by the Link Layer in the periodic AUX_SYNC_SUBEVENT_IND PDUs. The Link Layer shall send the advertising data sent by the Host once and then immediately discard the advertising data. The AUX_SYNC_SUBEVENT_IND PDUs should be continuously sent out until the Host directs the Link Layer to terminate the periodic advertising train. If the Host has not provided any data to the Link Layer, then an AUX_SYNC_SUBEVENT_IND_PDU should still be sent with an empty Payload field.

When instructed by the Host, the Link Layer shall transmit an AUX_CONNECT_REQ PDU instead of an AUX_SYNC_SUBEVENT_IND PDU, with the InitA field set to the address of the advertiser and the AdvA field set to the address of the synchronized device. The Link Layer shall transmit the AUX_CONNECT_REQ PDU even if the Host also instructed it to transmit data on the same subevent. After sending the AUX_CONNECT_REQ PDU, the periodic advertiser shall wait for the synchronized device to send an AUX_CONNECT_RSP PDU T_IFS_150 from the end of the AUX_CONNECT_REQ PDU on the same secondary advertising channel index. If an AUX_CONNECT_RSP PDU is received from the synchronized device and the periodic advertiser is not already connected to the synchronized device's device address, then the Link Layer of the periodic advertiser shall start a new state machine that immediately transitions to the Connection state in the Central role as defined in Section 4.5.4; the existing state machine shall remain in the Advertising state. If an AUX_CONNECT_RSP PDU is not received from the synchronized device, then the request to connect to the synchronized device is discarded.

If the synchronized device receives an AUX_CONNECT_REQ PDU from the periodic advertiser that contains its device address and is not already connected to the same device address, then the synchronized device shall reply with an AUX_CONNECT_RSP PDU on the same secondary advertising channel index with the AdvA field set to the address of the synchronized device and the TargetA field set to the address of the advertiser. After the AUX_CONNECT_RSP PDU is sent, the Link Layer shall start a new state machine that immediately transitions to the Connection state in the Peripheral role as defined in Section 4.5.5; the existing state machine shall remain in the Synchronization state.

4.4.2.13 Requirements

A device that supports Advertising State shall support transmitting advertising event types as specified in Table 4.3.

Advertising event type	Requirements
Non-connectable non-scannable undirected	May be supported; shall be supported if the device supports Periodic Advertising or does not support Connection State (Peripheral role).
Non-connectable non-scannable directed	Shall be supported if and only if the device supports both LE Extended Advertising and non-connectable non-scannable undirected type.
Scannable undirected	May be supported.
Scannable directed	Shall be supported if and only if the device supports both LE Extended Advertising and scannable undirected type.
Connectable directed Connectable and scannable undirected	Shall be supported if and only if the device supports Connection State (Peripheral role).
Connectable undirected	Shall be supported if and only if the device supports both LE Extended Advertising and connectable directed type.

Table 4.3: Requirements for supporting advertising event types

If a device supports the LE Extended Advertising feature, then for each advertising event type that it supports which can use either a legacy PDU or ADV_EXT_IND (i.e., non-connectable and non-scannable undirected, scannable undirected, and connectable directed), the device shall support transmitting that advertising event type using both PDU types.

4.4.3 Scanning state

The Link Layer shall enter the Scanning state when directed by the Host. When scanning, the Link Layer shall listen on the primary advertising physical channel for the types of PDU and on the PHYs that have been indicated by the Host. There are two types of scanning, determined by the Host: passive and active.

There are no strict timing or advertising channel index selection rules for scanning.

During scanning, the Link Layer should listen on a primary advertising channel index for the duration of the scan window, *scanWindow*. The scan interval, *scanInterval*, is defined as the interval between the start of two consecutive scan windows.

The Link Layer should listen for the complete *scanWindow* every *scanInterval* as directed by the Host unless there is a scheduling conflict. In each scan window, the Link Layer should scan on a different primary advertising channel index than the one

used in the previous scan window. The Link Layer shall use all the primary advertising channel indices.

The *scanWindow* and *scanInterval* parameters shall be less than 40.96 s. The *scanWindow* shall be less than or equal to the *scanInterval*. If the *scanWindow* and the *scanInterval* parameters are set to the same value by the Host, the Link Layer should scan continuously.

The scanning filter policy shall apply when receiving an advertising PDU or scan response PDU when scanning.

On receiving a PDU with the AuxPtr field present, the scanner should also listen for the auxiliary PDU it points to (provided that it supports the PHY specified in the AuxPtr field) and should then attempt to receive the entire subordinate set of the PDU. While doing so, it shall perform the window widening specified in Section 4.2.4. If it does not support the specified PHY or the value is reserved for future use, it shall not listen for the auxiliary PDU and shall behave as if it listened for it but failed to receive it.

When a scanner receives ADV_EXT_IND PDUs that contain an AuxPtr field, it may either always listen for the auxiliary packet or may sometimes skip listening. In the latter case, the following requirements shall apply.

For each Advertising SID value received:

- The Controller shall keep a cache of one or more recent Advertising DID values used by each advertising device (for this purpose, all anonymous advertising is treated as being from a single device different to all real devices) and shall update them whenever a PDU containing an ADI field is received. The Controller may delete any cache entry at any time. The Controller should delete the cache entry relating to an ADV_EXT_IND PDU if it fails to receive that PDU's entire subordinate set.
- The Controller may only skip listening for the auxiliary packet if the cache has an entry specifying the Advertising DID value in the ADI field being used by a device; if the ADV_EXT_IND PDU contains an AdvA field, the entry shall be for that device. Otherwise, the Controller shall not skip listening for the auxiliary packet.
- Irrespective of the cache contents, the Controller should sometimes listen for the AUX_ADV_IND PDU in case another advertiser has started using the same Advertising DID value or the existing advertiser has made a significant change to the Extended Header field (e.g., included the SyncInfo field).

If the Controller supports LL Privacy, then the requirements in Section 6.3 shall also be followed.

4.4.3.1 Passive scanning

When in passive scanning, the Link Layer will only receive packets; it shall not send any packets.

4.4.3.2 Active scanning

In active scanning, the Link Layer shall listen for advertising PDUs and, depending on the advertising PDU type, it may request an advertiser to send additional information.

After entering the Scanning State, if the Link Layer receives a scannable PDU (i.e. an ADV_IND, ADV_SCAN_IND, or scannable AUX_ADV_IND PDU) from an advertiser allowed by the scanning filter policy, it shall respond with a scan request PDU and then listen for the scan response PDU. It shall continue to respond to the same advertiser until it has successfully received the scan response PDU. It may then either respond to or ignore subsequent scannable PDUs from the same advertiser. It should ignore them if either they are legacy PDUs or if the Advertising DID field has not changed since the last advertisement from the same advertiser with the same Advertising SID field; it should not ignore them otherwise.

The Link Layer shall only send a SCAN_REQ PDU to an advertiser from which an ADV_IND PDU or ADV_SCAN_IND PDU is received. The Link Layer shall only send an AUX_SCAN_REQ PDU to an advertiser from which a scannable AUX_ADV_IND is received. The Link Layer shall ignore a scannable AUX_ADV_IND PDU if the TargetA field is present and it does not match the Link Layer's device address.

The scanner shall run a backoff procedure to minimize collisions of scan request PDUs from multiple scanners. An example of such a procedure is given in the following paragraphs.

The backoff procedure uses two parameters, *backoffCount* and *upperLimit,* to restrict the number of scan request PDUs sent when collisions occur on scan response PDUs. Upon entering the Scanning State, the *upperLimit* and *backoffCount* are set to one.

On every received ADV_IND, ADV_SCAN_IND, or scannable AUX_ADV_IND PDU that is allowed by the scanning filter policy and for which a scan request PDU is to be sent, the *backoffCount* is decremented by one until it reaches the value of zero. The scan request PDU is only sent when *backoffCount* becomes zero.

After sending a scan request PDU the Link Layer listens for a scan response PDU from that advertiser. If the scan response PDU was not received from that advertiser, it is considered a failure; otherwise it is considered a success. On every two consecutive failures, the *upperLimit* is doubled until it reaches the value of 256. On every two consecutive successes, the *upperLimit* is halved until it reaches the value of one. After success or failure of receiving the scan response PDU, the Link Layer sets *backoffCount* to a new (pseudo-)random integer between one and *upperLimit*.

If a device uses a different backoff algorithm it shall share the medium responsibly.

Two illustrations of advertising events using all the advertising channel indices during which a SCAN_REQ PDU is received and a SCAN_RSP PDU is sent are shown in Figure 4.13 and in Figure 4.14.

4.4.3.3 Advertising sets

The ADV_EXT_IND PDU may contain an ADI field. When the ADI field is present, it can be used to identify advertisement data that belong to the same set or group of sets. This is specified in the Advertising SID subfield in the ADI. The Advertising SID is set by the Host of the advertiser.

4.4.3.4 Scanning for periodic advertisements

When instructed by the Host, the scanner shall look for periodic advertising synchronization information located in the SyncInfo field and, for PAwR, the ACAD field of AUX_ADV_IND PDUs. If the syncPacketWindowOffset value of the SyncInfo is zero, the periodic advertising synchronization information is incomplete and the scanner should listen for a subsequent advertisement to be able to obtain the complete information. When it has received the complete information it shall start a new state machine that immediately transitions to the Synchronization State; the existing state machine shall remain in the Scanning State.

The Host may instruct the Controller not to synchronize to periodic advertising trains with certain types of Constant Tone Extensions or without a Constant Tone Extension. If the Controller receives an AUX_SYNC_IND or AUX_SYNC_SUBEVENT_IND with such a Constant Tone Extension while synchronizing, the synchronization attempt has failed and shall cease. Once synchronized, the presence or type of Constant Tone Extension shall not affect synchronization.

4.4.3.5 Advertising reports

The Link Layer shall send an advertising report to the Host for each advertising PDU on the primary advertising physical channel that is accepted by the scanning filter policy (see Section 4.3.3) and for each scan response PDU from an advertiser that is accepted by the scanning filter policy, except where stated otherwise in this section. The Controller shall send the report even if it does not respond to the advertiser.

If the Controller receives an ADV_EXT_IND PDU with an AuxPtr field, it shall delay the report until after the corresponding AUX_ADV_IND PDU has been received and the report shall combine the information in the PDUs; if the Controller does not listen for or does not receive the AUX_ADV_IND PDU, no report shall be generated. The advertising report shall contain at least the advertiser's device address and all of the advertising data or scan response data (including any data in any subordinate AUX_CHAIN_IND PDUs that were received) if present.

Note: The Controller may use more than one HCI event to send the report, for example, if the total data does not fit within a single event.

Note: The requirements above and those in Section 4.6.12 mean that the Controller must be able to store and report to the Host at least 251 octets of data from a single advertisement or scan response (irrespective of the number of PDUs used to transmit the data) if the Controller supports LE extended advertising and 31 octets otherwise.

The Host may request that duplicate advertising reports are filtered and so not sent. The Controller may nevertheless send a duplicate of any report.

Where a received ADV_EXT_IND PDU contains an ADI field, a duplicate advertising report is an advertising report for the same device address where the previous report that contained an ADI value with the same Advertising SID also had the same Advertising DID. For this purpose, all anonymous advertising is treated as being from a single device different to all non-anonymous devices.

Where the ADV_EXT_IND PDU does not contain an ADI field or a legacy PDU was received, a duplicate advertising report is an advertising report for the same device address while the Link Layer stays in the Scanning state.

Advertising data reports and scan data reports shall be processed separately when determining duplicate advertising reports; i.e., an advertising data report shall not be treated as a duplicate of a scan response report or vice versa.

In either case the actual data may change; advertising data or scan response data is not considered significant when determining duplicate advertising reports. However, if not all the subordinate set of an advertisement or scan response was received (i.e., an incomplete report), a subsequent report that contains more of the data should not be treated as a duplicate of the incomplete report.

4.4.3.6 Decision PDU scanning

The scanning or initiating filter policy may direct the Link Layer to listen for decision PDUs and, if so, may direct it to ignore other types of PDU on the primary advertising physical channel.

If a device has more than one active state machine, the following requirements apply to each state machine independently; for example, the same PDU can be ignored by one state machine but processed by another.

When the Link Layer receives a decision PDU when scanning or initiating and is not ignoring all decision PDUs for that purpose, it shall use decision instructions provided by the Host to determine whether to accept or reject the PDU. If the Controller does not support HCI then the decision instructions are specified in a vendor-specific way. If

the Host has not provided any decision instructions, then the Link Layer shall ignore all decision PDUs.

If the decision instructions indicate that the Link Layer shall accept a particular decision PDU, the Link Layer shall then behave in the same way as if it had received an ADV_EXT_IND PDU with the same Extended Header and AdvMode fields, except that the filter policy for decision PDUs continues to apply. If the decision instructions indicate that the Link Layer shall reject a particular decision PDU, or the filter policy means the Link Layer is ignoring the decision PDU, the Link Layer shall then behave as if it had not received that PDU: if scanning, it shall not report the advertisement to the Host, if active scanning, it shall not send a scan request PDU to the advertiser, and if initiating, it shall not connect to the advertiser.

4.4.3.7 Requirements

A device that supports Scanning State shall support receiving advertising event types as specified in Table 4.4.

Advertising event type	Requirements
Non-connectable non-scannable undirected	May be supported; shall be supported if the device supports Periodic Advertising or does not support either Connection State (Central role) or Active Scanning.
Non-connectable non-scannable directed	Shall be supported if and only if the device supports both LE Extended Advertising and non-connectable non-scannable undirected type.
Scannable undirected	May be supported; shall be supported if the device supports Active Scanning.
Scannable directed	Shall be supported if and only if the device supports both LE Extended Advertising and scannable undirected type.
Connectable directed	May be supported; shall be supported if the device supports Connection State (Central role).
Connectable undirected	Shall be supported if and only if the device supports both LE Extended Advertising and connectable directed type.
Connectable and scannable undirected	May be supported; shall be supported if the device supports Connection State (Central role) or Active Scanning.

Table 4.4: Requirements for supporting advertising event types

If a device supports the LE Extended Advertising feature, then for each advertising event type that it supports which can use either a legacy PDU or ADV_EXT_IND (i.e., non-connectable and non-scannable undirected, scannable undirected, and connectable directed), the device shall support receiving that advertising event type using both PDU types.

4.4.3.8 Monitoring Advertisers

When instructed by the Host, the Link Layer shall keep track of devices in the Monitored Advertisers List. When a device is entered in the Monitored Advertisers List and monitoring advertisers is enabled, a timer for that device is started. For each device in the Monitored Advertisers List, the Controller shall generate an event if, during the timeout period set by the Host, an advertisement has not been received from that device with an RSSI value above the RSSI low threshold set by the Host. These conditions are referred to as the loss-of-signal criteria, after which the entry shall be marked as awaiting an RSSI value above the RSSI high threshold and the timer shall be reset but not run. The timeout period is a value set in units of seconds by the Host.

If a device in the Monitored Advertisers List is awaiting an RSSI high threshold and an advertising packet is received with an RSSI value greater than or equal to the RSSI high threshold value, then the Controller shall generate an event, the entry is marked as not awaiting an RSSI high threshold, and the timer for this entry in the list is reset and runs.

Figure 4.33 shows the operation of monitoring advertisers as a state machine.

The Monitoring Advertisers feature operates independently from the Filter Accept List. For example, it is possible to use the Monitoring Advertisers feature on devices that are not in the Filter Accept List even if the Filter Accept List is enabled.

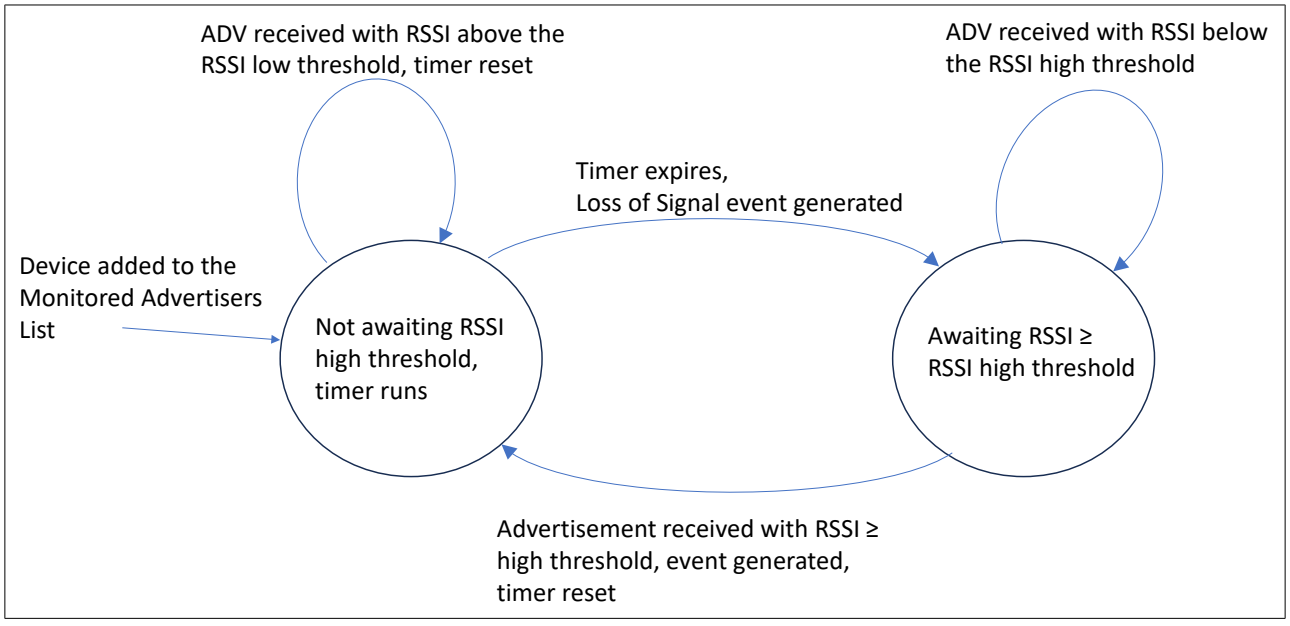

Figure 4.33: State machine

4.4.4 Initiating state

The Link Layer shall enter the Initiating state when directed by the Host. When initiating, the Link Layer shall listen on the primary advertising physical channel.

There are no strict timing or advertising channel index selection rules for initiators.

During initiating, the Link Layer listens on a primary advertising channel index for the duration of the scan window, *scanWindow*. The scan interval, *scanInterval*, is defined as the interval between the start of two consecutive scan windows.

The Link Layer should listen for the complete *scanWindow* every *scanInterval* as directed by the Host unless there is a scheduling conflict. In each scan window, the Link Layer should listen on a different primary advertising channel index. The Link Layer shall use all the primary advertising channel indices.

The *scanWindow* and *scanInterval* parameters shall be less than or equal to 40.96 s. The *scanWindow* shall be less than or equal to the *scanInterval*. If the *scanWindow* and the *scanInterval* parameters are set to the same value by the Host, the Link Layer should listen continuously.

Connection indications or requests in response to a connectable advertisement shall be sent on either the primary or secondary advertising physical channel depending on which advertising PDU contains an AdvA field. The following subsections describe the two procedures.

The initiator filter policy shall apply when receiving an advertising PDU while initiating a connection. If the Controller supports LL Privacy, then the requirements in Section 6.4 shall also be followed.

Note: If the Link Layer supports the Decision-Based Advertising Filtering feature, Section 4.4.3.6 also applies to initiating.

4.4.4.1 Connect requests on the primary advertising physical channel

If an ADV_IND PDU is received that is allowed by the initiator filter policy, the initiator shall send a CONNECT_IND PDU to the advertiser. If an ADV_DIRECT_IND PDU containing the initiator's Link Layer device address and allowed by the initiator filter policy is received, the initiator shall send a CONNECT_IND PDU to the advertiser; otherwise it shall be ignored. However, in both cases, the initiator shall not send a CONNECT_IND PDU to a device address that it is already connected to.

After sending the CONNECT_IND PDU, the Link Layer shall exit the Initiating State, and shall transition to the Connection State in the Central Role as defined in Section 4.5.4.

4.4.4.2 Connect requests on the secondary advertising physical channel

If a connectable ADV_EXT_IND PDU is received, the initiator shall listen for the connectable AUX_ADV_IND on the secondary advertising physical channel; while doing so, it shall perform the window widening specified in Section 4.2.4. If a connectable undirected AUX_ADV_IND PDU, or a connectable directed AUX_ADV_IND PDU

containing the initiator's Link Layer device address, is received and is allowed by the initiator filter policy, and if the initiator is not already connected to the advertiser's device address, then the initiator shall send an AUX_CONNECT_REQ PDU to the advertiser; otherwise, it shall be ignored.

After sending the AUX_CONNECT_REQ PDU, the initiator shall wait for the advertiser to send an AUX_CONNECT_RSP PDU. Once an AUX_CONNECT_RSP PDU is received, the Link Layer shall exit the Initiating State and shall transition to the Connection State in the Central Role as defined in Section 4.5.4. If the initiator does not receive an AUX_CONNECT_RSP PDU from the advertiser, it shall use the back-off algorithm described for SCAN_REQ in Section 4.4.3.2 before responding to the next connectable AUX_ADV_IND PDU.

4.4.4.3 Requirements

A device that supports Initiating State shall support receiving the connectable directed advertising event type using ADV_DIRECT_IND PDUs and the connectable and scannable undirected event type using ADV_IND PDUs. If the device supports the LE Extended Advertising feature, then it shall also support receiving the connectable directed and connectable undirected advertising event types using ADV_EXT_IND PDUs.

4.4.5 Synchronization state

In the Synchronization state, the Link Layer listens to regular broadcasts from another device. There are two types of such broadcasts: periodic advertising trains and broadcast isochronous streams.

Synchronization state has two sub-states: synchronizing and synchronized. The Link Layer shall enter the Synchronization state in the synchronizing sub-state when directed by the Host, provided that it is in possession of the necessary information to locate the regular broadcasts. Once it has successfully received a PDU from the broadcast, it transitions to the synchronized sub-state and is then said to be synchronized to the broadcast; until then, it is said to be synchronizing.

Once synchronized, if it fails to receive any PDUs forming the broadcast for a period specified by the Host, it shall transition to the Standby state and notify the Host.

4.4.5.1 Periodic advertising trains

To receive periodic advertising trains the Link Layer must obtain periodic advertising synchronization information. This information may be obtained from the SyncInfo field of an AUX_ADV_IND PDU (see Section 4.4.3.4) or from an LL_PERIODIC_SYNC_IND or an LL_PERIODIC_SYNC_WR_IND PDU sent by a connected device.

While in this state, the Link Layer shall listen on the secondary advertising channel indices specified in Section 4.4.2.1 for the AUX_SYNC_IND or AUX_SYNC_SUBEVENT_IND PDUs forming the periodic advertising train specified in the synchronization information. In the synchronizing sub-state, if the Controller does not receive any of these AUX_SYNC_IND or AUX_SYNC_SUBEVENT_IND PDUs within 6 periodic advertising events, starting with the first periodic advertising event it listened for, it shall notify the Host and transition to the Standby State.

A device shall not attempt to synchronize to a periodic advertising train with the same address, address type, and Advertising SID as one that it is already synchronized to. A device should not attempt to synchronize to a periodic advertising train with the same Access Address as one that it is already synchronized to.

The Link Layer shall perform the window widening specified in Section 4.2.4 while listening. If the *windowWidening* reaches ((*periodicInterval*÷2) − T_IFS_150 µs) in magnitude, the Controller should notify the Host and transition to the Standby State.

4.4.5.1.1 Trains without responses

If requested by the Host, the Link Layer shall report the advertising data received in the periodic advertisements to the Host. The Host may specify that not all such data is reported or that duplicate periodic advertising reports are filtered and so not sent to the Host. A duplicate periodic advertising report is a report for the same periodic advertising train where the previous report for that train that contained an ADI field had the same Advertising SID and DID. The Link Layer need not listen to AUX_SYNC_IND or AUX_CHAIN_IND PDUs where it will not be reporting the data or samples from Constant Tone Extensions to the Host, other than as necessary to maintain synchronization with the advertiser's clock or to receive any channel map updates.

4.4.5.1.2 Trains with responses

If requested by the Host, the Link Layer shall report the advertising data received in the periodic advertisements to the Host. The Host may specify that not all such data is reported. The Link Layer need not listen to an AUX_SYNC_SUBEVENT_IND PDU where it would not be reporting the data to the Host, other than as necessary to maintain synchronization with the advertiser's clock or to receive any channel map updates.

A synchronized device may transmit an AUX_SYNC_SUBEVENT_RSP PDU when instructed to by its Host. The response slot to use is determined by the Host.

4.4.5.2 Broadcast Isochronous Streams

To receive broadcast isochronous streams, the Link Layer must obtain the BIGInfo describing the streams (see Section 4.4.6.11). This information may be obtained from

the ACAD of periodic advertising. If the PHY field of the BIGInfo specifies a PHY that the Link Layer does not support or is reserved for future use, the Link Layer shall ignore the BIGInfo, shall not report the BIGInfo to the Host, and shall not enter the Synchronization state for the BIG specified in the BIGinfo.

Note: The Link Layer can still synchronize to a BIS even if it does not support the exact combination of BN, IRC, NSE, and PTO specified in the BIGInfo, provided that it can still receive every payload at least once. For example, if the BIGInfo has BN=2, IRC=2, NSE=8, and PTO=5, a Link Layer that synchronizes using any of the following combinations will receive fewer transmissions of each payload but will still be capable of receiving every payload:

- BN=2, IRC=2, NSE=6, PTO=5
- BN=2, IRC=2, NSE=4
- BN=2, IRC=1, NSE=2

While in this state, the Link Layer shall listen on the isochronous channel indices specified in Section 4.4.6.8 for BIS Data PDUs forming the BIG specified in the BIGInfo. In the synchronizing sub-state, if the Link Layer does not receive a BIS Data PDU within 6 BIG events, starting with the first BIG event it listened for, it shall notify the Host and transition to the Standby state.

Once in the synchronized sub-state, the Link Layer shall listen for the Isochronous Broadcaster at least once within any 6 consecutive BIS events.

A device shall not attempt to synchronize to a BIG with the same associated periodic advertising train as a BIG that it is already synchronized to.

A device that has synchronized to a BIG is called a Synchronized Receiver. A Synchronized Receiver may, but it is not required to, remain synchronized to the periodic advertising train.

If requested by the Host, the Link Layer shall report the isochronous data received in the BIS Data PDUs forming the BIG to the Host. The Host may specify that only the data from specific BISes within the BIG are reported. The Link Layer shall listen to and act on the contents of new BIG Control PDUs.

The Link Layer need not listen to Broadcast Isochronous PDUs that are retransmissions of PDUs already successfully received, or to BIS Data PDUs where it will not be reporting the data to the Host, other than as necessary to maintain synchronization with the Isochronous Broadcaster’s clock.

The Link Layer shall perform the window widening specified in Section 4.2.4 while listening.

The Link Layer shall stop listening to the BIG no later than when the *bisPayloadCounter* equals $2^{39} – 1$.

4.4.6 Isochronous Broadcasting state

The Link Layer shall enter the Isochronous Broadcasting state when directed by the Host, provided that it is able to schedule the BIG the Host is requesting to be transmitted. While in this state the Link Layer shall transmit BIS PDUs as described in the following subsections.

When the Link Layer enters the Isochronous Broadcasting state, it shall notify the Host.

In this state, the Host may disable and subsequently re-enable the periodic advertising train associated with the BIG.

Each instance of the Link Layer state machine in the Isochronous Broadcasting state shall transmit a BIG made up of one or more BISes. Each BIS carries a separate isochronous data flow. There shall be at most 31 BISes in a BIG.

Note: The Isochronous Broadcasting state is per BIG (i.e. every new BIG instantiates a new Link Layer state machine).

4.4.6.1 Broadcast Isochronous Stream (BIS)

A BIS is a logical transport that enables a device to transfer isochronous data. The isochronous data can be either framed or unframed.

A BIS supports variable size packets and the transmission of one or more packets in each BIS event, allowing a range of data rates to be supported. The data traffic is unidirectional from the broadcasting device; hence there is no acknowledgment protocol and broadcast isochronous traffic is inherently unreliable. To improve the reliability of packet delivery, the BIS supports multiple retransmissions.

4.4.6.2 Broadcast Isochronous Group (BIG)

A BIG consists of either two or more BISes that have the same ISO_Interval and are expected to have a time relationship at the application layer, or of a single BIS. The maximum number of BISes in a BIG shall be 31. A BIG also contains control subevents (see Section 4.4.6.7).

The packets forming the BIG should be transmitted at the same power level as those forming the associated periodic advertising train (see Section 4.4.6.9).

4.4.6.3 BIG parameters

Each BIG is defined by the following parameters:

- Num_BIS is the number of BISes in the BIG. The BISes in a BIG are each assigned a different BIS_Number from 1 to Num_BIS.
- ISO_Interval is the time between two adjacent BIG anchor points, in units of 1.25 ms. The value shall be between 4 and 3200 (i.e. 5 ms to 4 s).
- BIS_Spacing is the time between the start of corresponding subevents in adjacent BISes in the BIG.
- Sub_Interval is the time between the start of two consecutive subevents of each BIS.
- Max_PDU is the maximum number of data octets (excluding the MIC, if any) that can be carried in each BIS Data PDU in the BIG. The value shall be between 1 and 251 octets.
- Max_SDU is the maximum size of an SDU on this BIG (see [Vol 6] Part G, Section 1). The value shall be between 1 and 4095 octets.
- MPT shall equal the time taken to transmit a packet containing a BIS Data PDU with a Payload field of Max_PDU octets on the PHY being used for the BIS; on the LE Coded PHY, the S=8 coding shall be assumed.
- BN, PTO, and IRC control which data is transmitted in each BIG event. The value of BN shall be between 1 and 7. The value of PTO shall be between 0 and 15. The value of IRC shall be between 1 and 15.
- NSE is the number of subevents per BIS in each BIG event. The value shall be between 1 and 31 and shall be an integer multiple of BN.
- Framed indicates whether the BIG carries framed or unframed data.
- Framing_Mode only applies when framed data is being carried and indicates whether Segmentable or Unsegmented mode is being used.
- Encrypted indicates whether the BIG is encrypted or not.

These parameters shall not change during the lifetime of the BIG. They are discussed further in subsections 4.4.6.4 to 4.4.6.11. The mandatory range for each parameter is the entire range of valid values except for the following parameters, where only the listed values are mandatory:

- Num_BIS: 1
- BN: 1
- NSE: all supported values of BN
- PTO: 0

- IRC: all supported values of GC (see Section 4.4.6.6)

Each BIG shall have a 39-bit counter *bigEventCounter* associated with it. This shall be set to 0 for the first BIG event of a BIG and be incremented by 1 for each BIG event, whether or not the Isochronous Broadcaster transmits any Broadcast Isochronous PDUs during the event.

Each BIS shall have a 39-bit counter *bisPayloadCounter* associated with it, described further in Section 4.4.6.5. The Link Layers of an Isochronous Broadcaster and a Synchronized Receiver shall terminate the BIG no later than when the *bisPayloadCounter* equals $2^{39} – 1$.

Note: At the start of any BIG event, all the BISes in a BIG will have the same value for *bisPayloadCounter* and, in addition, *bigEventCounter* × BN = *bisPayloadCounter*.

4.4.6.4 BIG event

A BIG event consists of one or more BIS PDUs. The Link Layer shall transmit BIS PDUs only in BIG events. The Link Layer shall transmit only BIS PDUs as part of a BIG event.

Each BIG event is divided into Num_BIS separate BIS events and a control subevent if present. Each BIS event is divided into NSE subevents.

Each BIS event starts at a moment called the BIS anchor point and ends after its last subevent. Each BIG event starts at a moment called the BIG anchor point and ends after the control subevent, if there is one, and otherwise at the end of the last constituent BIS event. The BIG anchor points shall be spaced regularly, ISO_Interval apart. The BIS anchor points for BIS *n* of a BIG shall be (*n* − 1) × BIS_Spacing after the BIG anchor points and so are also spaced regularly, ISO_Interval apart. The subevents of each BIS shall be Sub_Interval apart. The Isochronous Broadcaster shall close each BIG event at least T_MSS_150 before the BIG anchor point of the next BIG event. Figure 4.34 shows a BIS event with subevents.

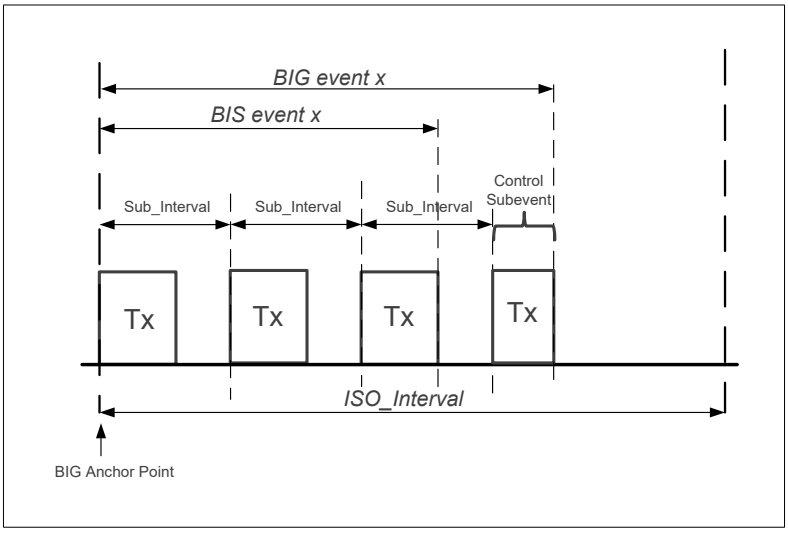

Figure 4.34: Example of BIG and BIS events

The BISes in a BIG shall be arranged either sequential or interleaved by setting the values of the Sub_Interval and BIS_Spacing parameters appropriately. If they are sequential, BIS_Spacing shall be greater than or equal to NSE × Sub_Interval and so all the subevents of a BIS event occur together. If they are interleaved, Sub_Interval shall be greater than or equal to Num_BIS × BIS_Spacing and so the first subevents of all BISes are adjacent, followed by the second subevents of all BISes, and so on. In each case, the minimum value for BIS_Spacing should be used. Figure 4.35 shows each arrangement for a BIG where Num_BIS = 2 and NSE = 2.

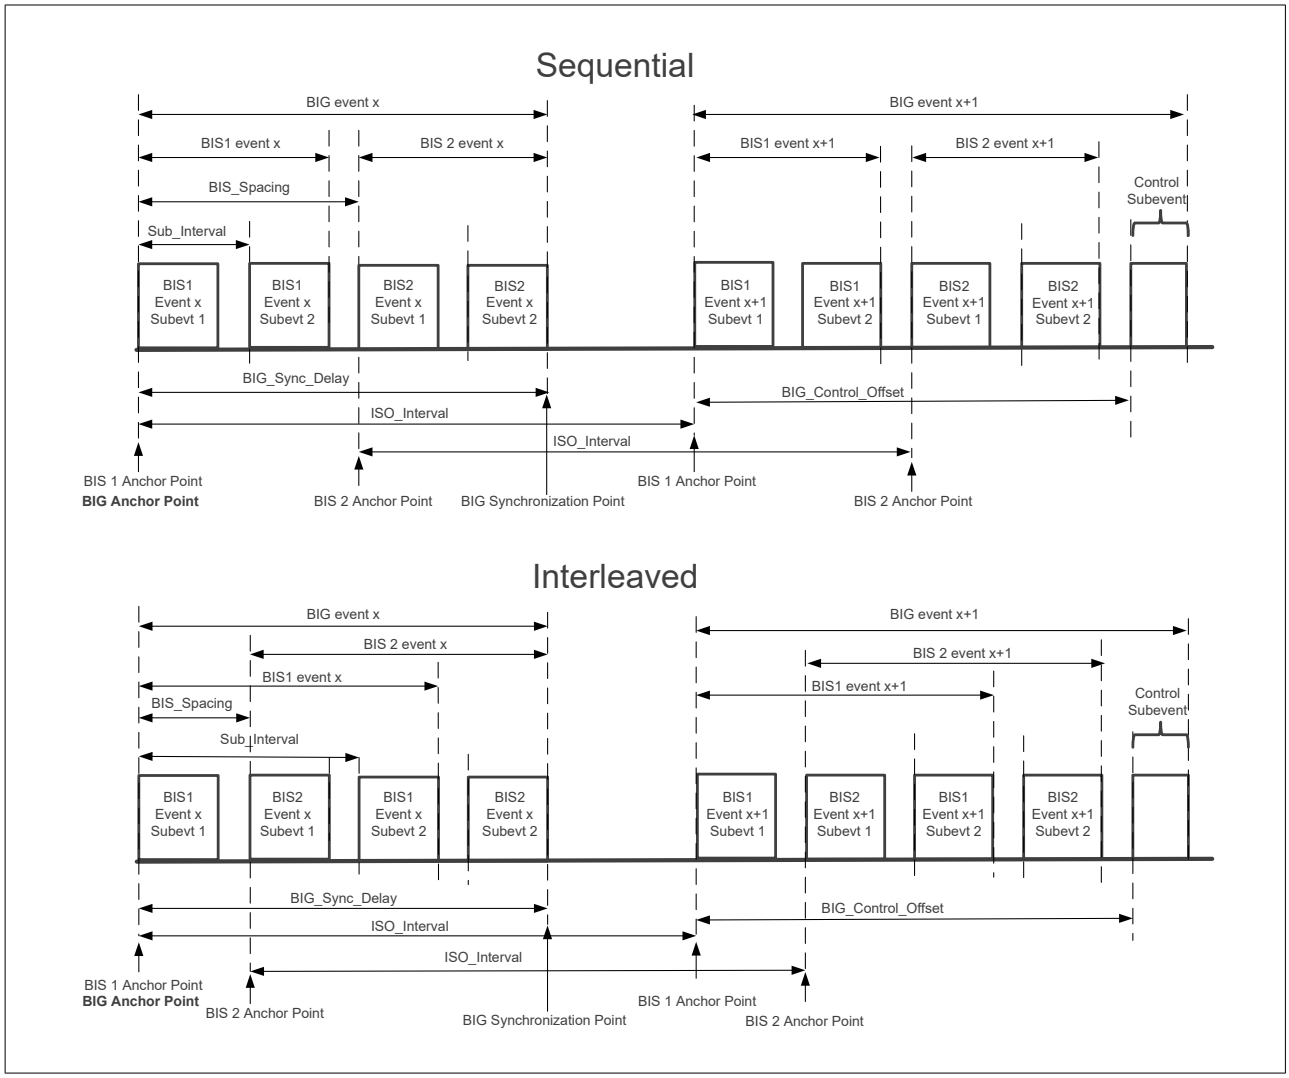

Figure 4.35: Two BISes in sequential and interleaved arrangement

The maximum possible length for the data portion of a BIG event (thus excluding any control subevent) is denoted as BIG_Sync_Delay. The value of BIG_Sync_Delay shall equal the time from the anchor point to the BIG Synchronization point, which is the instant at the end of a packet containing a Payload field of Max_PDU octets transmitted in the last subevent, as shown in Figure 4.35. Therefore, the BIG_Sync_Delay equals (Num_BIS – 1) × BIS_Spacing + (NSE – 1) × Sub_Interval + MPT.

4.4.6.5 Broadcast Isochronous Data

A BIS carries a single stream of isochronous data provided for broadcast. The data may be divided into payloads of at most Max_PDU octets, each of which is transmitted in a single BIS Data PDU; the payloads need not all be the same size and can be zero length. The BISes in a BIG carry separate but associated streams of data.

The Framed parameter of a BIG shall indicate whether all the constituent BISes are framed or unframed. Framed BIGs shall only use framed BIS Data PDUs to carry data; unframed BIGs shall only use unframed BIS Data PDUs to carry data.

Both BIS_Spacing and Sub_Interval shall be at least T_MSS_150 + MPT.

For each BIS, the payloads shall be numbered in the order provided, starting at zero. This number shall be used as the value of *bisPayloadCounter* for the PDU containing that payload. If the source of the data fails to provide BN payloads for a BIS event, *bisPayloadCounter* shall continue to increment as if it had provided the missing payloads and the Link Layer should transmit empty PDUs.

4.4.6.6 BIS subevents

A BIS subevent is an opportunity for an Isochronous Broadcaster to transmit a Broadcast Isochronous BIS PDU and a Synchronized Receiver to receive it. The Link Layer should transmit one BIS Data PDU at the start of each subevent of the isochronous broadcasting event unless, for example, it has scheduling conflicts, but shall transmit at least one BIS PDU within any 6 consecutive BIS events on a given BIS. Where it does not transmit a PDU, the Link Layer shall behave for all other purposes (e.g. the timing of packets and the choice of payload) as if it had done so.

Each BIS subevent ends at the end of the transmitted PDU or, if the Link Layer does not transmit a PDU, the subevent is MPT in duration.

For each BIS event the source of the data shall supply a burst of data consisting of BN (“Burst Number”) payloads, each of which in turn shall hold either a single fragment or one or more SDU segments. This burst is associated with the corresponding BIS event but may be transmitted in earlier events as well. Each PDU containing a given payload shall have the same LLID value but can have different CSSN and CSTF values (see Section 4.4.6.7).

Note: The burst associated with a BIS event consists of payloads with *bisPayloadCounter* between *bigEventCounter* × BN and (*bigEventCounter* + 1) × BN – 1.

The subevents of each BIS event are partitioned into groups of BN subevents each. Therefore, there are Group Count (GC) groups, where GC = NSE ÷ BN.

IRC ("Immediate Repetition Count") specifies the number of groups that carry the data associated with the current BIS event; the remaining groups carry data associated with the future BIS events specified by PTO ("Pre-Transmission Offset"). IRC shall be greater than zero and not greater than GC. If IRC = GC then PTO shall be ignored. Otherwise PTO shall be greater than zero.

The groups of subevents are numbered using g from 0 to GC – 1 in order.

- If g < IRC, then group g shall contain the data associated with the current BIS event.
- If g ≥ IRC, then group g shall contain the data associated with the future BIS event that is PTO × (g - IRC + 1) BIS events after the current BIS event.

The payloads in each burst shall always be transmitted in the same order.

Note: Setting GC to a value greater than 1 provides redundant transmissions to compensate for the lack of acknowledgments when broadcasting, while setting IRC to a value less than GC (called pre-transmission) provides a greater time diversity among the redundant copies of the data.

For example, Figure 4.36, Figure 4.37, and Figure 4.38 show the allocation of payloads to subevents for three different BISes.

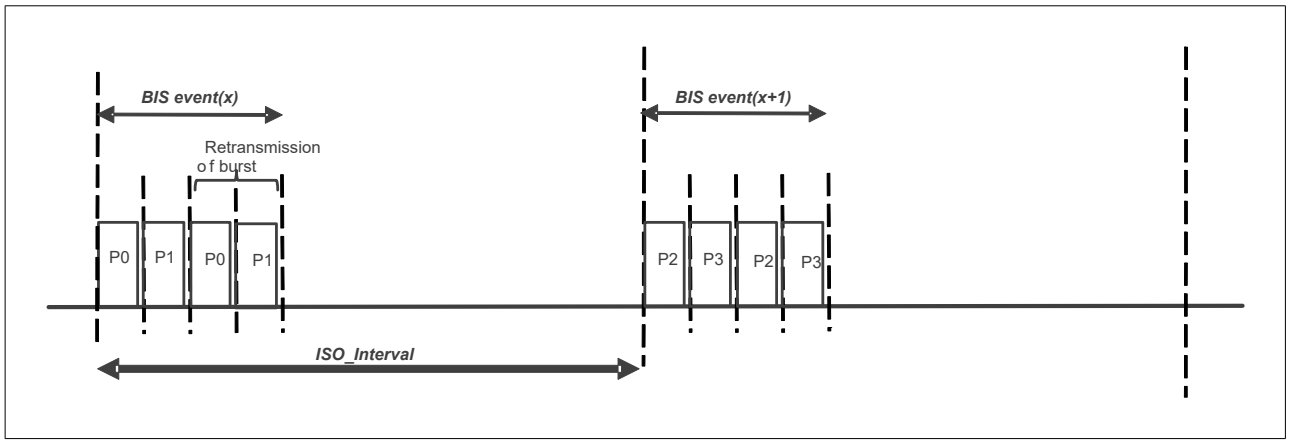

Figure 4.36: Allocations of payloads within a BIS with BN = 2, IRC = 2, PTO = 0, and NSE = 4

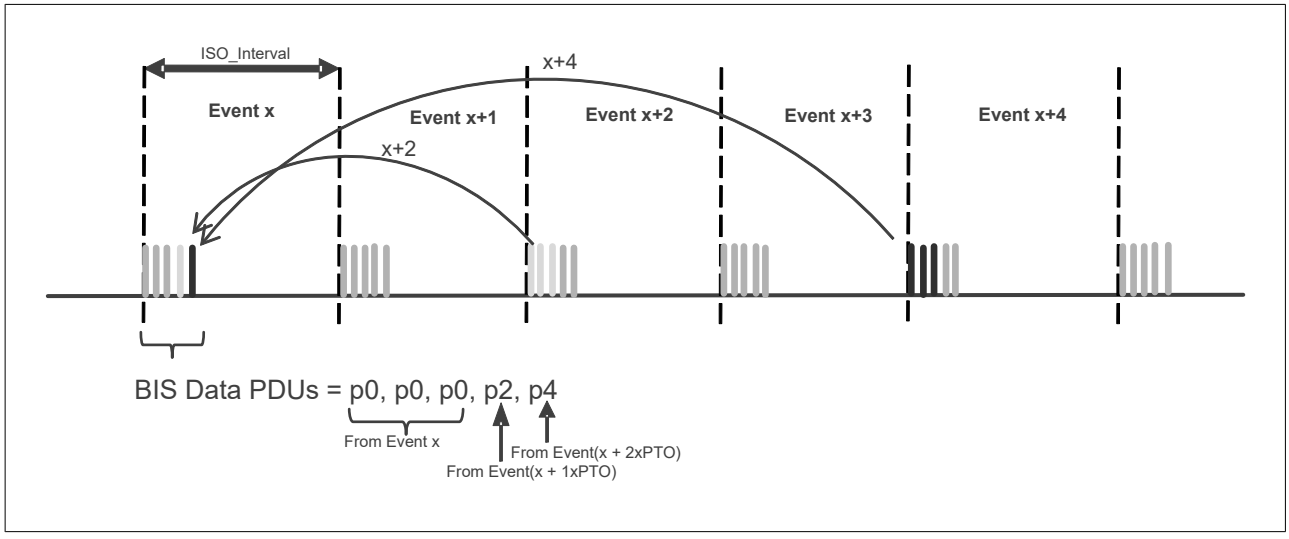

Figure 4.37: Allocations of payloads within a BIS with BN=1, IRC = 3, PTO = 2, and NSE = 5

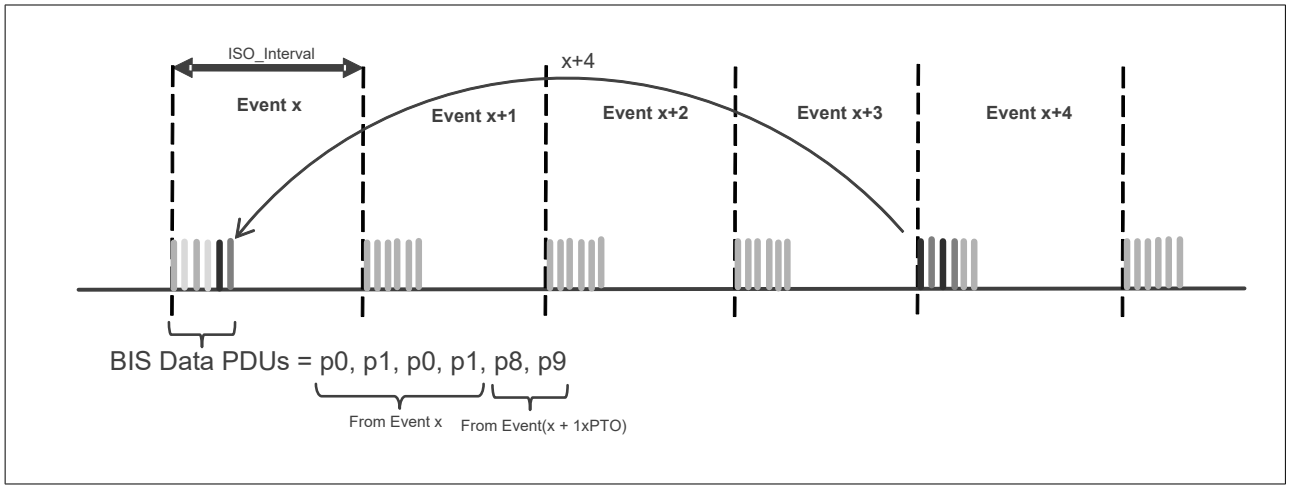

Figure 4.38: Allocations of payloads within a BIS with BN=2, IRC = 2, PTO = 4, and NSE = 6

4.4.6.7 Control subevents

Each BIG event may contain a control subevent. If so, the Link Layer shall transmit a single BIG Control PDU at the start of the control subevent to send control information about the BIG (see Section 5.6). The Link Layer shall not transmit a BIG Control PDU at any other time.

The time from the BIG anchor point to the start of the control subevent, designated BIG_Control_Offset, shall be:

BIG_Control_Offset = Num_BIS × BIS_Spacing for sequential arrangement
BIG_Control_Offset = NSE × Sub_Interval for interleaved arrangement

Note: See Section 4.4.6.4 for sequential and interleaved arrangements of the BISes in a BIG.

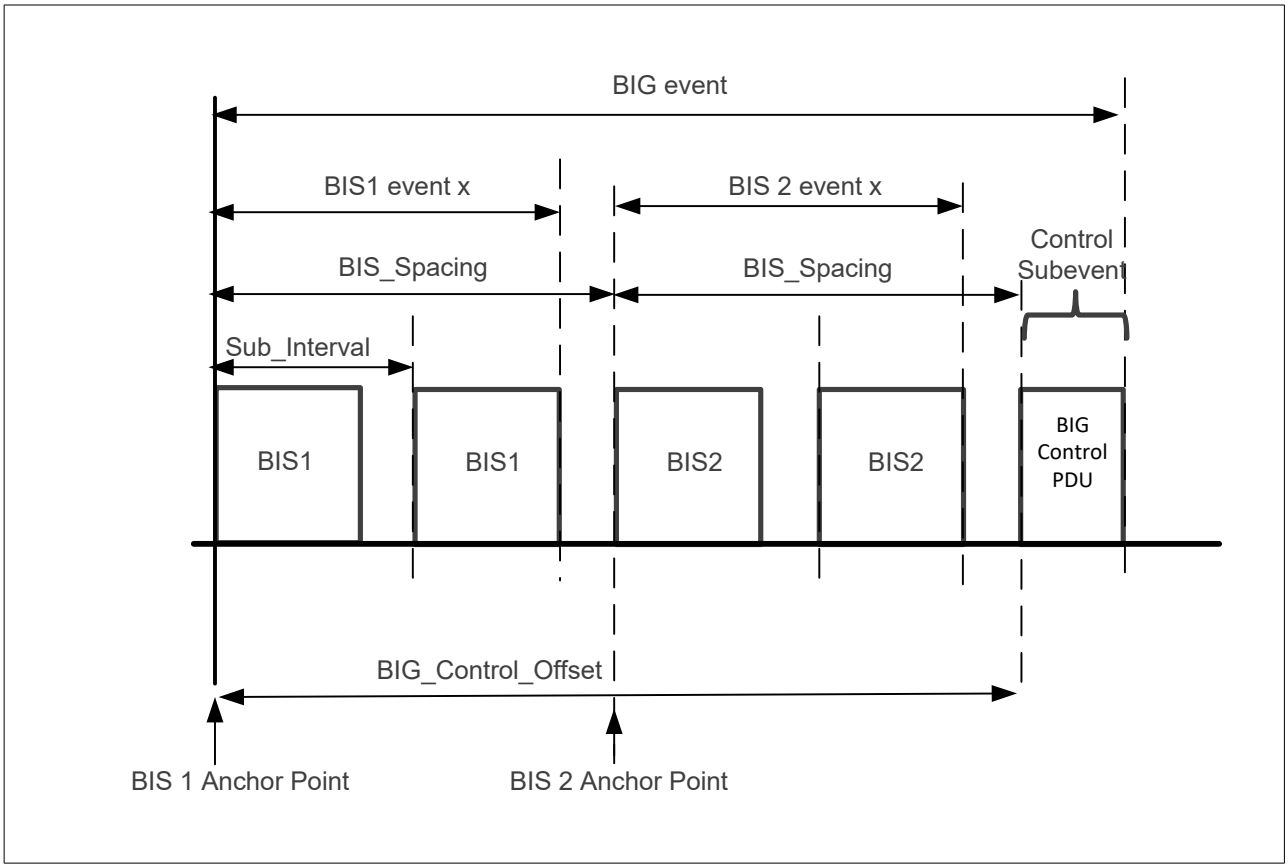

Figure 4.39: Example of a Control subevent in a BIG with 2 BISes in sequential arrangement

If the Link Layer schedules a BIG Control PDU to be transmitted in a BIG event, it shall set the CSTF bit to 1 in the Header field of every BIS Data PDU sent in that same BIG event; otherwise it shall set the bit to 0. It shall set the CSTF bit to 0 in the Header field of all BIG Control PDUs.

The value of the CSSN of every BIS PDU in a BIG event shall be the same. The Link Layer shall increment CSSN by 1 (with 7 wrapping to 0) at the start of a BIG event that contains the first transmission of a new BIG Control PDU and shall leave the CSSN unchanged otherwise (i.e. when a BIG Control PDU is being retransmitted or is not scheduled to be transmitted).

Note: A Synchronized Receiver may use the CSSN to determine that a BIG Control PDU is a retransmission of one that it has already received.

4.4.6.8 Channel indices

Each packet containing a BIS PDU shall be transmitted on the channel index specified by Channel Selection Algorithm #2 (see Section 4.5.8.3). The subevent number *se_n* shall be set to the values 1 to NSE, in order, for the subevents on a given BIS – the same values shall be used for all the BISes in a BIG.

The channel map used in the BIG shall be included in the BIGInfo. When the channel map changes, it shall be transmitted in the BIG Control logical link using the BIG Channel Map Update procedure (see Section 5.6.1).

4.4.6.9 Associated periodic advertising train

Every BIG shall have an associated periodic advertising train. A periodic advertising train shall not be associated with more than one BIG at the same time. The train and BIG may be enabled and disabled independently. The ACAD field of the AUX_SYNC_IND or AUX_SYNC_SUBEVENT_IND PDU in the periodic advertising train is used to carry the BIGInfo of a BIG. The BIGInfo shall not be transmitted when the BIG is disabled. Whenever the BIG and associated train are both active, the BIGInfo shall be transmitted in the periodic advertising train whenever the ACAD of the AUX_SYNC_IND or AUX_SYNC_SUBEVENT_IND PDU has sufficient space for carrying it.

It is vendor-specific whether the associated periodic advertising train may have responses.

The ACAD can be used for other information as well, such as a change in channel map. Even if it is not possible to fit both in the same PDU, the Link Layer will still need to schedule transmissions of each information so as to meet any relevant requirements.

The transmission of the AUX_SYNC_IND or AUX_SYNC_SUBEVENT_IND PDU of the associated periodic advertising train should not be scheduled within a BIG event.

4.4.6.10 Encryption

The Link Layer of an Isochronous Broadcaster or Synchronized Receiver shall support unencrypted BIGs.

A BIG may be encrypted, in which case all BIS PDUs (except those with an empty Payload field) of all BISes in that BIG shall be encrypted. The Link Layer shall determine if a BIG is encrypted by examining the length of the BIGInfo (see Section 4.4.6.11). The rest of this section only applies to encrypted BISes.

The following parameters shall be used in the process of encrypting or decrypting all Broadcast Isochronous PDUs in BIGs:

- Broadcast_Code – a 16-octet parameter provided by the Host.The Broadcast_Code applies to all the BISes in a single BIG and different BIGs broadcast by the same device may use different Broadcast_Codes.
- GIV – a 64-bit parameter generated by the Controller.
- GSKD – a 128-bit parameter generated by the Controller.

For each encrypted BIG, the Controller of an Isochronous Broadcaster shall generate a new GIV and GSKD using the requirements for random number generation as defined

in [Vol 3] Part H, Section 2 and shall transmit them in the BIGInfo. Each Broadcast Isochronous PDU in the encrypted BIG shall be encrypted using the CCM algorithm (see [Vol 6] Part E, Section 2).

4.4.6.11 BIGInfo

The length of the BIGInfo is 33 octets for an unencrypted BIG and 57 octets for an encrypted BIG. The format of the BIGInfo is shown in Figure 4.40.

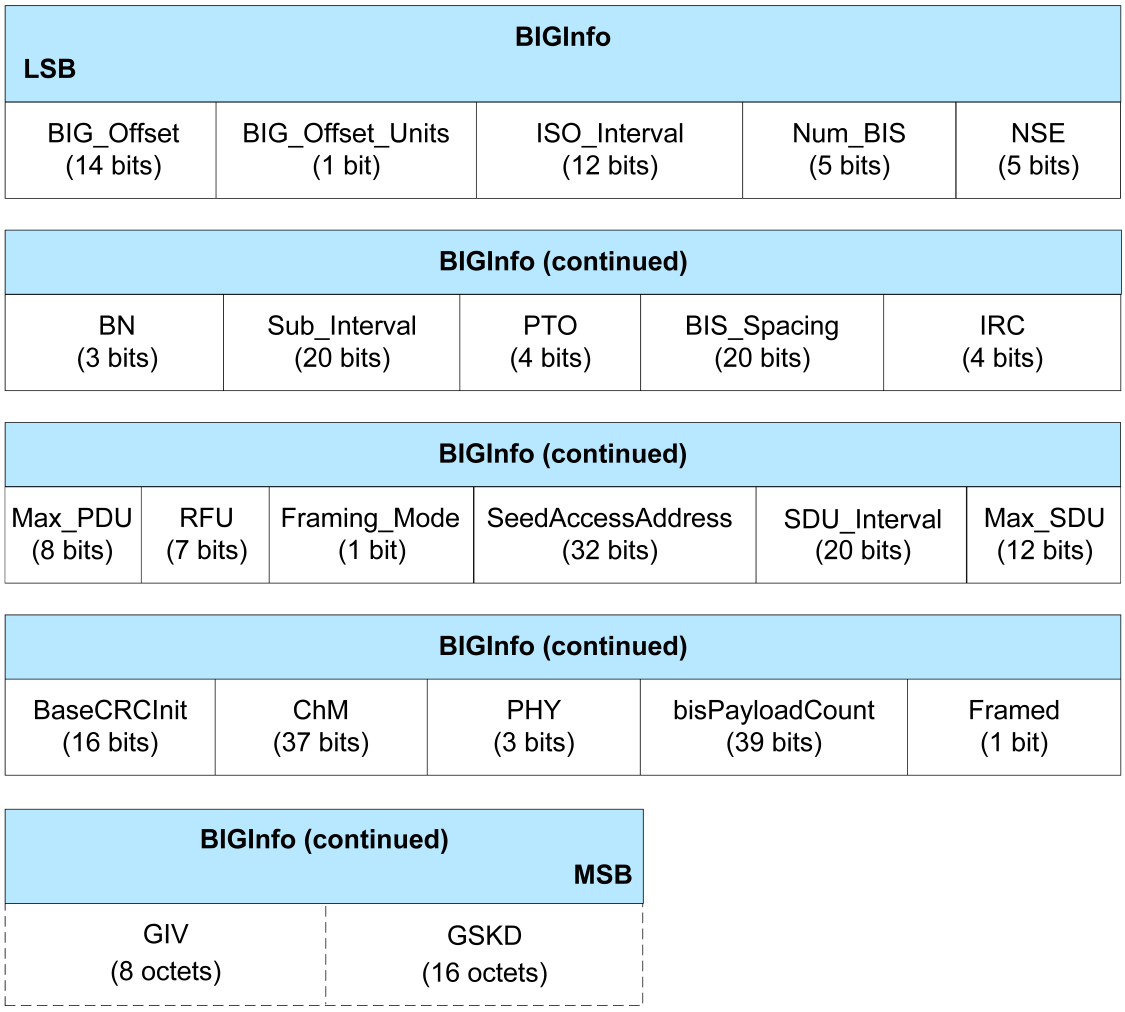

Figure 4.40: Format of BIGinfo

The BIG_Offset field contains the time from the start of the packet containing the BIGInfo to the BIG anchor point that this BIGInfo describes. The value of the BIG_Offset field is in the unit of time indicated by the BIG_Offset_Units bit; the actual time offset is determined by multiplying the value of BIG_Offset by the unit. The offset shall be greater than 600 µs.

If the BIG_Offset_Units bit is set then the unit is 300 µs; otherwise it is 30 µs. The BIG_Offset_Units bit shall not be set if the offset is less than 491,460 µs.

The BIG anchor point shall be no earlier than the offset and no later than the offset plus one unit after the start of the relevant packet, as shown in Figure 4.41.

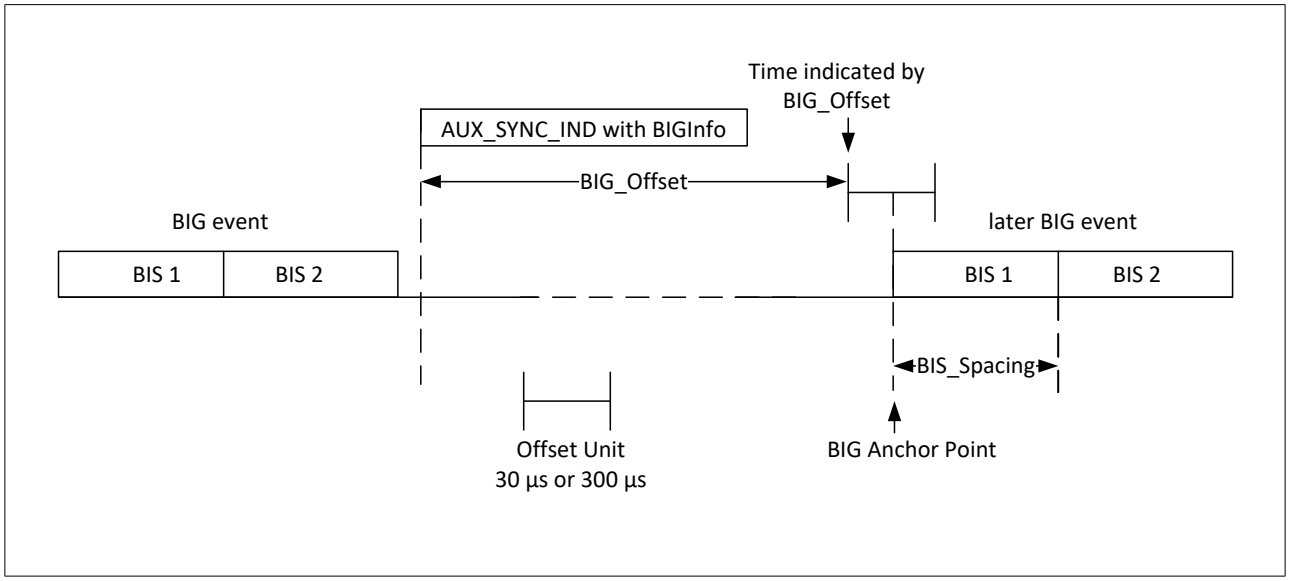

Figure 4.41: Time reference of a BIG event from a periodic advertising event.

The ISO_Interval, NSE, BN, Sub_Interval, PTO, BIS_Spacing, and IRC fields shall contain the values described in Section 4.4.6.3. Sub_Interval and BIS_Spacing shall be in units of microseconds.

The Num_BIS field shall contain the number of BISes in the BIG.

The Max_PDU field shall contain the value described in Section 4.4.6.3.

The SeedAccessAddress field shall contain the Seed Access Address for the BIG (see Section 2.1.2).

The SDU_Interval field shall contain the interval described in [Vol 6] Part G, Section 2.

The Max_SDU field shall contain the value specified in Section 4.4.6.3.

The BaseCRCInit field shall contain the value described in Section 3.1.1.

The ChM field shall have the same meaning as the corresponding field in the CONNECT_IND PDU (see Section 2.3.3.1).

The PHY field shall be set to indicate the PHY used by the BIG. The values for the PHYs are specified in Table 4.5.

Value	Meaning
0	LE 1M PHY
1	LE 2M PHY
2	LE Coded PHY
All other values	Reserved for future use

Table 4.5: PHY Types

The bisPayloadCount field shall contain the value specified in Section 4.4.6.5. The value shall be for the first subevent of the BIG event referred to by the BIG_Offset field

The Framed bit shall be set if the BIG carries framed data.

The Framing_Mode bit shall be set if the BIG carries framed data and Unsegmented mode is in use, and is zero for Segmentable mode. If the BIG carries unframed data, then Framing_Mode is RFU.

The GIV and GSKD fields shall contain the values described in Section 4.4.6.10 if the BIG is encrypted.

4.5 Connection state

The Link Layer enters the Connection state when an initiator sends a CONNECT_IND PDU on the primary advertising physical channel to an advertiser, an advertiser receives a CONNECT_IND PDU on the primary advertising physical channel from an initiator, an advertiser sends an AUX_CONNECT_RSP PDU on the secondary advertising physical channel to an initiator, or an initiator receives an AUX_CONNECT_RSP PDU on the secondary advertising physical channel from an advertiser.

After entering the Connection State, the connection is considered to be created. The connection is not considered to be established at this point. A connection is only considered to be established once a data physical channel packet has been received (regardless of a valid CRC match) from the peer device. The only difference between a connection that is created and a connection that is established is the Link Layer connection supervision timeout value that is used (see Section 4.5.2).

If the connection is first created using the CONNECT_IND PDU on the primary advertising physical channel, it shall use the LE 1M PHY in both directions. If the connection is first created on the secondary channel using the AUX_CONNECT_REQ and AUX_CONNECT_RSP PDUs, it shall use the same PHY in both directions as was used for the AUX_CONNECT_REQ and AUX_CONNECT_RSP PDU. Either PHY may be changed subsequently using the PHY Update procedure (Section 5.1.10). When the LE Coded PHY is in use, the coding of each packet is determined by the transmitting

Controller. The coding is indicated by the CI as defined in Section 2.2.3 and may be different in each direction and in adjacent packets in a given direction.

When two devices are in a connection, the two devices act in different roles. A Link Layer in the Central Role is called a Central. A Link Layer in the Peripheral Role is called a Peripheral. The Central controls the timing of a connection event. A connection event is a point of synchronization between the Central and the Peripheral. There shall be only one ACL connection, whether or not established, between two LE device addresses (including two different Resolvable Private Addresses that resolve to the same IRK). An initiator shall not send a connection request to an advertiser it is already connected to. A periodic advertiser shall not send a connection request to a synchronized device that it is already connected to.

If an advertiser receives a connection request from an initiator it is already connected to, then it shall ignore that request. If a synchronized device receives a connection request from a periodic advertiser it is already connected to, then it shall ignore that request.

If the initiator sent a CONNECT_IND PDU in response to an ADV_IND or ADV_DIRECT_IND PDU and either or both devices' PDU had the ChSel field set to 0, then Channel Selection Algorithm #1 (see Section 4.5.8.2) shall be used on the connection. Otherwise, Channel Selection Algorithm #2 (see Section 4.5.8.3) shall be used.

The Central, when directed by the Host, may create a Connected Isochronous Stream (CIS) with the peer device using the Connected Isochronous Stream Creation procedure (see Section 5.1.15). The CIS shall be associated with the ACL used to create it with the same device being Central on both connections. The Link Layer may create multiple CISes with the same Peripheral.

Note: A Peripheral cannot initiate a request to create a CIS at the Link Layer level but it can do so at a higher layer.

When the ACL connection between the Central and Peripheral is terminated, all associated CISes shall be terminated at the same time.

4.5.1 Connection events

The Link Layer in the Connection state shall only transmit Data Physical Channel PDUs (see Section 2.4) in connection events. The Central and Peripheral shall determine the data channel index for each connection event as defined in Section 4.5.8. The same data channel index shall be used for all packets in the connection event. Each connection event normally contains at least one packet sent by the Central. The Central can, however, completely fail to transmit in a connection event due to scheduling conflicts or the effect of the subrate factor (see below), but shall transmit at least one Data Channel PDU within each supervision timeout period (see Section 4.5.2).

During a connection event, the Central and Peripheral alternate sending and receiving packets spaced T_IFS_ACL_CP between a packet transmitted by the Central and one transmitted by the Peripheral and spaced T_IFS_ACL_PC between a packet transmitted by the Peripheral and one transmitted by the Central, as shown in Figure 4.42.

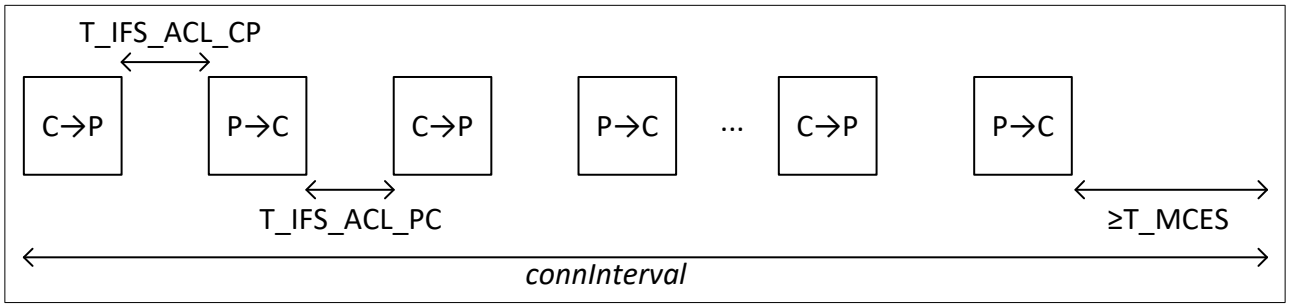

Figure 4.42: The different frame space values in a connection event

The connection event is considered open while both devices continue to send packets. The Peripheral shall always send a packet if it receives a packet from the Central regardless of a valid CRC match, except after multiple consecutive invalid CRC matches as specified in Section 4.5.6. The Central may send a packet if it receives a packet from the Peripheral regardless of a valid CRC match, except after multiple consecutive invalid CRC matches as specified in Section 4.5.6. When determining the end of the received packet, the Length and CP fields of the Header field, and the CTETime field of the CTEInfo field (if present), are assumed to be correct even if the CRC match was invalid; however, if the receiving device can determine the correct length and CTETime in some other way, it may use those values instead of those in the Header field.

The connection event can be closed by either device, as defined in Section 4.5.6.

Both the Central and the Peripheral shall have a 16-bit connection event counter (*connEventCounter*), containing the value connEventCount, for each ACL connection. Each counter shall be set to zero on the first connection event and shall be incremented by one for each new connection event; the *connEventCounter* shall wrap from 0xFFFF to 0x0000. This counter is used to synchronize Link Layer control procedures.

Both devices shall increment *connEventCounter* for all connection events, even if the Peripheral is not listening to the Central in those events or the Central did not transmit during the event (e.g., because of subrating or Peripheral latency).

The timing of connection events is determined by the following parameters: connection interval (*connInterval*), subrate base event (*connSubrateBaseEvent*), subrate factor (*connSubrateFactor*), continuation number (*connContinuationNumber*), and Peripheral latency (*connPeripheralLatency*).

The start of a connection event is called an anchor point. If the Central transmits in a connection event, it shall start to transmit a Data Physical Channel PDU to the Peripheral at the anchor point. The start of connection events are spaced regularly with an interval of *connInterval* and shall not overlap. The Central shall ensure that a connection event closes at least T_MCES before the anchor point of the next connection event. The Peripheral should listen for the packet sent by its Central at the anchor point.

The *connInterval* shall be a multiple of 1.25 ms in the range 7.5 ms to 4.0 s. The *connInterval* is set by the Initiator's Link Layer in the CONNECT_IND or AUX_CONNECT_REQ PDU from the range given by the Host and can be changed using the Connection Update procedure (see Section 5.1.1) or Connection Parameters Request procedure (see Section 5.1.7).

The subrate factor allows the Central and Peripheral to use a reduced number of connection events. The Central shall only transmit on subrated connection events, the events specified in Section 5.1.1, and, if the continuation number is non-zero, continuation events.

A subrated connection event is a connection event where (*connEventCount* - *connSubrateBaseEvent*) is an integer multiple of *connSubrateFactor*; *connSubrateBaseEvent* is a *connEventCount* that is used to determine the phase of the subrated events. The connection event where *connEventCount* equals *connSubrateBaseEvent* will always be a subrated connection event. Adding an integer multiple of *connSubrateFactor* to *connSubrateBaseEvent* (including a negative multiple) results in a *connEventCount* value that will also always be a subrated connection event. For example, if *connSubrateFactor* equals 100, then *connSubrateBaseEvent* values of 42, 6942, and 65442 are equivalent. In each case, connection event number 24242 is a subrated event because 24242 - 42 = 24200, 24242 - 6942 = 17300, and 24242 - 65442 = -41200 are all integer multiples of 100.

A continuation event is a connection event where, in at least one of the previous *connContinuationNumber* connection events (ignoring any before the last subrated connection event), at least one packet was transmitted or validly received containing a Link Layer PDU with a non-zero Length field. Continuation events are determined by activity in a subrated connection event and any subsequent continuation events. Some connection events between two consecutive subrated connection events might not be continuation events.

The value of *connSubrateFactor* shall be in the range 1 to 500 and shall be set to 1 for a new connection. A Controller shall either support only a *connSubrateFactor* of 1 (in which case the value of *connSubrateBaseEvent* will not be used) or shall support all valid subrate factors. The value of *connContinuationNumber* shall be in the range 0 to *connSubrateFactor* - 1 and shall be set to zero for a new connection. A Controller shall support all valid continuation numbers.

Figure 4.43 and Figure 4.44 show how the subrate base event affects which events are subrated connection events.

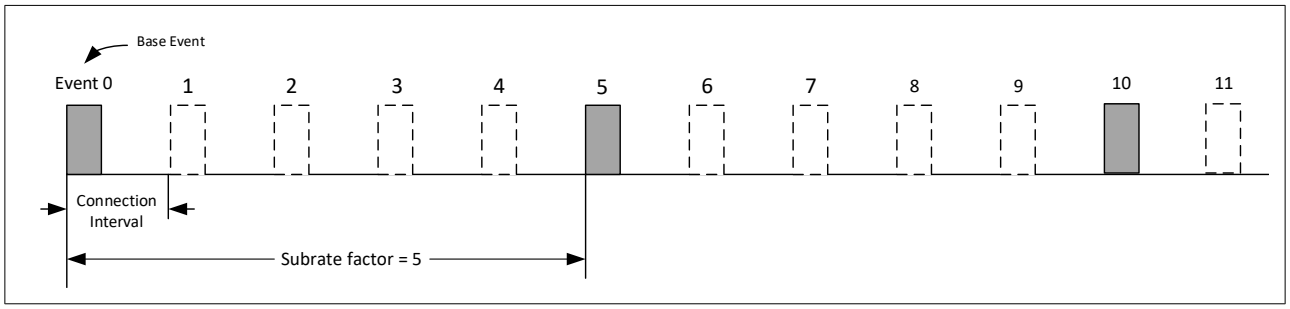

Figure 4.43: Connection events used when connSubrateFactor = 5 and connSubrateBaseEvent = 0

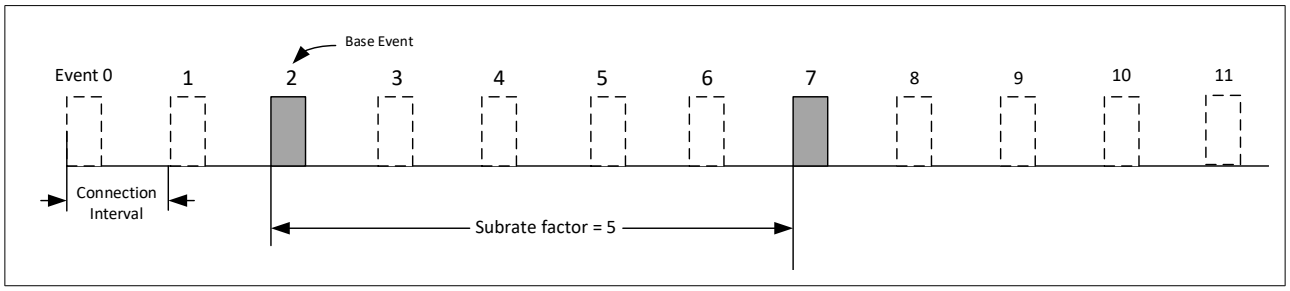

Figure 4.44: Connection events used when connSubrateFactor = 5 and connSubrateBaseEvent = 2

Peripheral latency also allows a Peripheral to use a reduced number of connection events. The *connPeripheralLatency* parameter defines the number of consecutive subrated connection events that the Peripheral is not required to listen for the Central. For example, if *connSubrateFactor* is 3, *connContinuationNumber* is 0, and *connPeripheralLatency* is 6, then a Peripheral implementation can choose to only listen to every 21st connection event (i.e., every 7th subrated connection event).

connPeripheralLatency shall be an integer such that *connSubrateFactor* × (*connPeripheralLatency* + 1) is less than or equal to 500 and *connInterval* × *connSubrateFactor* × (*connPeripheralLatency* + 1) is less than half *connSupervisionTimeout*. When *connPeripheralLatency* is set to zero the Peripheral should listen at the anchor point of every subrated connection event and continuation event. Irrespective of Peripheral latency, if the Peripheral receives a valid packet from the Central at a subrated connection event, it shall listen at the anchor point of every continuation event before the next subrated connection event. If the Peripheral does not receive a valid packet from the Central after applying Peripheral latency, it should listen at each of the subrated anchor points and not apply Peripheral latency until it receives a packet from the Central. Irrespective of the value of *connPeripheralLatency* or any scheduling conflicts, the Peripheral shall listen for the Central at least once within each connection supervision timeout duration (see Section 4.5.2).

Figure 4.45 to Figure 4.47 show how the connection events are used for various values of *connSubrateFactor*, *connPeripheralLatency*, and *connContinuationNumber*. In the figures, S indicates the subrated events, C indicates continuation events, and L indicates subrated events where Peripheral latency is applied. In Figure 4.46, the data is being transmitted by the Peripheral, not the Central.

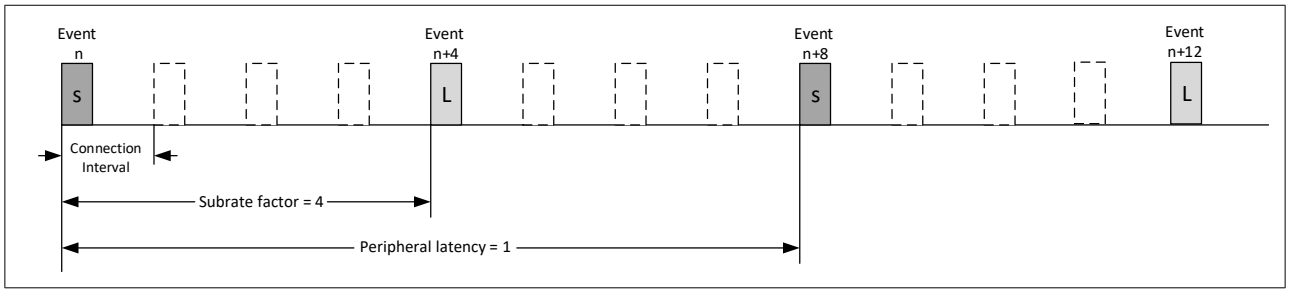

Figure 4.45: Connection events used when connSubrateFactor = 4, connPeripheralLatency = 1, and connContinuationNumber = 0

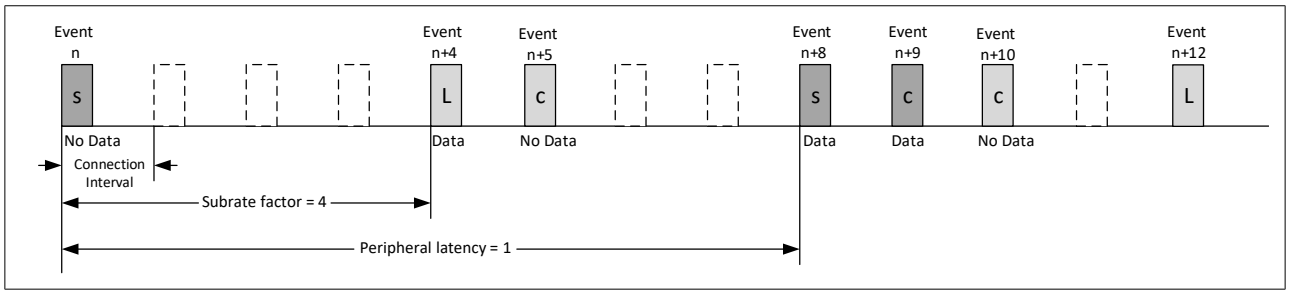

Figure 4.46: Connection events used when connSubrateFactor = 4, connPeripheralLatency = 1, and connContinuationNumber = 1

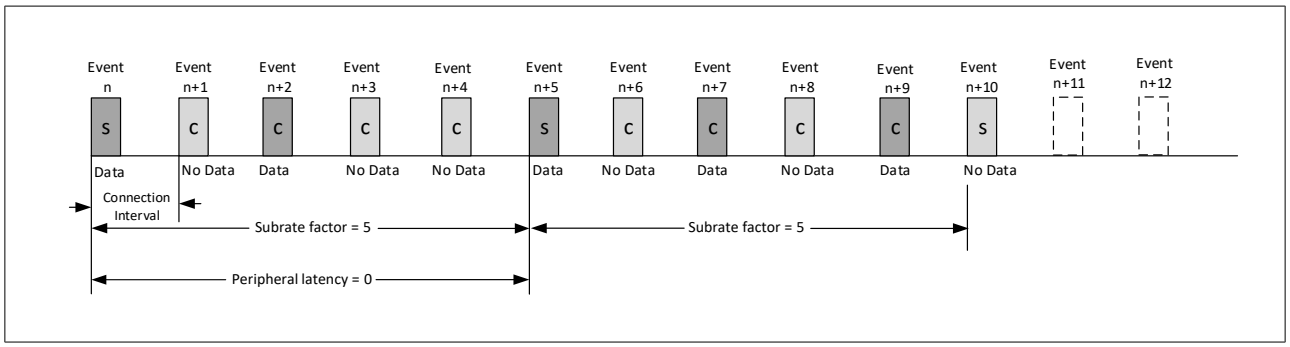

Figure 4.47: Connection events used when connSubrateFactor = 5, connPeripheralLatency = 0, and connContinuationNumber = 2

If the Connection Subrating feature is supported then, when *connEventCounter* wraps, the Link Layer shall set the value of *connSubrateBaseEvent* to (*connSubrateBaseEvent* + *K* × *connSubrateFactor* - 65536), where *K* is any integer that will cause the new value to be in the range 0 to 65535, so that the subrated connection events will remain equally spaced.

4.5.2 Supervision timeout

A connection can break down due to various reasons such as a device moving out of range, encountering severe interference or a power failure condition. Since this may happen without any prior warning, it is important for both the Central and the Peripheral to monitor the status of the connection.

To be able to detect link loss in an ACL connection, both the Central and the Peripheral shall use an ACL connection supervision timer, $T_{LLconnSupervision}$. Upon reception of a valid packet on the ACL, the timer shall be reset. To be able to detect link loss in a CIS, both the Central and the Peripheral shall use a CIS supervision timer, $T_{CISSupervision}$. Upon reception of a valid packet on the CIS, the timer $T_{CISSupervision}$ shall be reset.

If the ACL connection supervision timer reaches 6 × *connInterval* before the connection is established (see Section 4.5), the ACL connection may, but should not, be considered lost. If the ACL connection is not established after 6 connection events, it shall be considered lost. This enables fast termination of ACL connections that fail to establish.

Depending on the connection interval and whether a CONNECT_IND or AUX_CONNECT_REQ PDU was used, this timer can expire after 4, 5, or 6 connection events.

Because a packet with a CRC error is sufficient to establish the connection, the connection can become established without the timer $T_{LLconnSupervision}$ being reset.

When establishing a CIS, the Central shall start the CIS supervision timer at the start of the next CIS event after receiving the acknowledgment for the LL_CIS_IND. If the CIS supervision timer reaches 6 × ISO_Interval before the CIS is established, the CIS shall be considered lost.

When establishing a CIS, the Peripheral shall start the CIS supervision timer at the start of the next CIS event after receiving the LL_CIS_IND. If the CIS supervision timer reaches 6 × ISO_Interval before the CIS is established, the CIS shall be considered lost.

Connection supervision timeout (*connSupervisionTimeout*) is a parameter that defines the maximum time between two received Data Channel PDUs or Connected Isochronous PDUs before the connection is considered lost. The *connSupervisionTimeout* shall be a multiple of 10 ms in the range 100 ms to 32.0 s and it shall be larger than

$$(1 + connPeripheralLatency) \times connSubrateFactor \times connInterval \times 2.$$

If, at any time in Connection State outside a connection event after the connection has been established, the timer $T_{LLconnSupervision}$ reaches the *connSupervisionTimeout* value, the connection shall be considered lost (see Section 4.5.12).

If, at any time in Connection State outside a CIS event after the CIS has been established, the timer $T_{CISSupervision}$ reaches the *connSupervisionTimeout* value, the CIS shall be considered lost.

In either case, the Controller may send the notification of the loss earlier provided that the most recent event has closed and the timer will reach the *connSupervisionTimeout* value before the next ACL or CIS anchor point.

In either case the Controller may, but should not, consider the connection lost at any time within an event after the timer reaches *connSupervisionTimeout*.

The supervision timeout can be changed using the Connection Update procedure (see Section 5.1.1) or the Connection Parameters Request procedure (see Section 5.1.7). If either of these procedures are used, the new value shall be greater than twice the ISO_Interval of any associated CIS.

Each *supervision timeout period* starts with the event following the reception of a valid packet and ends with the last event before the timer reaches the *connSupervisionTimeout* value.

4.5.3 Connection event transmit window

To allow the Central to efficiently schedule connection events for multiple connections or other activities it may be involved in, the Central has the flexibility to schedule the first connection event anchor point at a time of its choosing. The CONNECT_IND and AUX_CONNECT_REQ PDUs include parameters to determine when the Central sends its first packet in the Connection State to set the anchor point and when the Peripheral listens.

The CONNECT_IND and AUX_CONNECT_REQ PDUs include three parameters used to determine the transmit window. The transmit window starts at *transmitWindowDelay* + *transmitWindowOffset* after the end of the packet containing the CONNECT_IND PDU or AUX_CONNECT_REQ PDU, and the *transmitWindowSize* parameter shall define the size of the transmit window. The *connInterval* is used in the calculation of the maximum offset and size of the transmit window. The *transmitWindowOffset* and *transmitWindowSize* parameters are determined by the Link Layer.

The *transmitWindowOffset* shall be a multiple of 1.25 ms in the range 0 ms to *connInterval*. The *transmitWindowSize* shall be a multiple of 1.25 ms in the range 1.25 ms to the lesser of 10 ms and (*connInterval* - 1.25 ms).

Therefore the start of the first packet will be no earlier than *transmitWindowDelay* + *transmitWindowOffset* and no later than *transmitWindowDelay* + *transmitWindowOffset* + *transmitWindowSize* after the end of the packet containing the CONNECT_IND PDU or AUX_CONNECT_REQ PDU.

The value of *transmitWindowDelay* shall be 1.25 ms when a CONNECT_IND PDU is used, 2.5 ms when an AUX_CONNECT_REQ PDU is used on an LE Uncoded PHY, and 3.75 ms when an AUX_CONNECT_REQ PDU is used on the LE Coded PHY.

4.5.4 Connection setup – Central Role

After the initiator sends a CONNECT_IND PDU on the primary advertising physical channel or receives an AUX_CONNECT_RSP PDU on the secondary advertising physical channel, the Link Layer is in the Connection state in the Central Role.
The Central shall reset the Link Layer connection supervision timer $T_{LLconnSupervision}$.
The Link Layer shall notify the Host that the connection has been created. The first connection event shall use the data channel index specified in Section 4.5.8.

The Central shall start to send the first packet within the transmit window as defined in Section 4.5.3. The Central's first packet can extend beyond the transmit window.

The first packet sent in the Connection State by the Central determines the anchor point for the first connection event, and therefore the timings of all future connection events in this connection.

The second connection event anchor point shall be *connInterval* after the first connection event anchor point. All the normal connection event transmission rules specified in Section 4.5.1 shall apply.

Two examples of the LL connection setup procedure timing from the Central's perspective are shown in Figure 4.48 and in Figure 4.49.

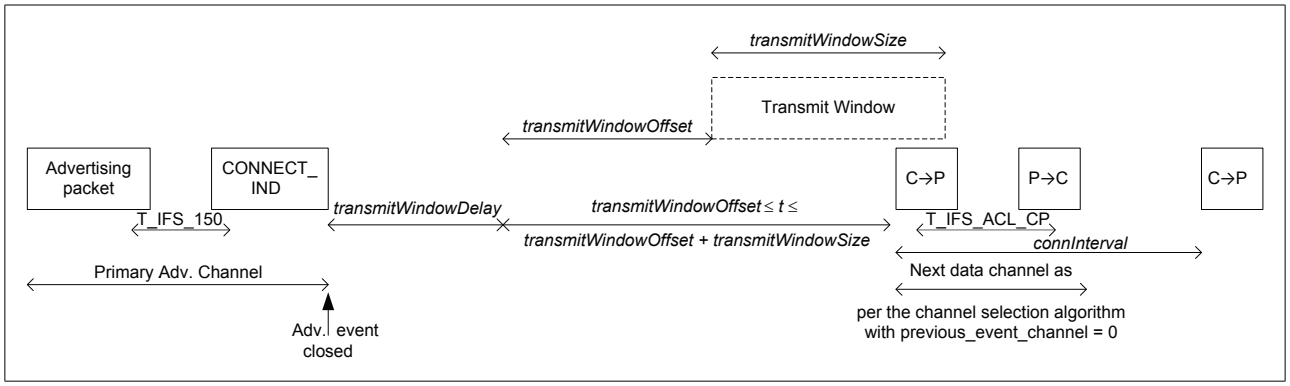

Figure 4.48: Central's view of LL connection setup with CONNECT_IND

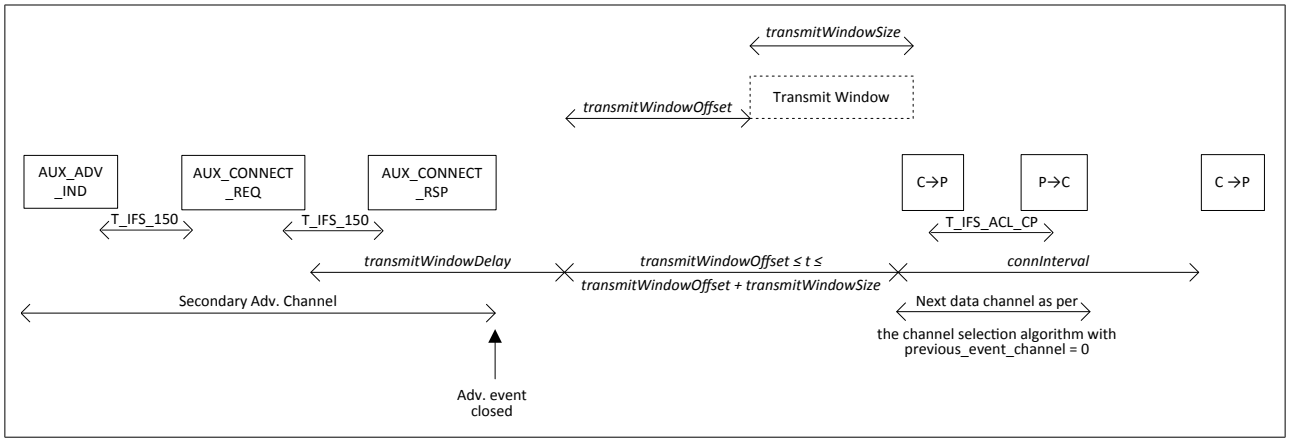

Figure 4.49: Central's view of LL connection setup with AUX_CONNECT_REQ

4.5.5 Connection setup – Peripheral Role

After the advertiser receives a CONNECT_IND PDU on the primary advertising physical channel or sends an AUX_CONNECT_RSP PDU on the secondary advertising physical channel, the Link Layer is in the Connection state in the Peripheral Role. The Peripheral shall reset the Link Layer connection supervision timer $T_{LLconnSupervision}$. The Link Layer shall notify the Host that the connection has been created. The first connection event shall use the data channel index specified in Section 4.5.8.

The Peripheral shall start to listen for the first packet within the transmit window as defined in Section 4.5.3; while doing so, it shall perform the window widening specified in Section 4.2.4. The Central's first packet can extend beyond the transmit window, and therefore the Peripheral must take this into account.

The first packet received, regardless of a valid CRC match (i.e., only the access address needs to match), in the Connection State by the Peripheral determines the anchor point for the first connection event, and therefore the timings of all future connection events in this connection.

If a packet is not received in a transmit window, the Peripheral shall attempt to receive a packet in a subsequent transmit window. A subsequent transmit window shall start *connInterval* after the start of the previous transmit window, with the same *transmitWindowSize*. The data channel index shall be the next data channel index as specified in Section 4.5.8. The *connEventCount* shall also be incremented by one.

Two examples of the procedure from the Peripheral's perspective are shown in Figure 4.50 and in Figure 4.51. In these examples the Peripheral fails to receive any part of the first packet (i.e., connEventCount = 0) from the Central and acquires anchor point timing from the second packet (i.e., connEventCount = 1).

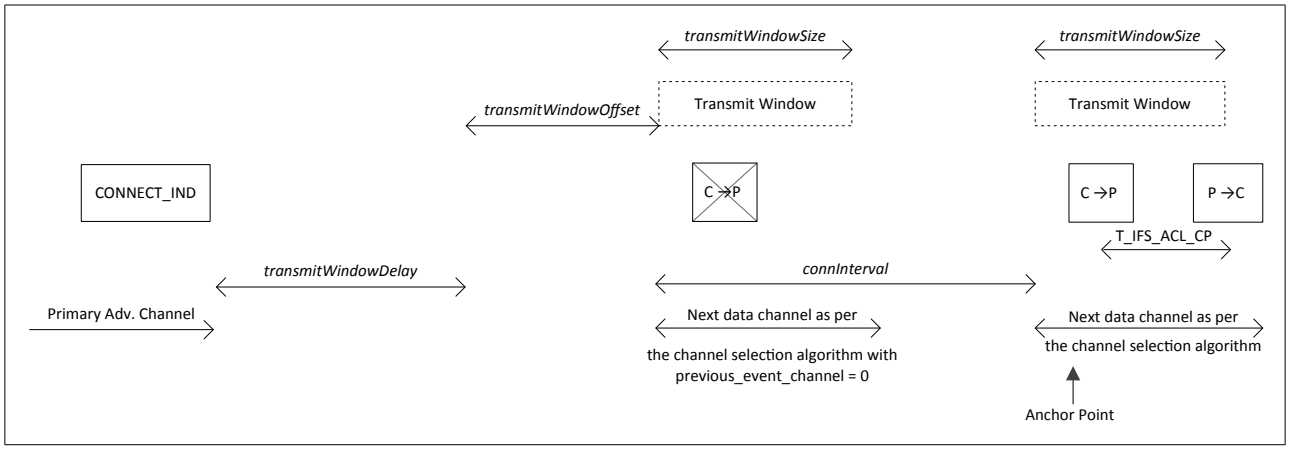

Figure 4.50: Peripheral closing LL connection setup in the second LL connection event with CONNECT_IND

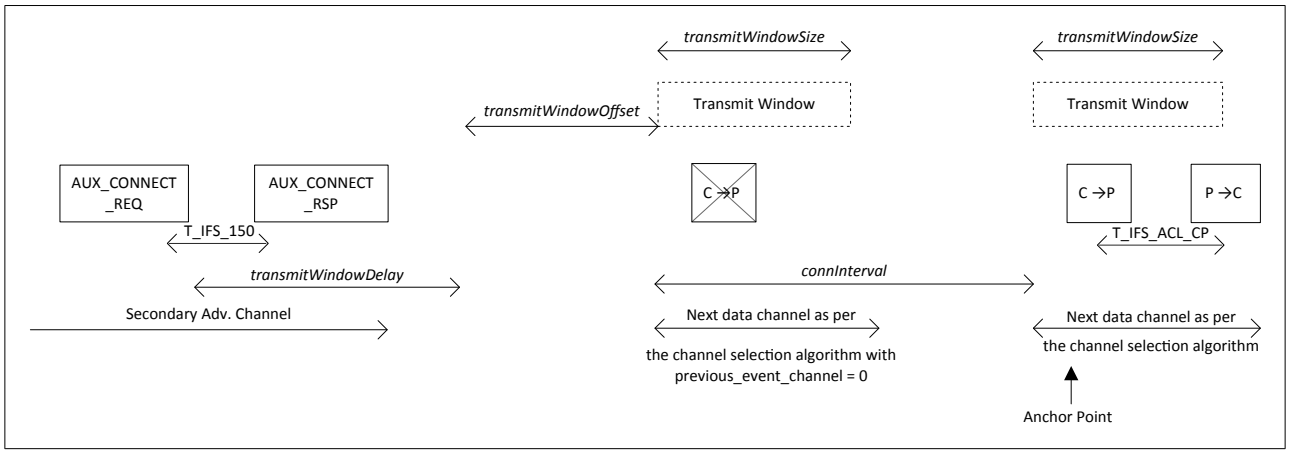

Figure 4.51: Peripheral closing LL connection setup in the second LL connection event with AUX_CONNECT_REQ

The Peripheral shall be active in every connection event until it receives a packet from the Central with the NESN set to one. From then on it may use Peripheral latency as defined in Section 4.5.1.

4.5.6 Closing connection events

The MD bit of the Header field of the Data Physical Channel PDU is used to indicate that the device has more data to send. If neither device has set the MD bit in their packets, the packet from the Peripheral closes the connection event. If either or both of the devices have set the MD bit, the Central may continue the connection event by sending another packet, and the Peripheral should listen after sending its packet.

Failure to receive a packet, or two consecutive packets received with an invalid CRC match within a connection event shall close the event.

MD bit usage is summarized in Table 4.6.

		Central	
		MD = 0	**MD = 1**
Peripheral	**MD = 0**	Central shall not send another packet, closing the connection event. Peripheral does not need to listen after sending its packet.	Central may continue the connection event. Peripheral should listen after sending its packet.
	MD = 1	Central may continue the connection event. Peripheral should listen after sending its packet.	Central may continue the connection event. Peripheral should listen after sending its packet.

Table 4.6: MD bit usage for closing connection events

4.5.7 Sleep clock accuracy

Because of sleep clock accuracies (see Section 4.2.2), there is uncertainty in the Peripheral of the exact timing of the Central's anchor point. Therefore the Peripheral shall re-synchronize to the Central's anchor point at each connection event where it listens for the Central. If the Peripheral receives a packet from the Central at the anchor point, regardless of a CRC match, the Peripheral shall update its timing of the anchor point.

If it listens for a packet, the Peripheral shall perform the window widening described in Section 4.2.4 at each anchor point and during the Connection Update procedure (see Section 5.1.1) and Connection Parameters Request procedure (see Section 5.1.7). In doing so, and in the absence of more accurate information about the Central's clock, the Peripheral shall use the Central's sleep clock accuracy (*centralSCA*) from the most recent CONNECT_IND, AUX_CONNECT_REQ, LL_CLOCK_ACCURACY_REQ, or LL_CLOCK_ACCURACY_RSP PDU on the connection.

4.5.7.1 Sleep clock accuracy for Channel Sounding

Sleep clock accuracies (see Section 4.2.2) result in uncertainty in the device's exact timing of the start of a Channel Sounding event (see Section 4.5.18.1). If the device is a reflector then it shall re-synchronize to the start of each subevent. The Central and Peripheral may either assume the initiator or reflector roles. In the case that the Central is the initiator, then the reflector shall use the Central's sleep clock accuracy (centralSCA). Alternatively, if the Peripheral is the initiator, then the reflector shall use the Peripheral's sleep clock accuracy (peripheralSCA).

The connection events that offset Channel Sounding events within that Channel Sounding procedure shall be subrated connection events.

If a device is a Peripheral and the initiator, then:

- The Peripheral shall listen to the connection event from which a Channel Sounding event is directly offset even if Peripheral latency means it would not normally do so (see Section 4.5.1).

At the beginning of each Channel Sounding subevent which includes the beginning of a Channel Sounding event, in the case that the device is the reflector, it shall perform window widening described in Section 4.2.4. In doing so, and in the absence of more accurate information about the initiator's clock, the reflector shall use the sleep clock accuracy from the most recent LL_CLOCK_ACCURACY_REQ or LL_CLOCK_ACCURACY_RSP on the connection.

4.5.8 General-purpose channel group index selection

This section specifies the requirements for channel classification and several channel selection algorithms used for connection events, advertising events, and isochronous events. Additional channel selection algorithms for Channel Sounding are described in [Vol 6] Part H, Section 4.

4.5.8.1 Channel classification

Support for Adaptive Frequency Hopping (AFH) is mandatory on the general-purpose channels. The Link Layer can classify each general-purpose channel as being *unknown*, *bad*, or *good*. These classifications are determined individually by the Link Layer based on local information (e.g., from active or passive channel assessment methods or from the Host). Information received from other devices (e.g., via an LL_CHANNEL_MAP_IND) shall not be included in the channel classification. The Host may provide channel classification information to the Link Layer. The Link Layer may use the information provided by the Host.

The three possible channel classifications are defined in Table 4.7.

Classification	Definition
unknown	A channel shall be classified as *unknown* if the channel assessment measurements are insufficient to reliably classify the channel.
bad	A channel may be classified as *bad*, for example, when it is marked as *bad* in the most recent HCI_LE_Set_Host_Channel_Classification command or when the assessment of failure rate or interference with other systems exceeds some threshold.
good	A channel shall be classified as *good* if it is neither *unknown* nor *bad*.

Table 4.7: Channel classification descriptions

The Central's, periodic advertiser's, and isochronous broadcaster's Link Layer shall classify the RF channels in the general-purpose group into *used channels* (used for

transmitting data) and *unused channels* (not used for transmitting data). This is called the channel map. The minimum number of used channels shall be 2.

A Central shall determine a channel map for the connection based on any combination of the following information:

- Channel classification from local measurements (e.g., active or passive channel assessment in the Controller or input from other collocated technologies)
- Channel classification information from the Host
- Channel classification reports received from the Peripheral in LL_CHANNEL_STATUS_IND PDUs (see Section 2.4.2.39)

The algorithm used by the Central to combine these information sources and generate the channel map is not defined in the specification and is vendor-specific.

For a connection, the Peripheral shall receive the channel map from the Central in the CONNECT_IND PDU or the AUX_CONNECT_REQ PDU. If the Central changes the channel map it shall notify the Peripheral as specified in Section 5.1.2. If the periodic advertiser changes the channel map then it shall notify any scanning devices using the Channel Map Update Indication (see Section 1.20 of [1]). On periodic advertising with responses, the advertiser shall transmit the Channel Map Update Indication data type in each subevent. If the isochronous broadcaster changes the channel map it shall notify any Synchronized Receivers as specified in Section 5.6.1.

4.5.8.2 Channel Selection algorithm #1

Channel Selection Algorithm #1 only supports channel selection for connection events.

Channel Selection Algorithm #1 consists of two stages: calculation of the unmapped channel index followed by mapping this index to a data channel index from the set of *used channels*.

The *unmappedChannel* and *lastUnmappedChannel* are the unmapped channel indices of two consecutive connection events. The *unmappedChannel* is the unmapped channel index for the current connection event. The *lastUnmappedChannel* is the unmapped channel index of the previous connection event. The *lastUnmappedChannel* shall be 0 for the first connection event of a connection.

At the start of a connection event, *unmappedChannel* shall be calculated using the following basic algorithm:

$$unmappedChannel = (lastUnmappedChannel + hopIncrement) \ mod \ 37$$

When a connection event closes, the *lastUnmappedChannel* shall be set to the value of the *unmappedChannel*.

If the *unmappedChannel* is a *used channel* according to the channel map, Channel Selection Algorithm #1 shall use the *unmappedChannel* as the data channel index for the connection event.

If the *unmappedChannel* is an *unused channel* according to the channel map, the *unmappedChannel* shall be re-mapped to one of the *used channels* in the channel map using the following algorithm:

remappingIndex = unmappedChannel mod numUsedChannels

where *numUsedChannels* is the number of *used channels* in the channel map.

A remapping table is built that contains all the *used channels* in ascending order, indexed from zero. The *remappingIndex* is then used to select the data channel index for the connection event from the remapping table.

The complete procedure is as shown in Figure 4.52.

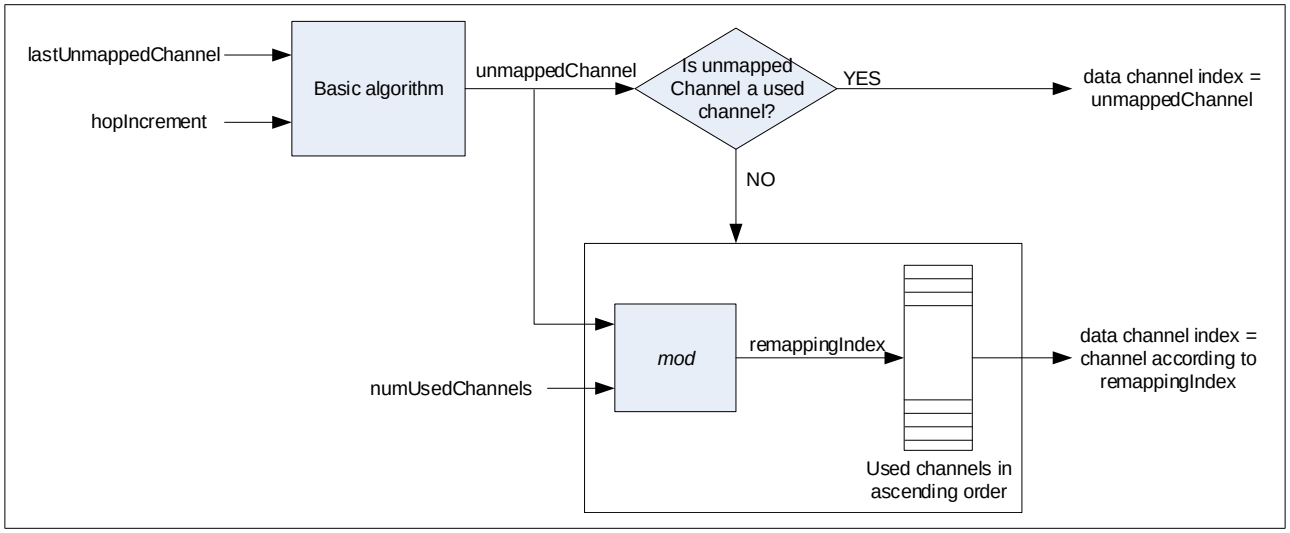

Figure 4.52: Block diagram of Channel Selection algorithm #1

4.5.8.3 Channel Selection algorithm #2

4.5.8.3.1 Overview

Channel Selection Algorithm #2 supports channel selection for both events and subevents.

For each connection event, isochronous subevent (which can be a BIS or CIS subevent), periodic advertising without responses event, or periodic advertising with responses subevent, the algorithm described here generates an event or subevent channel index (which is a general purpose channel index).

Note: In a given isochronous event, Channel Selection Algorithm #2 results in two consecutive subevents using different channel indices.

A block diagram of the overall algorithm is shown in Figure 4.53. The upper part generates "event" channel indices and the lower part "subevent" channel indices; in some cases event channel indices are used for subevents. Connection events, periodic advertising events, the first subevent of each isochronous event, and BIG control subevents shall use the event channel index as defined in Section 4.5.8.3.3 and Section 4.5.8.3.4; all subsequent subevent(s) in the same isochronous event shall use the subevent channel index as defined in Section 4.5.8.3.5 and Section 4.5.8.3.6.

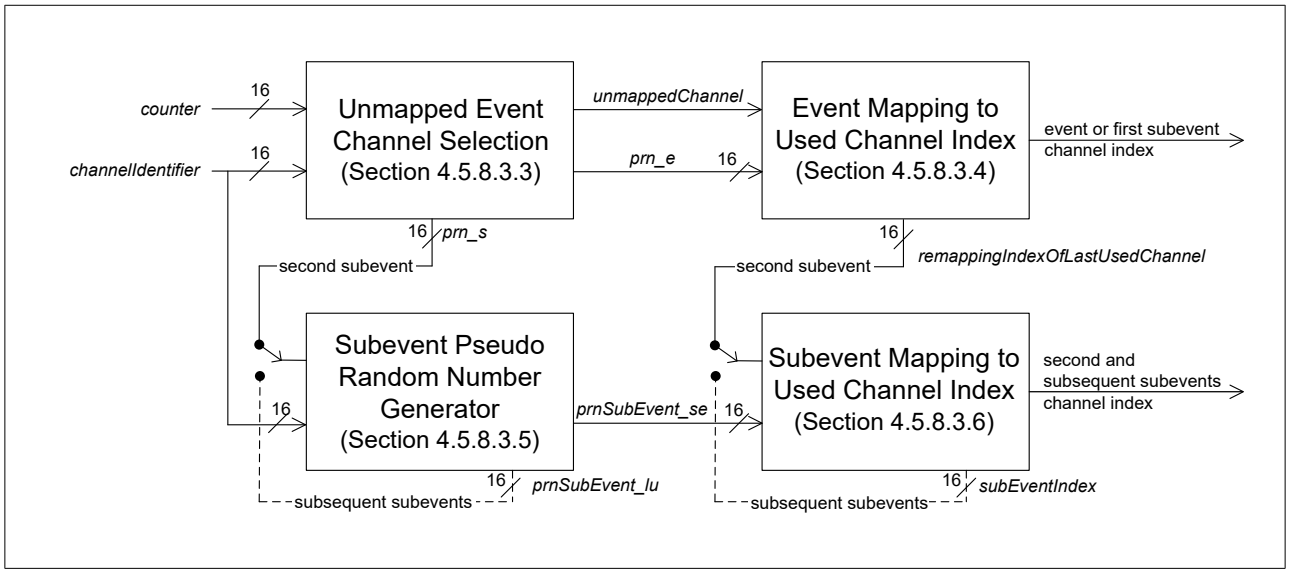

Figure 4.53: General block diagram of Channel Selection algorithm #2

4.5.8.3.2 Inputs and basic components

The algorithm makes use of several inputs and basic components.

The 6-bit input *N* is the number of channels classified as *Used* channels.

The 16-bit input *channelIdentifier* is fixed for any given connection, BIS, or periodic advertising train; it is calculated from the Access Address by: *channelIdentifier* = (Access Address$_{31\text{-}16}$) ⊕ (Access Address$_{15\text{-}0}$)

The 16-bit input *counter* depends on the event or sub-event type.

- For ACL connections, it is the connection event counter *connEventCounter* defined in Section 4.5.1.
- For periodic advertising without responses, it is the event counter *paEventCounter* defined in Section 4.4.2.1.

- For periodic advertising with responses, it is the XOR of the two event counters *paEventCounter* and *paSubEventCounter* defined in Section 4.4.2.1 (so is different for each subevent of an event).
- For isochronous logical transports, it is bits 0 to 15 of the event counter *bigEventCounter* defined in Section 4.4.6.3 or *cisEventCounter* defined in Section 4.5.13.1 (so does not change during an event).

For isochronous events, the input *se_n* is defined in Section 4.4.6.8 for BIS events and Section 4.5.13.6 for CIS events.

The permutation operation consists of separately bit-reversing the lower 8 input bits and upper 8 input bits, as illustrated in Figure 4.54.

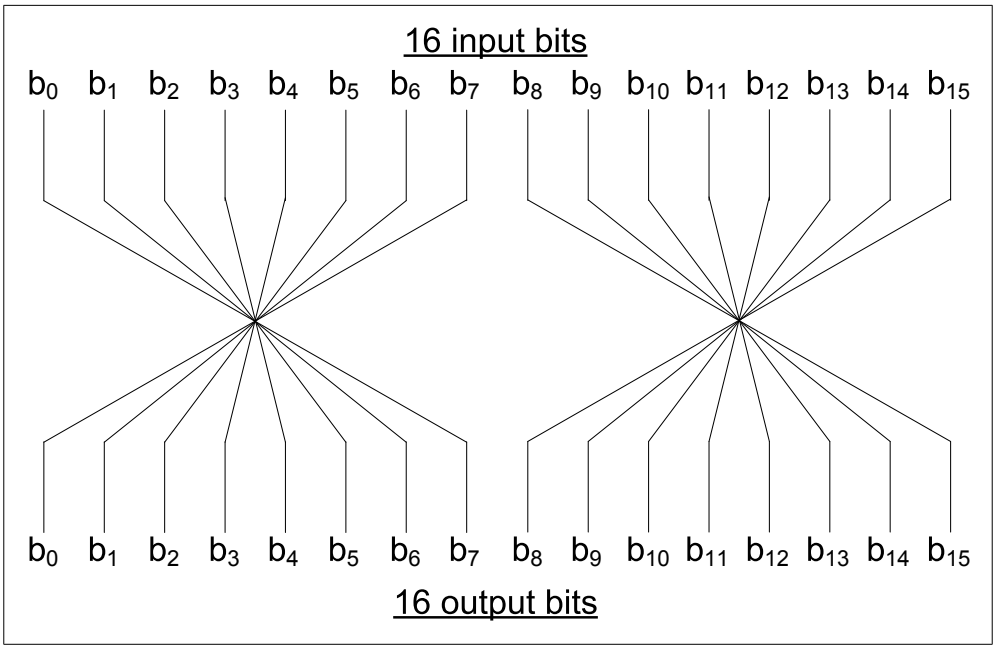

Figure 4.54: Permutation operation

The Multiply, Add, and Modulo (MAM) block performs a multiplication operation, an addition operation, and a *mod* operation, as illustrated in Figure 4.55.

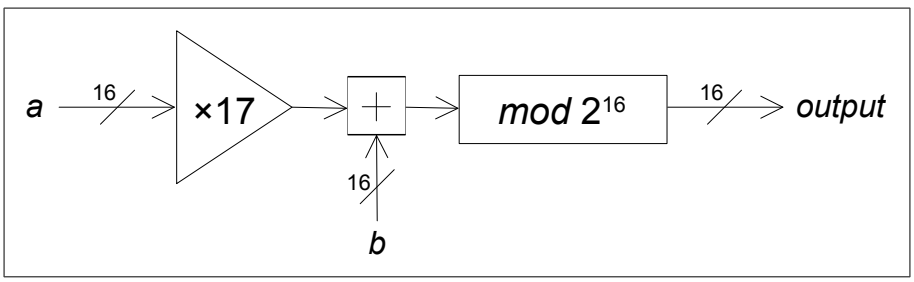

Figure 4.55: Multiply, Add, and Modulo block operation

The output of the MAM operation, given inputs *a* and *b*, is:

$$output = (17 \times a + b) \bmod 2^{16}$$

A *remapping table* is built that contains all the *used channels* in ascending order, indexed from zero.

4.5.8.3.3 Unmapped event channel selection

The unmapped event channel selection process consists of two stages. First, the two unsigned pseudo-random numbers *prn_e* and *prn_s* are generated (*prn_s* is only needed for subevent channel selection), after which the unmapped channel index *unmappedChannel* is derived from *prn_e*.

The first stage shall be as shown in Figure 4.56.

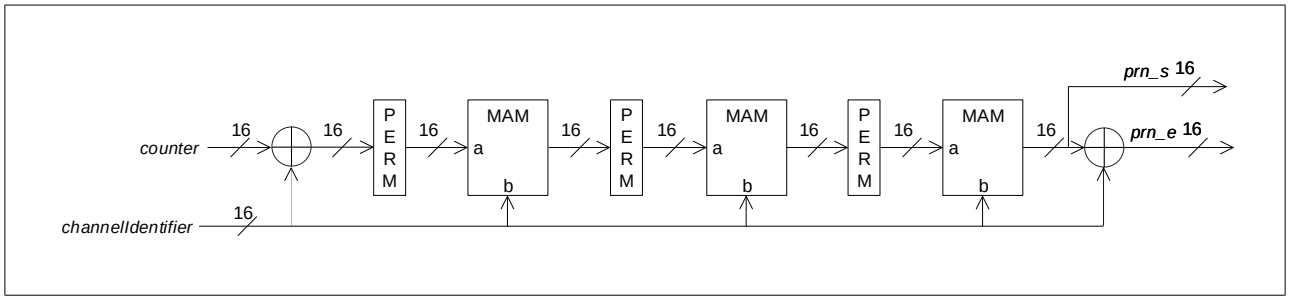

Figure 4.56: Event pseudo-random number generation

unmappedChannel is then calculated as *prn_e mod* 37. A block diagram of the overall process is shown in Figure 4.57.

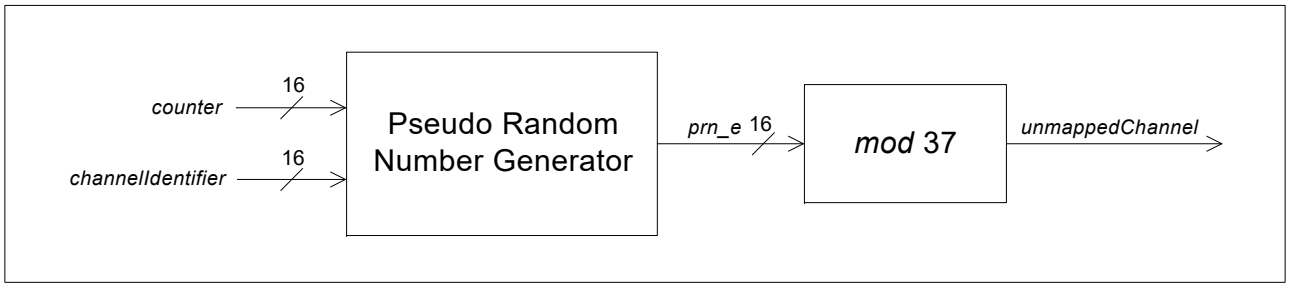

Figure 4.57: Unmapped channel selection process

4.5.8.3.4 Event mapping to used channel index

If *unmappedChannel* is the channel index of a *used channel* according to the channel map, it is used as the channel index for the event. If *unmappedChannel* is the index of an *unused channel* according to the channel map, then the channel index for the event

is calculated from *prn_e* and *N* (the number of *used channels*) by first calculating the value *remappingIndex* as:

$$remappingindex = \left\lfloor \left(\frac{N \times prn\_e}{2^{16}} \right) \right\rfloor$$

and then using *remappingIndex* as an index into the remapping table to obtain the channel index for the event.

In either case, the value *remappingIndexOfLastUsedChannel* is the index in the remapping table of the channel index for the event. This value is only needed for subevent channel selection.

The overall process is illustrated in Figure 4.58.

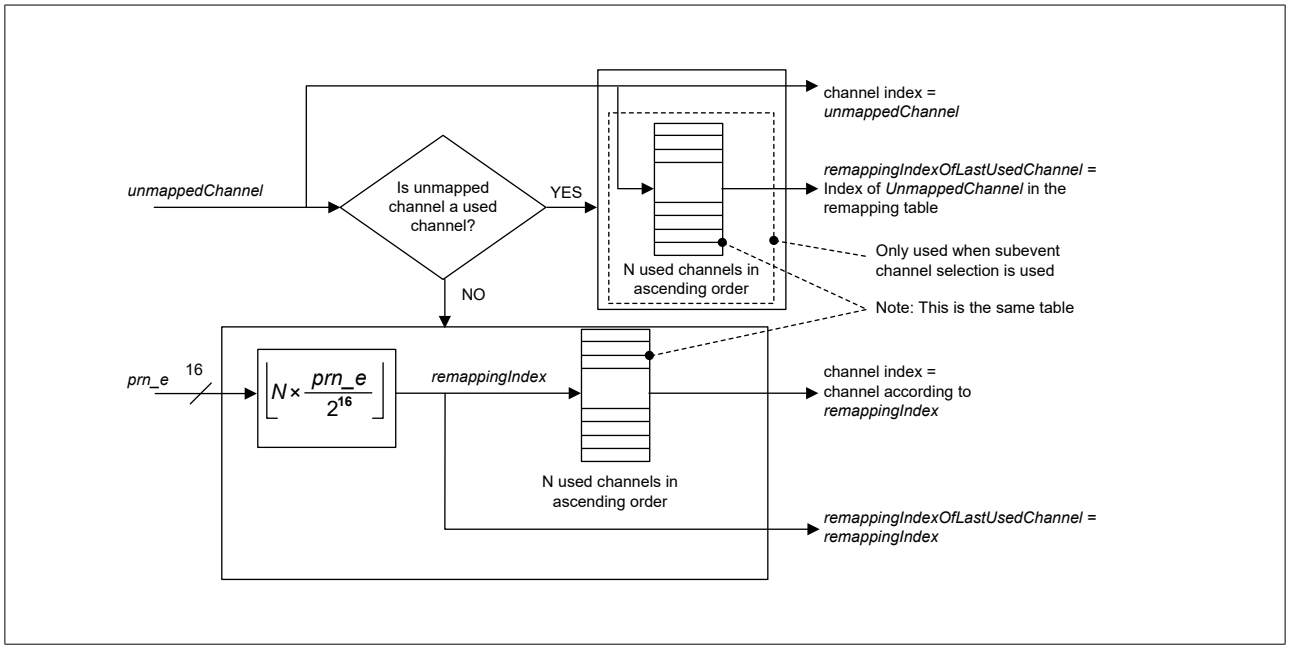

Figure 4.58: Event mapping to used channel index process

4.5.8.3.5 Subevent pseudo-random number generation

Subevent pseudo-random number generation involves generating two more pseudo-random numbers *prnSubEvent_se* and *prnSubEvent_lu* for each subevent except the first. The process shall be as shown in Figure 4.59.

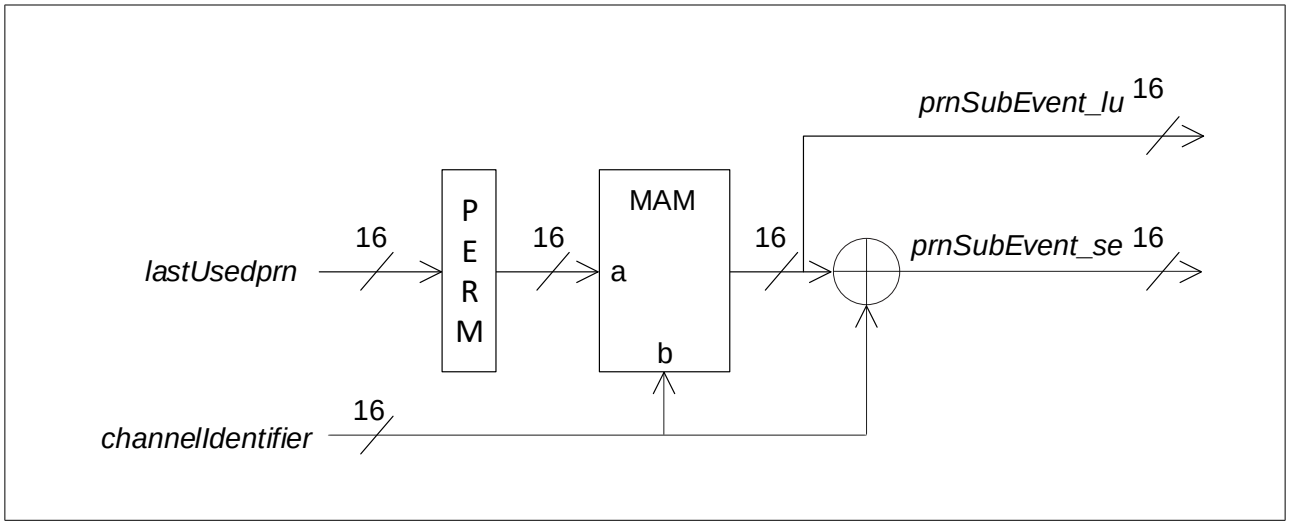

Figure 4.59: Subevent pseudo-random number generation process

Where:

$$lastUsedprn_{se\_n} = \begin{cases} prn\_s & for\ se\_n = 2 \\ prnSubEvent\_lu_{se\_n-1} & for\ se\_n > 2 \end{cases}$$

4.5.8.3.6 Subevent mapping to used channel index

The channel index for a subevent is determined in two stages: calculating the subevent index *subEventIndex* and then indexing into the remapping table. The value *subEventIndex* is calculated as:

$$subEventIndex_{se\_n} = \left(indexOfLastUsedChannel_{se\_n} + d + \left\lfloor prnSubEvent\_se_{se\_n} \times \frac{N - 2d + 1}{2^{16}} \right\rfloor\right) \bmod N$$

where *indexOfLastUsedChannel* is:

$$indexOfLastUsedChannel_{se\_n} = \begin{cases} remappingIndexOfLastUsedChannel & for\ se\_n = 2 \\ subEventIndex_{se\_n-1} & for\ se\_n > 2 \end{cases}$$

and *d* is calculated as:

$$d = max\left(1, max\left(min(3, N - 5), min\left(11, \left\lfloor \frac{N - 10}{2} \right\rfloor\right)\right)\right)$$

where *d* is the minimum distance between the channel indices used in consecutive subevents.

The value of *subEventIndex* is then used as an index into the remapping table. The overall process is illustrated in Figure 4.60.

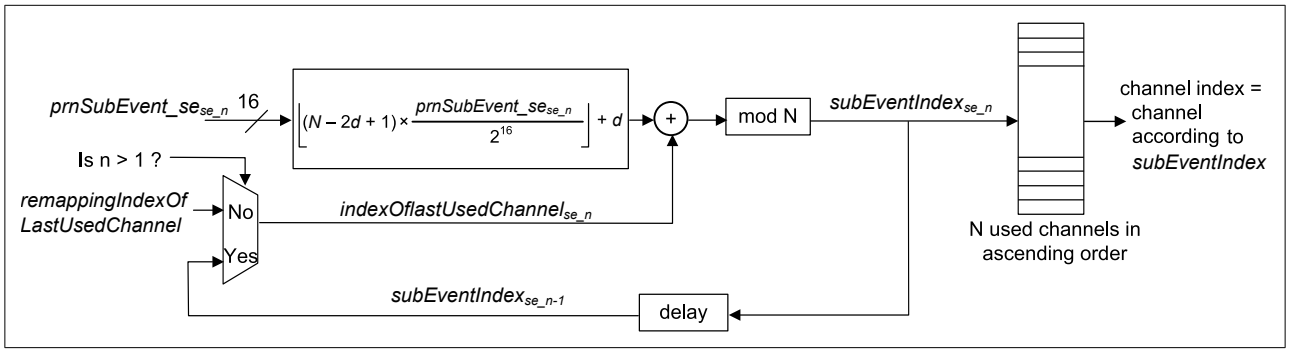

Figure 4.60: Subevent mapping to used channel index process

4.5.9 Acknowledgment and flow control

The Link Layer acknowledgment and flow control scheme shall be used in all ACL connections and CISes. Unless specified otherwise, the unqualified use of “PDU” in this section means either a Data Physical Channel PDU or a CIS Data PDU.

For each connection the Link Layer has two parameters, *transmitSeqNum* and *nextExpectedSeqNum*, each one bit in size. The *transmitSeqNum* parameter is used to identify packets sent by the Link Layer. The *nextExpectedSeqNum* parameter is used by the Link Layer to either acknowledge the last PDU sent by the peer, or to request the peer to resend the last PDU sent.

The *transmitSeqNum* and *nextExpectedSeqNum* parameters for an ACL or CIS shall be set to zero upon entering the Connection State or when the CIS is created.

If the last Data Physical Channel PDU was sent on the LE Coded PHY, the coding scheme (see Section 2.2.3) used when resending may be the same as or different from that used in the last Data Physical Channel PDU. If the instant of a PHY Update procedure (see Section 5.1.10) occurs while a Data Physical Channel PDU is waiting to be resent, the new PHY shall be used when resending.

A new PDU is a PDU sent for the first time by the Link Layer. A last PDU is a PDU that is resent by the Link Layer. When resending a Data Physical Channel PDU, the LLID, SN, and CP fields, the CTEInfo field (if present), and the Payload field of the sent Data Physical Channel PDU shall be equal to those of the last Data Physical Channel PDU sent by the Link Layer. When resending a CIS Data PDU, the LLID, SN, NPI fields, and the Payload field of the sent CIS Data PDU shall be equal to those of the last CIS Data PDU sent by the Link Layer.

For each new PDU that is sent, the SN bit of the Header field shall be set to *transmitSeqNum*. If a PDU is resent, then the SN bit shall not be changed.

Upon reception of a PDU, the SN bit shall be compared to *nextExpectedSeqNum*. If the bits are different, then this is a resent PDU, and *nextExpectedSeqNum* shall not be changed. If the bits are the same, then this is a new PDU, and *nextExpectedSeqNum* may be incremented by one (see Section 4.5.9.1).

When a PDU is sent, the NESN bit of the Header field shall be set to *nextExpectedSeqNum*.

Upon receiving a PDU (including a CIS Null PDU), if the NESN bit of that PDU is the same as *transmitSeqNum*, then the last sent PDU has not been acknowledged and shall be resent except as specified below. If the NESN bit of the PDU is different from *transmitSeqNum*, then the last sent PDU has been acknowledged, *transmitSeqNum* shall be incremented by one, and a new PDU may be sent.

The above process is illustrated in Figure 4.61 (tSqNo means *transmitSeqNum* and nExSqNo means *nextExpectedSeqNum*).

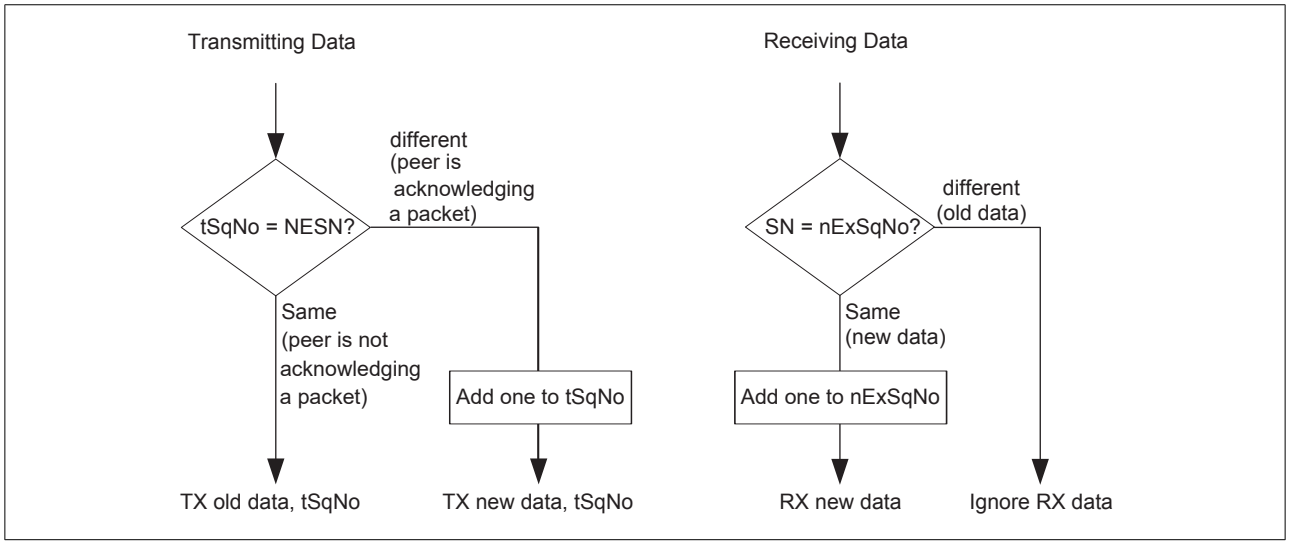

Figure 4.61: Transmit and receive SN and NESN flow diagram

If a PDU is received with an invalid CRC match, *nextExpectedSeqNum* shall not be changed except as specified below; this means that the PDU will not be acknowledged, causing the peer to resend the PDU. Since the received PDU has been rejected, the *nextExpectedSeqNum* from the peer device cannot be trusted, and therefore the last sent PDU from this device was not acknowledged and, as this section requires, must be retransmitted; *transmitSeqNum* shall not be changed.

The SN, NESN and MD bits shall be used from every received Data Physical Channel PDU which has passed the CRC check. The SN, NESN, CIE and NPI bits shall be used from every received CIS Data PDU that has passed the CRC check. The NESN, CIE and NPI bits shall be used from every received CIS Null PDU that has passed the CRC

check. The PDU Payload field shall be ignored on every received PDU that has the same SN value as the previously received PDU.

When the transmitting Link Layer either does not send a CIS Data PDU for a given payload number or sends one but does not receive an acknowledgment for that PDU by the time the flush point occurs (see Section 4.5.13.5), the *transmitSeqNum* shall be incremented by one and the PDU shall not be retransmitted after the flush point.

When the Link Layer expecting to receive a CIS Data PDU either does not receive that PDU or fails to acknowledge the PDU by the time the flush point occurs, the *nextExpectedSeqNum* shall be incremented by one and the Link Layer shall not expect the PDU to be retransmitted after the flush point.

The increments to *transmitSeqNum* and *nextExpectedSeqNum* shall not happen before the end of the CIS subevent that marks the flush point of the PDU in question.

These rules mean that both devices act, for the purposes of this section, as if, for every payload number, a CIS Data PDU was received and acknowledged at the flush point of that payload number if not before. For example, this means that two consecutive transmitted or successfully received CIS Data PDUs can have the same sequence number but different contents because the intermediate PDU was not transmitted. For any CIS Data PDU, *transmitSeqNum* will equal $cisPayloadCounter_0$.

4.5.9.1 Flow control

A Link Layer may fail to update *nextExpectedSeqNum* for reasons, including, but not limited to, lack of receive buffer space. This will cause the peer to resend the Data Physical Channel PDU at a later time, thus enabling flow control.

4.5.10 Data PDU length management

The Controller shall maintain the following global parameters.

Note: All parameters with "Octets" in the name represent the length of the Payload field of an LL Data PDU. All parameters with "Time" in the name represent the time taken to transmit a packet in microseconds.

- *connInitialMaxTxOctets* - the value of *connMaxTxOctets* that the Controller will use for a new connection.
- *connInitialMaxTxTime* - a value that the Controller will use to determine the value of *connMaxTxTime* that it will use for a new connection.
- *connInitialMaxTxTimeUncoded* - the value of *connMaxTxTime* that the Controller will use for a new connection on an LE Uncoded PHY. The value of *connInitialMaxTxTimeUncoded* shall be the greater of 328 and the value of *connInitialMaxTxTime*.

- *connInitialMaxTxTimeCoded* - the value of *connMaxTxTime* that the Controller will use for a new connection on the LE Coded PHY. The value of *connInitialMaxTxTimeCoded* shall be the greater of 2704 and the value of *connInitialMaxTxTime*.
- *supportedMaxTxOctets* - the maximum value of *connMaxTxOctets* that the Controller supports.
- *supportedMaxTxTime* - the maximum value of *connMaxTxTime* that the Controller supports.
- *supportedMaxRxOctets* - the maximum value of *connMaxRxOctets* that the Controller supports.
- *supportedMaxRxTime* - the maximum value of *connMaxRxTime* that the Controller supports.

Note: 2704 µs is derived from the duration of a packet with a 27 octet Payload field when sent on the LE Coded PHY using S=8 coding.

The Controller shall maintain the following parameters for each connection:

- *connMaxTxOctets* - the maximum number of octets in the Payload field that the local device will send to the remote device.
- *connMaxRxOctets* - the maximum number of octets in the Payload field that the local device is able to receive from the remote device.
- *connRemoteMaxTxOctets* - the maximum number of octets in the Payload field that the remote device will send to the local device.
- *connRemoteMaxRxOctets* - the maximum number of octets in the Payload field that the remote device is able to receive from the local device.
- *connMaxTxTime* - the maximum number of microseconds that the local device will take to transmit a packet to the remote device.
- *connMaxRxTime* - the maximum number of microseconds that the local device can take to receive a packet from the remote device.
- *connRemoteMaxTxTime* - the maximum number of microseconds that the remote device will take to transmit a packet to the local device.
- *connRemoteMaxRxTime* - the maximum number of microseconds that the remote device can take to receive a packet from the local device.

The values of the above parameters (both global and per-connection) shall each be within the range given in Table 4.8:

LE Data Packet Length Extension feature supported	LE Coded PHY feature supported	CTEs supported on Data Physical Channel PDUs	Parameters with names containing "Octets"		Parameters with names containing "Time"	
			Minimum	Maximum	Minimum	Maximum
No	No	No	27	27	328	328
Yes	No	No	27	251	328	2120
No	No	Yes	27	27	328	336
Yes	No	Yes	27	251	328	2128
No	Yes	Don’t care	27	27	328	2704
Yes	Yes	Don’t care	27	251	328	17040

Table 4.8: Valid ranges for data PDU length management parameters

The following values are derived from the parameters maintained by the Controller:

- *connEffectiveMaxTxOctets* - the lesser of *connMaxTxOctets* and *connRemoteMaxRxOctets*.
- *connEffectiveMaxRxOctets* - the lesser of *connMaxRxOctets* and *connRemoteMaxTxOctets*.
- *connEffectiveMaxTxTimeUncoded* - the lesser of *connMaxTxTime* and *connRemoteMaxRxTime*.
- *connIntervalRequired* - the value T_IFS_ACL_CP + T_MCES + min (*connEffectiveMaxRxTime*, ((*connEffectiveMaxRxOctets* × 64) + 976)).
- *connIntervalUncodedMin* - *connIntervalRequired* + 328.
- *connIntervalCodedMin* - *connIntervalRequired* + 2704.

  Note: 976 µs and 2704 µs are the durations of packets with a zero octet and 27 octet Payload field when sent on the LE Coded PHY using S=8 coding.
- *connIntervalPortionAvailable* - the current *connInterval* for the connection minus *connIntervalRequired*.
- *connEffectiveMaxTxTimeAvailable* - the lesser of *connEffectiveMaxTxTimeUncoded* and *connIntervalPortionAvailable*.
- *connEffectiveMaxTxTimeCoded* - the greater of 2704 and *connEffectiveMaxTxTimeAvailable*.

- *connEffectiveMaxTxTime* - equal to *connEffectiveMaxTxTimeUncoded* while the connection is on an LE Uncoded PHY and equal to *connEffectiveMaxTxTimeCoded* while the connection is on the LE Coded PHY.
- *connEffectiveMaxRxTimeUncoded* - the lesser of *connMaxRxTime* and *connRemoteMaxTxTime*.
- *connEffectiveMaxRxTimeCoded* - the greater of 2704 and *connEffectiveMaxRxTimeUncoded*.
- *connEffectiveMaxRxTime* - equal to *connEffectiveMaxRxTimeUncoded* while the connection is on an LE Uncoded PHY and equal to *connEffectiveMaxRxTimeCoded* while the connection is on the LE Coded PHY.

Note: Corresponding octet and time parameters do not have to be mutually consistent. For example, it is permissible for a time parameter to be 2120 µs even though, on some PHYs, the maximum possible time is less.

The Controller shall not change the values of *supportedMaxTxOctets*, *supportedMaxTxTime*, *supportedMaxRxOctets*, and *supportedMaxRxTime*.

For a new connection:

- *connMaxTxOctets* shall be set to *connInitialMaxTxOctets* and *connMaxRxOctets* shall be chosen by the Controller. If either value is not 27 then the Controller should initiate the Data Length Update procedure (Section 5.1.9) at the earliest practical opportunity.
- *connRemoteMaxTxOctets* and *connRemoteMaxRxOctets* shall be 27.

For a new connection on an LE Uncoded PHY:

- *connMaxTxTime* shall be set to *connInitialMaxTxTimeUncoded* and *connMaxRxTime* shall be chosen by the Controller. If either value is not 328, then the Controller should initiate the Data Length Update procedure (Section 5.1.9) at the earliest practical opportunity.
- *connRemoteMaxTxTime* and *connRemoteMaxRxTime* shall be 328.

For a new connection on the LE Coded PHY:

- *connMaxTxTime* shall be set to *connInitialMaxTxTimeCoded* and *connMaxRxTime* shall be chosen by the Controller. If either value is not 2704, then the Controller should initiate the Data Length Update procedure (Section 5.1.9) at the earliest practical opportunity.
- *connRemoteMaxTxTime* and *connRemoteMaxRxTime* shall be 2704.

The Controller may change the values of *connMaxTxOctets, connMaxRxOctets, connMaxTxTime,* and *connMaxRxTime* at any time after entering the Connection

State. Whenever it does so, it shall communicate these values to the peer device using the Data Length Update procedure. The values shall not exceed the values of *supportedMaxTxOctets*, *supportedMaxTxTime*, *supportedMaxRxOctets*, and *supportedMaxRxTime* respectively.

The values of *connMaxTxOctets*, *connMaxRxOctets*, *connMaxTxTime*, and *connMaxRxTime* can be used to represent limitations in the implementation; for example, *connMaxRxOctets* can be set to the size of the receiver's data buffer or *connMaxTxTime* can be set so that the transmitter frequency will not have enough time to drift outside permitted limits. Their values are only restricted by Table 4.8 and there is no requirement to change them because, for example, the current value is greater than the largest possible value on a new PHY.

The Controller shall not transmit packets containing LL Data PDUs that have a maximum Payload field length greater than *connEffectiveMaxTxOctets* or that take more than *connEffectiveMaxTxTime* microseconds to transmit (excluding any Constant Tone Extension) except during the period where the values of either *connEffectiveMaxTxOctets* or *connEffectiveMaxTxTime* are being modified. During that period, the Controller may still have LL Data PDUs queued for transmission that conformed to the old parameters but violate the new ones. These PDUs remain valid; only PDUs queued after the Data Length Update procedure has completed are required to conform to the changed parameters. However, a Controller should ensure that it has no LL Data PDUs queued for transmission when it transmits an LL_LENGTH_REQ or LL_LENGTH_RSP PDU.

Note: These requirements do not apply to LL Control PDUs (see Section 4.5.11).

If the Controller decreases the value of *connMaxRxOctets* or *connMaxRxTime*, it shall not apply the new values until a Data Length Update procedure (Section 5.1.9) that sends the new value has completed.

The Controller shall notify its Host if any of the parameters *connEffectiveMaxTxOctets*, *connEffectiveMaxRxOctets*, *connEffectiveMaxTxTime*, or *connEffectiveMaxRxTime* have changed.

Note: These parameters can change as part of a Data Length Update procedure (Section 5.1.9), a PHY Update procedure (Section 5.1.10), a Connection Update procedure (Section 5.1.1), or a Connection Parameters Request procedure (Section 5.1.7).

4.5.11 Control PDU length management

The Link Layer shall not transmit a packet containing an LL Control PDU with a CtrData field longer than 26 octets until it has successfully completed a Feature Exchange procedure (see Section 5.1.4) on the same connection.

If the Link Layer in the Central role supports receiving LL Control PDUs with a CtrData field longer than 26 octets, it should initiate the Feature Exchange procedure on each connection.

Note: As specified in Section 4.6, once the feature exchange has completed, the Link Layer must not use a procedure that the peer did not mark as supported. Therefore the Link Layer will never transmit an LL Control PDU with a CtrData field longer than 26 octets to a device that does not support it.

4.5.12 Connection termination and loss

An ACL or CIS connection can be terminated by either Link Layer using the ACL Termination procedure (see Section 5.1.6) or the CIS termination procedure (see Section 5.1.16) respectively. A connection can also be considered lost for various reasons. The Host shall be notified when the termination procedure completes, irrespective of whether the Central or Peripheral initiated it.

If an ACL connection is considered lost, the Link Layer shall not send or receive any further packets on the Data Physical Channel for the ACL connection or on the Isochronous Physical Channel for any associated CIS. The Link Layer shall exit the Connection State, shall transition to the Standby State, and shall notify the Host of the loss of the ACL and of any associated CIS.

If a CIS is considered lost, the Link Layer shall not send or receive any further packets on the Isochronous Physical Channel and shall notify the Host of the loss of the CIS. The associated ACL connection shall not be affected, except that the Link Layer shall not send any further PDUs related to that CIS on the ACL connection.

4.5.13 Connected Isochronous Stream (CIS)

A CIS is a logical transport that enables connected devices to transfer isochronous data in either direction. The data may be fixed or variable size and may be framed or unframed. The isochronous data can be transferred either in an LE-S or LE-F logical link using the CIS logical transport. Each CIS shall be associated with an ACL.

A CIS supports variable size packets and transmission of one or more packets in each CIS event, allowing a range of data rates to be supported. Data traffic is unidirectional or bidirectional between the devices. There is an acknowledgment protocol to improve the reliability of packet delivery in a CIS.

4.5.13.1 CIS parameters

Each CIS shall have an identifier, denoted as CIS_ID, that is assigned by the Host. The CIS_ID shall be sent to the Peripheral's Host via the two Link Layers as part of creation of the CIS, but is not otherwise used by the Link Layer.

Each CIS is defined by the following parameters:

- ISO_Interval is the time between the CIS anchor points of adjacent CIS events.
- Sub_Interval is the time between start of two consecutive subevents of a CIS.
- SE_Length is the time that needs to be reserved for a subevent.
- Max_PDU is the maximum number of data octets that can be carried in each CIS Data PDU; the value may be different in each direction.
- Max_SDU is the maximum size of an SDU on this CIS (see [Vol 6] Part G, Section 1); the value may be different in each direction.
- MPT_C and MPT_P shall equal the time taken by the Central and Peripheral respectively to transmit a packet containing a CIS PDU with a Payload field of Max_PDU octets (for that direction) on the PHY being used for the CIS; on the LE Coded PHY, the S=8 coding shall be assumed. These values should include the MIC if it is possible that the CIS will be encrypted.
- NSE is the maximum number of subevents in each CIS event.
- BN and FT control which data is transmitted in each CIS event; the values may be different in each direction.
- Framed indicates whether the CIS carries framed or unframed data; the value shall be the same in both directions.
- Framing mode indicates whether Segmentable or Unsegmented mode is being used when the CIS carries framed data. The value shall be the same in both directions.

These parameters shall not change during the lifetime of the CIS. They are discussed further in the following subsections. The mandatory range for each parameter is the entire range of valid values except for the following, where only the listed values are mandatory:

- BN: 0 and 1
- NSE: all supported values of BN except 0
- FT: 1

Note: The encryption status of a CIS follows the encryption status of the associated ACL.

Both the Central and Peripheral shall have a 39-bit counter *cisEventCounter*. It shall be set to 0 for the first CIS event of a CIS and incremented by 1 for each CIS event whether or not the Central transmits any Connected Isochronous PDUs during the event.

Each CIS shall have a 39-bit *cisPayloadCounter* associated with it, described further in Section 4.5.13.3. The Link Layer of the Central and Peripheral shall terminate the CIS no later than when *cisPayloadCounter* equals $2^{39} - 1$.

4.5.13.2 CIS events and subevents

A CIS event is an opportunity for the Central and Peripheral to exchange CIS PDUs; CIS events occur at regular intervals. Each CIS event in turn contains NSE subevents. Each subevent can be used to transmit a CIS PDU from the Central to the Peripheral followed by a response from the Peripheral to the Central. As described in Section 4.5.13.4, not all subevents are always used in an event.

Each CIS event starts at a moment called the CIS anchor point and ends when closed as specified in Section 4.5.13.4. The CIS anchor points shall be spaced regularly, ISO_Interval apart.

The first subevent of a CIS event starts at the CIS anchor point. The start of two consecutive subevents of a CIS shall be Sub_Interval apart. A subevent ends at the end of the Peripheral's packet, if any, and at the end of the Central's packet if not.

Each CIS event normally contains at least one CIS PDU sent by the Central. The Central can, however, completely fail to transmit in a CIS event due to scheduling conflicts but shall transmit at least one CIS PDU within each CIS supervision timeout.

The length of a particular CIS event is at most (NSE − 1) × Sub_Interval + MPT_C + T_IFS_CIS + MPT_P.

The Link Layer shall transmit CIS PDUs only in CIS events. The Link Layer shall transmit only CIS PDUs as part of a CIS event.

Figure 4.62 shows a CIS with two subevents.

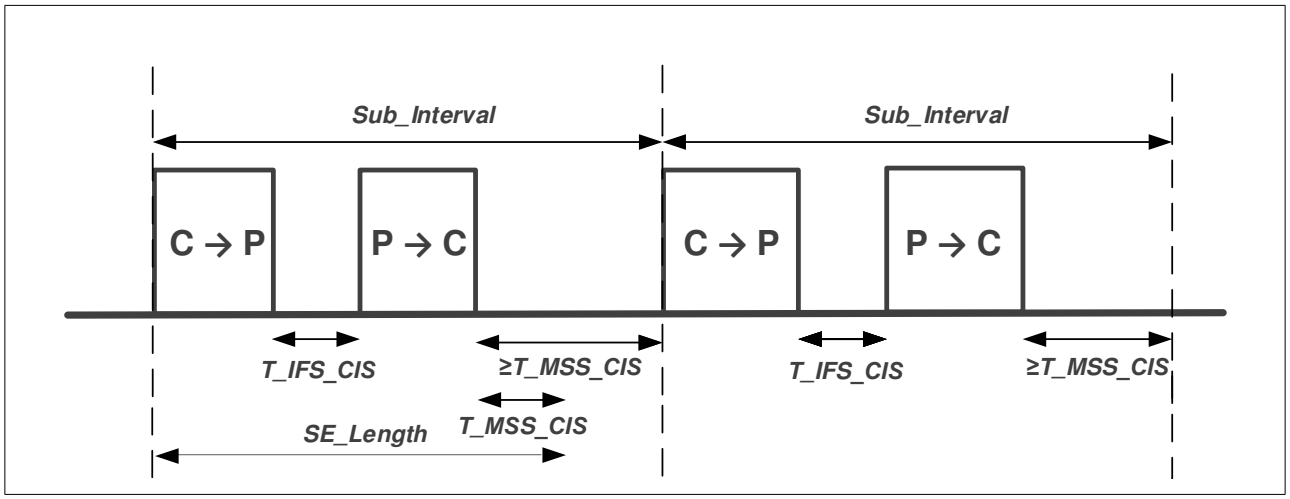

Figure 4.62: Example of two CIS subevents

Figure 4.63 shows an example of a CIS event where not all the subevents are used.

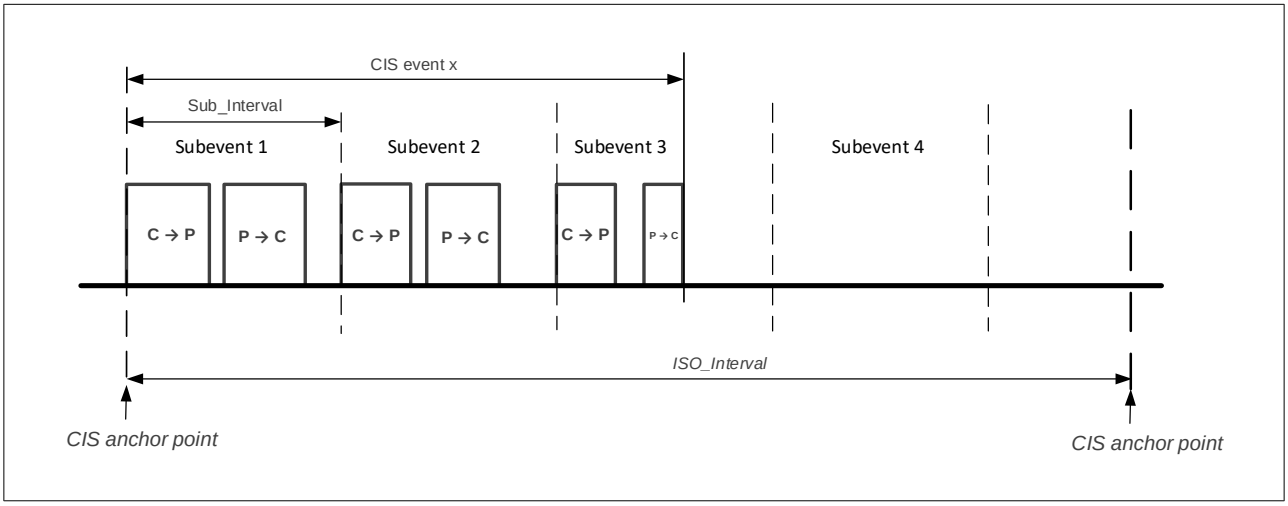

Figure 4.63: Example of a CIS event in a CIS with NSE = 4 and 3 actual subevents

The Central should transmit a packet at the start of each subevent until the event is closed. If the Peripheral receives a packet from the Central, regardless of whether the CRC is valid, it may transmit a response T_IFS_CIS after the end of the Central's packet. The Peripheral shall not transmit if it does not receive a packet from the Central in the same subevent. Where either device does not transmit during a subevent, the Link Layer shall behave for all other purposes (e.g. the timing of packets and the choice of payload) as if it had done so.

ISO_Interval shall be a multiple of 1.25 ms in the range of 5 ms to 4 s, shall be at least NSE × Sub_Interval, and shall be less than half the *connSupervisionTimeout* for the associated ACL.

SE_Length shall be MPT_C + T_IFS_CIS + MPT_P + T_MSS_CIS.

Sub_Interval shall be greater than or equal to SE_Length (also see Section 4.5.14.2).

BN shall be in the range 0 to 15. For a bidirectional link the value shall be non-zero for both directions. For a unidirectional link it shall be non-zero in the direction that data is being sent and zero in the other direction.

NSE shall be in the range max (BN_C_To_P, BN_P_To_C) to 31.

4.5.13.3 Connected Isochronous Data

A CIS carries a single stream of isochronous data in each direction or in a single direction. The data is divided into payloads of at most Max_PDU octets, each of which is transmitted as the Payload field of a single CIS Data PDU; the payloads need not all be the same size and can be zero length.

Note: Max_PDU is the size of the data and excludes the MIC in the CIS Data PDU, if any. Therefore, it has a value in the range 0 to 251.

The Framed parameter of a CIS shall indicate whether the CIS is framed or unframed. Framed CISes shall only use framed CIS Data PDUs to carry data; unframed CISes shall only use unframed CIS Data PDUs to carry data.

For each CIS event the source of the data shall supply, via ISOAL, a burst of data consisting of up to BN payloads, each of which in turn shall hold either a single fragment or one or more SDU segments, or shall be empty. This burst is associated with the corresponding CIS event but the payloads may be transmitted in later events as well; they shall not be transmitted in earlier events. These payloads shall be numbered in order (though not necessarily consecutively); this number shall be used as the value of *cisPayloadCounter* for the PDU containing that payload. The burst of payloads associated with the CIS event where *cisEventCounter* has the value E shall consist of payloads with *cisPayloadCounter* between E × BN and (E + 1) × BN - 1.

CIS Null PDUs do not have a payload and so do not have a *cisPayloadCounter*.

The payloads shall be transmitted in the order provided. In those subevents that the Link Layer transmits on, it shall continue to retransmit the same CIS Data PDU until either it is acknowledged or the data within it has reached its flush point. The Link Layer shall not transmit the CIS Data PDU with *cisPayloadCounter* N until either payload number N-1 has reached its flush point or the CIS Data PDU with *cisPayloadCounter* N-1 (if any) has been acknowledged (therefore if payload number N-1 is not provided, payload number N will be delayed until that flush point; the source of the data can provide an empty payload to avoid or reduce this delay). The Link Layer shall not transmit a payload after its flush point. If the source of the data fails to provide a payload in time for a CIS subevent, then the Link Layer shall either transmit a CIS Null PDU instead or not transmit on that subevent.

Note: It is not specified how the payload numbers assigned by ISOAL are communicated to the Link Layer or how the receiving Link Layer communicates the payload numbers to ISOAL.

Note: If BN is zero, then no payloads are provided and therefore the Link Layer will only transmit CIS Null PDUs.

4.5.13.4 Closing CIS events

The Link Layer shall close a CIS event at the end of its last subevent.

The Central or Peripheral may close a CIS event early and may indicate this to the peer device by setting the Close Isochronous Event (CIE) bit. A device that sends a CIS PDU with the CIE bit set to 1 shall not transmit in the remaining subevents in the current CIS event.

Note: Link Layer implementations will normally end a CIS event early when all the scheduled payloads in both directions have been transmitted and acknowledged.

4.5.13.5 Flush Timeout and Flush Points

The Flush Timeout (FT) parameter is the maximum number of CIS events that may be used to transmit (and retransmit) a given payload. FT shall be between 1 and 255. Each payload number shall have a flush point: a point in time at which the corresponding payload and associated CIS Data PDU, if any, shall be discarded by the Link Layer. The flush point of a payload number occurs immediately after U subevents in the CIS event with *cisEventCounter* equal to (E + FT – 1), where:

- E = floor (*cisPayloadCounter* ÷ BN)
- U = NSE – floor (NSE ÷ BN) × (BN – 1 – *cisPayloadCounter mod* BN)

Figure 4.64 and Figure 4.65 show examples of data transmissions and payloads reaching their flush points. In these figures, "ACK" and "NAK" have the meaning given in Figure 4.61.

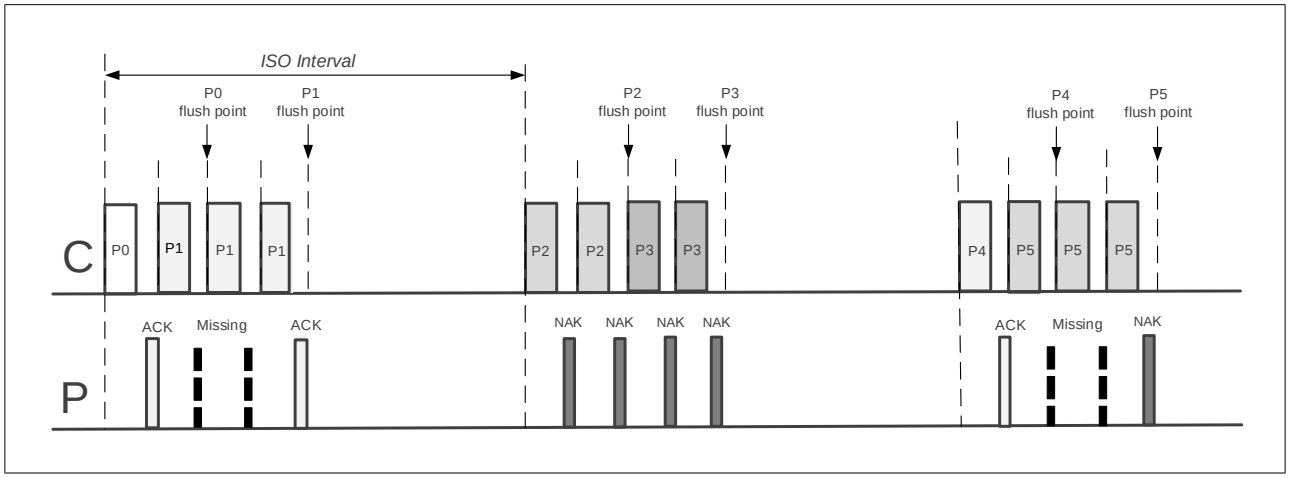

Figure 4.64: Example of flush points with BN=2, FT=1, and NSE=4

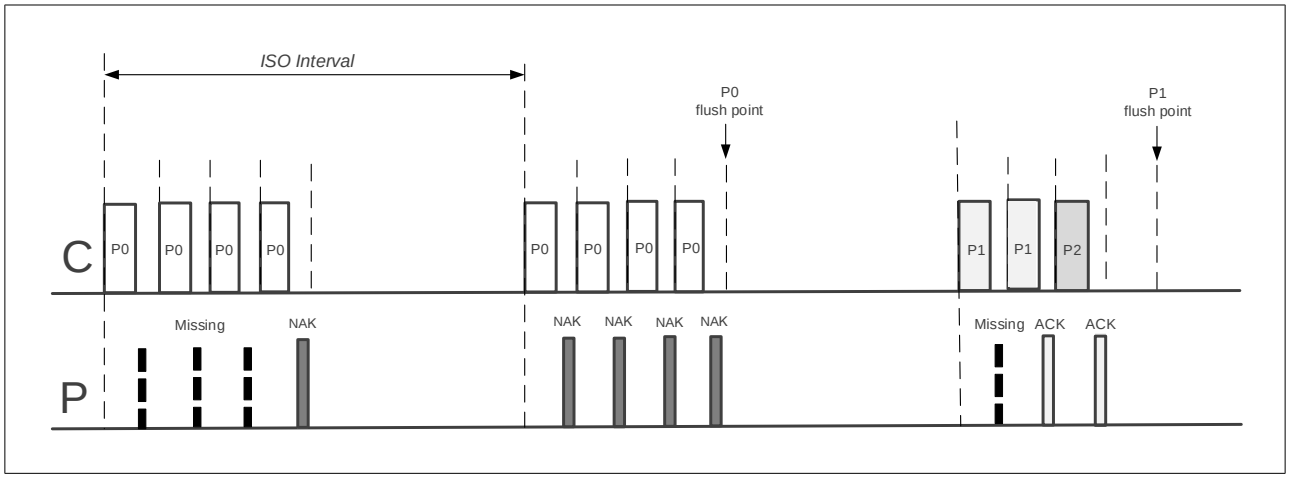

Figure 4.65: Example of flush points with BN=1, FT=2, and NSE=4

4.5.13.6 Channel indices

Each packet containing a CIS PDU shall be transmitted on the channel index specified by Channel Selection Algorithm #2 (see Section 4.5.8.3). The subevent number *se_n* shall be set to the values 1 to NSE, in order, for the subevents of each CIS event. The Peripheral shall transmit on the same channel index as the Central. The channel map used by the CIS shall be the same as the channel map of the associated ACL.

4.5.13.7 CIS Encryption

If an ACL is not encrypted, any associated CIS shall not be encrypted. If an ACL is encrypted, all associated CISes shall be encrypted, in which case all CIS Data PDUs (except those with an empty Payload field) on those CISes shall be encrypted using the same session key as that used by the associated ACL.

4.5.14 Connected Isochronous Group (CIG)

A CIG consists of either two or more CISes that have the same ISO_Interval and are expected to have a time relationship at the application layer, or of a single CIS. The maximum number of CISes in a CIG shall be 31. An implementation in the Central role is not required to support CIGs with more than 1 CIS.

The Central's Host assigns an identifier to each CIG, denoted by the parameter CIG_ID. The CIG_ID shall be sent to the Peripheral's Host via the two Link Layers as part of creation of each CIS in the CIG but is not otherwise used by the Link Layer.

All CISes in a CIG shall have the same Central but may have different Peripherals.

All CISes in a CIG shall have the same value of FT applying from the Central to the Peripheral and the same value of FT applying from the Peripheral to the Central (these two values may be different).

All CISes in a CIG shall have the same Framed configuration and the same Framing_Mode.

All CISes in a CIG shall have different CIS_IDs, but if a CIS is terminated or considered lost its configuration remains stored within the CIG so that another CIS may then be created in the same CIG with the same CIS_ID and configuration. The configuration is deleted when the CIG is removed.

The Link Layer may use different parameters for a CIS each time that it is created provided that the parameters meet the configuration provided by the Host.

On the Central, a CIG represents a data structure within the Link Layer and does not involve any connection separate from the CISes that make it up. On the Peripheral(s), it represents those CISes with the same CIG_ID.

4.5.14.1 CIG event

A CIG event consists of the corresponding CIS events of the CISes currently making up that CIG. Each CIG event starts at the anchor point of the earliest (in transmission order) CIS of the CIG and ends at the end of the last subevent of the latest CIS of the same CIG event. Two CIG events on the same CIG shall not overlap (that is, the last CIS event of a given CIG event shall end before the first CIS anchor point of the next CIG event).

The Central's Link Layer shall provide timing parameters (CIS_Sync_Delay and CIG_Sync_Delay) to the Peripherals' Link Layers which enable synchronization of isochronous data at the application layer.

Each CIG event shall have a CIG reference point and a CIG synchronization point; these shall be CIG_Sync_Delay apart. Each CIG event shall start no earlier than the CIG reference point and shall end no later than the CIG Synchronization point. For a given CIS, the CIS anchor point shall be a fixed offset (which may be zero) after the CIG reference point; therefore CIG reference points are spaced ISO_Interval apart and CIG synchronization points are also spaced ISO_Interval apart. For each CIS, CIS_Sync_Delay shall equal the time from the CIS anchor point to the CIG synchronization point.

Figure 4.66 shows the various elements of a CIG event.

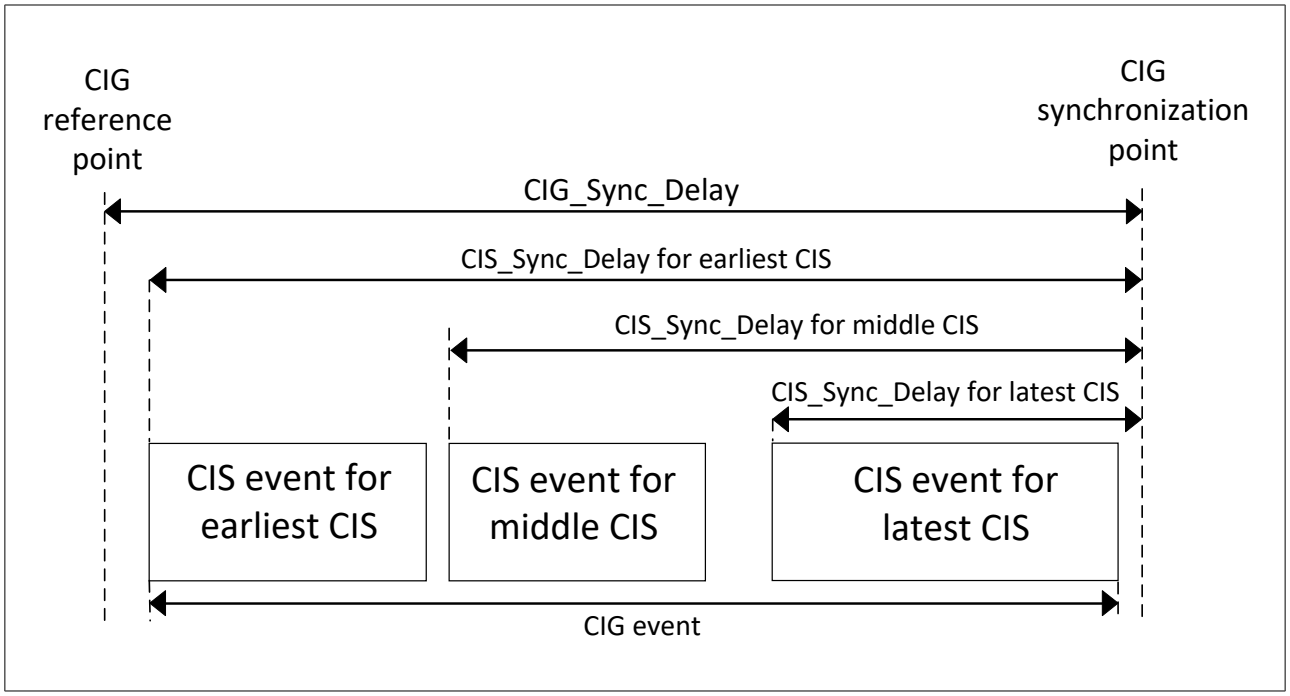

Figure 4.66: Layout of a CIG event with three CISes

Note: CIG_Sync_Delay will be no less than the maximum possible time for a CIG event; i.e. the time from the CIG reference point to the end of the Peripheral's packet in the last subevent when both Central and Peripheral transmit packets containing Max_PDU octets. It will have the same value for all CISes in the same CIG. CIS_Sync_Delay for each CIS will equal CIG_Sync_Delay minus the offset from the CIG reference point to the CIS anchor point. The actual maximum possible time for a CIG event cannot be determined until all the CISes in the CIG have been created. Therefore the value that the Central sends is an upper bound.

Note: The maximum possible time for a CIS event equals (NSE − 1) × Sub_Interval + MPT_C + T_IFS_CIS + MPT_P for that CIS.

Note: The CIS events making up a CIG event need not have the same values of *cisEventCounter*, but the difference between the counters will be the same for the lifetime of the CIG.

4.5.14.2 Arrangement of multiple CISes

The CISes in a CIG shall be arranged either sequentially or interleaved by setting the values of the Sub_Interval and the spacing between the CIS anchor points appropriately.

If they are sequential, the CIS events of the different CISes do not overlap and so all the subevents of a CIS event occur together. For each adjacent pair of CISes, the interval

between their CIS anchor points shall be at least NSE × Sub_Interval, using the values for the lower numbered CIS.

If they are interleaved, all the first subevents of the CISes are adjacent, followed by the second subevents, and so on. For each CIS, its value of Sub_Interval shall be at least the sum of the values of SE_Length for all the CISes in the CIG. For each adjacent pair of CISes, the interval between their CIS anchor points shall be at least SE_Length of the lower numbered CIS.

Figure 4.67 shows each arrangement for a CIG with two CISes and NSE = 2.

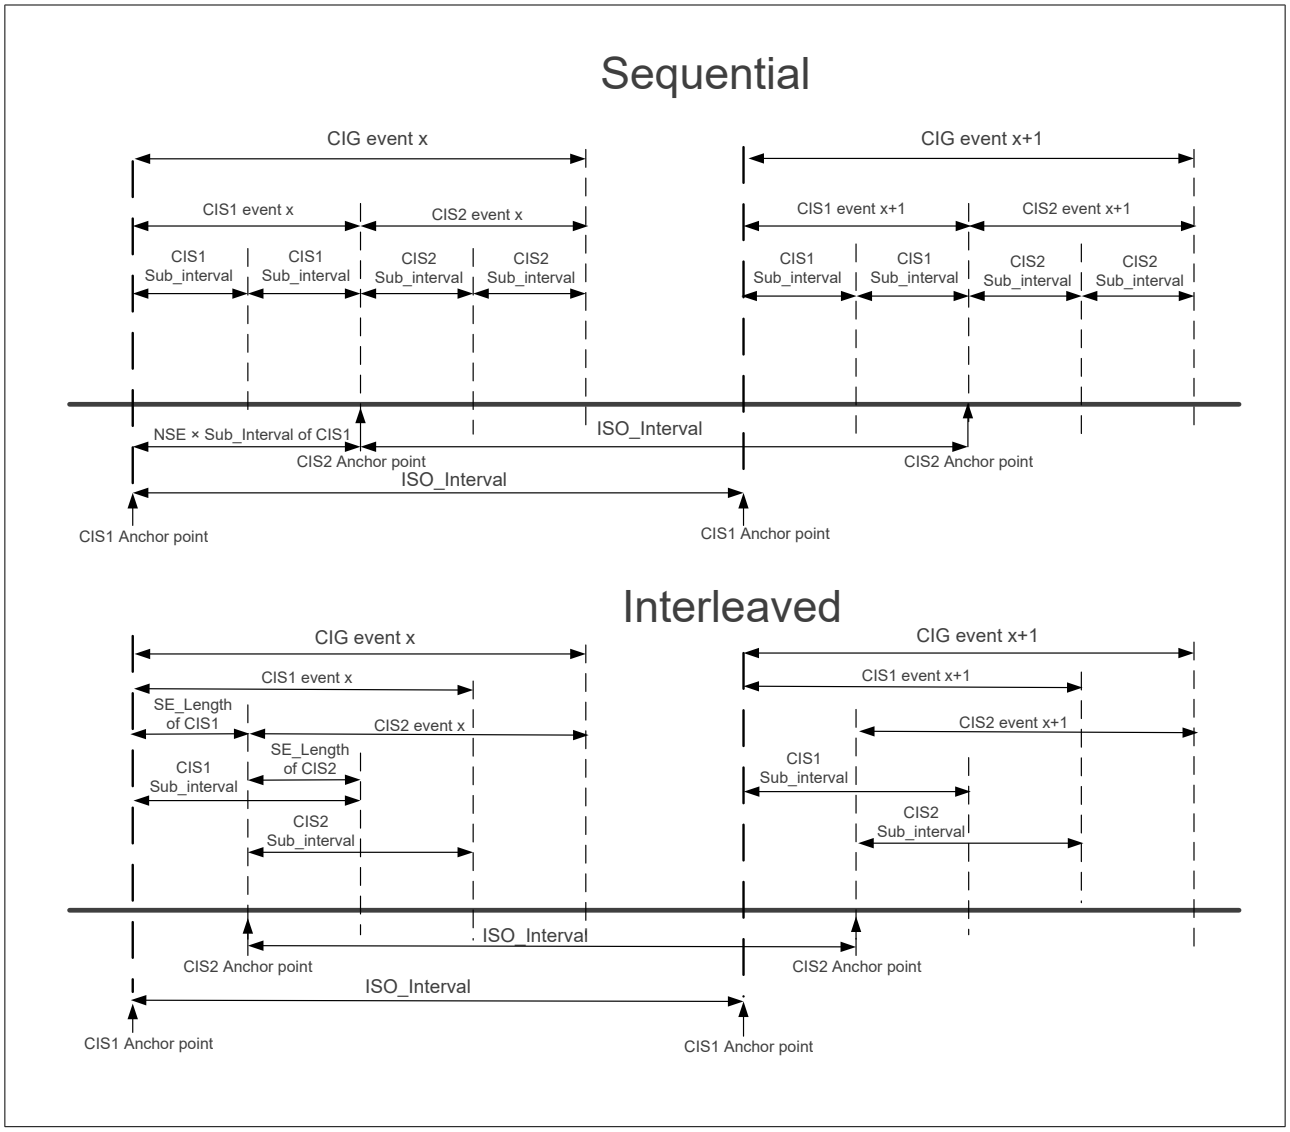

Figure 4.67: CIG event with events for two CISes in sequential and interleaved arrangement

4.5.14.3 States of a CIG

On the Central, a CIG has three states: configurable, active, and inactive. When the Host creates the CIG, it shall be in the configurable state. When the Host creates a CIS in the CIG, if the CIG is not already in the active state, then the Controller shall change the state of the CIG to active. When all CISes in a CIG are terminated or considered lost, the Controller shall change the state of the CIG to inactive. If the Host sends an explicit request to remove the CIG and the CIG is not in the active state, then the Controller shall remove the CIG.

The Host configures the CIG by notifying the Link Layer of the individual configurations of CIS(es) to be stored within the CIG. The Link Layer shall only change the configuration when requested by the Host and while the CIG is in the configurable state.

If the Link Layer is unable to schedule a CIG of the requested configuration, it shall notify the Host and not create any of the CISes in the CIG.

Note: The Controller can use the configuration information to determine whether it is able to schedule all the CISes in the CIG without conflict with each other or other activities. If it is unable to do so, it can notify the Host when requested to create the first CIS. Once it has successfully created a schedule, subsequent CISes can then be created without any risk of conflict. Figure 4.68 illustrates the states of a CIG and the CIS configurations stored within it.

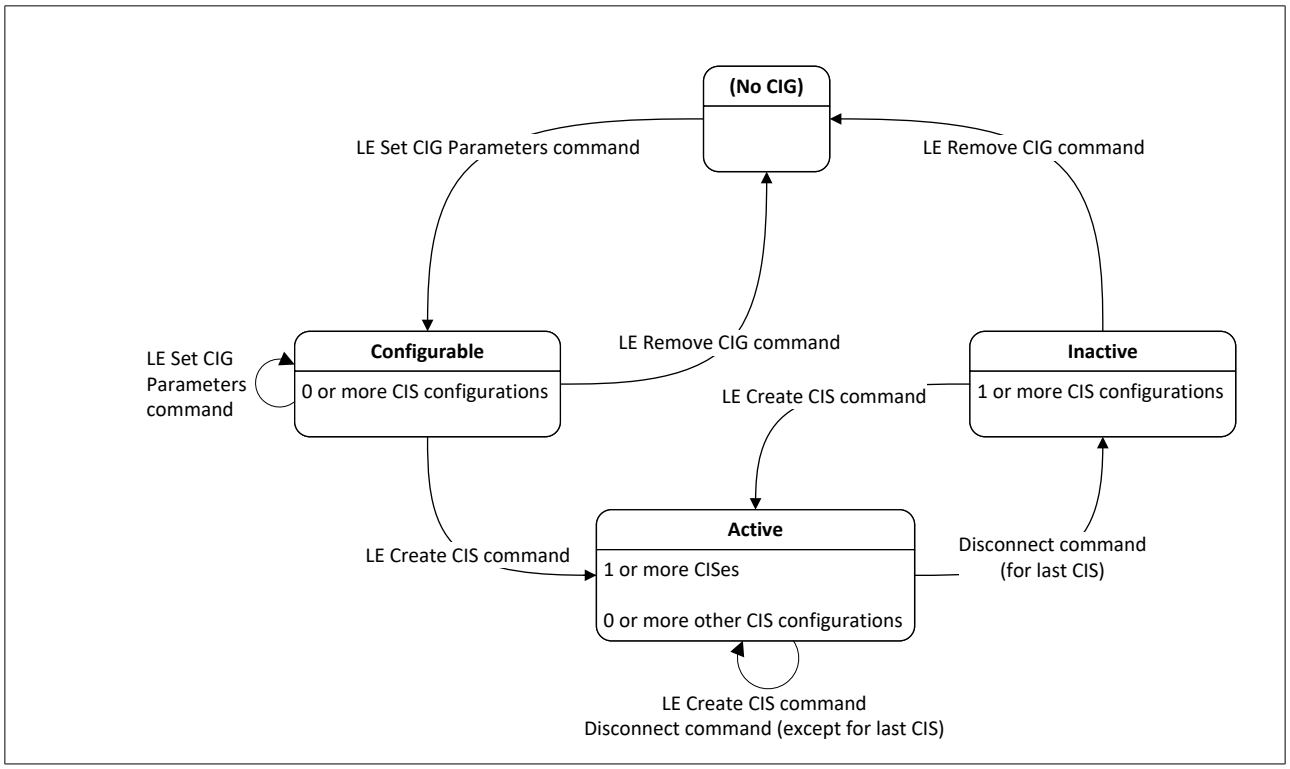

Figure 4.68: States of a CIG and its CIS configurations

4.5.15 Power level management

A Link Layer that supports power control shall manage power levels on all active PHYs for a given peer and may manage power levels for some or all non-active PHYs that it supports. An active PHY for a peer is the current PHY for the ACL connection to that peer or a PHY for an associated CIS. This implies that, when a CIS is created on a new PHY or the ACL connection changes to a new PHY, the Link Layer must start managing that PHY if it doesn't already do so.

When a device is managing the power level for a PHY, it shall store the power level for that PHY and shall transmit all packets to the peer on that PHY using that power level. The device shall change the power level when requested by the peer and may change it autonomously.

If a device starts to manage the power level for a PHY (e.g. because it has become an active PHY) then the implementation shall choose an initial power level.

Where a PHY has more than one power level, then the different power levels shall be treated as separate PHYs for the purpose of this section, the Power Control Request procedure (see Section 5.1.17), and the Power Change Indication procedure (see Section 5.1.18). In the case of the LE Coded PHY, the two power levels are "packets transmitted with an S=8 payload" and "packets transmitted with an S=2 payload"; the power level shall not change during a packet. Nevertheless, both shall be active or inactive at the same time.

4.5.16 Path loss monitoring

The Host may request the Controller to perform path loss monitoring on an ACL connection. There shall be two path loss zones, called the Low and Middle zones, and optionally a third High zone. The Controller shall notify the Host whenever the path loss changes from one zone to another. The path loss is defined as the difference between the remote transmit power level and the average local RSSI measurement for the connection; how measurements are averaged is not specified. The path loss shall be deemed to have entered a new zone when it becomes greater than or equal to the upwards boundary when moving to a higher zone or becomes less than or equal to the downwards boundary when moving to a lower zone, as shown in Figure 4.69, and, in each case, has spent at least the minimum time specified in the new zone if one is specified. For each pair of zones, the upwards boundary shall be greater than or equal to the downwards boundary and should not be equal so as to provide some hysteresis.

The zone boundaries in each direction and, optionally, the minimum time to spend in a new zone are specified by the Host.

The Controller may notify the Host when the path loss becomes unavailable. If so, it shall notify the Host when the path loss becomes available again as if it had just changed zones.

Two consecutive reports shall not indicate entering the same zone.

Notes:

- Path loss can be measured by making use of the Power Control Request procedure or the Power Change Indication procedure to obtain the remote transmit power level, and by making local RSSI measurements.
- Path loss is often correlated with distance from the peer device and, therefore, moving to a higher zone might indicate that the peer has moved further away.
- A Controller may use path loss measurements from associated physical links, such as CISes, when determining path loss threshold events on the ACL connection.

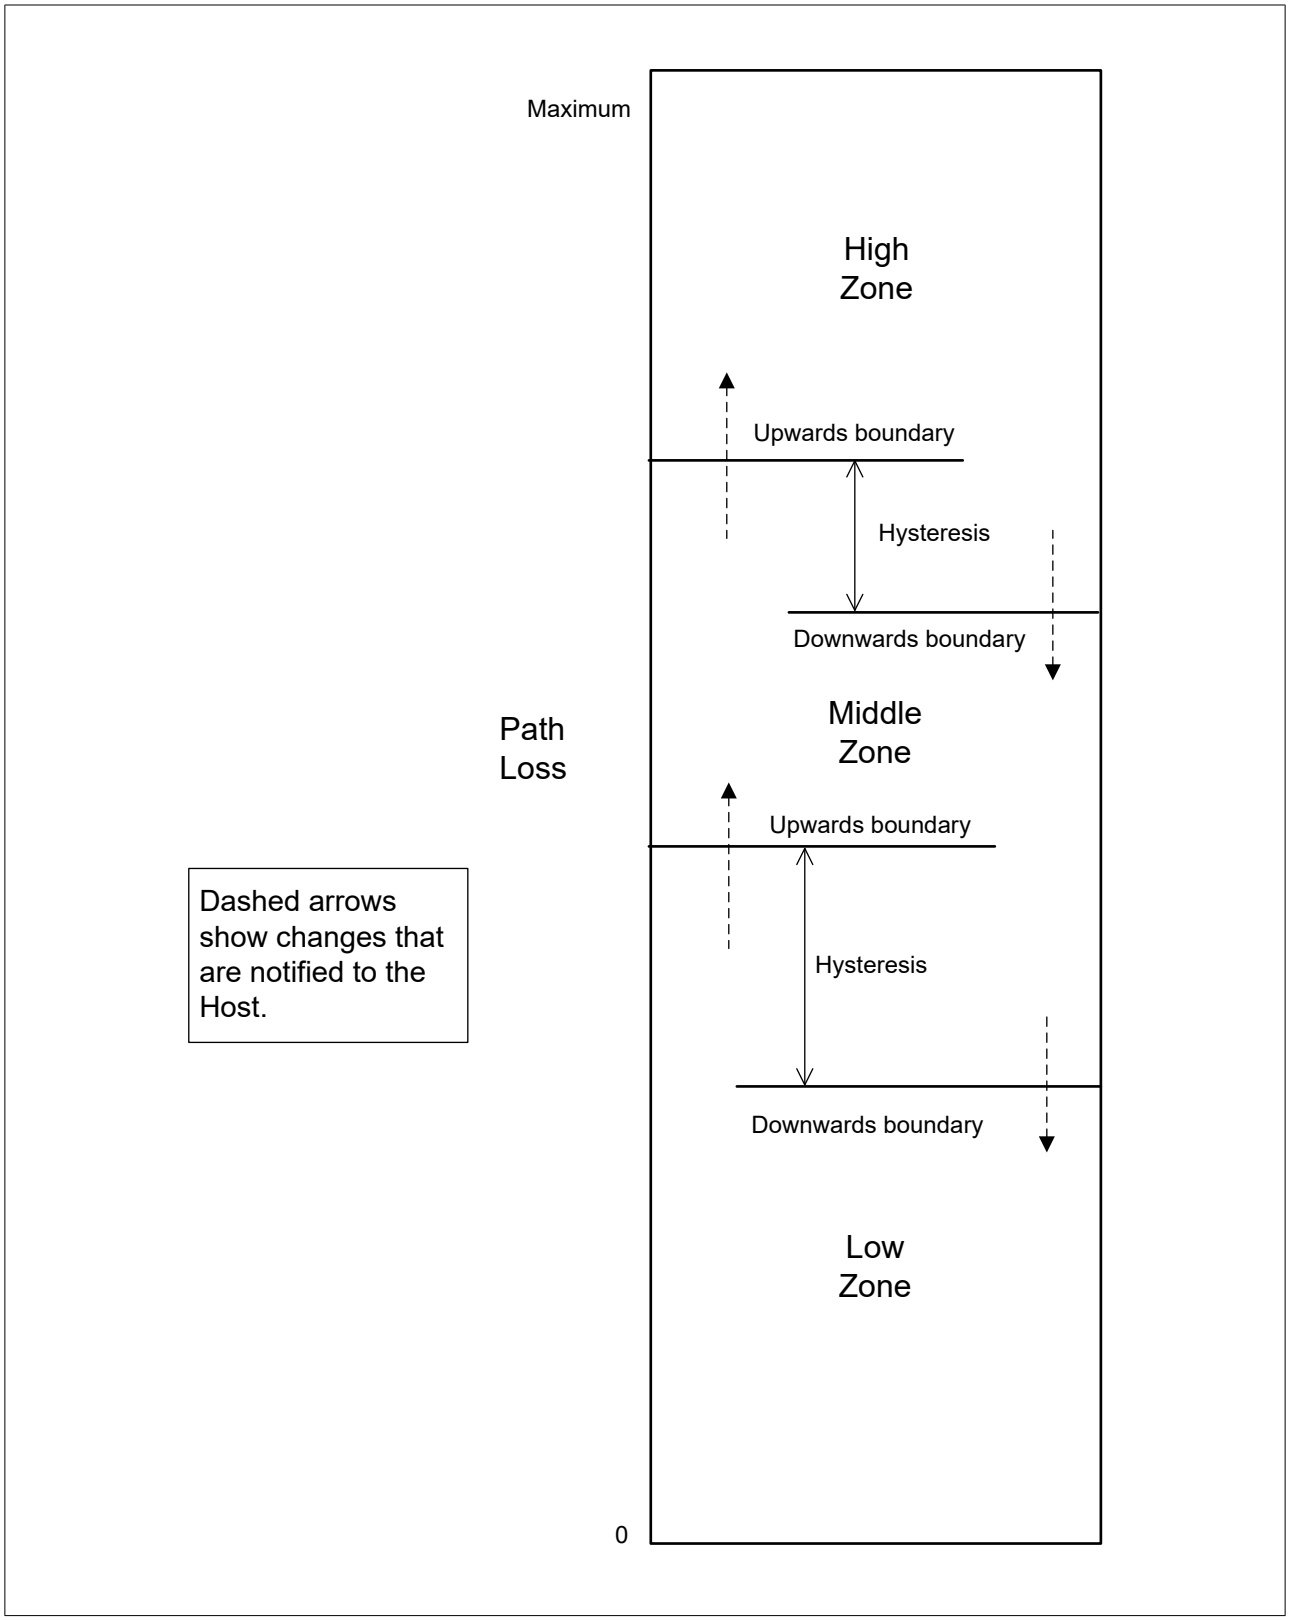

Figure 4.69: Path loss notification zones

4.5.17 ACL data Host transport

For each logical link, the Controller shall transmit data over the air in the same order that it is received from the Host. The boundaries between packets over the air for a specific L2CAP PDU may be different from the boundaries in the data provided by the Host. Each new L2CAP PDU shall start a new packet over the air. (See [Vol 3] Part A, Section 7.2.1 for related requirements in L2CAP.)

For each logical link, the Controller shall transmit the data received over the air to the Host (whether over HCI or otherwise) in the same order that it was received. The boundaries in the data sent to the Host for a specific L2CAP PDU may be different from the boundaries between packets received over the air. The Controller shall retain boundaries between L2CAP PDUs. Data from different logical links may be interleaved. (See [Vol 3] Part A, Section 7.2.2 for related requirements in L2CAP.)

4.5.18 Channel Sounding

A CS procedure is subdivided into one or more CS events which each contain one or more CS subevents, which in turn may contain two or more CS steps. The duration of a CS subevent is selected during the CS Start procedure as described in Section 5.1.26. The maximum duration of a CS event and subevent may extend to the processing time for the entire CS procedure and is negotiated during the CS Configuration procedure.

Both devices shall have a 16-bit CS procedure counter (*CSProcCount*), which increments before the start of each CS procedure occurrence. *CSProcCount* shall wrap from 0xFFFF to 0x0000.

4.5.18.1 Channel Sounding procedures and subevents

During the CS Start procedure described in Section 5.1.26, CS procedures may be set up to run one or more procedure instances in a sequential manner. The selection of the LE connection event anchor point used for the scheduling of the first CS procedure is also described in Section 5.1.26, as is the selection of the following parameters which are used in the scheduling of additional CS procedure instances:

- T_PROCEDURE_INTERVAL – the number of LE connection intervals between the LE connection event anchor points from which subsequent CS procedure instances are offset.
- N_PROCEDURE_COUNT – the number of consecutive CS procedures to execute.

CS procedures may be run for more than one occurrence known as CS procedure repeat instances, as indicated by N_PROCEDURE_COUNT. Figure 4.70 shows an example with T_PROCEDURE_INTERVAL = 4 and N_PROCEDURE_COUNT = 4. In Figure 4.70, the length shown for each CS procedure is not intended to match the entire span of T_PROCEDURE_INTERVAL.

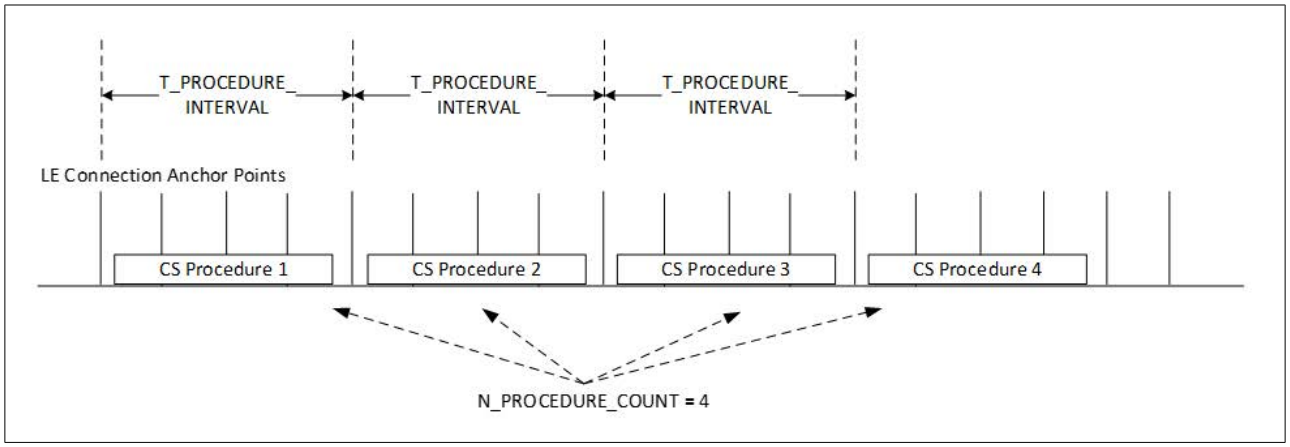

Figure 4.70: CS procedure reoccurrence with N_PROCEDURE_COUNT = 4

Within a CS procedure, there shall be 1 to N_MAX_SUBEVENTS_PER_PROCEDURE CS subevents, where N_MAX_SUBEVENTS_PER_PROCEDURE is equal to 32. CS subevents are composed of a structured sequence of CS steps. CS steps are described in [Vol 6] Part H, Section 4.3. The minimum number of CS steps in a CS subevent shall be N_MIN_STEPS_PER_SUBEVENT, where N_MIN_STEPS_PER_SUBEVENT is equal to 2. The maximum number of CS steps within any CS subevent shall be N_MAX_STEPS_PER_SUBEVENT, where N_MAX_STEPS_PER_SUBEVENT is equal to 160. The maximum number of CS steps in a CS procedure, N_STEPS_MAX, shall be 256. The first CS step for each CS subevent shall be a mode-0 step. Multiple mode-0 steps may be selected to begin each CS subevent within a CS procedure.

The following CS event and subevent parameters are exchanged during the CS configuration and start procedures (see Section 5.1.25 and Section 5.1.26).

- T_SUBEVENT_LEN – the maximum duration of a CS subevent, in units of 625 microseconds.
- T_EVENT_OFFSET – the time in microseconds between the LE connection event anchor point and the beginning of the CS event.
- T_EVENT_INTERVAL – the time in units of LE connection intervals between the LE connection event anchor points from where the start of two consecutive CS events are offset.
- T_SUBEVENT_INTERVAL – the time in units of 625 microseconds between the beginning of a CS subevent and the beginning of the next CS subevent within the same CS event.
- N_SUBEVENTS_PER_EVENT – the number of CS subevents in a CS event.

CS events are scheduled at regular intervals based on the timing of the LE connection event anchor points of the underlying LE connection, as shown in Figure 4.71. CS events are scheduled with an offset from an ACL anchor point. This offset is specified

in microseconds. The extent of a CS event may exceed that of the underlying LE connection interval. In Figure 4.71, connInterval is the LE connection interval as defined in Section 4.5.1.

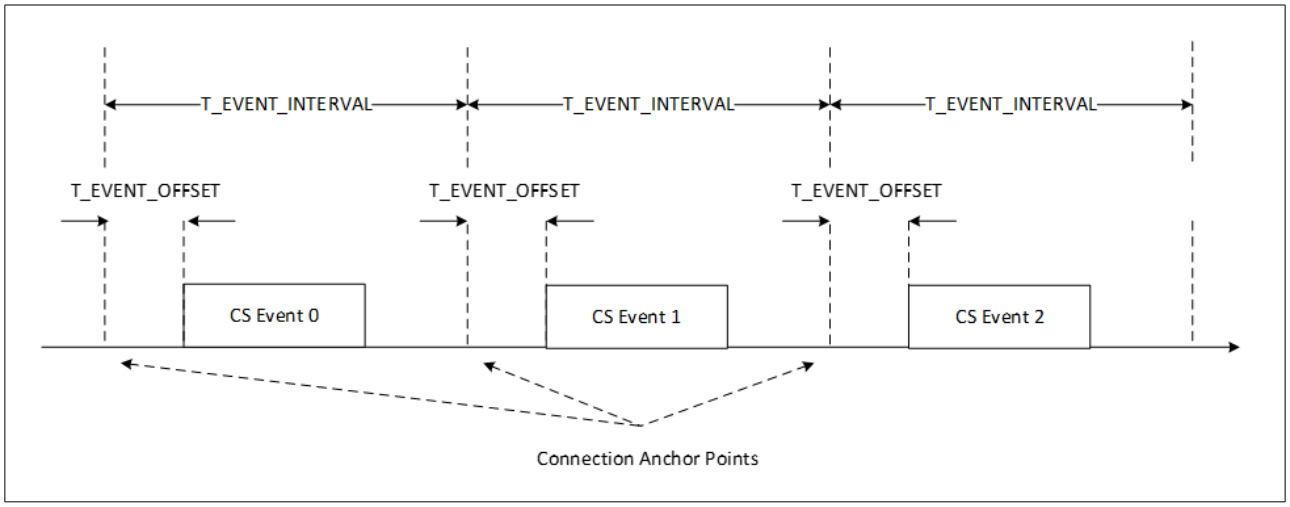

Figure 4.71: CS event scheduling offset from ACL anchor points

To accommodate various coexistence scenarios, a Controller may schedule more than one CS subevent within a CS event, as shown in Figure 4.72. The first CS subevent within a CS event shall always occur T_EVENT_OFFSET from the connection event anchor point. Subsequent CS subevents within that CS event shall occur T_SUBEVENT_INTERVAL from the start of the prior CS subevent. The value of T_SUBEVENT_INTERVAL shall be greater than the selected duration of CS subevents, T_SUBEVENT_LEN, plus a minimum subevent spacing value of T_MES (see Section 4.1.4). The extent of a CS subevent may exceed that of the underlying LE connection interval.

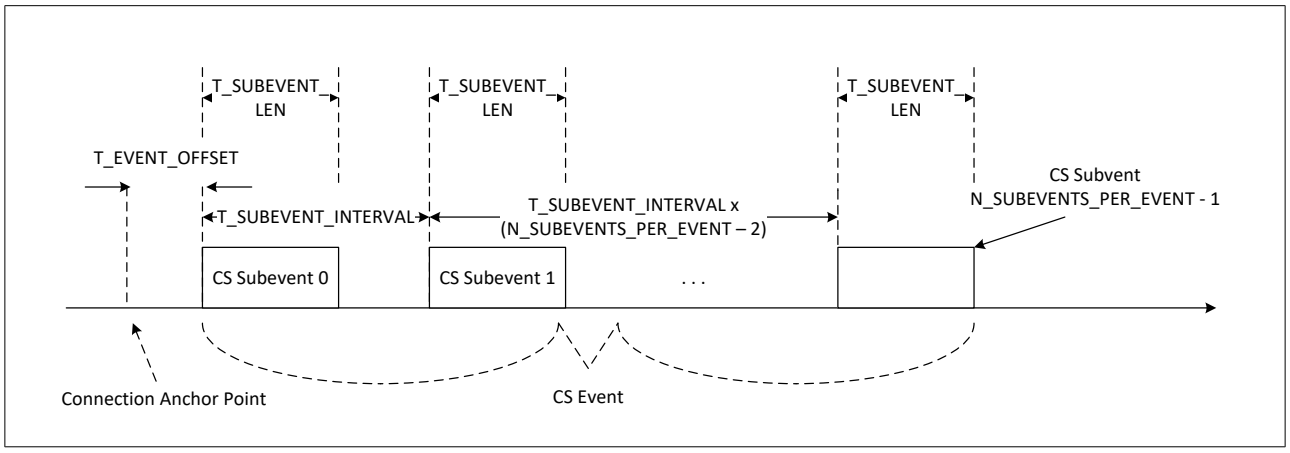

Figure 4.72: Multiple CS subevents of one CS event scheduled from the same LE connection event anchor point

Within a CS subevent, the duration of each CS step will vary based on the mode selected for that step, the duration of the CS tone selected if mode-2 or mode-3 is being used, the type of the selected RTT exchange (with or without the optional sounding sequence or random sequence) if mode-1 or mode-3 is being used, or other selectable factors. As a result, the number of CS steps included in each CS subevent may also vary. After a CS step is processed within a CS subevent, there may be a remaining duration in that subevent. A Link Layer shall not begin the next CS step within a CS subevent unless the remaining duration within that subevent is greater than or equal to the time needed to fully include that CS step.

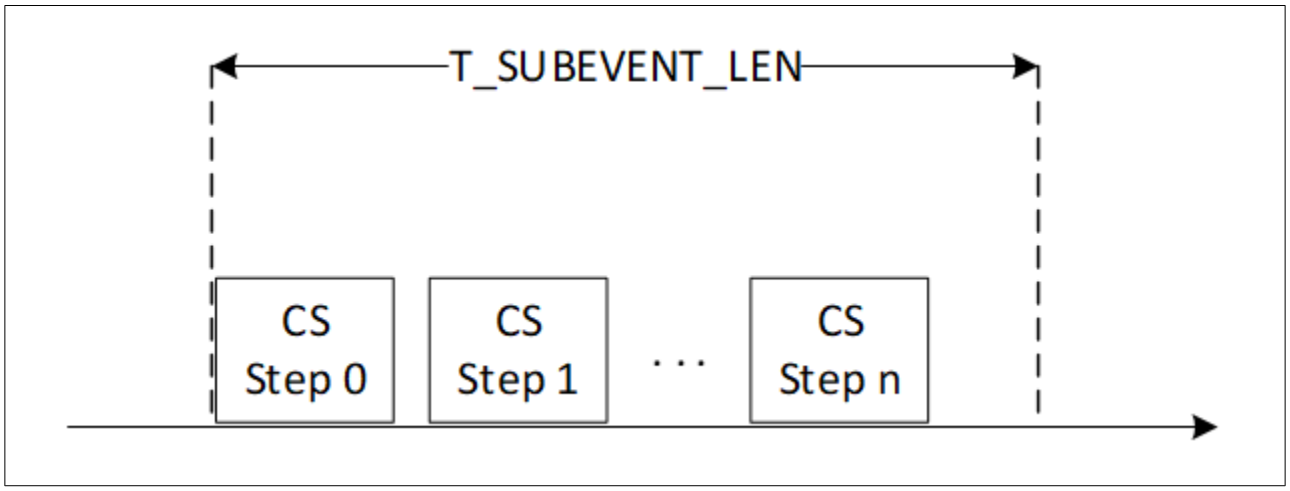

Figure 4.73: CS subevent maximum extent

A Controller that supports CS should be capable of reporting all result data generated from that procedure. When starting a CS procedure as described in Section 5.1.26, a Controller shall report an error to the Host if the Controller determines that it has insufficient resources to collect and report all procedure results for that procedure.

If the Controller has insufficient resources to hold result information for a specific CS subevent, the Controller shall discard the result information for that subevent and report this action to the Host.

In addition, at the start of any subsequent CS procedure instance a Controller shall discard any remaining CS procedure result data that it may be holding for a previous CS procedure instance, under the following circumstances:

- The Controller has been instructed to run multiple CS procedure instances, and
- The Controller has already discarded CS subevent result information for the previous CS procedure instance.

The remaining CS procedure result data is discarded so that enough resources are available for the newly started procedure instance. The Controller shall also report this action to the Host.

4.5.18.2 Channel Sounding security

The ACL shall be encrypted before the CS feature is used, as well as before any of the following LL control PDU exchanges:

- LL_CS_SEC_REQ
- LL_CS_SEC_RSP
- LL_CS_CAPABILITIES_REQ
- LL_CS_CAPABILITIES_RSP
- LL_CS_CONFIG_REQ
- LL_CS_CONFIG_RSP
- LL_CS_REQ
- LL_CS_RSP
- LL_CS_IND
- LL_CS_TERMINATE_REQ
- LL_CS_TERMINATE_RSP
- LL_CS_FAE_REQ
- LL_CS_FAE_RSP
- LL_CS_CHANNEL_MAP_IND

4.6 Feature support

The set of features supported by a Link Layer is represented by a bit mask called FeatureSet. This mask consists of 1984 bits divided into page 0 containing bits 0 to 63 (octets 0 to 7) and 10 pages of 192 bits (24 octets) each, numbered starting from 1 (i.e., page 1 is octets 8 to 31, page 2 is octets 32 to 55, etc.).

The value of FeatureSet shall not change while the Controller has a connection to another device. A peer device may cache information about features that the device supports. The Link Layer may cache information about features that a peer supports during a connection.

Within FeatureSet, a bit set to 0 indicates that the Link Layer feature is not supported in this Controller; a bit set to 1 indicates that the Link Layer feature is supported in this Controller.

Except where explicitly stated elsewhere in this specification, if the peer Link Layer has indicated either during a feature exchange procedure or by responding with an LL_UNKNOWN_RSP PDU that it does not support a procedure, then the Link Layer

shall not use that procedure. A Link Layer shall not transmit a PDU listed in the following subsections unless it supports at least one of the features that requires support for that PDU.

Unless explicitly stated otherwise, when a Link Layer supports a feature it shall support it on all PHYs that the Controller supports.

The bit positions for each Link Layer feature shall be as shown in Table 4.9, which also shows various properties of the feature bits. In the "Send to Peer" column:

- "Y" indicates that the bit shall be set correctly when sent to the peer.
- "O" indicates that the bit shall either be zero or set correctly when sent to the peer. The peer device shall ignore the value of this bit.
- "N" indicates that the bit shall be set to zero when sent to the peer.

When sent to the Host, the bit shall always be set correctly. If a bit is shown as Host Controlled, the value may be set by the Host and shall default to zero.

If a bit does not have "Y" for "Send to Peer", it shall not be used to determine whether a peer device supports any associated procedure.

Bit position	Link Layer Feature	Send to Peer	Host Controlled
0	LE Encryption	Y	N
1	Connection Parameters Request procedure	Y	N
2	Extended Reject Indication	Y	N
3	Peripheral-initiated Features Exchange	Y	N
4	LE Ping	O	N
5	LE Data Packet Length Extension	Y	N
6	LL Privacy	O	N
7	Extended Scanning Filter Policies	O	N
8	LE 2M PHY	Y	N
9	Stable Modulation Index - Transmitter	Y	N
10	Stable Modulation Index - Receiver	Y	N
11	LE Coded PHY	Y	N
12	LE Extended Advertising	O	N
13	LE Periodic Advertising	O	N
14	Channel Selection Algorithm #2	Y	N
15	LE Power Class 1 (see [Vol 6] Part A, Section 3)	Y	N

Bit position	Link Layer Feature	Send to Peer	Host Controlled
16	Minimum Number of Used Channels procedure	Y	N
17	Connection CTE Request	Y	N
18	Connection CTE Response	Y	N
19	Connectionless CTE Transmitter	O	N
20	Connectionless CTE Receiver	O	N
21	Antenna Switching During CTE Transmission (AoD)	O	N
22	Antenna Switching During CTE Reception (AoA)	O	N
23	Receiving Constant Tone Extensions	Y	N
24	Periodic Advertising Sync Transfer - Sender	Y	N
25	Periodic Advertising Sync Transfer - Recipient	Y	N
26	Sleep Clock Accuracy Updates	Y	N
27	Remote Public Key Validation	N	N
28	Connected Isochronous Stream – Central	Y	N
29	Connected Isochronous Stream – Peripheral	Y	N
30	Isochronous Broadcaster	Y	N
31	Synchronized Receiver	Y	N
32	Connected Isochronous Stream (Host Support)	Y	Y
33	LE Power Control Request	Y	N
34	LE Power Control Request	Y	N
35	LE Path Loss Monitoring	Y	N
36	Periodic Advertising ADI support	O	N
37	Connection Subrating	Y	N
38	Connection Subrating (Host Support)	Y	Y
39	Channel Classification	Y	N
40	Advertising Coding Selection	Y	N
41	Advertising Coding Selection (Host Support)	Y	Y
42	Decision-Based Advertising Filtering	N	N
43	Periodic Advertising with Responses - Advertiser	Y	N
44	Periodic Advertising with Responses - Scanner	Y	N
45	Unsegmented Framed Mode	Y	N
46	Channel Sounding	Y	N
47	Channel Sounding (Host Support)	Y	Y

Bit position	Link Layer Feature	Send to Peer	Host Controlled
48	Channel Sounding Tone Quality Indication	N	N
56 to 62	Reserved for specification development purposes		
63	LL Extended Feature Set	Y	N
64	Monitoring Advertisers	N	N
65	Frame Space Update	Y	N
All other bits	Reserved for future use		

Table 4.9: FeatureSet field's bit mapping to Controller features

Bits 33 and 34 shall always have the same value.

If the Link Layer supports any feature with bit number 64 or greater, then it shall also support the LL Extended Feature Set feature.

4.6.1 LE Encryption

A Controller that supports LE Encryption shall support encryption on all logical transports that it supports and the following sections of this document:

- LL_ENC_REQ (Section 2.4.2.4)
- LL_ENC_RSP (Section 2.4.2.5)
- LL_START_ENC_REQ (Section 2.4.2.6)
- LL_START_ENC_RSP (Section 2.4.2.7)
- LL_PAUSE_ENC_REQ (Section 2.4.2.11)
- LL_PAUSE_ENC_RSP (Section 2.4.2.12)
- Encryption Start procedure (Section 5.1.3.1)
- Encryption Pause procedure (Section 5.1.3.2)

4.6.2 Connection Parameters Request procedure

A Controller that supports Connection Parameters Request procedure shall support the Extended Reject Indication feature and the following sections of this document:

- LL_CONNECTION_PARAM_REQ (Section 2.4.2.16)
- LL_CONNECTION_PARAM_RSP (Section 2.4.2.17)
- Connection Parameters Request procedure (Section 5.1.7)

4.6.3 Extended Reject Indication

A Controller that supports Extended Reject Indication shall support the following sections of this document:

- LL_REJECT_EXT_IND (Section 2.4.2.18)

4.6.4 Peripheral-initiated Features Exchange

A Controller that supports Peripheral-initiated Features Exchange shall support the following sections of this document:

- LL_PERIPHERAL_FEATURE_REQ (Section 2.4.2.15)
- Receiving LL_FEATURE_RSP (see Section 2.4.2.10)

4.6.5 LE Ping

A Controller that supports LE Ping shall support the following sections of this document:

- LL_PING_REQ (Section 2.4.2.19)
- LL_PING_RSP (Section 2.4.2.20)
- LE Ping procedure (Section 5.1.8)
- LE Authenticated Payload Timeout (Section 5.4)

4.6.6 LE Data Packet Length Extension

A Controller that supports LE Data Packet Length Extension shall support the following sections of this document:

- LL_LENGTH_REQ and LL_LENGTH_RSP (Section 2.4.2.21)
- Data Length Update procedure (Section 5.1.9)

4.6.7 LL Privacy

A Controller that supports LL Privacy shall support the following sections of this document:

- Resolving List (Section 4.7)
- LL Privacy (Section 6)

4.6.8 Extended Scanning Filter Policies

A Controller that supports Extended Scanning Filter Policies shall support the following sections of this document:

- Extended Scanning Filter Policies (Section 4.3.3.1)

4.6.9 Multiple PHYs

A Controller that supports any PHY other than LE 1M PHY shall support the Extended Reject Indication feature and the following sections of this document:

- Transmission and reception using the supported modulation schemes ([Vol 6] Part A, Section 1)
- Longer preamble when supporting the LE 2M PHY (see Section 2.2.1)
- LL_PHY_REQ (Section 2.4.2.22)
- LL_PHY_RSP (Section 2.4.2.22)
- LL_PHY_UPDATE_IND (Section 2.4.2.23)
- PHY Update procedure (Section 5.1.10)

and, when supporting the LE Coded PHY:

- Packet format for the LE Coded PHY (Section 2.2)
- Coding (Section 3.3)

4.6.9.1 Symmetric and asymmetric connections

A Controller shall support connections using the same PHY in each direction (“symmetric connections”) and may support connections using different PHYs in each direction (“asymmetric connections”).

If a Controller cannot support asymmetric connections then:

- Any LL_PHY_REQ, LL_PHY_RSP, or LL_CIS_REQ PDUs sent shall indicate that it wants a symmetric connection.
- Any LL_PHY_UPDATE_IND PDU sent shall not specify an asymmetric connection.

4.6.10 Stable Modulation Index - Transmitter

A Controller that supports Stable Modulation Index - Transmitter shall support the following section of this document:

- Stable Modulation Index ([Vol 6] Part A, Section 3.1.1)

4.6.11 Stable Modulation Index - Receiver

A Controller that supports Stable Modulation Index - Receiver shall support the following section of this document:

- Stable Modulation Index ([Vol 6] Part A, Section 4.7)

4.6.12 LE Extended Advertising

A Controller that supports LE Extended Advertising shall support reception of an Advertising Physical Channel PDU Payload field of 255 octets, shall support the following sections of this document:

- ADV_EXT_IND (Section 2.3.1.5)
- AUX_ADV_IND (Section 2.3.1.6)
- AUX_CHAIN_IND (Section 2.3.1.8)
- AUX_SCAN_REQ (see Section 2.3.2.1)
- AUX_SCAN_RSP (Section 2.3.2.3)
- AUX_CONNECT_REQ (see Section 2.3.3.1)
- AUX_CONNECT_RSP (Section 2.3.3.2)
- Common Extended Advertising Payload Format (Section 2.3.4)
- Advertising Sets (Section 4.4.2.10)
- Using AdvDataInfo (ADI) (Section 4.4.2.11)
- Advertising Sets (Section 4.4.3.3)
- Connect Requests on the Secondary Advertising Physical Channel (Section 4.4.4.2)

and shall support the following sections of this document in accordance with the requirements in Section 4.4.2.13, Section 4.4.3.7, and Section 4.4.4.3:

- Connectable Directed event type using ADV_EXT_IND (Section 4.4.2.4.4)
- Scannable Undirected event type using ADV_EXT_IND (Section 4.4.2.5.2)
- Connectable Undirected event type (Section 4.4.2.7)
- Scannable Directed event type (Section 4.4.2.8)
- Non-Connectable and Non-Scannable Directed event type (Section 4.4.2.9)

A Controller that supports connections shall also support the Channel Selection Algorithm #2 feature.

4.6.13 LE Periodic Advertising

A Controller that supports LE Periodic Advertising shall support the LE Extended Advertising feature, Channel Selection Algorithm #2 feature, and the following sections of this document:

- AUX_SYNC_IND (Section 2.3.1.7)
- Periodic Advertising (Section 4.4.2.12)

A Controller that supports Scanning state shall also support the following sections of this document:

- Scanning for periodic advertisements (Section 4.4.3.4)
- Synchronization state (Section 4.4.5) for periodic advertising trains

4.6.14 Channel Selection Algorithm #2

A Controller that supports Channel Selection Algorithm #2 shall support the following sections of this document:

- ChSel bit set to 1 (see Section 2.3, Section 2.3.1.1, Section 2.3.1.2, and Section 2.3.3.1)
- Channel Selection Algorithm #2 (Section 4.5.8.3).

4.6.15 Minimum Number of Used Channels procedure

A Controller that supports the Minimum Number of Used Channels procedure shall support the following sections of this document:

- LL_MIN_USED_CHANNELS_IND (Section 2.4.2.24)
- Minimum Number Of Used Channels procedure (Section 5.1.11)

4.6.16 Connection CTE Request

A Controller that supports Connection CTE Request shall support the Receiving Constant Tone Extensions feature, the Extended Reject Indication feature, and the following sections of this document on all supported PHYs that allow Constant Tone Extensions:

- LL_CTE_REQ (Section 2.4.2.25)
- LL_CTE_RSP (Section 2.4.2.26)
- Constant Tone Extension Request procedure (Section 5.1.12) - as initiator

4.6.17 Connection CTE Response

A Controller that supports Connection CTE Response shall support the Extended Reject Indication feature and the following sections of this document on all supported PHYs that allow Constant Tone Extensions:

- LL_CTE_REQ (Section 2.4.2.25)
- LL_CTE_RSP (Section 2.4.2.26)
- Transmitting Constant Tone Extensions (Section 2.5.3)
- Constant Tone Extension Request procedure (Section 5.1.12) - as responder

4.6.18 Connectionless CTE Transmitter

A Controller that supports Connectionless CTE Transmitter shall support the LE Periodic Advertising feature in Advertising state and the following section of this document on all supported PHYs that allow Constant Tone Extensions:

- Transmitting Constant Tone Extensions (Section 2.5.3)

4.6.19 Connectionless CTE Receiver

A Controller that supports Connectionless CTE Receiver shall support the LE Periodic Advertising feature in Synchronization state and the following sections of this document on all supported PHYs that allow Constant Tone Extensions:

- Receiving Advertising Physical Channel PDUs containing a CTEInfo field in the Extended Header field (see Section 2.3.4)
- IQ Sampling (Section 2.5.4)

4.6.20 Antenna Switching During CTE Transmission (AoD)

A Controller that supports Antenna Switching During CTE Transmission (AoD) shall support the following sections of this document on all supported PHYs that allow Constant Tone Extensions:

- Transmitting Constant Tone Extensions (Section 2.5.3)
- Antenna Switching ([Vol 6] Part A, Section 5)

4.6.21 Antenna Switching During CTE Reception (AoA)

A Controller that supports Antenna Switching During CTE Reception (AoA) shall support the Receiving Constant Tone Extensions feature and the following section of this document on all supported PHYs that allow Constant Tone Extensions:

- Antenna Switching ([Vol 6] Part A, Section 5)

4.6.22 Receiving Constant Tone Extensions

A Controller that supports Receiving Constant Tone Extensions shall support the following sections of this document on all supported PHYs that allow Constant Tone Extensions:

- Receiving Data Channel PDUs with the CP bit set to 1 and containing a CTEInfo field (see Section 2.4)
- IQ Sampling (Section 2.5.4)

4.6.23 Periodic Advertising Sync Transfer - Sender

A Controller that supports Periodic Advertising Sync Transfer - Sender shall support the LE Periodic Advertising feature and the following sections of this document:

- LL_PERIODIC_SYNC_IND (Section 2.4.2.27)
- Periodic Advertising Sync Transfer procedure (Section 5.1.13) - as initiator

4.6.24 Periodic Advertising Sync Transfer - Recipient

A Controller that supports Periodic Advertising Sync Transfer - Recipient shall support the LE Periodic Advertising feature and the following sections of this document:

- LL_PERIODIC_SYNC_IND (Section 2.4.2.27)
- Periodic Advertising Sync Transfer procedure (Section 5.1.13) - as recipient

4.6.25 Sleep Clock Accuracy Updates

A Controller that supports Sleep Clock Accuracy Updates shall support the following sections of this document:

- LL_CLOCK_ACCURACY_REQ and LL_CLOCK_ACCURACY_RSP (Section 2.4.2.28)
- Sleep Clock Accuracy Update procedure (Section 5.1.14)

4.6.26 Remote Public Key Validation

A Controller that supports Remote Public Key Validation shall validate the remote public key (see [Vol 3] Part H, Section 2.3.5.6.1) sent by the Host (e.g., in the HCI_LE_Generate_DHKey command; see [Vol 4] Part E, Section 7.8.37).

4.6.27 Connected Isochronous Stream - Central and Connected Isochronous Stream - Peripheral

A Controller that supports the Connected Isochronous Stream - Central feature or the Connected Isochronous Stream - Peripheral feature shall support the Channel Selection Algorithm #2 feature, the Sleep Clock Accuracy Updates feature, the Extended Reject Indication feature, and the following sections of this document:

- LL_CIS_REQ (Section 2.4.2.29)
- LL_CIS_RSP (Section 2.4.2.30)
- LL_CIS_IND (Section 2.4.2.31)
- LL_CIS_TERMINATE_IND (Section 2.4.2.32)
- Connected Isochronous PDU (Section 2.6.1)
- Connected Isochronous Stream (Section 4.5.13)
- Connected Isochronous Group (Section 4.5.14)
- Connected Isochronous Stream Creation procedure (Section 5.1.15)
- Connected Isochronous Stream Termination procedure (Section 5.1.16)
- ISO Transmit Test Mode (Section 7.1)
- ISO Receive Test Mode (Section 7.2)
- Isochronous Adaptation Layer (ISOAL) ([Vol 6] Part G)

4.6.28 Isochronous Broadcaster

A Controller that supports the Isochronous Broadcaster feature shall support the LE Periodic Advertising feature and the following sections of this document:

- Broadcast Isochronous PDU (Section 2.6.2)
- BIG Control PDU (Section 2.6.3)
- Isochronous Broadcasting State (Section 4.4.6)
- BIG control procedures (Section 5.6)
- ISO Transmit Test Mode (Section 7.1)
- Isochronous Adaptation Layer (ISOAL) ([Vol 6] Part G)

4.6.29 Synchronized Receiver

A Controller that supports the Synchronized Receiver feature shall support the LE Periodic Advertising feature and the following sections of this document:

- Broadcast Isochronous PDU (Section 2.6.2)
- BIG Control PDU (Section 2.6.3)
- Synchronization state (see Section 4.4.5)
- BIG control procedures (Section 5.6)
- ISO Receive Test Mode (Section 7.2)
- Isochronous Adaptation Layer (ISOAL) ([Vol 6] Part G)

4.6.30 [This section is no longer used]

4.6.31 LE Power Control Request

A Controller that supports LE Power Control Request shall support the Extended Reject Indication feature and the following sections of this document:

- LL_POWER_CONTROL_REQ (Section 2.4.2.33)
- LL_POWER_CONTROL_RSP (Section 2.4.2.34)
- LL_POWER_CHANGE_IND (Section 2.4.2.35)
- Power level management (Section 4.5.15)
- Power Control Request procedure (Section 5.1.17)
- Power Change Indication procedure (Section 5.1.18)

4.6.32 LE Path Loss Monitoring

A Controller that supports LE Path Loss Monitoring shall support the following sections of this document:

- LE Path Loss Monitoring (Section 4.5.16)

4.6.33 Host-set feature bits

The Controller shall only set these bits on request from the Host. The Controller shall reject a request to set a bit if the conditions in this section are not met.

4.6.33.1 Connected Isochronous Stream (Host Support)

This feature bit indicates that the Host supports creating CISes.

The Controller shall only set this feature bit if it supports the Connected Isochronous Stream - Central or Connected Isochronous Stream - Peripheral feature.

4.6.33.2 Connection Subrating (Host Support)

This feature bit indicates that the Host supports Connection Subrating.

The Controller shall only set this feature bit if it supports the LE Connection Subrating feature.

4.6.33.3 Advertising Coding Selection (Host Support)

This feature bit indicates that the Host supports Advertising Coding Selection.

The Controller shall only set this feature bit if it supports the Advertising Coding Selection feature.

4.6.33.4 Channel Sounding (Host Support)

This feature bit indicates that the Host supports the Channel Sounding feature.

The Controller shall only set this feature bit if the Controller supports the Channel Sounding feature.

4.6.34 Periodic Advertising ADI Support

A Controller that supports the Periodic Advertising ADI Support feature shall support the LE Periodic Advertising feature and the ability to transmit and interpret the ADI field in the AUX_SYNC_IND PDU as described in the following sections of this document:

- AUX_SYNC_IND PDU (Section 2.3.1.7)
- Periodic Advertising (Section 4.4.2.12)
- Periodic Advertising Trains (Section 4.4.5.1)

A Controller that does not support the Periodic Advertising ADI Support feature shall not transmit or interpret the ADI field in the AUX_SYNC_IND PDU.

4.6.35 Connection Subrating

A Controller that supports the Connection Subrating feature shall support all valid values for *connSubrateFactor* (see Section 4.5.1) and the following sections of this document:

- LL_SUBRATE_REQ (Section 2.4.2.36)
- LL_SUBRATE_IND (Section 2.4.2.37)

- Connection Subrate Update procedure (Section 5.1.19)
- Connection Subrate Request procedure (Section 5.1.20)

A Controller that does not support the Connection Subrating feature shall only support a *connSubrateFactor* of 1.

4.6.36 Channel Classification

A Controller that supports the Channel Classification feature shall support the following sections of this document:

- LL_CHANNEL_REPORTING_IND (Section 2.4.2.38)
- LL_CHANNEL_STATUS_IND (Section 2.4.2.39)
- Channel Classification Enable procedure (Section 5.1.21)
- Channel Classification Reporting procedure (Section 5.1.22)

4.6.37 Advertising Coding Selection

A Controller that supports Advertising Coding Selection shall support the LE Extended Advertising and LE Coded PHY features and the following section of this document:

- Host selection of the coding scheme used in advertising (see Section 4.4)

and, if the Controller supports HCI:

- advertising reports specifying the coding scheme used (see [Vol 4] Part E, Section 7.7.65.13).

4.6.38 Periodic Advertising with Responses - Advertiser

A Controller that supports Periodic Advertising with Responses - Advertiser shall support the LE Periodic Advertising feature in the Advertising state, the Periodic Advertising Sync Transfer - Sender feature, and the following sections of this document:

- AUX_SYNC_SUBEVENT_IND (Section 2.3.1.9)
- AUX_SYNC_SUBEVENT_RSP (Section 2.3.1.10)
- LL_PERIODIC_SYNC_WR_IND (Section 2.4.2.40)
- Trains with responses (Section 4.4.2.12.2)

4.6.39 Periodic Advertising with Responses - Scanner

A Controller that supports Periodic Advertising with Responses - Scanner shall support the LE Periodic Advertising feature in the Scanning state, the Periodic Advertising Sync Transfer - Recipient feature, and the following sections of this document:

- AUX_SYNC_SUBEVENT_IND (Section 2.3.1.9)
- AUX_SYNC_SUBEVENT_RSP (Section 2.3.1.10)
- LL_PERIODIC_SYNC_WR_IND (Section 2.4.2.40)
- Scanning for periodic advertisements (Section 4.4.3.4)
- Trains with responses (Section 4.4.5.1.2)

4.6.40 LL Extended Feature Set

A Controller that supports the LL Extended Feature Set feature shall support the Peripheral-initiated Features Exchange feature and the following sections of this document:

- LL_FEATURE_EXT_REQ and LL_FEATURE_EXT_RSP (Section 2.4.2.41)
- Feature Page Exchange procedure (Section 5.1.4.3)

4.6.41 Channel Sounding

A Controller that supports the Channel Sounding feature shall support the Extended Reject Indication feature, the Peripheral-initiated Features Exchange feature, and the following sections of this document:

- Channel Sounding RF frequencies (see [Vol 6] Part A, Section 2)
- Stable phase ([Vol 6] Part A, Section 3.4)
- Antenna switching for Channel Sounding ([Vol 6] Part A, Section 5.3)
- Phase measurements ([Vol 6] Part A, Section 6)
- LL_CS_SEC_REQ (Section 2.4.2.42)
- LL_CS_SEC_RSP (Section 2.4.2.43)
- LL_CS_CAPABILITIES_REQ (Section 2.4.2.44)
- LL_CS_CAPABILITES_RSP (Section 2.4.2.44)
- LL_CS_CONFIG_REQ (Section 2.4.2.45)
- LL_CS_CONFIG_RSP (Section 2.4.2.46)
- LL_CS_REQ (Section 2.4.2.47)

- LL_CS_RSP (Section 2.4.2.48)
- LL_CS_IND (Section 2.4.2.49)
- LL_CS_TERMINATE_REQ (Section 2.4.2.50)
- LL_CS_TERMINATE_RSP (Section 2.4.2.50)
- LL_CS_FAE_REQ (Section 2.4.2.51)
- LL_CS_FAE_RSP (Section 2.4.2.52)
- LL_CS_CHANNEL_MAP_IND (Section 2.4.2.53)
- Minimum Channel Sounding subevent space (Section 4.1.4)
- Channel Sounding (Section 4.5.18)
- Channel Sounding Security Start procedure (Section 5.1.23)
- Channel Sounding Capabilities Exchange procedure (Section 5.1.24)
- Channel Sounding Configuration procedure (Section 5.1.25)
- Channel Sounding Start procedure (Section 5.1.26)
- Channel Sounding Procedure Repeat Termination procedure (Section 5.1.27)
- Channel Sounding Channel Map Update procedure (Section 5.1.28)
- Channel Sounding Mode-0 FAE Table Request procedure (Section 5.1.29)
- Channel Sounding ([Vol 6] Part H)

4.6.42 Channel Sounding Tone Quality Indication

A Controller that supports the Channel Sounding Tone Quality Indication feature shall support the Channel Sounding feature and the following section of this document:

- Phase measurements during T_PM ([Vol 6] Part H, Section 4.6)

4.6.43 Decision-Based Advertising Filtering

A Controller that supports the Decision-Based Advertising Filtering feature shall support the LE Extended Advertising feature and the following sections of this document:

- ADV_DECISION_IND (Section 2.3.1.11)
- Decision scanning filter policies (Section 4.3.3.2)
- Decision PDU scanning (Section 4.4.3.6)

4.6.44 ISOAL Unsegmented Framed Mode

A Controller that supports the ISOAL Unsegmented Framed Mode feature shall support at least one of the following features:

- Connected Isochronous Stream - Central
- Connected Isochronous Stream - Peripheral
- Isochronous Broadcaster
- Synchronized Receiver

and shall support the following sections of this document:

- Unsegmented mode for framed PDUs (see [Vol 6] Part G, Section 2.2)
- Unsegmented mode in SDU synchronization reference and transport latency using framed PDUs (see [Vol 6] Part G, Section 3.2.1)

4.6.45 Monitoring Advertisers

A Controller that supports the Monitoring Advertisers feature shall support the following section of this document:

- Monitoring Advertisers (Section 4.4.3.8)

4.6.46 Frame Space Update

A Controller that supports the Frame Space Update feature shall support a minimum frame space value that is less than or equal to 145 µs or support a maximum frame space value that is greater than or equal to 155 µs (or both), support the Extended Reject Indication feature, and support the following sections of this document:

- LL_FRAME_SPACE_REQ (Section 2.4.2.54)
- LL_FRAME_SPACE_RSP (Section 2.4.2.55)
- Frame Space Update procedure (Section 5.1.30)

4.7 Resolving List

All Link Layers supporting Link Layer privacy (see Section 6) shall contain a set of records for local and peer IRK value pairs. These values are known as the Local IRK and the Peer IRK. The Resolving List IRK pairs shall be associated with a public or static device address known as the Identity Address. The Identity Address may be in the Filter Accept List. All Link Layers supporting Link Layer privacy shall support a Resolving List capable of storing at least one Resolving List Record.

On reset, the Resolving List shall be empty.

The Resolving List is configured by the Host and is used by the Link Layer to resolve Resolvable Private Addresses used by advertisers, scanners or initiators. This allows the Host to configure the Link Layer to act on a request without awakening the Host.

The Filter Accept List and filter policies set by the Host are applied to the associated Identity Address once the Resolvable Private Address has been resolved.

The Identity Address of an associated advertiser in the Monitored Advertisers List of devices set by the Host is applied once the Resolvable Private Address has been resolved.

If the Host, when populating the resolving list, sets a peer IRK to all zeros, then the peer address used within an advertising physical channel PDU shall use the peer's Identity Address, which is provided by the Host.

The Host specifies the privacy mode to be used with each peer identity on the resolving list. If it specifies that device privacy mode is to be used, then the Controller shall accept both the peer's device Identity Address and a resolvable private address generated by the peer device using its distributed IRK. Otherwise, network privacy mode is used: the Controller shall only accept resolvable private addresses generated by the peer device using its distributed IRK. If the Host has added the peer device to the resolving list with an all-zero peer IRK, the Controller shall only accept the peer's Identity Address, as defined in Section 6.5.

If the Host, when populating the resolving list, sets a local IRK to all zeros, then any local address used within an advertising physical channel PDU shall use the local Identity Address, which is provided by the Host.

If the Link Layer is using the Resolving List and the peer device has been resolved, the Address returned to the Host is the peer device's Identity Address.

If the Link Layer is using the Resolving List and the peer device has been resolved but the encryption fails then the current Resolvable Private Address(es) shall be immediately discarded and new Resolvable Private Address(es) shall be generated.

Note: Encryption may fail when the address was resolved successfully using an incorrect IRK and, therefore, encryption keys on both sides did not match.

When the Controller address resolution is enabled, both peer and local RPAs received by the Link Layer shall be resolved using the same Resolving List Record.

Note: The Controller may generate Resolvable Private Addresses even when address resolution is disabled.

5 LINK LAYER CONTROL

The Link Layer Control protocol is used to control and negotiate aspects of the operation of a connection between two Link Layers. This includes procedures for control of the connection, starting and pausing encryption and other link procedures.

Procedures have specific timeout rules as defined in Section 5.2. The ACL Termination procedure may be initiated at any time, even if any other Link Layer control procedure is currently active. For all other Link Layer control procedures, only one Link Layer control procedure shall be initiated in the Link Layer at a time per connection per device. A new Link Layer control procedure shall not be initiated until any previous Link Layer control procedure initiated by the same device on the same connection has completed. However, except where forbidden elsewhere in this section, a Link Layer may initiate an LL control procedure while responding to a procedure initiated by its peer device.

Except where stated otherwise in this section, there are no restrictions on the order that Link Layer control procedures are carried out except that no procedure shall be started until after entering the Connection state.

The prioritization of LL Control PDUs and LL Data PDUs is implementation specific. For example, a Host cannot assume that pending data will be sent when a termination of the link is requested without waiting for those data PDUs to have completed and be indicated to the Host.

If the remote device does not support a procedure, the Link Layer will normally receive an LL_UNKNOWN_RSP with the UnknownType field set to the opcode of the initiating PDU. In this case, the procedure is terminated when the LL_UNKNOWN_RSP PDU is received.

5.1 Link Layer ACL control procedures

Except for any wording describing the behavior of a Link Layer that does not support a feature, the requirements in each subsection below only apply if the Link Layer supports the relevant feature (see Section 4.6).

5.1.1 Connection Update procedure

The Central or Peripheral may update the Link Layer parameters for a connection (*connInterval*, *connPeripheralLatency,* and *connSupervisionTimeout*) by applying the following rules.

If both the Central and Peripheral support the Connection Parameters Request procedure (see Section 5.1.7) then either device should use that procedure. However,

if the Peripheral rejects the proposed connection parameters, the Central may update them using the Connection Update procedure.

If the Central, the Peripheral, or both do not support the Connection Parameters Request procedure, then the Central shall send an LL_CONNECTION_UPDATE_IND PDU (the Peripheral shall not send this PDU) while the Peripheral shall use the L2CAP LE Signaling channel (see [Vol 3] Part A, Section 4.20 and Section 4.21).

If a device supports the Connection Parameters Request procedure but does not know whether its peer does because, in the current connection, neither device has previously attempted that procedure or performed a Feature Exchange procedure, then it shall initiate the Connection Parameters Request procedure and, if the peer responds with an LL_UNKNOWN_RSP PDU, by then using the method described in the previous paragraph.

A Central shall not issue the LL_CONNECTION_UPDATE_IND PDU when a CS procedure or CS procedure repeat instances, as described in Section 4.5.18.1, are in progress.

The Link Layer of the Central shall determine the *connInterval* from the interval range given by the Host ($connInterval_{min}$ and $connInterval_{max}$); the value chosen shall be at least *connIntervalUncodedMin* µs. However, if the current PHY is the LE Coded PHY and the Controller supports the LE Data Packet Length Extension feature, then the new connection interval shall be at least *connIntervalCodedMin* µs.

The Link Layer shall indicate to the Host the selected interval value.

Section 5.5 shall apply to the LL_CONNECTION_UPDATE_IND PDU. The Central should transmit on the connection event where *connEventCount* equals Instant and the connection event before that event, irrespective of subrating. When the Peripheral receives such a PDU with the instant in the future, it shall listen to the connection event where *connEventCount* equals Instant and the connection event before that event, even if subrating or Peripheral latency means it would not normally do so.

The connection interval used before the instant is known as $connInterval_{OLD}$. The connection interval contained in the LL_CONNECTION_UPDATE_IND PDU and used at the instant and after, is known as $connInterval_{NEW}$.

The connection Peripheral latency used before the instant is known as $connPeripheralLatency_{OLD}$. The connection Peripheral latency contained in the LL_CONNECTION_UPDATE_IND PDU and used at the instant and after, is known as $connPeripheralLatency_{NEW}$.

The connection supervision timeout used before the instant is known as $connSupervisionTimeout_{OLD}$. The connection supervision timeout contained in the

LL_CONNECTION_UPDATE_IND PDU and used at the instant and after, is known as *connSupervisionTimeout*$_{NEW}$. The connection supervision timer shall be reset at the instant.

If the connection interval is changed, the subrate factor shall be set to 1 and the continuation number shall be set to 0 at the instant.

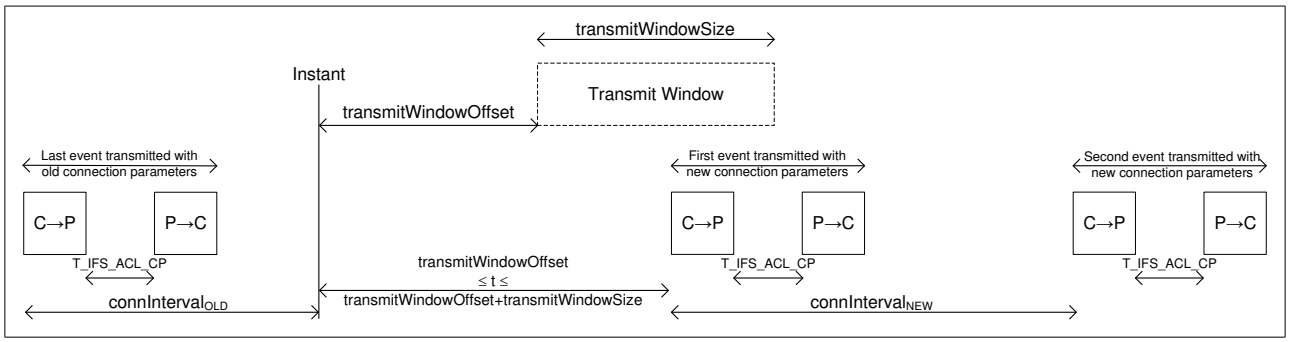

Figure 5.1: Connection event timing in the case of connection parameter update

For example, the interval between the preceding connection event before the instant and the instant will be *connInterval*$_{OLD}$. The interval between the connection event after the instant and the following connection event will be *connInterval*$_{NEW}$.

The Central may adjust the anchor point when deciding the timing of the first packet transmitted with new connection parameters. A transmit window is used, as defined in Section 4.5.3. The transmit window starts at *connInterval*$_{OLD}$ + *transmitWindowOffset* after the anchor point of the connection event before the instant. The *transmitWindowOffset* shall be a multiple of 1.25 ms in the range 0 ms to *connInterval*$_{NEW}$.The *transmitWindowSize* shall be a multiple of 1.25 ms in the range 1.25 ms to the lesser of 10 ms and (*connInterval*$_{NEW}$ - 1.25 ms).

Note: If the Peripheral first receives the LL_CONNECTION_UPDATE_IND PDU on the instant, it can immediately use that packet as the new anchor point and does not apply the *transmitWindowOffset* and *transmitWindowSize*.

The Central shall start to send the first packet within the transmit window as defined in Section 4.5.3. The Central's first packet may extend beyond the transmit window.

The first packet sent after the instant by the Central determines the new anchor point for the connection events, and therefore the timings of all future connection events in this connection.

The instant occurs after *connInterval*$_{OLD}$ and before *transmitWindowOffset*. All the normal connection event transmission rules specified in Section 4.5.1 shall apply.

At the start of the transmit window, the Link Layer shall reset $T_{LLconnSupervision}$.

If the Link Layer of the Central transmits an LL_CONNECTION_UPDATE_IND PDU autonomously, for example without being requested to by the Host, the Latency and Timeout parameters shall not be changed and shall remain the same as in the last LL_CONNECTION_UPDATE_IND, CONNECT_IND, or AUX_CONNECT_REQ PDU. Any of the other parameters (*transmitWindowSize*, *transmitWindowOffset*, *connInterval*, Instant) may be changed within the restrictions given above.

Note: Autonomous updates can be used to change the anchor points to allow the Central to change the scheduling of the connection due to other activities.

The Link Layer shall notify its Host if any of the three connection parameters have changed. If no connection parameters are changed, the Host would not be notified; this is called an anchor point move.

The procedure has completed when the instant has passed, and the new connection event parameters have been applied.

5.1.2 Channel Map Update procedure

The Central may update the Link Layer parameter for channel map (*channelMap*) by sending an LL_CHANNEL_MAP_IND PDU. The Peripheral shall not send this PDU. The Central's Controller may update the channel map without being requested to by the Host.

Section 5.5 shall apply to the LL_CHANNEL_MAP_IND PDU.

The channel map used before the instant is known as $channelMap_{OLD}$. The channel map contained in the LL_CHANNEL_MAP_IND PDU and used at the instant and after, is known as $channelMap_{NEW}$.

When *connEventCount* is equal to the Instant field, the $channelMap_{NEW}$ shall be the current *channelMap*. The *lastUnmappedChannel* shall not be reset. If the *unmappedChannel* is an unused channel, then the $channelMap_{NEW}$ will be used when remapping. The only parameter that changes is the *channelMap*.

For example:

At connection set-up:

- initial $channelMap_{OLD}$: 0x1FFFFFFFFF (i.e., all channels enabled)
- initial *hopIncrement*: 10 (decimal)

An LL_CHANNEL_MAP_IND PDU with the following parameters is then issued:

- Instant: 100 (decimal). Assume that no connection event count wrap-around occurred since the start of the connection.

- *channelMap*$_{NEW}$: 0x1FFFFFF7FF (i.e. all channels enabled except channel 11)

Channels used:

- *connEventCount* 99 --> data channel index 1 (*channelMap*$_{OLD}$)
- *connEventCount* 100 --> data channel index 12 (remapped from 11) (*channelMap*$_{NEW}$)
- *connEventCount* 101 --> data channel index 21 (*channelMap*$_{NEW}$)

The procedure has completed when the instant has passed and the new channel map has been applied to the ACL. If the ACL has any associated CISes, the new channel map shall be used on each CIS starting with the next CIS event after the instant.

5.1.3 Encryption procedure

The Link Layer of the Central or Peripheral, upon request from the Host, may enable the encryption of packets using the encryption start procedure.

Once the connection is encrypted, the Link Layer may change the encryption key by using the encryption pause procedure, which encapsulates the encryption start procedure.

The Link Layer shall not initiate the encryption start procedure or pause procedure while there is an established CIS associated with the ACL.

5.1.3.1 Encryption Start procedure

To enable encryption, two parameters have to be exchanged, IV and SKD. Both are composed of two parts, a Central part and a Peripheral part, and exchanged in LL_ENC_REQ and LL_ENC_RSP PDUs. After these are exchanged, and the Peripheral's Host has notified its Link Layer of the Long Term Key to be used on this connection, encryption is started using a three way handshake, using LL_START_ENC_REQ and LL_START_ENC_RSP PDUs.

To start encryption, the Link Layer of the Central shall generate the Central’s part of the initialization vector (IV_C) and the Central’s part of the session key diversifier (SKD_C). IV_C shall be a 32 bit random number generated by the Link Layer of the Central. SKD_C shall be a 64 bit random number generated by the Link Layer of the Central. Both IV_C and SKD_C shall be generated using the requirements for random number generation defined in [Vol 2] Part H, Section 2.

Before transmitting the LL_ENC_REQ PDU, the Link Layer of the Central shall finalize the sending of the current Data Physical Channel PDU and may finalize the sending of additional Data Physical Channel PDUs queued in the Controller. After these Data Physical Channel PDUs are acknowledged, until this procedure has completed

or specifies otherwise, the Link Layer of the Central shall only send Empty PDUs, LL_TERMINATE_IND PDUs, and PDUs required by this procedure.

The Link Layer of the Central shall then send an LL_ENC_REQ PDU; the Rand and EDIV fields are provided by the Host. After the Central receives the LL_ENC_RSP PDU in response, only PDUs required by this procedure are expected.

If encryption is not supported by the Link Layer of the Peripheral, the Link Layer of the Peripheral shall send an LL_REJECT_IND or LL_REJECT_EXT_IND PDU with the ErrorCode set to *Unsupported Remote Feature* (0x1A). The Link Layer of the Central receiving the LL_REJECT_IND or LL_REJECT_EXT_IND PDU shall notify the Host. The Link Layer of the Central may now send LL Data PDUs and LL Control PDUs; these packets will not be encrypted. This procedure has completed in the Central when the Central receives the LL_REJECT_IND or LL_REJECT_EXT_IND PDU from the Peripheral. The Central should acknowledge this PDU using an Empty PDU. The procedure has completed in the Peripheral when it sends the LL_REJECT_IND or LL_REJECT_EXT_IND PDU to the Central.

Otherwise, when the Link Layer of the Peripheral receives an LL_ENC_REQ PDU it shall generate the Peripheral's part of the initialization vector (IV_P) and the Peripheral's part of the session key diversifier (SKD_P). IV_P shall be a 32 bit random number generated by the Link Layer of the Peripheral. SKD_P shall be a 64 bit random number generated by the Link Layer of the Peripheral. Both IV_P and SKD_P shall be generated using the requirements for random number generation defined in [Vol 2] Part H, Section 2.

The Link Layer of the Peripheral shall finalize the sending of the current Data Physical Channel PDU and may finalize the sending of additional Data Physical Channel PDUs queued in the Controller. After these Data Physical Channel PDUs are acknowledged, until this procedure has completed or specifies otherwise, the Link Layer of the Peripheral shall only send Empty PDUs, LL_TERMINATE_IND PDUs, and PDUs required by this procedure.

If any of the Data Physical Channel PDUs sent by the Peripheral is an LL Control PDU, the Link Layers shall resume any outstanding procedure(s) after the Encryption Start procedure has completed.

The Link Layer of the Peripheral shall then send an LL_ENC_RSP PDU. The Link Layer of the Peripheral shall then notify the Host with the Rand and EDIV fields. After having sent the LL_ENC_RSP PDU, the Link Layer of the Peripheral can receive an LL_UNKNOWN_RSP PDU corresponding to an LL Control PDU sent by the Peripheral. The Peripheral should not disconnect the link in this case.

Each Link Layer shall combine the initialization vector parts and session key diversifier parts in the following manner:

SKD = SKD_P || SKD_C
IV = IV_P || IV_C

The SKD_C is concatenated with the SKD_P. The least significant octet of SKD_C becomes the least significant octet of SKD. The most significant octet of SKD_P becomes the most significant octet of SKD.

The IV_C is concatenated with the IV_P. The least significant octet of IV_C becomes the least significant octet of IV. The most significant octet of IV_P becomes the most significant octet of IV.

The Long Term Key is always provided by the Host to the Link Layer in the Central and may be provided by the Host to the Link Layer in the Peripheral. One of the following three actions shall occur:

- If this procedure is being performed after a Pause Encryption procedure, and the Peripheral's Host does not provide a Long Term Key, the Peripheral shall perform the ACL Termination procedure with the error code *PIN or Key Missing* (0x06).
- If the Peripheral's Host does not provide a Long Term Key, either because the event to the Host was masked out or if the Host indicates that a key is not available, the Peripheral shall either send an LL_REJECT_IND with the ErrorCode set to *PIN or Key Missing* (0x06) or an LL_REJECT_EXT_IND PDU with the RejectOpcode set to "LL_ENC_REQ" and the ErrorCode set to *PIN or Key Missing* (0x06). Upon receiving an LL_REJECT_IND or LL_REJECT_EXT_IND PDU, the Central's Link Layer shall notify its Host. Both Link Layers may now send LL Data PDUs and LL Control PDUs; these packets will not be encrypted. This procedure has completed in the Central when the Central receives the LL_REJECT_IND or LL_REJECT_EXT_IND PDU from the Peripheral. The procedure has completed in the Peripheral when the acknowledgment has been received for the LL_REJECT_IND or LL_REJECT_EXT_IND PDU from the Central.
- If the Peripheral's Host does provide a Long Term Key, both Link Layers shall calculate the session key as e(LTK, SKD), where e is defined in [Vol 3] Part H, Section 2.2.1.

After the Peripheral's Link Layer has calculated the session key, it shall send an LL_START_ENC_REQ PDU. This packet shall be sent unencrypted and the Link Layer shall be set up to receive an encrypted packet in response.

When the Link Layer of the Central receives an LL_START_ENC_REQ PDU it shall send an LL_START_ENC_RSP PDU. This PDU shall be sent encrypted and the Link Layer shall be set up to receive an encrypted packet in response.

When the Link Layer of the Peripheral receives an LL_START_ENC_RSP PDU it shall transmit an LL_START_ENC_RSP PDU. This packet shall be sent encrypted.

When the Link Layer of the Central receives the LL_START_ENC_RSP PDU, the connection is encrypted. The Link Layer may now send LL Data PDUs and LL Control PDUs; these PDUs will be encrypted.

The Link Layers shall notify the Hosts that the connection is encrypted.

The procedure has completed in the Central when the Central receives the LL_START_ENC_RSP PDU from the Peripheral. The procedure has completed in the Peripheral when the Peripheral receives the LL_START_ENC_RSP PDU from the Central.

If, at any time during the encryption start procedure after the Peripheral has received the LL_ENC_REQ PDU or the Central has received the LL_ENC_RSP PDU, the Link Layer of the Central or the Peripheral receives an unexpected Data Physical Channel PDU from the peer Link Layer, it shall immediately exit the Connection state, and shall transition to the Standby state. The Host shall be notified that the link has been disconnected with the error code *Connection Terminated Due to MIC Failure* (0x3D).

5.1.3.2 Encryption Pause procedure

To enable a new encryption key to be used without disconnecting the link, encryption is disabled and then enabled again. During the pause, data PDUs shall not be sent unencrypted to protect the data.

The Link Layer of the Central shall finalize the sending of the current Data Physical Channel PDU and may finalize the sending of additional Data Physical Channel PDUs queued in the Controller. After these Data Physical Channel PDUs are acknowledged, until this procedure has completed, the Link Layer of the Central shall only send Empty PDUs, LL_TERMINATE_IND PDUs, and PDUs required by this procedure.

The Link Layer of the Central shall then send an LL_PAUSE_ENC_REQ PDU. After the Central receives the LL_PAUSE_ENC_RSP PDU in response, only PDUs required by this procedure are expected.

When the Link Layer of the Peripheral receives an LL_PAUSE_ENC_REQ PDU it shall finalize the sending of the current Data Physical Channel PDU and may finalize the sending of additional Data Physical Channel PDUs queued in the Controller. After these Data Physical Channel PDUs are acknowledged, until this procedure has completed, the Link Layer of the Peripheral shall only send Empty PDUs, LL_TERMINATE_IND PDUs, and PDUs required by this procedure.

If any of the Data Physical Channel PDUs sent by the Peripheral is an LL Control PDU, the Link Layers shall resume any outstanding procedure(s) after the Encryption Start procedure has completed.

The Link Layer of the Peripheral shall then send an LL_PAUSE_ENC_RSP PDU. This packet shall be sent encrypted and Link Layer shall be set up to receive an unencrypted packet in response.

When the Link Layer of the Central receives an LL_PAUSE_ENC_RSP PDU it shall be set up to send and receive unencrypted. It shall then send an LL_PAUSE_ENC_RSP PDU to the Peripheral unencrypted.

When the Link Layer of the Peripheral receives an LL_PAUSE_ENC_RSP PDU it shall be set up to also send unencrypted.

The two Link Layers shall then carry out the steps of the encryption start procedure to re-enable encryption using a new session key. The encryption pause procedure has completed when this encapsulated encryption start procedure has completed.

If, at any time during the encryption pause procedure after the Peripheral has received the LL_PAUSE_ENC_REQ PDU or the Central has received the LL_PAUSE_ENC_RSP PDU, the Link Layer of the Central or the Peripheral receives an unexpected Data Physical Channel PDU from the peer Link Layer, it shall immediately exit the Connection state, and shall transition to the Standby state. The Host shall be notified that the link has been disconnected with the error code *Connection Terminated Due to MIC Failure* (0x3D).

5.1.4 Feature Exchange procedure

The Central or Peripheral may initiate the Feature Exchange procedure to exchange the Link Layer parameter for the current supported feature set (FeatureSet).

The FeatureSet information may be cached either during a connection or between connections. A Link Layer should not request this information on every connection if the information has been cached for this device. Cached information for a device from a previous connection is not authoritative and, therefore, an implementation must be able to accept the LL_UNKNOWN_RSP PDU if use of a feature is attempted that is not currently supported or used by the peer (see Section 2.4.2).

The FeatureSet_C parameter is the feature capabilities of the Link Layer of the Central with certain bits set to zero as specified in Section 4.6.

The FeatureSet_P parameter is the feature capabilities of the Link Layer of the Peripheral with certain bits set to zero as specified in Section 4.6.

The FeatureSet_USED parameter is one octet long and is the logical AND of the least significant octets of FeatureSet_C and FeatureSet_P.

5.1.4.1 Central-initiated Feature Exchange procedure

The Link Layer of the Central initiates this procedure by sending an LL_FEATURE_REQ PDU to the Peripheral. This may be done on request from the Host or autonomously. When the Link Layer of the Peripheral receives this, it shall respond by sending an LL_FEATURE_RSP PDU.

When the Link Layer of the Central sends an LL_FEATURE_REQ PDU, the FeatureSet field shall be set to the first 8 octets of FeatureSet_C.

When the Link Layer of the Peripheral sends an LL_FEATURE_RSP PDU, octet 0 of the FeatureSet field shall be set to FeatureSet_USED and the remaining octets shall be set to octets 1 to 7 of FeatureSet_P.

The procedure has completed when the Central receives the LL_FEATURE_RSP PDU from the Peripheral.

5.1.4.2 Peripheral-initiated Feature Exchange procedure

The Link Layer of the Peripheral initiates this procedure by sending an LL_PERIPHERAL_FEATURE_REQ PDU to the Central. This may be done on request from the Host or autonomously. When the Link Layer of the Central receives this, it shall respond by sending an LL_FEATURE_RSP PDU.

When the Link Layer of the Peripheral sends an LL_PERIPHERAL_FEATURE_REQ PDU, the FeatureSet field shall be set to the first 8 octets of FeatureSet_P.

When the Link Layer of the Central sends an LL_FEATURE_RSP PDU, octet 0 of the FeatureSet field shall be set to FeatureSet_USED and the remaining octets shall be set to octets 1 to 7 of FeatureSet_C.

If the LL_PERIPHERAL_FEATURE_REQ PDU was issued as a result of a Host-initiated read remote features procedure (see [Vol 4] Part E, Section 7.8.21) and the Central does not support this procedure, then the Host shall be notified that the read remote features procedure has completed with the ErrorCode set to *Unsupported Remote Feature* (0x1A).

The procedure has completed when the Peripheral receives the LL_FEATURE_RSP PDU from the Central.

5.1.4.3 Feature Page Exchange procedure

The Link Layer of the Central or Peripheral initiates this procedure by sending an LL_FEATURE_EXT_REQ PDU to the peer device. This may be done on request from

the Host or autonomously. When the peer device receives this PDU, it shall respond by sending an LL_FEATURE_EXT_RSP PDU to the initiating device.

The responding device shall set the PageNumber field of the LL_FEATURE_EXT_RSP PDU to the same value as received in the PageNumber field of the LL_FEATURE_EXT_REQ PDU. Each device shall set FeaturePage to the corresponding page of FeatureSet_C if the device is the Central or of FeatureSet_P if the device is the Peripheral.

Each device shall set MaxPage to the number of the highest-numbered page of FeatureSet_C (if the device is the Central) or FeatureSet_P (if the device is the Peripheral) containing at least one bit set to 1.

The procedure has completed when the initiating device receives the LL_FEATURE_EXT_RSP PDU from the responding device.

5.1.5 Version Exchange procedure

The Central or Peripheral may initiate the Version Exchange procedure to exchange the Link Layer parameters for version information (*companyID*, *subVerNum*, *linkLayerVer*, as defined in Section 2.4.2.13) by sending an LL_VERSION_IND PDU. This procedure should be used when requested by the Host. This procedure may be initiated autonomously by the Link Layer.

The Link Layer shall only queue for transmission a maximum of one LL_VERSION_IND PDU during a connection.

If the Link Layer receives an LL_VERSION_IND PDU and has not already sent an LL_VERSION_IND then the Link Layer shall send an LL_VERSION_IND PDU to the peer device.

If the Link Layer receives an LL_VERSION_IND PDU and has already sent an LL_VERSION_IND PDU then the Link Layer shall not send another LL_VERSION_IND PDU to the peer device.

The procedure has completed when an LL_VERSION_IND PDU has been received from the peer device.

5.1.6 ACL Termination procedure

This procedure is used for voluntary termination of an ACL connection while in the Connection state. Voluntary termination occurs when the Host requests the Link Layer to terminate the connection. Either the Link Layer of the Central or Peripheral may initiate this procedure by sending an LL_TERMINATE_IND PDU. The ACL Termination procedure is not used in the event of the loss of the connection, for example after link supervision timeout or after a procedure timeout.

The Link Layer shall start a timer, $T_{terminate}$, when the LL_TERMINATE_IND PDU has been queued for transmission. The initiating Link Layer shall send LL_TERMINATE_IND PDUs until an acknowledgment is received or until the timer, $T_{terminate}$, expires, after which it shall exit the Connection State and transition to the Standby State. The initial value for $T_{terminate}$ shall be set to the value of the *connSupervisionTimeout*.

When the Link Layer receives an LL_TERMINATE_IND PDU it shall send the acknowledgment, exit the Connection State and shall transition to the Standby State.

As soon as the Link Layer has received or queued for transmission an LL_TERMINATE_IND PDU all associated CISes shall be considered lost (see Section 4.5.12). The Link Layer shall not send separate LL_CIS_TERMINATE_IND PDUs when the Host requests termination.

The procedure has completed when the acknowledgment has been received or the timer, $T_{terminate}$, expires.

5.1.7 Connection Parameters Request procedure

The Central or Peripheral may initiate a Connection Parameters Request procedure to request the remote device to have the Link Layer parameters for the connection (*connInterval*, *connPeripheralLatency* and *connSupervisionTimeout*) updated any time after entering the Connection State.

A device shall only initiate this procedure when permitted by Section 5.1.1. A device shall not initiate this procedure while a Connection Subrate Update procedure is in progress. A device shall not initiate this procedure while a CS procedure or CS procedure repeat instances, as described in Section 4.5.18.1, are in progress.

5.1.7.1 Issuing an LL_CONNECTION_PARAM_REQ PDU

The Connection Parameters Request procedure is initiated by issuing an LL_CONNECTION_PARAM_REQ PDU. The procedure may be initiated as a result of a Host initiated connection update procedure (see [Vol 4] Part E, Section 7.8.18) or autonomously by the Link Layer (that is, without being requested by the Host).

If the LL_CONNECTION_PARAM_REQ PDU was issued by the Link Layer of the Peripheral as a result of a Host initiated connection update procedure and the Central does not support this procedure, then the Host shall be notified that the connection update procedure has completed with the ErrorCode set to *Unsupported Remote Feature* (0x1A).

If the Link Layer initiates this procedure as a result of a Host initiated connection update procedure, then the Link Layer:

- Should set the Interval_Min, Interval_Max, Timeout, and Latency fields to the values received from the Host.

  Note: The Link Layer may modify the values of these fields, for example, because the values received from the Host would prevent the Link Layer from meeting commitments in another piconet.
- May indicate the preferred periodicity by setting the PreferredPeriodicity field to a value other than zero, as described in Section 2.4.2.16.
- May set the Offset0 to Offset5 fields to a value other than 0xFFFF as described in Section 2.4.2.16. If all of the Offset0 to Offset5 fields have been set to 0xFFFF, then the Link Layer has no preference about the offset to be used. If one or more of the Offset0 to Offset5 fields have been set to a value other than 0xFFFF, then:
  - The ReferenceConnEventCount field shall be set to indicate that at least one of the Offset0 to Offset5 fields is valid. If the ReferenceConnEventCount field is set, then it shall always be set to the connEventCount of a connection event that is less than 32767 connection events in the future from the first transmission of the PDU.

    Note: Retransmissions of the PDU can result in the ReferenceConnEventCount to be up to 32767 events in the past when the PDU is successfully received by the remote device. See Section 5.1.7.3.2 for examples on how to set the ReferenceConnEventCount field.
  - If Interval_Min is not equal to Interval_Max then the PerferredPeriodicity field shall be set to a value other than zero. If Interval_Min is equal to Interval_Max then the PreferredPeriodicity field may be set to any value and shall be ignored by the recipient.

If the Link Layer initiates this procedure autonomously, then the Latency field shall be set to the current value of *connPeripheralLatency* and the Timeout field (in milliseconds) shall be set to the current value of *connSupervisionTimeout*. Any of the other fields (Interval_Min, Interval_Max, PreferredPeriodicity, ReferenceConnEventCount and Offset0 to Offset5) may be changed within the restrictions given above.

The Link Layer shall ensure that the parameters in the LL_CONNECTION_PARAM_REQ shall not cause supervision timeout. That is, the Link Layer shall ensure that the Timeout (in milliseconds) is greater than 2 × Interval_Max × (Latency + 1).

5.1.7.2 Responding to LL_CONNECTION_PARAM_REQ and LL_CONNECTION_PARAM_RSP PDUs

Upon receiving an LL_CONNECTION_PARAM_REQ PDU:

- The Peripheral shall respond with either an LL_CONNECTION_PARAM_RSP PDU or an LL_REJECT_EXT_IND PDU.
- The Central shall respond with either an LL_CONNECTION_UPDATE_IND PDU or an LL_REJECT_EXT_IND PDU.

If an LL_CONNECTION_PARAM_REQ PDU is received while a CS procedure or CS procedure repeat instances, as described in Section 4.5.18.1, are in progress, then the receiving Link Layer shall respond with an LL_REJECT_EXT_IND PDU with the ErrorCode set to *Controller Busy* (0x3A).

Upon receiving an LL_CONNECTION_PARAM_RSP PDU, the Central shall respond with either an LL_CONNECTION_UPDATE_IND PDU or an LL_REJECT_EXT_IND PDU.

The Central shall not send the LL_CONNECTION_PARAM_RSP PDU. The Peripheral shall send an LL_CONNECTION_PARAM_RSP PDU only in response to an LL_CONNECTION_PARAM_REQ PDU.

If the received LL_CONNECTION_PARAM_REQ PDU contains parameters that are not acceptable to the Link Layer, then the Link Layer of the device shall respond to the LL_CONNECTION_PARAM_REQ PDU with one of the following:

- An LL_CONNECTION_PARAM_RSP PDU (if the Link Layer is the Peripheral of the connection) or an LL_CONNECTION_UPDATE_IND PDU (if the Link Layer is the Central of the connection), in each case containing alternative parameters.
- An LL_REJECT_EXT_IND PDU with the ErrorCode set to *Unsupported LL Parameter Value* (0x20).

If the received LL_CONNECTION_PARAM_REQ PDU contains any fields that are out of valid range, then the Link Layer shall reject the LL_CONNECTION_PARAM_REQ PDU by issuing an LL_REJECT_EXT_IND PDU with the ErrorCode set to *Invalid LL Parameters* (0x1E).

If an LL_REJECT_EXT_IND PDU is sent during the Connection Parameters Request procedure, then the procedure has completed on a device when it receives the LL_REJECT_EXT_IND PDU, and has completed on the device that issued the LL_REJECT_EXT_IND PDU when it receives the acknowledgment for the LL_REJECT_EXT_IND PDU.

If the received LL_CONNECTION_PARAM_REQ PDU requests only a change in the anchor points of the LE connection, then the Link Layer shall not indicate this request to its Host.

If the received LL_CONNECTION_PARAM_REQ PDU requests a change to one or more of *connInterval*, *connPeripheralLatency*, and *connSupervisionTimeout* and if the values selected by the Link Layer are, respectively, within the range of the *connInterval*, the value of *connPeripheralLatency* and the value of *connSupervisionTimeout* provided by the local Host, then the Link Layer may choose to not indicate this request to its Host and proceed as if the Host has accepted the remote device's request. Otherwise, if the event to the Host is not masked, then the Link Layer shall first indicate this request to its Host.

If the local Host has not provided the range of *connInterval*, the value of *connPeripheralLatency* and the value of *connSupervisionTimeout* to the Link Layer of the Peripheral, then the Link Layer of the Peripheral may indicate the received request to its Host if the event to the Host is not masked.

If the request is being indicated to the Host and the event to the Host is masked, then the Link Layer shall issue an LL_REJECT_EXT_IND PDU with the ErrorCode set to *Unsupported Remote Feature* (0x1A).

Note: The device could have issued the LL_REJECT_EXT_IND PDU temporarily, and thus the initiating device may retry.

Note: If the request is not being indicated to the Host, then the event mask is ignored.

If the Host is indicated of the request, it shall either accept or reject this request. If the Host rejects this request, then the device shall issue an LL_REJECT_EXT_IND PDU with the ErrorCode set to *Unacceptable Connection Parameters* (0x3B).

If the Host accepts this request or if the request was not indicated to the Host, then:

- The Peripheral shall respond to an LL_CONNECTION_PARAM_REQ PDU with an LL_CONNECTION_PARAM_RSP PDU. The rules for filling in various fields of the LL_CONNECTION_PARAM_RSP PDU are the same as those for filling in various fields of the LL_CONNECTION_PARAM_REQ PDU, as described in Section 5.1.7.1. The rules for handling a received LL_CONNECTION_PARAM_RSP PDU on the Link Layer of the Central are identical to the rules for handling a received LL_CONNECTION_PARAM_REQ PDU that are described earlier in this section.
- The Central shall respond to an LL_CONNECTION_PARAM_REQ PDU or an LL_CONNECTION_PARAM_RSP PDU with an LL_CONNECTION_UPDATE_IND PDU. The Central should try to choose a value of Interval that is a multiple of PreferredPeriodicity if the Peripheral has set the PreferredPeriodicity field of the

LL_CONNECTION_PARAM_REQ or LL_CONNECTION_PARAM_RSP PDU. The chosen value shall be at least *connIntervalUncodedMin* µs. However, if the current PHY is the LE Coded PHY and the Controller supports the LE Data Packet Length Extension feature, then the new connection interval shall be at least *connIntervalCodedMin* µs. The Central should try to pick the values of WinOffset and WinSize such that the timing of the new connection events matches one of the Offset0 to Offset5 fields of the LL_CONNECTION_PARAM_REQ PDU or the LL_CONNECTION_PARAM_RSP PDU sent by the Peripheral. The Instant field of the LL_CONNECTION_UPDATE_IND PDU is set as described in Section 5.1.1.

Once the Central issues the LL_CONNECTION_UPDATE_IND PDU, the connection parameters get updated as described in Section 5.1.1.

If the connection interval is changed, the subrate factor shall be set to 1 and the continuation number shall be set to 0 at the instant of the procedure.

The procedure has completed when the instant has passed and the new connection event parameters have been applied.

5.1.7.3 Examples

5.1.7.3.1 Peripheral initiated anchor point move

The following example shows the Link Layer of the Peripheral requesting a change in the anchor points of the LE connection by 3.75 ms.

The Link Layer of the Peripheral issues an LL_CONNECTION_PARAM_REQ PDU with the following parameters:

- Interval_Min: *connInterval*
- Interval_Max: *connInterval*
- Latency: *connPeripheralLatency*
- Timeout: *connSupervisionTimeout*
- PreferredPeriodicity: 0
- ReferenceConnEventCount: <any value that is less than 32767 connection events in the future>
- Offset0: 0x0003
- Offset1: 0xFFFF
- Offset2: 0xFFFF
- Offset3: 0xFFFF
- Offset4: 0xFFFF

- Offset5: 0xFFFF

If the Link Layer of the Central accepts the Peripheral's request, then it could respond with an LL_CONNECTION_UPDATE_IND PDU that contains any one of the following set of parameters. In all the sets, Interval is set to *connInterval*, Latency is set to *connPeripheralLatency*, Timeout is set to *connSupervisionTimeout* and Instant is set to any value that is less than 32767 connection events in the future.

- Option 1: the first packet sent after the instant by the Central is inside the Transmit Window and 3.75 ms from the beginning of the Transmit Window.
  - 3 ≤ WinSize ≤ 8
  - WinOffset: 0
- Option 2: the first packet sent after the instant by the Central is inside the Transmit Window and 2.5 ms from the beginning of the Transmit Window.
  - 2 ≤ WinSize ≤ 8
  - WinOffset: 1
- Option 3: the first packet sent after the instant by the Central is inside the Transmit Window and 1.25 ms from the beginning of the Transmit Window.
  - 1 ≤ WinSize ≤ 8
  - WinOffset: 2
- Option 4: the first packet sent after the instant by the Central is inside the Transmit Window and 0 ms from the beginning of the Transmit Window.
  - 1 ≤ WinSize ≤ 8
  - WinOffset: 3

5.1.7.3.2 ReferenceConnEventCount

Figure 5.2 and Figure 5.3 show examples of how the ReferenceConnEventCount and the Offset0 to Offset5 fields of the LL_CONNECTION_PARAM_REQ and the LL_CONNECTION_PARAM_RSP PDU can be utilized to indicate the possible position of the anchor points of the connection with the new connection parameters relative to the anchor points of the connection with the old connection parameters. This figure only shows Offset0 (and not Offset1 to Offset5) for simplicity. The figure also shows the Instant where the updated connection parameters are applied. The actual Instant occurs $connInterval_{OLD}$ after the last connection event transmitted with the old connection parameters whereas the Instant field in the LL_CONNECTION_UPDATE_IND PDU is set to the *connEventCount* of the connection event transmitted with the old connection parameters.

The ReferenceConnEventCount is set to the *connEventCount* of the connection event on the old connection parameters such that the start of the very next connection event

on the new connection parameters is Offset0 (in milliseconds) away from the start of the ReferenceConnEventCount connection event.

Figure 5.2 shows the case where the Instant is before the ReferenceConnEventCount. Figure 5.3 shows the case where the Instant is after the ReferenceConnEventCount. Imaginary connection events transmitted with the old connection parameters have been shown beyond the Instant and imaginary connection events transmitted with the new connection parameters have been shown before the Instant.

In Figure 5.2 and Figure 5.3, the time interval, Δt, between the Instant and the start of the first connection event transmitted with the new connection parameters can be calculated using the following equation:

$$\Delta t = (connInterval_{NEW} - ((Instant - ReferenceConnEventCount) \times connInterval_{OLD}) \bmod connInterval_{NEW} + offset0) \bmod connInterval_{NEW}$$

Note: The case where the ReferenceConnEventCount and Instant are on different sides of the eventCount wraparound point is not shown in the equations above.

Based on the calculated Δt, the WinOffset and WinSize fields in the LL_CONNECTION_UPDATE_IND PDU could be set accordingly. See Section 5.1.7.3.3 for an example.

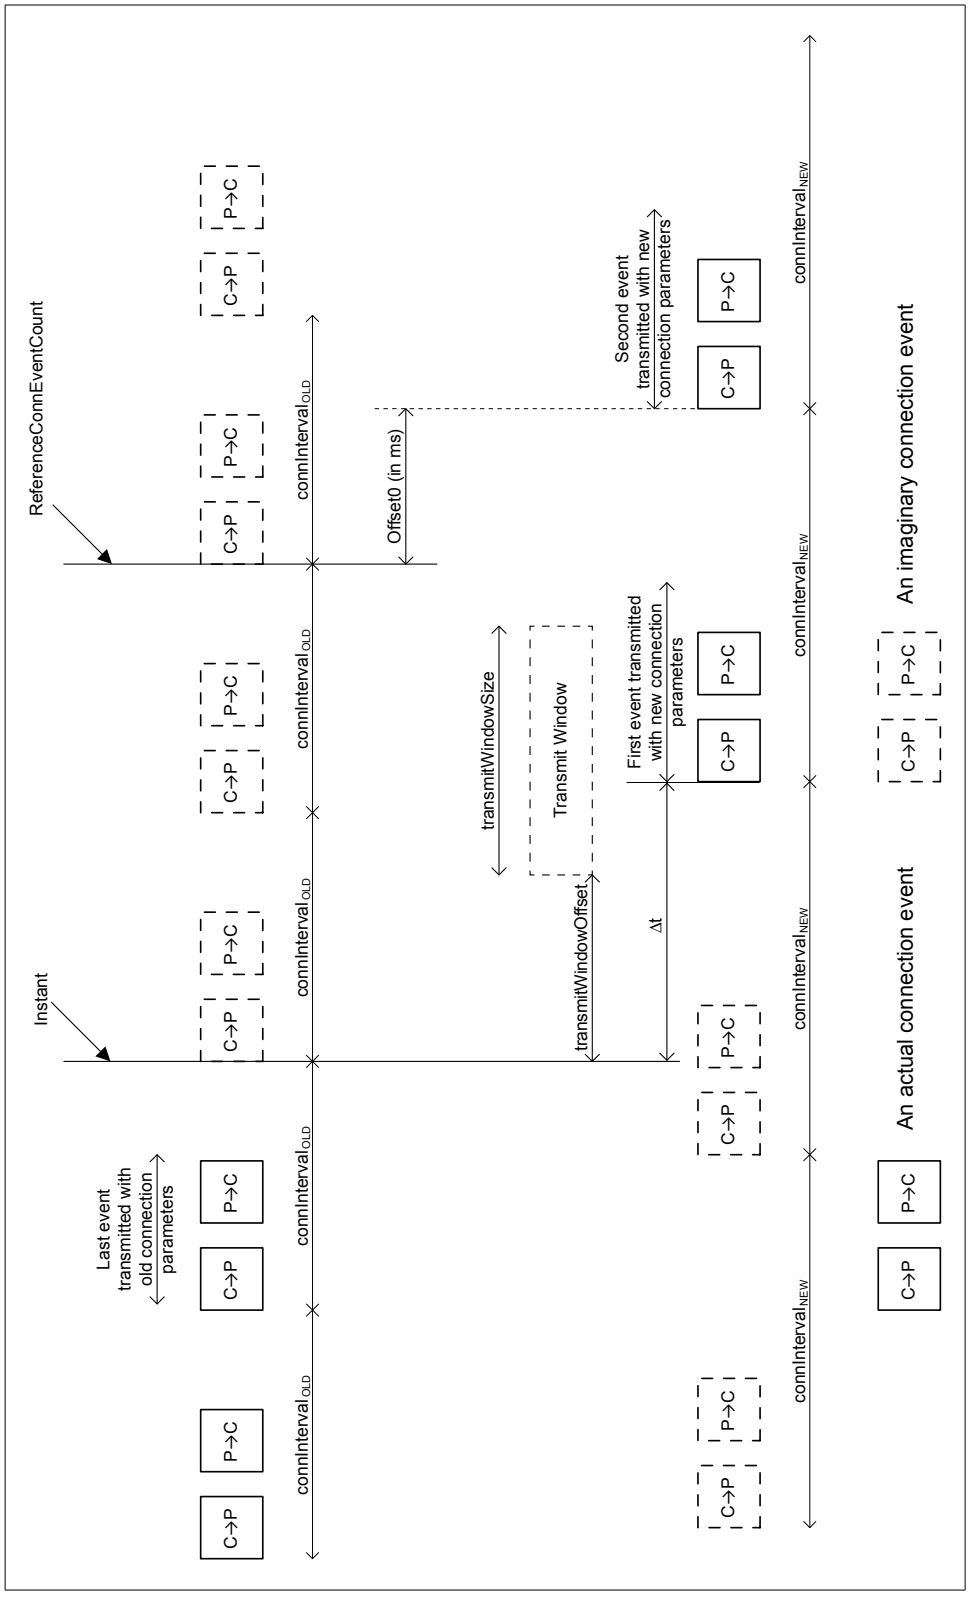

Figure 5.2: Utilizing the ReferenceConnEventCount and Offset0 fields to indicate position of the new anchor points (Instant is before the ReferenceConnEventCount)

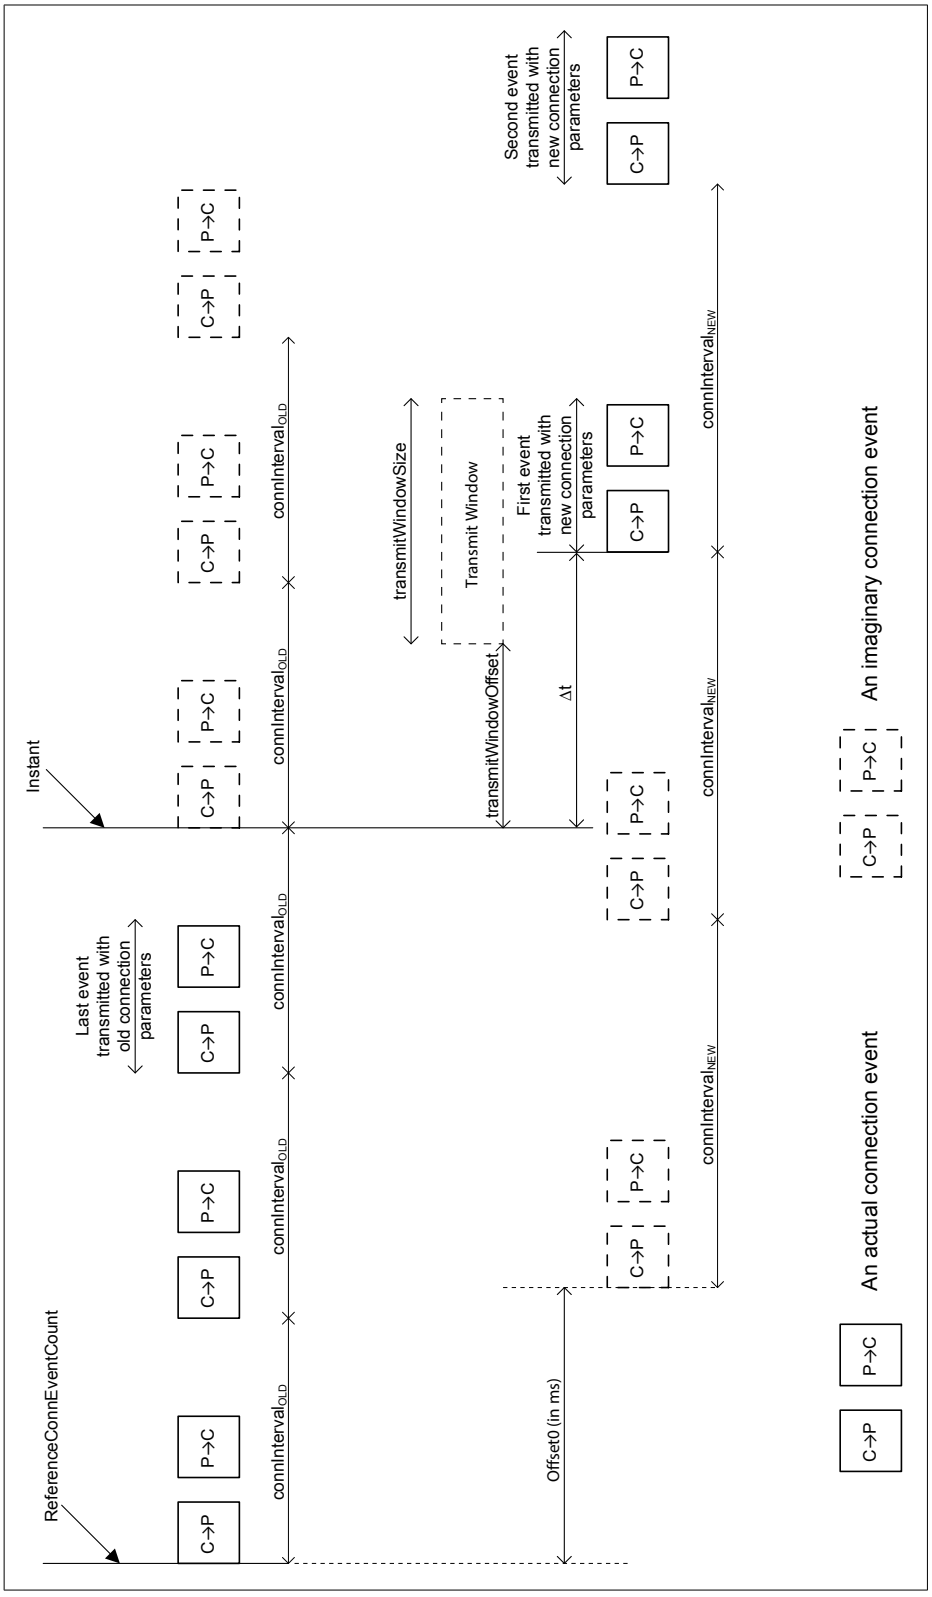

Figure 5.3: Utilizing the ReferenceConnEventCount and Offset0 fields to indicate position of the new anchor points (Instant is after the ReferenceConnEventCount)

5.1.7.3.3 Peripheral initiated interval and anchor point move

The following example shows the Link Layer of the Peripheral requesting a change in both the connection interval (by indicating a PreferredPeriodicity such that PreferredPeriodicity and $connInterval_{OLD}$ are not integer multiples of one another) and a change in anchor points of the LE connection by 3.75 ms with respect to the ReferenceConnEventCount.

In this example, $connInterval_{OLD}$ is 0x0C (15 ms). The Link Layer of the Peripheral issues an LL_CONNECTION_PARAM_REQ PDU with the following parameters:

- Interval_Min: 0x16
- Interval_Max: 0x20
- Latency: *connPeripheralLatency*
- Timeout: *connSupervisionTimeout*
- PreferredPeriodicity: 0x0A
- ReferenceConnEventCount: 0x1F00
- Offset0: 0x0003
- Offset1: 0xFFFF
- Offset2: 0xFFFF
- Offset3: 0xFFFF
- Offset4: 0xFFFF
- Offset5: 0xFFFF

If the Link Layer of the Central accepts the Peripheral's request, then it could respond with an LL_CONNECTION_UPDATE_IND PDU that contains any one of the following set of parameters. In all the sets, the new connection interval $connInterval_{NEW}$ is set to 0x1E (37.5 ms), Latency is set to *connPeripheralLatency*, Timeout is set to *connSupervisionTimeout* and Instant is set to 0x1F06.

Δt, as described in Section 5.1.7.3.2 is calculated as 21 (26.25 ms).

The WinSize and WinOffset fields in the LL_CONNECTION_UPDATE_IND PDU can contain any of the following example set of parameters:

- Option 1: the first packet sent after the instant by the Central is inside the Transmit Window and 3.75 ms from the beginning of the Transmit Window.
  - 3 ≤ WinSize ≤ 8
  - WinOffset: 18

- Option 2: the first packet sent after the instant by the Central is inside the Transmit Window and 2.5 ms from the beginning of the Transmit Window.
  - 2 ≤ WinSize ≤ 8
  - WinOffset: 19
- Option 3: the first packet sent after the instant by the Central is inside the Transmit Window and 1.25 ms from the beginning of the Transmit Window.
  - 1 ≤ WinSize ≤ 8
  - WinOffset: 20
- Option 4: the first packet sent after the instant by the Central is inside the Transmit Window and 0 ms from the beginning of the Transmit Window.
  - 1 ≤ WinSize ≤ 8
  - WinOffset: 21

5.1.7.4 Packet transmit time restrictions

This section only applies if the current PHY is the LE Coded PHY and the Controller supports the LE Data Packet Length Extension feature.

After having sent or received an LL_CONNECTION_UPDATE_IND PDU that decreases the connection interval, and until the instant has been reached, the Link Layer shall not transmit a packet that would take longer than *connEffectiveMaxTxTime* microseconds (see Section 4.5.10) to transmit, calculated using the connection interval that will apply after the instant.

After a Peripheral sends an LL_CONNECTION_PARAM_REQ or LL_CONNECTION_PARAM_RSP PDU where *Interval_Min* indicates an interval less than the current connection interval, and until it receives an LL_CONNECTION_UPDATE_IND, LL_UNKNOWN_RSP, or LL_REJECT_EXT_IND PDU in response, its Link Layer shall not transmit a packet that would take longer than *connEffectiveMaxTxTime* microseconds to transmit, calculated using a connection interval corresponding to the *Interval_Min* value in the transmitted PDU.

If the value of *connEffectiveMaxTxTime* changes during the procedure, the above requirements apply to the value at the moment the LL Data PDU is queued for transmission.

Note: The requirements of this section are in addition to, and do not override, those in Section 4.5.10.

Note: If a Link Layer has any LL Data PDUs queued for transmission at the start of the procedure or queues any during the procedure, it may need to re-fragment those PDUs in order to meet these requirements.

5.1.8 LE Ping procedure

The Link Layer may use the LE Ping procedure, when supported, to verify the presence of the remote Link Layer, or to verify message integrity on the LE ACL logical transport, by forcing the remote device to send an LE ACL packet that contains a valid MIC.

This procedure may be used even if it is not supported by the peer's Link Layer.

Either the Central or the Peripheral Link Layer may initiate this procedure at any time after entering the Connection state by sending an LL_PING_REQ PDU. The responding Link Layer responds with the LL_PING_RSP PDU.

The Link Layer supporting this feature shall send an LL_PING_REQ PDU when the remote device has not sent a packet containing a Payload field protected by a MIC within the authenticated payload timeout set by the Host ([Vol 4] Part E, Section 7.3.94). The Link Layer should send an LL_PING_REQ PDU in advance enough of the expiration of the authenticated payload timeout to allow the remote device reasonable time to respond with an LL_PING_RSP PDU before the timeout expires.

The procedure has completed when an LL_PING_RSP is received.

5.1.9 Data Length Update procedure

A Controller uses the Data Length Update procedure to transmit the latest values of the current maximum Receive LL Data PDU Payload length and PDU Time (*connMaxRxOctets* and *connMaxRxTime*) and the current maximum Transmit LL Data PDU Payload length and PDU Time (*connMaxTxOctets* and *connMaxTxTime*) to the peer device.

Both the Central and Peripheral may initiate this procedure by sending an LL_LENGTH_REQ PDU. This procedure shall be initiated by the Link Layer whenever any of these parameters change, whether requested by the Host or autonomously by the Link Layer. However, if this procedure has already been initiated by the remote Controller and the local Controller has not yet responded, it shall use the response to communicate the changes instead of initiating a new procedure.

If the Link Layer receives an LL_LENGTH_REQ, or an LL_LENGTH_RSP PDU that was a response to an LL_LENGTH_REQ PDU, then it shall update its *connRemoteMaxTxOctets*, *connRemoteMaxRxOctets*, *connRemoteMaxTxTime*, and *connRemoteMaxRxTime* parameters for the connection with the values in the PDU. It shall immediately start using the updated values for all new LL Data PDUs queued for transmission (including any response as specified in the next paragraph). The lengths of any LL Data PDUs that have already been queued for transmission or transmitted at least once shall not be changed.

Note: Because Link Layer PDUs are not required to be processed in real time, it is possible for the local Controller to have queued but not yet transmitted an LL_LENGTH_REQ PDU when it receives an LL_LENGTH_REQ PDU from the peer device. In this situation each device responds as normal; the resulting collision is harmless.

Upon receiving an LL_LENGTH_REQ PDU, the Link Layer shall respond with an LL_LENGTH_RSP PDU containing its own *connMaxTxOctets*, *connMaxRxOctets*, *connMaxTxTime*, and *connMaxRxTime* values for the connection (which it may have updated based on the values received, for example so as to allow the remote device to transmit longer packets).

If the peer device does not support the LE Coded PHY feature, then the MaxRxTime and MaxTxTime fields in the LL_LENGTH_REQ and LL_LENGTH_RSP PDUs shall be set to a value less than or equal to 2128 microseconds.

The procedure has completed when the initiating Controller receives an LL_LENGTH_RSP PDU.

5.1.10 PHY Update procedure

The Central or Peripheral may use the PHY Update procedure, when supported, to change the transmit or receive PHYs, or both, of an ACL connection; it does not affect the transmit or receive PHY of any associated Connected Isochronous Streams. The procedure may be initiated either on a request by the Host or autonomously by the Link Layer. Link Layer PHY preferences may change during a connection or between connections and, therefore, they should not be cached by the peer device.

When this procedure is initiated by the Central, it sends an LL_PHY_REQ PDU. The Peripheral responds with an LL_PHY_RSP PDU. The Central then responds to this with an LL_PHY_UPDATE_IND PDU.

When this procedure is initiated by the Peripheral, it sends an LL_PHY_REQ PDU. The Central responds with an LL_PHY_UPDATE_IND PDU.

The TX_PHYS and RX_PHYS fields of the LL_PHY_REQ and LL_PHY_RSP PDUs shall be used to indicate the PHYs that the sending Link Layer prefers to use. These shall represent PHYs that the sending Link Layer supports. If the sender wants a symmetric connection (one where the two PHYs are the same) it should make both fields the same, only specifying a single PHY.

The PHY_C_TO_P and PHY_P_TO_C fields of the LL_PHY_UPDATE_IND PDU shall indicate the PHYs that shall be used after the instant.

If the Central initiated the procedure, it shall determine the PHY to use in each direction based on the contents of the LL_PHY_REQ and LL_PHY_RSP PDUs using the following rules:

- the PHY_C_TO_P field of the LL_PHY_UPDATE_IND PDU shall be determined from the Central's TX_PHYS field and the Peripheral's RX_PHYS field;
- the PHY_P_TO_C field of the LL_PHY_UPDATE_IND PDU shall be determined from the Central's RX_PHYS field and the Peripheral's TX_PHYS field.

In each of those cases the following rules apply:

- if, for at least one PHY, the corresponding bit is set to 1 in both the TX_PHYS and RX_PHYS fields, the Central shall select any one of those PHYs for that direction;
- if there is no PHY for which the corresponding bit is set to 1 in both the TX_PHYS and RX_PHYS fields, the Central shall not change the PHY for that direction.

If the Peripheral initiated the procedure, the Central shall determine the PHY to use in each direction based on the contents of the LL_PHY_REQ PDU sent by the Peripheral using the following rules:

- the PHY_C_TO_P field of the LL_PHY_UPDATE_IND PDU shall be determined from the RX_PHYS field of the Peripheral’s PDU;
- the PHY_P_TO_C field of the LL_PHY_UPDATE_IND PDU shall be determined from the TX_PHYS field of the Peripheral’s PDU.

In each of those cases the following rules apply:

- if, for at least one PHY, the PHY is one that the Central prefers to use and the corresponding bit is set to 1 in the relevant field of the Peripheral’s PDU, the Central shall select any one of those PHYs for that direction;
- if there is no PHY which the Central prefers to use and for which the corresponding bit is set to 1 in the relevant field of the Peripheral’s PDU, the Central shall not change the PHY for that direction.

The remainder of this section shall apply irrespective of which device initiated the procedure.

Irrespective of the above rules, the Central may leave both directions unchanged. If the Peripheral specified a single PHY in both the TX_PHYS and RX_PHYS fields and both fields are the same, the Central shall either select the PHY specified by the Peripheral for both directions or shall leave both directions unchanged.

If either PHY will change, Section 5.5 shall apply to the LL_PHY_UPDATE_IND PDU. Both devices shall use the new PHYs starting at the instant.

The procedure has completed when:

- an LL_REJECT_EXT_IND PDU has been sent or received;
- an LL_PHY_UPDATE_IND PDU indicating that neither PHY will change has been sent or received; or
- the Central sends an LL_PHY_UPDATE_IND PDU indicating that at least one PHY will change and the instant has been reached. In this case, the procedure response timeout shall be stopped on the Central when it sends that PDU and on the Peripheral when it receives that PDU.

If the Peripheral receives an LL_PHY_UPDATE_IND where either PHY field specifies a PHY that the Peripheral does not support, has a bit set that is reserved for future use, or has more than one bit set, the Peripheral shall not change the PHY in that direction.

The Controller shall notify the Host of the PHYs now in effect when the PHY Update procedure completes if either it has resulted in a change of one or both PHYs or if the procedure was initiated by a request from the Host. Otherwise, it shall not notify the Host that the procedure took place.

The Link Layer can reject a proposed change to either PHY (by not setting the corresponding bit in its response) because, for example, a PHY with a lower bit rate could not be scheduled among other activities or because the requested PHY does not support Constant Tone Extensions. Such a rejection could, however, result in link loss if the change was requested to improve reliability.

5.1.10.1 Packet transmit restrictions

For each row of Table 5.1, on the Link Layer(s) in the role(s) listed in the first column and during the period starting with the event described in the second column and ending with the event described in the third column, the Link Layer shall not transmit either of:

- any packet that would take longer than *connEffectiveMaxTxTime* microseconds (see Section 4.5.10) to transmit on any relevant PHY
- any packet with a Constant Tone Extension if any relevant PHY does not allow Constant Tone Extensions

where a “relevant PHY” is a PHY described in the fourth column.

Role(s)	Starting event	Ending event	Relevant PHY(s)
Either	the Link Layer sends or receives an LL_PHY_UPDATE_-IND PDU that changes either PHY	the instant	the PHY that will apply after the instant
Peripheral	the Link Layer sends an LL_PHY_REQ PDU	the Link Layer receives an LL_PHY_UPDATE_IND, LL_UNKNOWN_RSP, or LL_REJECT_EXT_IND PDU in response	any PHY that appears in the TX_PHYS field of that LL_PHY_REQ PDU
Peripheral	the Link Layer sends an LL_PHY_RSP PDU	the Link Layer receives the LL_PHY_UPDATE_IND PDU in response	any PHY that appears in both the TX_PHYS field of the Peripheral's LL_PHY_RSP PDU and the RX_PHYS field of the Central's LL_PHY_REQ PDU

Table 5.1: PHY update packet transmit restrictions

If the value of *connEffectiveMaxTxTime* changes during the procedure (for example, if the Data Length Update procedure is performed before the Instant is reached), the above requirements apply to the value at the moment the LL Data PDU is queued for transmission.

Note: The requirements of this section are in addition to, and do not override, those in Section 4.5.10.

If a Link Layer has any LL Data PDUs queued for transmission at the start of the procedure or queues any during the procedure, it might need to re-fragment those PDUs in order to obey the requirements in this section. This can be necessary if, for example, the transmit PHY changes from the LE 2M PHY to the LE 1M PHY and the value of *connEffectiveMaxTxTime* does not increase enough to compensate for the lower bit rate.If a Link Layer has any packets with a Constant Tone Extension queued for transmission at the start of the procedure or queues any during the procedure, it might need to delay them, cancel them, or (if the packets contain an LL_CTE_RSP PDU) replace them by LL_REJECT_EXT_IND PDUs in order to obey the requirements in this section.

5.1.11 Minimum Number Of Used Channels procedure

A Peripheral's Controller may use the Minimum Number Of Used Channels procedure to request that the peer device uses a minimum number of channels on a given PHY.

The Peripheral initiates this procedure by sending an LL_MIN_USED_CHANNELS_IND PDU. The Central shall not send this PDU.

If the Link Layer receives an LL_MIN_USED_CHANNELS_IND PDU, it should ensure that, whenever the Peripheral-to-Central PHY is one of those specified, the connection uses at least the number of channels given in the MinUsedChannels field of the PDU.

The procedure has completed when the Link Layer acknowledgment of the LL_MIN_USED_CHANNELS_IND PDU is sent or received.

If the channel map does not include the minimum number of channels the Peripheral requires for regulatory compliance, the Peripheral must take steps to remain regulatory compliant, which can include disconnecting the link or reducing the output power.

5.1.12 Constant Tone Extension Request procedure

The Central or Peripheral may use the Constant Tone Extension Request procedure, when supported, to request the remote Link Layer to send a packet containing an LL_CTE_RSP PDU and a Constant Tone Extension (see Section 2.5.3).

Either the Central or the Peripheral Link Layer initiates this procedure by sending an LL_CTE_REQ PDU.

If:

- Constant Tone Extension responses are enabled;
- the current transmitter PHY is one that allows Constant Tone Extensions;
- Section 5.1.10.1 would not prohibit the response from being transmitted;
- the length of Constant Tone Extension requested in the LL_CTE_REQ PDU is not greater than the maximum length the responding device supports; and
- the responding device is currently configured to respond with the type of Constant Tone Extension requested in the LL_CTE_REQ PDU;

then the remote Link Layer shall respond with an LL_CTE_RSP PDU that includes a Constant Tone Extension of the requested type and whose length is greater than or equal to that requested. Otherwise the remote Link Layer shall respond with an LL_REJECT_EXT_IND PDU. If Constant Tone Extension responses are disabled or the Link Layer is not currently configured to respond with the type and length of the requested Constant Tone Extension, the ErrorCode shall be set to *Unsupported LMP Parameter Value/Unsupported LL Parameter Value* (0x20). If Constant Tone Extensions are not allowed on the current transmitter PHY, the ErrorCode shall be set to *Invalid LMP Parameters/Invalid LL Parameters* (0x1E). If Section 5.1.10.1 would prohibit the response from being transmitted, the ErrorCode shall be set to *Different Transaction Collision* (0x2A).

IQ sampling (see Section 2.5.4) shall be performed while receiving the Constant Tone Extension of the LL_CTE_RSP PDU and the sampling results shall be reported to the Host.

The procedure has completed when either an LL_CTE_RSP PDU has been sent or received or an LL_REJECT_EXT_IND PDU is sent or received with the RejectOpcode set to LL_CTE_REQ.

5.1.13 Periodic Advertising Sync Transfer procedure

A Controller may use the Periodic Advertising Sync Transfer procedure to transfer, to a connected peer device, the synchronization information necessary to synchronize to a periodic advertising train (see Section 4.4.3.4).

Either the Central or the Peripheral Link Layer initiates this procedure by sending an LL_PERIODIC_SYNC_IND PDU or an LL_PERIODIC_SYNC_WR_IND PDU. The PDU used is determined by the type of the periodic advertising used. For PAwR, the LL_PERIODIC_SYNC_WR_IND PDU shall be used, otherwise the LL_PERIODIC_SYNC_IND PDU shall be used. If the LL_PERIODIC_SYNC_WR_IND PDU is used, then the RspAA shall be set to an Access Address value as specified in Section 2.1.2.

If the Host has enabled receipt of transfers and the Link Layer receives an LL_PERIODIC_SYNC_IND PDU or an LL_PERIODIC_SYNC_WR_IND PDU that describes a periodic advertising train that the Link Layer is neither already synchronized with nor in the process of synchronizing with, the Link Layer shall synchronize with the described periodic advertising train and then notify the Host; it shall also notify the Host if synchronization fails. However, if the PHY field of the LL_PERIODIC_SYNC_IND PDU or the LL_PERIODIC_SYNC_WR_IND PDU has no bits or more than one bit set, or the bit set corresponds to a PHY that the recipient does not support or is reserved for future use, the recipient shall ignore the PDU.

The procedure has completed when an LL_PERIODIC_SYNC_IND PDU or an LL_PERIODIC_SYNC_WR_IND PDU has been sent or received.

5.1.13.1 Timing considerations

This section explains the issues in handling the relative drifts of three separate device clocks and does not create any requirements. This section does not apply when devices A and B are the same because there is then no clock drift between the two.

In general there are three devices involved in the Periodic Advertising Sync Transfer procedure: the periodic advertiser A, the initiating device B, and the receiving device C. Each of these can have a different sleep clock accuracy. Therefore device C needs to carry out various steps to determine the timing and required receive window for synchronizing to the periodic advertising.

In the following formulae and in Figure 5.4:

- *PEa* is the value of *paEventCounter* stored in the SyncInfo within the LL_PERIODIC_SYNC_IND PDU.
- *PEb* is the value of *paEventCounter* for a recent AUX_SYNC_IND PDU that device B has received; this value is stored in the *lastPaEventCounter* field of the LL_PERIODIC_SYNC_IND PDU.
- *PEc* is the value of *paEventCounter* for the AUX_SYNC_IND PDU that device C is attempting to receive.

  Note: *PEc* can be before, after, or the same as *PEa*.
- *PAI* is the periodic advertising interval as represented by the *Interval* field of the SyncInfo within the LL_PERIODIC_SYNC_IND PDU.
- *CEs* is the value of *connEventCounter* for the connection event when devices B and C synchronized their anchor points and that device B used to determine the contents of the LL_PERIODIC_SYNC_IND PDU; this value is stored in the *syncConnEventCount* field of the PDU.
- *CEt* is the value of *connEventCounter* for the connection event when the LL_PERIODIC_SYNC_IND PDU was (re)transmitted by device B and received by device C.
- *CEref* is the value of *connEventCount* in the LL_PERIODIC_SYNC_IND PDU.
- *CEc* is a connection event before the AUX_SYNC_IND PDU that device C is attempting to receive.
- *CI* is the connection interval for the connection between devices B and C.
- *Offset* is the value represented by the syncPacketWindowOffset value within the LL_PERIODIC_SYNC_IND PDU.
- *Target* is the time from the anchor point of connection event *CEc* to the AUX_SYNC_IND PDU that device C is attempting to receive.
- *CAa*, *CAb*, and *CAc* are the clock accuracies of devices A, B, and C respectively. *CAa* is stored in the *SCA* field of the SyncInfo within the LL_PERIODIC_SYNC_IND PDU and *CAb* is stored in the *SCA* field of the LL_PERIODIC_SYNC_IND PDU.

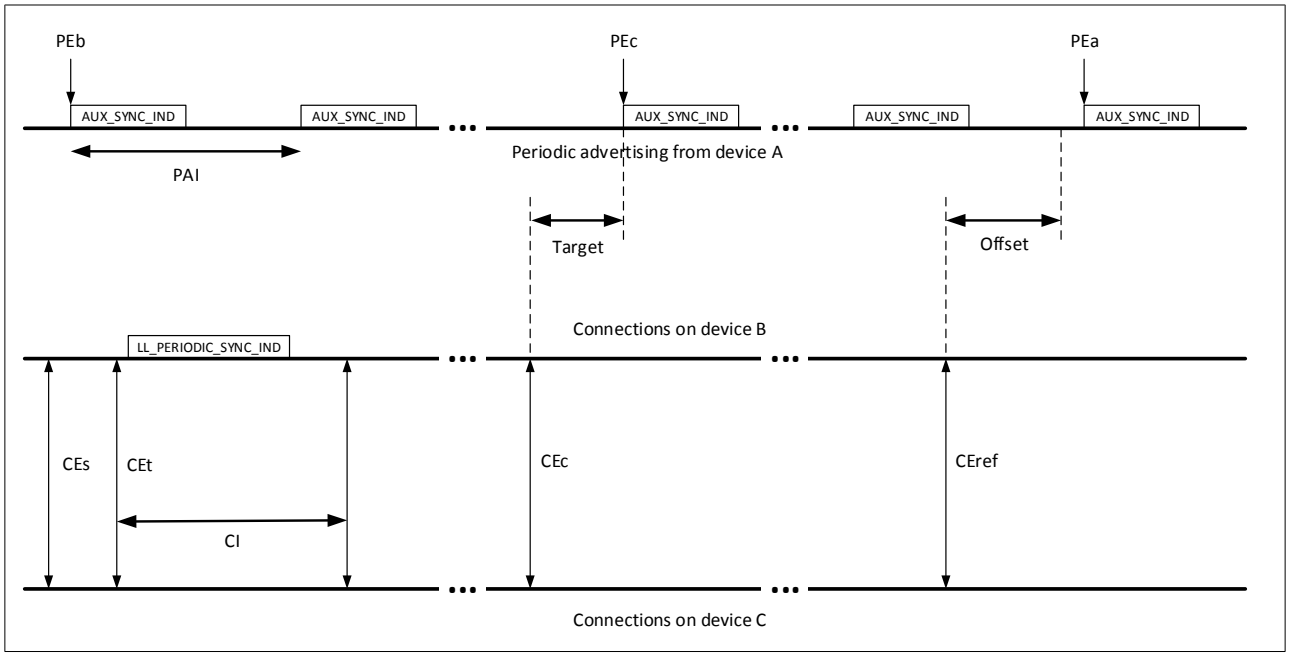

Figure 5.4: Periodic Advertising Sync Transfer procedure timings

If all three devices had a perfectly accurate clock, then:

$$Tnominal \leq Target < Tnominal + U$$

where:

$$Tnominal = (CEref - CEc) \times CI + Offset - (PEa - PEc) \times PAI$$

U = 30 µs or 300 µs depending on the value of the Offset Units field of the SyncInfo

Because of clock drift and jitter, this becomes:

$$Tnominal - D - 16\ \mu s \leq Target < Tnominal + U + D + 16\ \mu s$$

where:

$$D = (Da + Db) \times (1 + CAa + CAb + CAc)$$

Da represents the drift of the periodic advertising and Db the drift of B's clock between CEs and PEb:

$$Da = |PEc - PEb| \times PAI \times (CAa + CAc)$$

$$Db = |CEt - CEs| \times CI \times (CAb + CAc)$$

D should be rounded to the next whole microsecond above.

These values are derived from the assumption that device B will have calculated *Offset* without making any allowance for drift in its own clock. So if *PEb* occurred at time *TPEb* and *CEs* at time *TCEs*, both according to its own clock, device B will have chosen values for *PEa* and *CEref* and then calculated:

$$Offset = (TPEb + (PEa - PEb) \times PAI) - (TCEs + (CEref - CEs) \times CI)$$

When device C calculates *Tnominal*, it again does so without allowing for drift. So, by substituting the above expression for *Offset* in that for *Tnominal* above, we find that:

Tnominal

$= (CEref - CEc) \times CI + (TPEb + (PEa - PEb) \times PAI) - (TCEs + (CEref - CEs) \times CI) - (PEa - PEc) \times PAI$

$= TPEb + (PEa - PEb) \times PAI - (PEa - PEc) \times PAI - TCEs - (CEref - CEs) \times CI + (CEref - CEc) \times CI$

$= TPEb + (PEc - PEb) \times PAI - TCEs - (CEc - CEs) \times CI$

$= (PEc - PEb) \times \mathrm{PAI} + (TPEb - TCEs) - (CEc - CEs) \times CI$

Each of these three terms is based on a different clock:

- The first term depends on *PAI*, which is measured using device A's clock. However, since device C is calculating *Tnominal*, device C's clock must be allowed for as well. The drift in this term is represented by *Da*.
- The expression (*TPEb* – *TCEs*) is the change in B's clock between the two events and so is measured using that clock; again, it is necessary to allow for device C's clock as well. The drift in this term is represented by *Db;* the term in parentheses in the expression for *Db* is an upper bound for the difference.
- The last term is on device C's clock and therefore does not require any adjustment.

The second factor in the formula for *D* allows for second-order effects: if the relevant periodic events are 12 seconds apart, a 500 ppm drift will result in a $20 \times 0.0005^2 = 3$ µs residual error in the required window.

If device C allows for clock drift when making these calculations, it may be able to reduce the window it uses accordingly. If device B allows for clock drift (e.g. by measuring the drift in the periodic advertising timing), the actual drift will be less than that calculated above but device C will not be aware of this. A more detailed analysis based on the exact techniques used in the implementation may allow device C to compute a narrower window.

5.1.14 Sleep Clock Accuracy Update procedure

The Link Layer of the Central or Peripheral may inform its peer of a change to its sleep clock accuracy (*centralSCA* or *peripheralSCA* – see Section 4.2.2), or may query the

peer's sleep clock accuracy, by sending an LL_CLOCK_ACCURACY_REQ PDU. The procedure may be initiated either on a request by the Host or autonomously by the Link Layer. A device should not initiate this procedure more than once per second.

Where the Link Layer will specify a more accurate clock than that currently in use, it shall switch to that clock before initiating or responding to this procedure.

When the Link Layer receives an LL_CLOCK_ACCURACY_REQ PDU, it shall send an LL_CLOCK_ACCURACY_RSP PDU in reply. The sleep clock accuracy specified in the reply shall not be less than the value in use when the request was received on the Link Layer sending that reply.

Note: The Link Layer can delay its response in order to make any necessary internal adjustments to the accuracy change, but not for so long as to trigger a timeout. If the responding device wants to change to a less accurate clock, then, as this section requires, it must do so by initiating this procedure separately.

The procedure has completed when the LL_CLOCK_ACCURACY_RSP is sent or received. Where the initiating Link Layer has specified a less accurate clock than that currently in use, it shall not switch to that clock until it has received the LL_CLOCK_ACCURACY_RSP PDU in reply. If it receives an LL_UNKNOWN_RSP PDU, it shall maintain at least the accuracy specified in the CONNECT_IND or AUX_CONNECT_REQ PDU that created the connection.

5.1.15 Connected Isochronous Stream Creation procedure

The Central Link Layer may use the Connected Isochronous Stream Creation procedure to create a CIS between a Central and a Peripheral. The Central Link Layer initiates this procedure by sending an LL_CIS_REQ PDU. The Peripheral Link Layer shall not initiate this procedure. The Central's Link Layer shall only create a CIS when requested by the Host, only using a CIS_ID that the Host has already stored a configuration for in this CIG, and not using a CIS_ID that corresponds to an existing CIS in the CIG (see Section 4.5.14.3). The Central shall not initiate this procedure if the Connected Isochronous Stream (Host Support) feature bit is not set in its Controller.

When the Peripheral's Link Layer receives the LL_CIS_REQ PDU, it shall either reject the proposed CIS immediately or notify the Host. In the latter case, the Host requests the Link Layer to either accept or reject the proposed CIS. If the Connected Isochronous Stream (Host Support) feature bit is not set in the local Link Layer, then the Peripheral shall reject the proposed CIS with the error code *Unsupported Remote Feature* (0x1A). If either PHY field of the LL_CIS_REQ PDU has no bits or more than one bit set, or if the bit set corresponds to a PHY that the recipient does not support or is reserved for future use, then the Peripheral shall reject the proposed CIS. If the Peripheral does not support the BN, FT, and NSE values in the LL_CIS_REQ PDU, it shall reject the proposed CIS with the error code *Parameter Out of Mandatory Range* (0x30). If the

Framing_Mode field of the LL_CIS_REQ PDU specifies a mode that the Peripheral does not support, then the Peripheral shall reject the proposed CIS. If the Peripheral rejects the proposed CIS, then it shall send an LL_REJECT_EXT_IND PDU with the appropriate reason code. If it accepts the CIS, then it shall send an LL_CIS_RSP PDU.

When the Central's Link Layer receives an LL_CIS_RSP PDU, it shall either create the CIS by replying with an LL_CIS_IND PDU or shall cancel it by replying with an LL_REJECT_EXT_IND PDU with the appropriate reason code. The Central shall not cancel the CIS if the proposed timings are within those specified in the LL_CIS_REQ PDU unless the Host requested that the CIS be terminated.

When the Central sends and the Peripheral receives the LL_CIS_IND PDU, both devices shall stop the procedure response timeout timer, create the CIS, and start transmitting and receiving CIS PDUs. The first anchor point of the CIS, with *cisEventCounter* equal to zero, shall be at the moment specified in the LL_CIS_IND PDU. The CIS is considered established by each Link Layer when that Link Layer has received a CIS PDU from the peer that is part of the CIS.

The Central's Link Layer shall calculate CIG_Sync_Delay and CIS_Sync_Delay for each CIS and send them to the Peripheral in the LL_CIS_IND PDU.

If either Link Layer sends or receives an LL_REJECT_EXT_IND PDU, it shall terminate the procedure immediately and not create the CIS. The CIS configuration nevertheless remains stored within the CIG and the corresponding CIS can be created later. The procedure has completed on each Link Layer when the CIS is established or when an LL_REJECT_EXT_IND PDU has been sent or received. Each Link Layer shall notify its Host when the procedure has completed.

The values of the CIS_Offset_Min, CIS_Offset_Max, and connEventCount fields of the LL_CIS_REQ and LL_CIS_RSP PDUs each specify a window for the CIS anchor point. The window specified by the LL_CIS_RSP PDU shall lie entirely within a window equivalent to that specified by the LL_CIS_REQ PDU. The first CIS anchor point shall lie within a window equivalent to that specified by the LL_CIS_RSP PDU. For this purpose, two windows are equivalent if they have the same width and the difference between their start times is an integer multiple of ISO_Interval for the CIS. The edges of each window are part of the window so, for example, the two windows can be identical.

Section 5.5 shall apply to the LL_CIS_IND PDU as if the *connEventCount* field was an Instant.

The Link Layer should schedule the CIS so that the CIS events do not overlap with the connection events on the associated ACL.

5.1.16 Connected Isochronous Stream Termination procedure

The Central or Peripheral may use this procedure for voluntary termination of a CIS while in the Connection state. Voluntary termination occurs when the Host requests the Link Layer to terminate the connection. The Link Layer initiates this procedure by sending an LL_CIS_TERMINATE_IND PDU.

The Link Layer shall not transmit or receive on the CIS after it has received or queued for transmission the LL_CIS_TERMINATE_IND PDU.

The procedure has completed when the Link Layer acknowledgment has been sent or received.

Note: Terminating a CIS does not affect the associated ACL.

5.1.17 Power Control Request procedure

The Link Layer of the Central or Peripheral may use the Power Control Request procedure, when supported, to request a remote Controller to adjust its transmit power level on a specified PHY by a given amount. Power Control requests carried over an LE-ACL logical link only affect the power level used on that link and any associated physical link(s) such as isochronous physical links and CS physical links; they do not affect the power level used on the physical links to other connected and unconnected devices.

The Link Layer initiates this procedure by sending an LL_POWER_CONTROL_REQ PDU.

The Link Layer can query the current transmit power level and acceptable power reduction of the remote Controller by sending an LL_POWER_CONTROL_REQ PDU with Delta set to zero.

The responding Link Layer shall make the requested change to its transmit power level unless that would take it above the maximum or below the minimum supported power levels or unless it is not currently managing power levels on the requested PHY. If the requested change would take it above the maximum, it shall change the power level to the maximum supported. Otherwise, if it is unable to make exactly the requested change, it shall change the power level to the lowest available level greater than the requested level. In any case, it shall then reply with an LL_POWER_CONTROL_RSP PDU whose contents indicate the actual change made, if any, or that it is not managing the power level for the requested PHY (by setting the power level to 126).

Note: A request to make a small decrease in the power level can result in the power level not changing.

Note: A request with delta equal to zero on a PHY that is not an active PHY can indicate that the sender is about to make that PHY an active PHY.

The Link Layer shall not initiate the Power Control Request procedure until any outstanding CS Start procedure, as described in Section 5.1.26, has completed. If the LL_POWER_CONTROL_REQ PDU is received in this case, then the receiving Link Layer shall respond with an LL_REJECT_EXT_IND PDU with the ErrorCode set to *Controller Busy* (0x3A).

If the Link Layer has sent an LL_POWER_CONTROL_REQ PDU and not yet received a response, or has an LL_POWER_CONTROL_REQ PDU queued for transmission, and then receives an LL_POWER_CONTROL_REQ PDU from the same peer device, it shall set the APR field to 0xFF in its response to that PDU. A responding Link Layer may also set the APR field to 0xFF when it is not managing the power level of the requested PHY, if it does not have a valid value to report, or if it does not support this field. Otherwise the responding Link Layer shall set the APR field as described in Section 5.1.17.1.

The new power level for the PHY shall take effect before the response is sent.

Note: The Link Layer may request the remote Link Layer to change the preferred transmit power level for a different PHY, for example before initiating a PHY Update procedure or creating an associated CIS on a PHY different from the one used for the ACL. To do this, it may query the remote Link Layer for the transmit power level that it would use for that PHY and then request a change to the transmit power level.

If the PHY in the LL_POWER_CONTROL_REQ PDU is not supported by the remote Link Layer in its transmit direction or the PHY field contains no set bits, more than one set bit, or a bit set that is reserved for future use, the remote Link Layer shall respond with an LL_REJECT_EXT_IND PDU with the ErrorCode set to *Unsupported LMP Parameter Value/Unsupported LL Parameter Value* (0x20).

If the TxPower in the LL_POWER_CONTROL_REQ PDU is set to 126, the remote Link Layer shall respond with an LL_REJECT_EXT_IND_PDU with the ErrorCode set to *Invalid LL Parameters* (0x1E).

The procedure has completed when either an LL_POWER_CONTROL_RSP PDU has been sent or received or an LL_REJECT_EXT_IND PDU has been sent or received with the RejectOpcode field set to LL_POWER_CONTROL_REQ.

5.1.17.1 Acceptable power reduction

A radio receiver may have a “golden range” of RSSI that it prefers the incoming signal to remain within. A device with such a receiver can use the Power Control Request procedure to bring the current RSSI ($RSSI_{curr}$) of the incoming signal to a preferred

value within its golden range. Nevertheless, it may still be able to receive the signal at a level that is equal to or above a minimum acceptable RSSI ($RSSI_{min}$) that is lower than the current RSSI. A device can use the Power Control Request procedure to check whether its peer can accept such a reduction in power and, if so, adjust its transmit power based on the response.

When a device sends an LL_POWER_CONTROL_RSP PDU, it should set the APR field to the value given by the following equation:

$$APR = \begin{cases} 0, & if\ RSSI_{curr} \leq RSSI_{min} \\ RSSI_{curr} - RSSI_{min}, & if\ RSSI_{curr} > RSSI_{min} \end{cases}$$

When a device reports an APR value to the peer device other than zero or 0xFF, it should wait at least two connection intervals to see if the peer device has made use of it to change its local transmit power before initiating a new Power Control Request procedure to request a remote transmit power level change. A device can determine if the peer device has changed its transmit power by sending an LL_POWER_CONTROL_REQ PDU with Delta set to zero, by looking for changes in the RSSI of incoming packets, or by the receipt of an LL_POWER_CHANGE_IND PDU.

When a device receives an APR value from the peer device other than 0xFF, the time period for which that value is considered to remain valid is implementation-specific; for example, the Link Layer can examine changes in received RSSI and remote transmit power level since the APR value was received. When a device receives an APR value other than 0xFF from the peer device, it shall not reduce its power level more than the value specified. When the device receives an APR value of 0xFF, it may choose to ignore any previous APR values.

5.1.18 Power Change Indication procedure

The Link Layer uses the Power Change Indication procedure, when supported, to notify the remote Link Layer of transmit power changes.

After the peer has sent at least one LL_POWER_CONTROL_REQ PDU, a Link Layer shall send an autonomous notification consisting of an LL_POWER_CHANGE_IND PDU each time that any of the following happens:

- It changes the power level autonomously on any PHY that it is managing power levels for.
- It changes the maximum power level on its current transmit PHY to the current power level.
- It starts managing the power level for a PHY.
- It stops managing the power level for a PHY.

A Link Layer shall not send the LL_POWER_CHANGE_IND PDU in any other circumstance. If two or more of the above situations occur for the same PHY at the same time or within a connection interval, it may combine the reports into a single LL_POWER_CHANGE_IND PDU. A Link Layer should not perform autonomous power level updates more than once per second to avoid sending too many LL_POWER_CHANGE_IND PDUs to the remote device.

If the notification is for the current ACL PHY, it shall be sent at the power level specified in the notification.

The procedure has completed when the LL_POWER_CHANGE_IND PDU has been sent or received.

The recipient shall ignore all bits of the PHY field of the LL_POWER_CHANGE_IND PDU that correspond to PHYs that it does not support or are reserved for future use. If the PHY field has no bits set or if every bit set corresponds to a PHY that the recipient does not support or is reserved for future use, the recipient shall ignore the PDU.

5.1.19 Connection Subrate Update procedure

The Central's Link Layer may update the subrate parameters (*connSubrateBaseEvent*, *connSubrateFactor*, and *connContinuationNumber*), *connPeripheralLatency*, and *connSupervisionTimeout* of a connection by sending an LL_SUBRATE_IND PDU. The Peripheral shall not send this PDU. The Central shall only initiate this procedure when requested by the Host, when requested by the Peripheral via the Connection Subrate Request procedure, or as recommended in Section 5.5. The Central shall not initiate this procedure while a Connection Parameters Request procedure is in progress. The Central shall not initiate this procedure until it has performed a Feature Exchange procedure (see Section 5.1.4) to determine that the Connection Subrating (Host Support) bit is set in the Peripheral's FeatureSet. A device shall not initiate this procedure while a CS procedure or CS procedure repeat instances, as described in Section 4.5.18.1, are in progress.

After the Central transmits this PDU for the first time during a Connection Subrate Update procedure, it shall enter subrate transition mode. The Central leaves subrate transition mode when it receives the Link Layer acknowledgment for the PDU and then uses the new subrate base event, subrate factor, continuation number, Peripheral latency, and supervision timeout.

During subrate transition mode, the Central shall retransmit the PDU on all connection events which are subrated connection events based on the old subrate base event and subrate factor or are subrated connection events based on the new subrate base event and subrate factor (ignoring Peripheral latency). It shall continue to use the old supervision timeout. If the new continuation number is non-zero then the Central may also transmit on other connection events. The Central's Link Layer may take the

Peripheral's opportunities for reception into account when determining which connection events it chooses to transmit on while in subrate transition mode.

When the Peripheral receives this PDU it shall immediately switch to the new subrate base event, subrate factor, continuation number, Peripheral latency, and supervision timeout.

For example, as shown in Figure 5.5, if the old subrate base event is 32, the old subrate factor is 5, the new subrate base event is 38, the new subrate factor is 3, and the Central transmitted the LL_SUBRATE_IND PDU on connection event 42, then the old parameters will result in the devices using connection events 37, 42, 47, 52, 57 etc. while the new parameters will result in the devices using connection events 44, 47, 50, 53, 56, etc. Therefore, while it is in subrate transition mode, the Central will use connection events 42, 44, 47, 50, 52, 53, 56, 57, and so on until it receives the acknowledgment.

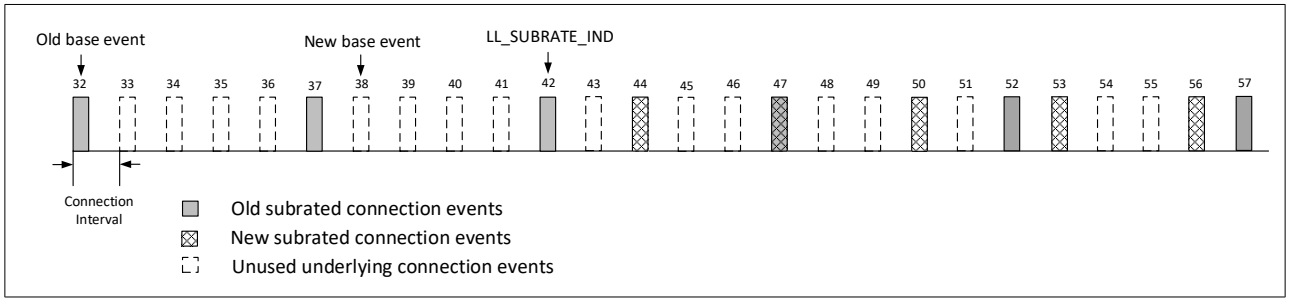

Figure 5.5: Connection events used during subrate transition mode

The Central shall set the value of SubrateBaseEvent ("S") in the PDU so that $S_{15\text{-}14} = E_{15\text{-}14}$, where E is the value of *connEventCount* for the connection event when the PDU is first queued for transmission. If the Peripheral receives an LL_SUBRATE_IND PDU with $S_{15\text{-}14}$ = 0b11 in a connection event with $connEventCounter_{15\text{-}14}$ = 0b00 then, immediately after updating the parameters, it shall change *connSubrateBaseEvent* as described in Section 4.5.1 as if the value of *connEventCount* had just wrapped.

The requirement on the value of $S_{15\text{-}14}$ means the Peripheral can determine whether the Central intended to send the PDU before or after *connEventCount* wrapped. For example, consider the situation where the current *connSubrateFactor* is 10 and the current *connSubrateBaseEvent* is 12002. As the point of wrap approaches, these parameters mean that the connection events used are 65522, 65532, 6, 16, 26, etc. If the LL_SUBRATE_IND PDU contained those values for these two parameters then, if the PDU was queued, sent, and received on event 65532, it indicated that the same connection events are to be used; on the other hand, if the PDU was queued, sent, and received on event 6, then it implies a change of phase so that connection events 12, 22, 32, etc. are to be used instead. Since internal queues and retransmissions can mean that a packet queued for event 65532 could be received in event 6, the Peripheral

needs to be able to distinguish these two cases, which it does by making the test described.

The procedure has completed when the Link Layer acknowledgment for the LL_SUBRATE_IND PDU has been sent or received.

The Peripheral shall accept an LL_SUBRATE_IND PDU. However, if the Peripheral's Host would prefer a different subrate factor it may, after this procedure has completed, initiate the Connection Subrate Request procedure or the Connection Parameters Request procedure to change the connection parameters.

5.1.20 Connection Subrate Request procedure

The Peripheral's Link Layer may request the Central to update the subrate factor, Peripheral latency, continuation number, and supervision timeout by sending an LL_SUBRATE_REQ PDU. The Central shall not send this PDU. The Peripheral shall only initiate this procedure when requested by the Host.

A device shall not initiate this procedure while a CS procedure or CS procedure repeat instances, as described in Section 4.5.18.1, are in progress.

When the Central receives this PDU it shall either initiate the Connection Subrate Update procedure or shall respond with an LL_REJECT_EXT_IND PDU to reject the request. If the Central's Host has not set the Connection Subrating (Host Support) bit in the FeatureSet, the Central's Link Layer shall reject the request. If the Central's Host has provided acceptable subrate parameters for requests from the Peripheral, then the Central's Link Layer shall initiate the Connection Subrate Update procedure if and only if all of the following are true ("acceptable" indicates values provided by the Host, see [Vol 4] Part E, Section 7.8.123 and [Vol 4] Part E, Section 7.8.124; "requested" indicates values in the LL_SUBRATE_REQ PDU):

- $Max\_Latency_{requested} \leq Max\_Latency_{acceptable}$,
- $Timeout_{requested} \leq Supervision\_Timeout_{acceptable}$,
- $SubrateFactorMax_{requested} \geq Subrate\_Min_{acceptable}$,
- $SubrateFactorMin_{requested} \leq Subrate\_Max_{acceptable}$,
- $(connInterval_{current} \times SubrateFactorMin_{requested} \times (Max\_Latency_{requested} + 1)) \times 2 < Timeout_{requested}$

If the Central accepts the Peripheral’s request, then:

- the new *connSubrateFactor* shall be between $Subrate\_Min_{acceptable}$ and $Subrate\_Max_{acceptable}$ and shall also be between $SubrateFactorMin_{requested}$ and $SubrateFactorMax_{requested}$,

- the new *connContinuationNumber* shall equal min(max(Continuation_Number$_{acceptable}$, ContinuationNumber$_{requested}$), (new *connSubrateFactor*) - 1),
- the new *connPeripheralLatency* shall be less than or equal to min(Max_Latency$_{requested}$, Max_Latency$_{acceptable}$),
- the new *connSupervisionTimeout* shall equal min(Timeout$_{requested}$, Supervision_Timeout$_{acceptable}$).

The procedure has completed when the resulting Connection Subrate Update procedure has completed or an LL_REJECT_EXT_IND PDU has been sent or received.

5.1.21 Channel Classification Enable procedure

A Controller uses the Channel Classification Enable procedure to enable or disable reporting of channel classification information on the peer device. Until the Central initiates this procedure, reporting shall be disabled.

The Central can initiate this procedure at any time after entering the Connection state by sending an LL_CHANNEL_REPORTING_IND PDU. The Peripheral shall not send this PDU.

When a Peripheral that supports the Channel Classification feature receives this PDU, it shall enable or disable reporting of channel classification information to the Central as specified in the PDU. When reporting is enabled, the Peripheral should send channel classification information by initiating the Channel Classification Reporting procedure (see Section 5.1.22). When reporting is disabled, the Peripheral shall not send channel classification information.

The procedure has completed when the Link Layer acknowledgment of the LL_CHANNEL_REPORTING_IND PDU is sent or received.

5.1.22 Channel Classification Reporting procedure

A Controller uses the Channel Classification Reporting procedure to report channel classification information to the peer device.

The Peripheral may initiate this procedure by sending an LL_CHANNEL_STATUS_IND PDU after channel classification reporting has been enabled by the Central. The Central shall not send this PDU.

If channel classification information has not changed since the last time the Peripheral reported the information to the Central, then the Peripheral shall not initiate this procedure. Otherwise, the Peripheral shall initiate this procedure within, or in the first subrated connection event after, the maximum reporting delay from determining that a

change in channel classification has occurred or from channel classification reporting being enabled, whichever is later. Two consecutive channel classification reports shall be spaced apart by a duration that is greater than or equal to the minimum reporting spacing.

The procedure has completed when the Link Layer acknowledgment of the LL_CHANNEL_STATUS_IND PDU is sent or received.

5.1.23 Channel Sounding Security Start procedure

The Link Layer, upon request from the Host, may enable ciphered bit stream generation for CS after the Encryption Start procedure has successfully completed as specified in Section 5.1.3.1, using the CS Security Start procedure.

To start or restart CS security, three parameters are exchanged: the CS_IV, CS_IN, and the CS_PV. Each value is composed of two parts: a Central part and a Peripheral part. Both parts are exchanged in the LL_CS_SEC_REQ and LL_CS_SEC_RSP PDUs. After these parameters are exchanged, CS security is also started.

To start CS security, the Link Layer of the Central shall generate the Central's part of the CS initialization vector (CS_IV_C), instantiation nonce (CS_IN_C), and personalization vector (CS_PV_C). CS_IV_C shall be a 64-bit random number and CS_IN_C shall be a 32-bit random number. Both shall be generated using the requirements for random number generation defined in [Vol 2] Part H, Section 2.

The CS_PV_C shall be a 64-bit value. There are no requirements on the content of the personalization vector, and it is not considered a critical security parameter. The intent of this value is to introduce additional input into the DRBG instantiation function, as described in [Vol 6] Part E, Section 3.1.5. The personalization vector may be generated from a cryptographic module or from other pseudo-random sources.

The Link Layer of the Central initiates the CS Security Start procedure by sending an LL_CS_SEC_REQ PDU to the Peripheral. Before transmitting the LL_CS_SEC_REQ PDU, the Link Layer of the Central shall have completed all outstanding CS procedures, including CS procedure repeats, associated with the ACL. While the CS Security Start procedure is in progress, the local Link Layer shall reject the start of any new CS procedures until the CS Security Start procedure has completed.

The Central or Peripheral shall not enable the CS Security Start procedure if the Channel Sounding (Host Support) feature bit is not set in the Controller. If the remote Link Layer sends an LL_CS_SEC_REQ PDU when the Channel Sounding (Host Support) feature bit is not set in the local Link Layer, then the local Link Layer shall send an LL_REJECT_EXT_IND PDU with the error code *Unsupported Remote Feature / Unsupported LMP Feature* (0x1A).

The Central or Peripheral shall not enable a CS Security Start procedure if the Encryption Start procedure has not successfully completed, as specified in Section 5.1.3.1. If the remote Link Layer sends an LL_CS_SEC_REQ PDU without the Encryption Start procedure having successfully completed, the local Link Layer shall send an LL_REJECT_EXT_IND PDU with the error code *Insufficient Security* (0x2F).

If the Encryption Start procedure has successfully completed, then when the Link Layer of the Peripheral receives an LL_CS_SEC_REQ PDU, it shall generate the Peripheral's part of the CS initialization vector (CS_IV_P), instantiation nonce (CS_IN_P), and personalization vector (CS_PV_P). CS_IV_P shall be a 64-bit random number and CS_IN_P shall be a 32-bit random number. Both shall be generated using the same requirements used for the generation of CS_IV_C and CS_IN_C. The CS_PV_P shall be a 64-bit value generated using the same requirements used for the generation of the CS_PV_C.

The Link Layer of the Peripheral shall then transmit these values back to the Central by sending an LL_CS_SEC_RSP PDU.

Each Link Layer shall combine the initialization vector, instantiation nonce, and personalization vector parts in the following manner:

CS_IV = CS_IV_P || CS_IV_C
CS_IN = CS_IN_P || CS_IN_C
CS_PV = CS_PV_P || CS_PV_C

The CS_IV_C is concatenated with the CS_IV_P. The least significant octet of CS_IV_C becomes the least significant octet of CS_IV. The most significant octet of CS_IV_P becomes the most significant octet of CS_IV.

The CS_IN_C is concatenated with the CS_IN_P. The least significant octet of CS_IN_C becomes the least significant octet of CS_IN. The most significant octet of CS_IN_P becomes the most significant octet of CS_IN.

The CS_PV_C is concatenated with the CS_PV_P. The least significant octet of CS_PV_C becomes the least significant octet of CS_PV. The most significant octet of CS_PV_P becomes the most significant octet of CS_PV.

The procedure has completed when the LL_CS_SEC_RSP PDU has been sent or received. On completion, the CSProcCount shall be initialized to 0.

5.1.24 Channel Sounding Capabilities Exchange procedure

The Link Layer parameters for CS capabilities information are exchanged before executing the CS Configuration procedure described in Section 5.1.25. The Link Layer of either the initiator or reflector can initiate the Channel Sounding Capabilities

Exchange procedure by sending an LL_CS_CAPABILITIES_REQ PDU. This procedure should be used when requested by the Host. The procedure may also be initiated autonomously by the Link Layer. The Link Layer shall not allow the CS Capability Exchange procedure if the Channel Sounding (Host Support) feature bit is not set in the Controller. If the remote Link Layer sends an LL_CS_CAPABILITIES_REQ PDU when the Channel Sounding (Host Support) feature bit is not set in the local Link Layer, the local Link Layer shall send an LL_REJECT_EXT_IND PDU with the error code *Unsupported Remote Feature / Unsupported LMP Feature* (0x1A).

CS capabilities of the peer device may be supplied by the Host if previously known, or cached by the Controller, including between connections. A Link Layer should not send an LL_CS_CAPABILITIES_REQ PDU on every connection if the information has been cached for this device. A Link Layer, however, may send an LL_CS_CAPABILITIES_REQ PDU to refresh this cached information. Cached information for a device from a previous connection may have changed and an implementation shall be able to accept an error response from a subsequent CS Link Layer control exchange if a capability is not supported or not used by the peer.

The Link Layer that receives an LL_CS_CAPABILITIES_REQ PDU shall respond with an LL_CS_CAPABILITIES_RSP PDU.

The peer device's capabilities shall be reported to the local Host on successful completion of this exchange.

The procedure has completed when either an LL_CS_CAPABILITIES_RSP PDU or the LL_REJECT_EXT_IND PDU has been sent or received.

5.1.25 Channel Sounding Configuration procedure

The Host may supply CS procedure configuration parameters and a previously associated configuration ID parameter if previously cached from a prior connection by that Host. Otherwise, the CS procedure configuration parameters shall be exchanged before starting a CS procedure. This exchange shall only occur after the peer device's CS capabilities are known, as described in Section 5.1.24. A configuration ID is selected by the Host of the Link Layer issuing the LL_CS_CONFIG_REQ PDU and is assigned to each CS parameter group. The ID assigned shall be unique among all created configuration parameter sets between two devices. The parameter exchange may be started by either side. CS configuration parameters may be exchanged by sending an LL_CS_CONFIG_REQ PDU. A Link Layer shall only begin the exchange of CS configuration parameters when requested by the Host. The Central or Peripheral device shall not allow an exchange of CS configuration parameters if the Channel Sounding (Host Support) feature bit is not set in the Controller. If the remote Link Layer sends an LL_CS_CONFIG_REQ PDU when the Channel Sounding (Host Support) feature bit is not set in the local Link Layer, then the local Link Layer shall send

an LL_REJECT_EXT_IND PDU with the error code *Unsupported Remote Feature / Unsupported LMP Feature* (0x1A).

If the parameters received in an LL_CS_CONFIG_REQ PDU are not acceptable to that Link Layer, then it shall immediately reject the configuration parameter set with an LL_REJECT_EXT_IND PDU with the error code *Unsupported LL Parameter Value* (0x20). If the receiving Link Layer accepts the LL_CS_CONFIG_REQ PDU parameters, then it shall send an LL_CS_CONFIG_RSP PDU.

Several CS procedure configuration parameter sets may be supported concurrently between Link Layers and shall be identified by the Config_ID parameter. The value of the Config_ID parameter returned in the LL_CS_CONFIG_RSP PDU shall be the same as the value received in the LL_CS_CONFIG_REQ PDU.

Configuration parameter sets may be changed using the CS Configuration procedure, with the same configuration ID used to set up the configuration parameter set. A device shall not initiate this procedure while a CS procedure or CS procedure repeat instances, as described in Section 4.5.18.1, with the same configuration ID is in progress. A Link Layer receiving an LL_CS_CONFIG_REQ PDU while a CS procedure or CS procedure repeat instances using the same configuration ID is in progress shall immediately respond with an LL_REJECT_EXT_IND with the error code *Command Disallowed* (0x0C).

If an attempt to change or remove a configuration parameter set is rejected, then that configuration set and the associated configuration ID shall not be updated by both Link Layers. Otherwise, if an LL_CS_CONFIG_REQ Action field is set to removed, then that configuration set shall no longer be used for subsequent CS procedures. Either device may remove a configuration ID even if the peer device originally created that configuration ID. A previously removed configuration ID may be reused to establish a new configuration parameter set.

The procedure collision rules described in Section 5.3 apply so that the Central and the Peripheral cannot simultaneously create or update a configuration parameter set. These procedure collision rules may result in the Peripheral Link Layer receiving an LL_REJECT_EXT_IND PDU to allow the Central initiated procedure to complete.

The Link Layer transmitting the LL_CS_CONFIG_REQ PDU shall select either the initiator or reflector role for that configuration, as requested by the Host. The Link Layer responding with the LL_CS_CONFIG_RSP PDU is then in the other role for the duration of that configuration.

Devices may support various parameter values or ranges of values that are discovered during the CS Capabilities Exchange procedure, as described in Section 5.1.24. If the Link Layer that receives the LL_CS_CONFIG_REQ PDU does not support a suggested

parameter selection, then it shall respond with an LL_REJECT_EXT_IND PDU with the error code *Unsupported LL Parameter Value* (0x20).

Table 5.2 describes how the values suggested in the LL_CS_CONFIG_REQ PDU shall take into account the various capabilities of the peer device. Values suggested in Table 5.2 shall also take into account the CS capabilities supported by the local device. Parameters with mandatory settings are always included in both the local and peer device settings as if they were included in either the LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.

Parameter	Content of the LL_CS_CONFIG_REQ PDU
Main_Mode	Shall be selected from one of the valid Main_Mode and Sub_Mode combinations described in [Vol 6] Part H, Section 4.4.2 that also uses one of the Main_Mode types included in the peer's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.
Sub_Mode	Shall be selected from one of the valid Main_Mode and Sub_Mode combinations described in [Vol 6] Part H, Section 4.4.2 that also uses one of the Sub_Mode types included in the peer's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.
CS_SYNC_PHY_Capability	Shall be selected from one of the CS_SYNC_PHY_Capability values included in both the local and peer device's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.
RTT_Type	Shall be selected based on the supported RTT capabilities indicated in the peer's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.
Role	Shall be selected to be compatible with what was included in the peer's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU. Specifically, if the peer indicated support for the initiator role, then the reflector role may be selected; if the peer indicated support for the reflector role, then the initiator role may be selected.
ChSel	Shall be set by default to Channel Selection Algorithm #3b and may be set to Channel Selection Algorithm #3c if support for this parameter was indicated in the peer's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.
T_IP1	Shall be selected from one of the valid values for T_IP1_Capability described in [Vol 6] Part H, Section 4.3.1 that is greater than or equal to the value contained in the peer's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.
T_IP2	Shall be selected from one of the valid values for T_IP2_Capability described in [Vol 6] Part H, Section 4.3.3 that is greater than or equal to the value contained in the peer's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.

Parameter	Content of the LL_CS_CONFIG_REQ PDU
T_FCS	Shall be selected from one of the valid values for T_FCS_Capability described in Section 4.5.18.1 that is greater than or equal to the value contained in the peer's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.
T_PM	Shall be selected from one of the valid values for T_PM_Capability described in [Vol 6] Part H, Section 4.3.3 that is greater than or equal to the value contained in the peer's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.

Table 5.2: Content of the CS_CONFIG_REQ_PDU as limited by the peer's LL_CS_CAPABILITIES content

After the LL_CS_CONFIG_RSP PDU has been received, then the CS configuration associated with the configuration ID shall be considered available for use within the CS Start procedure, as described in Section 5.1.26.

The CS Start procedure has completed when an LL_CS_CONFIG_RSP PDU or the LL_REJECT_EXT_IND PDU has been sent or received. Each Link Layer shall notify its Host when the Configuration procedure has completed.

5.1.26 Channel Sounding Start procedure

CS procedures may be initiated by either the initiator or reflector. Initiators and reflectors may be in either the Central or Peripheral role. A CS Start procedure shall only be started by sending an LL_CS_REQ PDU, which may be sent any time after entering the Connection state, but only after the CS Security Start procedure has completed, the CS Capability Exchange procedure has completed or the capabilities are previously known, the CS Configuration procedure has completed or the configuration content is previously known, and either the mode-0 FAE table is previously known or the Channel Sounding Mode-0 FAE Table Request procedure has completed. A Link Layer shall only begin a CS Start procedure when configured to do so by the Host. The Central or Peripheral shall not allow a CS procedure to start if the Channel Sounding (Host Support) feature bit is not set in the Controller. If the remote Link Layer sends an LL_CS_REQ PDU when the Channel Sounding (Host Support) feature bit is not set in the local Link Layer, the local Link Layer shall send an LL_REJECT_EXT_IND PDU with the error code *Unsupported Remote Feature / Unsupported LMP Feature* (0x1A).

The Link Layer shall not initiate the CS Start procedure until any outstanding CS Procedure Repeat Termination procedure, as described in Section 5.1.27, or Power Control Request procedure, as described in Section 5.1.17, or Connection Update procedure, as described in Section 5.1.1, or Connection Parameters Request procedure, as described in Section 5.1.7, or Connection Subrate Update procedure, as described in Section 5.1.19, or Connection Subrate Request procedure, as described in Section 5.1.20, has completed. CS procedures are dependent on parameters selected

during a previous Power Control Request procedure. After a CS procedure starts, including when an individual instance of a CS procedure starts within procedure repeat activity, the selected transmit power values relative to the values selected in a prior Power Control Request procedure shall remain unchanged for the duration of that procedure instance, regardless of later changes to the respective ACL power control parameters.

CS procedures are also dependent on parameters selected during the CS Configuration procedure, as described in Section 5.1.25, which are identified by the Config_ID identifier. If the CS configuration ID received during the CS Start procedure is not properly created, then the receiving Link Layer shall immediately respond with an LL_REJECT_EXT_IND PDU with the error code *Invalid LL Parameters* (0x1E).

If the receiving Link Layer is in the Peripheral role and accepts the parameters received in the LL_CS_REQ PDU or chooses to select alternative parameters, then it shall send an LL_CS_RSP PDU. If the parameters received in an LL_CS_REQ PDU are not acceptable to the receiving Link Layer (Central or Peripheral), then that Link Layer shall immediately reject the procedure by sending an LL_REJECT_EXT_IND PDU with the appropriate error code.

When a Link Layer in the Central role receives either an LL_CS_REQ PDU or an LL_CS_RSP PDU, it shall either prepare to start the CS procedure by replying with an LL_CS_IND PDU or it shall cancel the CS Start procedure by replying with an LL_REJECT_EXT_IND PDU with the appropriate error code.

When an LL_CS_IND PDU is sent by the Link Layer of the Central and received by the Link Layer of the Peripheral, both devices shall stop the procedure response timeout timer and start the CS procedure. The first CS subevent shall be anchored at the connection event specified in the LL_CS_IND PDU.

If either Link Layer sends or receives an LL_REJECT_EXT_IND PDU, that Link Layer shall terminate the CS Start procedure. The CS Start procedure has completed on each Link Layer when the LL_REJECT_EXT_IND PDU has been transmitted or received.

If a Link Layer agrees with suggested parameters received in the LL_CS_REQ PDU, then it shall reply with the same Config_ID, and with the same parameter or set of parameters that are within the suggested range in the LL_CS_RSP or LL_CS_IND PDU. Alternatively, the values of connEventCount, Offset_Min, Offset_Max, Event_Interval, Subevents_Per_Event, Subevent_Interval, Subevent_Len, and ACI may be re-suggested to better suit the internal scheduling and resource availability of the Link Layer replying with the LL_CS_RSP PDU. Because some of these values are related to Link Layer scheduling, changes to the values might not coincide with the scheduling constraints of the Link Layer that transmitted the LL_CS_REQ PDU and might cause that Link Layer to reject the suggested values.

The value of the connEventCount field specifies the LE connection event anchor point from which the first CS event within a CS procedure is offset. The connEventCount value supplied in either the LL_CS_RSP or LL_CS_IND PDU shall be no sooner in time than the value received in the LL_CS_REQ or LL_CS_RSP PDU that is being responded to.

Section 5.3 shall apply to the LL_CS_IND PDU as if the connEventCount field were an instant. The selection of the connEventCount field supplied in the LL_CS_RSP or LL_CS_IND PDU shall follow the requirements specified in Section 5.5. The instant passed requirements specified in Section 5.5.1 do not apply to this connEventCount field and instead the following requirements apply.

Let currConnEventCount represent the current *connEventCount* value as described in Section 4.5.1. The connEventCount field is determined to be in the past when (connEventCount – currConnEventCount) *mod* 65535 is greater than or equal to 32767. In this case, the first few CS subevents of the CS procedure may be lost and if so, the requirements described in [Vol 6] Part H, Section 4.4.5 shall apply.

The values of the Offset_Min and Offset_Max fields of the LL_CS_REQ and LL_CS_RSP PDUs each specify a window for the start of the first CS event within a CS procedure. The window specified in the LL_CS_RSP PDU shall lie entirely within that the window specified by the LL_CS_REQ PDU. The start of the first CS event within a CS procedure shall lie within the window specified by the LL_CS_REQ PDU and the LL_CS_RSP PDU.

The value of Subevent_Interval supplied in either the LL_CS_RSP PDU or the LL_CS_IND_PDU shall be greater than or equal to the value received in the LL_CS_REQ or LL_CS_RSP PDU that is being responded to.

The Subevent_Interval shall be greater than or equal to the sum of the Subevent_Len selected plus T_MES. A Controller shall be capable of supporting a minimum Subevent_Len of 2.5 ms. The value of Subevent_Len supplied in either the LL_CS_RSP or LL_CS_IND PDU shall be less than or equal to the value received in the LL_CS_REQ or LL_CS_RSP PDU that is being responded to.

Suggesting different values for Event_Interval, Subevents_Per_Event, Subevent_Interval, or Subevent_Len in the LL_CS_RSP or the LL_CS_IND PDU should result in an overall CS procedure duration that is less than or equal to the value of Max_Procedure_Len specified in the CS_REQ_PDU. If the Link Layer previously transmitted an LL_CS_REQ PDU, then received an LL_CS_RSP PDU without any changes to the Event_Interval, Subevents_Per_Event, Subevent_Interval, or Subevent_Len fields, then the Link Layer shall not alter those values when sending the LL_CS_IND PDU.

The ACI parameter is set according to the Num_Ant and Max_Ant_Path parameters from the CS Capabilities Exchange procedure described in Section 5.1.24. The Num_Ant value reflected in the peer's LL_CS_CAPABILITIES_REQ PDU or the LL_CS_CAPABILITIES_RSP PDU indicates the maximum number of antenna elements supported by the sending Link Layer. The Max_Ant_Path value reflected in the peer's LL_CS_CAPABILITIES_REQ PDU or the LL_CS_CAPABILITIES_RSP PDU indicates the maximum number of antenna paths supported by the sending Link Layer. The ACI parameter selected for the LL_CS_REQ PDU and finalized in the LL_CS_IND PDU shall yield an antenna configuration setting with an antenna element count that is equal to or less than the Num_Ant limit indicated for both Link Layers. The ACI parameter shall also contain an antenna path count that is equal to or less than the value for Max_Ant_Path indicated by both Link Layers. The ACI parameter shall be selected according to the ACI value described in [Vol 6] Part A, Section 5.3. Re-suggested ACI values shall only propose modification for the local device antenna selection and shall use a setting that contains antenna element numbers that are equal to or less than those suggested.

Example 1:

Device A supports a value of two for Num_Ant and a value of four for Max_Ant_Path. Device B supports a value of four Num_Ant and a value of four Max_Ant_Path. Device A initially suggests a 1:4 ACI configuration. Device B can then re-suggest a 1:3 ACI configuration but cannot re-suggest a 2:2 ACI configuration.

Example 2:

Device A supports a value of three for Num_Ant and a value of four for Max_Ant_Path. Device B supports a value of one Num_Ant and a value of two Max_Ant_Path. Device A can initially suggest a 2:1 ACI configuration but cannot initially suggest a 3:1 ACI configuration.

The Preferred_Peer_Ant field indicates the preferred ordered antenna elements that should be used, if possible, by the device that receives the LL_CS_REQ PDU. This ordering is described in Section 2.4.2.44 in the description for the Num_Ant field. The number of bits set in this field shall not exceed the Num_Ant parameter from the CS Capabilities Exchange procedure described in Section 5.1.24. The number of bits set in this field shall be greater than or equal to the number of antenna elements denoted by the ACI field. If the number of bits set in this field exceeds the number of antenna elements denoted by the ACI field, then the ordered antenna elements specified should be used, with the lowest ordered antenna elements denoted by this field preferred. If the local device is not concerned with the peer's ordered antenna selection, then it shall set the lowest ordered Num_Ant (received from the CS Capabilities Exchange) bits within this field.

Each Link Layer may use the PHY and Pwr_Delta fields to request the peer Controller to adjust the transmit power level it uses during the CS procedure. The power control adjustment is specified relative to the current power level of the ACL connection PHY specified by the PHY parameter. The Link Layer receiving the LL Control PDU shall adjust its transmit power level as requested during all transmissions within the CS procedure. If the requested change would take the Link Layer receiving the LL Control PDU above the maximum power level the device supports, it shall change the power level to the maximum supported. If it is unable to make the requested change for any other reason, the Link Layer receiving the LL Control PDU shall change the power level to the lowest available level greater than the requested level. If the power level of the local transmit PHY indicated by the PHY parameter received during the CS Start procedure is not the PHY in use by the current ACL connection and is not currently being managed (as described in Section 5.1.17 and Section 5.1.18) by the receiving Link Layer, then that Link Layer shall immediately respond with an LL_REJECT_EXT_IND PDU with the error code *Unsupported LMP Parameter Value / Unsupported LL Parameter Value* (0x20). Refer to Section 5.1.17 for information on managing power levels for specific PHYs.

If the local CS role is that of the initiator, then the value of the TX_SNR_I field shall be selected from one of the TX_SNR_Capabilities included in the local device's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU. Similarly, the value of the TX_SNR_R field shall be selected from one of the TX_SNR_Capabilities included in the peer device's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.

Alternatively, if the local CS role is that of the reflector, then the value of the TX_SNR_R field shall be selected from one of the TX_SNR_Capabilities included in the local device's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU. Similarly, the value of the TX_SNR_I field shall be selected from one of the TX_SNR_Capabilities included in the peer device's LL_CS_CAPABILITIES_REQ or LL_CS_CAPABILITIES_RSP PDU.

If the Link Layer that transmits the LL_CS_IND PDU also previously transmitted the LL_CS_REQ PDU within the same CS Start procedure, then it shall use the same values for the PHY and Pwr_Delta fields in both transmissions.

CSChM shall be set to the ChM parameter value of the CS configuration used for the procedure.

CSNumRepetitions shall be set to the ChM_Repetition parameter value of the CS configuration used for the procedure.

CSMode0Steps shall be set to the Mode_0_Steps parameter value of the CS configuration used for the procedure.

CSShapeSelection shall be set to Ch3cShape parameter value of the CS configuration used for the procedure.

CSChannelJump shall be set to the Ch3cJump parameter value of the CS configuration used for the procedure.

Parameter values exchanged during the CS Start procedure are used to select the values for CS event and subevent scheduling, as described in Section 4.5.18.1. Table 5.3 shows this mapping.

LL_CS_REQ, LL_CS_RSP, LL_CS_IND Parameter	CS Event/Subevent Parameter
Offset_Min, Offset_Max, Offset	T_EVENT_OFFSET
Event_Interval	T_EVENT_INTERVAL
Subevents_Per_Event	N_SUBEVENTS_PER_EVENT
Subevent_Interval	T_SUBEVENT_INTERVAL
Subevent_Len	T_SUBEVENT_LEN
Procedure_Interval	T_PROCEDURE_INTERVAL
Procedure_Count	N_PROCEDURE_COUNT
Max_Procedure_Len	T_MAX_PROCEDURE_LEN

Table 5.3: CS LL PDU parameter versus CS Event/Subevent parameter

The procedure has completed when the LL_CS_IND PDU or an LL_REJECT_EXT_IND PDU has either been transmitted or received. The Controller shall notify its Host when the CS Start procedure completes either if it has completed successfully or if the procedure was initiated by a request from the Host. Otherwise, it shall not notify the Host that the procedure took place.

The CS procedure counter CSProcCount shall be incremented by one after every successful completion of the CS Start procedure, except for the occurrence that immediately follows the completion of the CS Security Start procedure (see Section 5.1.23). CSProcCount shall also be incremented by one at the start of each subsequent CS procedure repeat. The CSProcCount value shall wrap from 0xFFFF to 0x0000. Between any initiator and reflector pair, the CS Start procedure may be invoked again before the completion of an ongoing CS procedure. However, the timing and execution of two CS procedures between that pair, which includes the timing of any procedure repeat activity, shall not overlap.

5.1.27 Channel Sounding Procedure Repeat Termination procedure

The initiator or reflector may only use the Channel Sounding Procedure Repeat Termination procedure to terminate repetitions of CS procedure instances if N_PROCEDURE_COUNT has been set to 0 or a value greater than 1 (see

Section 4.5.18.1). The CS Procedure Repeat Termination procedure is started by sending an LL_CS_TERMINATE_REQ PDU.

The procedure collision rules described in Section 5.3 apply so that the Central and Peripheral cannot simultaneously execute the CS Procedure Repeat Termination procedure. These procedure collision rules may result in the Peripheral Link Layer receiving an LL_REJECT_EXT_IND PDU to allow the Central initiated procedure to complete.

If N_PROCEDURE_COUNT (as described in Section 5.1.26) is greater than 1, then the CS procedure repeat instance series is bounded by a maximum procedure count value. For this purpose, let StartCSProcCount be defined as the starting CSProcCount value used for the first instance of the CS procedure series that is being terminated. The Link Layer receiving the LL_CS_TERMINATE_REQ PDU shall respond by sending an LL_REJECT_EXT_IND PDU with the error code *Command Disallowed* (0x0C) if the ProcCount value received in the LL_CS_TERMINATE_REQ PDU satisfies the following condition:

(ProcCount - StartCSProcCount + 1) *mod* 65536 > N_PROCEDURE_COUNT

Additionally, the Link Layer receiving the LL_CS_TERMINATE_REQ PDU shall respond by sending an LL_REJECT_EXT_IND PDU with error code *Command Disallowed* (0x0C) if the Config_ID value received is not associated with the CS procedure repeat series associated with the received ProcCount value.

Otherwise, the Link Layer receiving the LL_CS_TERMINATE_REQ PDU shall respond by transmitting an LL_CS_TERMINATE_RSP PDU.

This procedure shall complete at most once per CS procedure repeat instance series.

Termination of all subsequent procedure instances shall occur when the LL_CS_TERMINATE_REQ PDU is sent or received. This termination shall occur before the start of the next procedure instance and shall not be applied to a CS procedure that is in progress.

Based on implementation delays, the ProcCount value received in either the LL_CS_TERMINATE_REQ PDU or the LL_CS_TERMINATE_RSP PDU may differ from the value transmitted. In this case, the higher of the two values shall be used by the two Link Layers to keep their respective DRBGs synchronized as it relates to the DRBG backtracking resistance as described in [Vol 6] Part E, Section 3.1.7. The higher of the two values is determined by subtracting the transmitted ProcCount value from the received ProcCount value modulo 65536. If this result is greater than or equal to 32767, then the transmitted ProCount value is higher, otherwise the received ProcCount value is higher.

The CS Procedure Repeat Termination procedure has completed when an LL_CS_TERMINATE_RSP PDU or the LL_REJECT_EXT_IND PDU has been sent or received.

5.1.28 Channel Sounding Channel Map Update procedure

The channel map used in any CS procedure may be updated before initiating the start of that procedure (see Section 5.1.26) or before the start of any procedure instance (see Section 4.5.18.1). The Link Layer initiating the start of the CS procedure can update the channel map by sending the LL_CS_CHANNEL_MAP_IND PDU.

Because either the initiator or reflector may initiate the start of a CS procedure by transmitting an LL_CS_REQ PDU, either side may issue the LL_CS_CHANNEL_MAP_IND PDU. However, only the channel map update issued by the Link Layer initiating a subsequent CS procedure shall be applied toward that CS procedure.

An LL_CS_CHANNEL_MAP_IND PDU sent or received while any CS procedure is in progress shall not take effect for that CS procedure. These updates shall apply to all CS procedures starting after the specified instant, until the next occurrence of the CS Channel Map Update procedure.

An LL_CS_CHANNEL_MAP_IND PDU sent or received while both no CS procedure is in progress and no CS procedure instances are pending shall take effect immediately and the Instant parameter shall be processed as if that field was RFU.

The value of the instant parameter supplied in the LL_CS_CHANNEL_MAP_UPDATE_-IND PDU shall follow the requirements specified in Section 5.5. The instant passed requirements specified in Section 5.5.1 do not apply to the instant parameter of the LL_CS_CHANNEL_MAP_IND PDU, and instead the following requirements apply.

Any pending CS procedure repeat instances shall be terminated using the rules defined in Section 5.1.27 with error code *Instant Passed* (0x28) if the instant is determined to be in the past. An instant is determined to be in the past when (Instant – *connEventCount*) *mod* 65535 is greater than or equal to 32767. In this case, updates include in the LL_CS_CHANNEL_MAP_UPDATE_IND PDU shall still be applied to all subsequent CS procedures, until the next occurrence of the CS Channel Map Update procedure.

The default channel map shall include all allowed CS channels as defined in [Vol 6] Part H, Section 1 and is equivalent to the ChM field of the LL_CS_CHANNEL_MAP_IND PDU with all valid channel bits set to 1.

The channel map derived from the CS Channel Map Update procedure shall be combined with the CSChM parameter selected during the CS Start procedure (see Section 5.1.26) with a logical AND operation to generate the CSFilteredChM channel

map value. This value has the same format as the ChM parameter used in this update procedure and represents the filtered channel map to be used in the next CS procedure.

CSFilteredChM = CSChM & (CS Channel Map Update procedure parameter ChM)

The CSFilteredChM shall be used in the Channel Selection Algorithm #3 procedure as described in [Vol 6] Part H, Section 4.1.

The minimum number of channels in CSFilteredChM shall be 15. If, at the start of any procedure instance and after applying a channel map update, the number of channels is less than 15, then that CS procedure shall not start, and the Host shall be notified of this. If a series of procedure instances are in progress (see Section 4.5.18.1), and at the start of a procedure instance the number of channels in CSFilteredChM is less than 15, then that specific procedure instance shall not start, the procedure instance series shall terminate, and the Host shall be notified that the procedure instance series has been aborted.

The procedure has completed when the instant has passed and the new channel map has been applied.

5.1.29 Channel Sounding Mode-0 FAE Table Request procedure

This Table Request procedure shall only be used when the peer's No_FAE bit is set to 0 in its CS capabilities, as described in Section 2.4.2.44.

A reflector's mode-0 FAE table shall be known by the initiator before starting a CS procedure as described in Section 5.1.26. The reflector's mode-0 FAE table may be provided by the initiator's Host to the local Controller if known previously by that Host. If not previously known, then a potential initiator shall issue the LL_CS_FAE_REQ PDU to a prospective reflector to request the table. A Link Layer shall only begin a request for a peer device's mode-0 FAE table when requested by the Host. A Controller shall not allow a local Host to request a peer's FAE table if the Channel Sounding (Host Support) feature bit is not set in the Controller. Likewise, a Link Layer shall not allow the exchange of its mode-0 FAE table if the Channel Sounding (Host Support) feature bit is not set in that Controller. If a remote Link Layer sends an LL_CS_FAE_REQ PDU when the Channel Sounding (Host Support) feature bit is not set in the local Link Layer, then the local Link Layer shall send an LL_REJECT_EXT_IND PDU with the error code *Unsupported Remote Feature / Unsupported LMP Feature* (0x1A).

The Link Layer shall not transmit the LL_CS_FAE_REQ PDU if that peer device has indicated support for zero FAE in its CS capabilities (see Section 5.1.24).

Because either side may be the initiator of a CS procedure, either side may issue the LL_CS_FAE_REQ PDU.

A Link Layer receiving an LL_CS_FAE_REQ PDU after having set the No_FAE bit in its CS capabilities shall immediately respond with an LL_REJECT_EXT_IND PDU with the error code *Unsupported Feature or Parameter Value* (0x11). Otherwise, the Link Layer that receives the LL_CS_FAE_REQ PDU shall respond with the LL_CS_FAE_RSP PDU and its local per-channel mode-0 FAE table.

The procedure has completed when an LL_CS_FAE_RSP PDU or the LL_REJECT_EXT_IND PDU has been sent or received.

5.1.30 Frame Space Update procedure

The Central or Peripheral may initiate the Frame Space Update procedure, when supported, to change one or more of the following frame space parameters:

- T_IFS_ACL_CP
- T_IFS_ACL_PC
- T_MCES
- T_IFS_CIS
- T_MSS_CIS

The Frame Space Update procedure may be initiated when requested by the Host, or autonomously by the Link Layer.

The Spacing_Types and PHYS fields shall be used to indicate the parameters and PHYs to be changed.

The procedure shall affect the ACL in use and any CIS associated with the ACL created after the procedure has completed; it does not affect any other ACL connections or any existing CISes. Subject to Section 5.1.30.1, the affected values shall change on the initiating device no later than the 6th connection anchor point after it receives the LL_FRAME_SPACE_RSP PDU and on the responding device before it first sends the LL_FRAME_SPACE_RSP PDU.

When the Controller receives an LL_FRAME_SPACE_REQ PDU, it shall respond with an LL_FRAME_SPACE_RSP PDU to accept the request or an LL_REJECT_EXT_IND PDU to reject the request. The Controller may reject the request for any reason.

FS_Max shall be greater than or equal to the frame space value in use. If FS_Min and FS_Max in the LL_FRAME_SPACE_REQ PDU are both less than the frame space value in use for any of the selected frame space types and PHYs, then the responding device may reject the request by sending an LL_REJECT_EXT_IND PDU with the error code set to *Unsupported Feature or Parameter Value* (0x11).

If the resulting frame space value causes *connIntervalUncodedMin* (if the current PHY is an LE Uncoded PHY) or *connIntervalCodedMin* (if the current PHY is the LE Coded

PHY) to exceed the connection interval and the change is being done on the existing ACL connection on the PHY in use, then the responding device shall reject the request by sending an LL_REJECT_EXT_IND PDU with the error code set to *Unsupported LMP Parameter Value / Unsupported LL Parameter Value* (0x20).

The responding device shall set the FS field of the LL_FRAME_SPACE_RSP PDU to a value between the FS_Min and FS_Max of the LL_FRAME_SPACE_REQ PDU, and should set it to the lowest value the responding device supports within that range.

All bits set to 0 in the PHYS and Spacing_Types fields of an LL_FRAME_SPACE_REQ PDU shall be set to 0 in the LL_FRAME_SPACE_RSP PDU sent in response. If a bit is set to 1 in the PHYS field or the Spacing_Types field of the LL_FRAME_SPACE_RSP PDU and the corresponding bit(s) are not set in the LL_FRAME_SPACE_REQ PDU, then this is considered invalid behavior (see [Vol 1] Part E, Section 2.7).

If either the PHYS or the Spacing_Types field of an LL_FRAME_SPACE_REQ PDU is set to 0, then the responding device shall reject the request by sending an LL_REJECT_EXT_IND PDU with the error code set to *Invalid LL Parameters* (0x1E).

The procedure has completed when an LL_FRAME_SPACE_RSP PDU or LL_REJECT_EXT_IND PDU has been sent or received.

If the procedure results in a change to one or more frame space values regardless of whether the PHYs or Frame_Space changed is in use, then each Controller shall notify the Host about the change.

5.1.30.1 Adjacent packets in the same connection event

For the purposes of this section:

- TIA_C is the T_IFS_ACL_CP for the PHY(s) in use on the ACL.
- TIA_P is the T_IFS_ACL_PC for the PHY(s) in use on the ACL.
- If the initiating device is the Central, then TIA_I is TIA_C and TIA_R is TIA_P.
- If the initiating device is the Peripheral, then TIA_I is TIA_P and TIA_R is TIA_C.

If the Frame Space Update procedure affects TIA_I, then the initiating device shall use the following parameters instead of those in Table 4.1 during the period between transmitting the first packet containing the LL_FRAME_SPACE_REQ PDU and receiving an LL_FRAME_SPACE_RSP PDU or LL_REJECT_EXT_IND PDU:

- *receiveWindowStart* shall be the smaller of FS_Min and TIA_I after the end of the previous packet
- *receiveWindowEnd* shall be the greater of FS_Max and TIA_I after the end of the previous packet

where FS_Min and FS_Max are the corresponding values in the LL_FRAME_SPACE_REQ PDU. In addition, during the period between transmitting the first packet containing the LL_FRAME_SPACE_RSP PDU and receiving either an ACK or a new PDU:

- If the responding device is the Central and the response is sent as a continuation of a connection event, then the LL_FRAME_SPACE_RSP PDU shall be transmitted after an Inter Frame Space specified by the FS value in the LL_FRAME_SPACE_RSP PDU.
- If the responding device is the Peripheral, then the LL_FRAME_SPACE_RSP PDU shall be transmitted after an Inter Frame Space specified by the FS value in the LL_FRAME_SPACE_RSP PDU.

If the Frame Space Update procedure affects TIA_R, then the responding device shall use the following parameters instead of those in Table 4.1 during the period between transmitting the first packet containing the LL_FRAME_SPACE_RSP PDU and receiving a packet using the new frame space value:

- *receiveWindowStart* shall be the smaller of FS and TIA_R after the end of the previous packet
- *receiveWindowEnd* shall be the greater of FS and TIA_R after the end of the previous packet

where FS is the value in the LL_FRAME_SPACE_RSP PDU.

5.2 Procedure response timeout

This section specifies procedure timeout rules that shall be applied to all the Link Layer control procedures specified in Section 5.1, except for the Connection Update and Channel Map Update procedures for which there are no timeout rules.

To be able to detect a non-responsive Link Layer Control procedure, both the Central and the Peripheral shall use a procedure response timeout timer, T_{PRT} . Upon the initiation of a procedure, the procedure response timeout timer shall be reset and started.

Each LL Control PDU that is queued for transmission resets the procedure response timeout timer.

When the procedure has completed, the procedure response timeout timer shall be stopped.

If the procedure response timeout timer reaches 40 seconds, the ACL connection is considered lost (see Section 4.5.12). The Link Layer exits the Connection state and shall transition to the Standby state. The Host shall be notified of the loss of connection.

5.3 Procedure collisions

Since LL Control PDUs are not interpreted in real time, collisions can occur where the Link Layer of the Central and the Link Layer of the Peripheral initiate incompatible procedures. Two procedures are incompatible in the following cases:

- The two procedures both involve an instant.
- The two procedures are the Channel Sounding Configuration procedure as described in Section 5.1.25.
- The two procedures are the Channel Sounding Procedure Repeat Termination procedure as described in Section 5.1.27.
- The two procedures are the Connection Subrate Request procedure (described in Section 5.1.20) and the Channel Sounding Start procedure (described in Section 5.1.26).
- One procedure is the Frame Space Update procedure (see Section 5.1.30); the other is either the Frame Space Update procedure or the Connected Isochronous Stream Creation procedure (see Section 5.1.15).

In these cases, the rules in this section shall be followed:

A device shall not initiate a procedure after responding to a PDU that had initiated an incompatible procedure until that procedure has completed.

If device initiates a procedure A and, while that procedure has not completed, receives a PDU from its peer that initiates an incompatible procedure B, then:

- If the peer has already sent at least one PDU as part of procedure A, the device should immediately exit the Connection State and transition to the Standby State.
- Otherwise, if the device is the Central, it shall reject the PDU received from the Peripheral by issuing an LL_REJECT_EXT_IND (if supported by both devices) or LL_REJECT_IND (otherwise) PDU. It shall then proceed with procedure A.
- Otherwise (the device is the Peripheral) it shall proceed to handle the Central-initiated procedure B and take no further action in the Peripheral-initiated procedure A except processing the rejection from the Central.

The Host shall be notified that the link has been disconnected with, or the rejection PDU shall use (as appropriate):

- the error code *LMP Error Transaction Collision / LL Procedure Collision* (0x23) if procedures A and B are the same procedure;

- the error code *LMP Error Transaction Collision / LL Procedure Collision* (0x23) if procedure A is the Connection Update procedure and procedure B is the Connection Parameters Request procedure;
- the error code *Different Transaction Collision* (0x2A) otherwise.

5.4 LE Authenticated Payload Timeout

LE Authenticated Payload Timeout (*authenticatedPayloadTO*) is a parameter that defines the maximum amount of time, in milliseconds, allowed between receiving ACL packets containing a valid MIC. The Host can change the value of *authenticatedPayloadTO* using the HCI_Write_Authenticated_Payload_Timeout command ([Vol 4] Part E, Section 7.3.94). The default value for *authenticatedPayloadTO* is 30 seconds.

When the connection is encrypted, a device supporting LE Ping feature shall start the LE Authenticated Payload timer $T_{LE\_Authenticated\_Payload}$ to monitor the time since the last reception of a packet containing a valid MIC from the remote device. Each device shall reset the timer $T_{LE\_Authenticated\_Payload}$ upon reception of a packet with a valid MIC. The timer shall not be reset upon the reception of a resent packet.

If at any time in the CONNECTION state the timer $T_{LE\_Authenticated\_Payload}$ reaches the *authenticatedPayloadTO* value, the Host shall be notified (using the HCI_Authenticated_Payload_Timeout_Expired event if the Controller supports HCI; see [Vol 4] Part E, Section 7.7.75). The $T_{LE\_Authenticated\_Payload}$ Timer restarts after it is expired.

The timer $T_{LE\_Authenticated\_Payload}$ shall continue to run during encryption pause procedure.

Whenever the Host sets the *authenticatedPayloadTO* while the timer $T_{LE\_Authenticated\_Payload}$ is running, the timer shall be reset.

5.5 Procedures with Instants

Where a procedure involves a PDU with an Instant field, then the following rules shall apply.

The Instant field shall be used to indicate the *connEventCount* or *bigEventCounter* when the relevant change shall be applied; this is known as the instant for the procedure. In the case of the LL_CS_CHANNEL_MAP_IND PDU, either Link Layer may select the instant value. In all other cases, only the Link Layer of the Central shall select the instant value.

If the Link Layer of the Central is selecting the instant value, then the Central should allow a minimum of 6 connection events when it intends to transmit and that the

Peripheral will be listening for before the instant occurs, considering that the Peripheral may only be listening once every *connSubrateFactor* × (*connPeripheralLatency* + 1) events. If the Link Layer of the Peripheral is selecting the instant value, then the Peripheral should allow a minimum of 6 connection events that it intends to schedule before the instant occurs, considering that the Central may only transmit once every *connSubrateFactor* events. The event shall be the next one with the specified value of *connEventCount* or of $bigEventCounter_{15-0}$.

Note: Comparisons of the *connEventCount* or *bigEventCounter* and the Instant field are performed using *mod* 65536 math (only values from 0 to 65535 are allowed).

When performing a Link Layer procedure that has an instant that is selected by the Central's Link Layer, it may (particularly for large values of the subrate factor) use the Connection Subrate Update procedure to set the subrate factor to 1 and the Peripheral latency to 0 before performing the procedure and then use it again to restore the previous values afterwards. If the Link Layer does so, it should not notify the Host of these changes. However, the Link Layer shall not restore the settings autonomously after a Connection Update procedure that changed the connection interval and shall not restore *connPeripheralLatency* or *connSupervisionTimeout* after a Connection Update procedure that did not change the connection interval.

5.5.1 ACL control procedures

When a Peripheral receives such a PDU where (Instant – *connEventCount*) *mod* 65536 is less than 32767 and Instant is not equal to *connEventCount*, the Peripheral shall listen to all the connection events until it has confirmation that the Central has received its acknowledgment of the PDU or *connEventCount* equals Instant.

When a Peripheral receives such a PDU where (Instant – *connEventCount*) *mod* 65536 is greater than or equal to 32767 (because the instant is in the past), it shall take the following actions:

- If the PDU is an LL_CONNECTION_UPDATE_IND, the Link Layer of the Peripheral shall consider the connection to be lost.
- Otherwise, the Link Layer of the Peripheral may consider the connection to be lost.

If the connection is considered to be lost, the Link Layer of the Peripheral shall exit the Connection state and transition to the Standby state, and shall notify the Host using the error code *Instant Passed* (0x28).

5.5.2 BIG control procedures

The Isochronous Broadcaster shall set the instant at least 6 BIG events after the first BIG event where the BIG Control PDU is transmitted.

When a Synchronized Receiver receives such a PDU where (Instant – *bigEventCounter*) *mod* 65536 is greater than or equal to 32767 (because the instant is in the past), the Link Layer may stop synchronization with the BIG.

5.6 BIG control procedures

BIG control procedures are used to send control information concerning a BIG from the Isochronous Broadcaster to the Synchronized Receivers.

Each BIG Control procedure involves transmitting a single BIG Control PDU during the control subevent of BIG events. Each such PDU shall be transmitted in six consecutive BIG events and may be transmitted in other BIG events (not necessarily consecutive) after these six; the procedure ends when the BIG Control PDU has been retransmitted for the last time. Only one BIG control procedure shall be in progress at a time for a given BIG.

5.6.1 BIG Channel Map Update procedure

The BIG Channel Map Update procedure is used to send a new channel map for all BISes in a BIG.

When instructed by the Host or autonomously, the Link Layer of an Isochronous Broadcaster shall initiate this procedure by transmitting a BIG_CHANNEL_MAP_IND PDU.

The Link Layer of the Isochronous Broadcaster shall not initiate a subsequent instance of this procedure until the instant has passed.

The Link Layer of both Isochronous Broadcaster and Synchronized Receiver shall use the new channel map starting with the BIG event identified by the instant. The Link Layer shall update the ChM field in the BIGInfo and send the updated BIGInfo in the associated periodic advertising train (if enabled) at the nearest future periodic advertising event to the instant.

5.6.2 BIG Termination procedure

The BIG Termination procedure is used to notify all Synchronized Receivers of a BIG that the transmission of that BIG is about to be terminated.

When instructed by the Host, the Link Layer shall initiate this procedure by transmitting a BIG_TERMINATE_IND PDU. The Link Layer shall stop transmitting BIG events at the instant and shall return to the Standby state. If the Link Layer is still transmitting the associated BIGInfo, it shall stop doing so no later than the instant.

The Link Layer shall terminate the BIG no later than when the *bisPayloadCounter* equals $2^{39} – 1$.

When the Link Layer receives a BIG_TERMINATE_IND PDU, it shall stop synchronization with the BIG and, unless it is still synchronized to the periodic advertising train, shall return to the Standby state.

6 PRIVACY

The Link Layer provides Privacy by using Private Addresses (see Section 1.3.2).

If a device is using Resolvable Private Addresses Section 1.3.2.2, it shall also have an Identity Address that is either a Public or Random Static address type.

6.1 Resolvable Private address generation interval

A resolvable private address shall be generated using the Resolvable Private Address Generation (see Section 1.3.2.2).

The Link Layer shall set a timer determined by the Host. A new resolvable private address shall be generated when the timer expires. If the Link Layer is reset, a new resolvable private address shall be generated and the timer started with any value in the allowed range.

Note: If the resolvable private address is generated frequently, connection establishment times may be affected. It is recommended to set the timer to 15 minutes.

If requested by the Host, the Controller shall generate a new resolvable private address each time the advertising data or scan response data changes.

6.2 Privacy in the Advertising state

Privacy in the advertising state determines how the Link Layer processes Resolvable Private Addresses for advertising events.

The requirements in the following subsections apply in addition to those in Section 4.4.2 and Section 4.7.

6.2.1 Connectable and scannable undirected event type

The Link Layer may use resolvable private addresses or non-resolvable private addresses for the advertiser's device address (AdvA field) when entering the Advertising State and using connectable and scannable undirected events.

The AdvA field of the connectable and scannable undirected advertising event PDU is generated using the resolving list's Local IRK value and the Resolvable Private Address Generation procedure (see Section 1.3.2.2). If the Host has not provided any Resolving List IRK pairs for the peer to the Link Layer, then the AdvA field shall use a Host-provided address.

When an advertiser receives a connection request that contains a resolvable private address for the initiator's address (InitA field) and address resolution is enabled, the

Link Layer shall resolve the private address (see Section 1.3.2.3). The advertising filter policy (see Section 4.3.2) shall then determine if the advertiser establishes a connection.

When an advertiser receives a connection request that contains a device Identity Address for the initiator's address field (InitA field), and if that device is in the Resolving List with a non-zero peer IRK for which the Host has specified device privacy mode, then the advertising filter policy (see Section 4.3.2) shall determine if the advertiser establishes a connection.

When an advertiser receives a scan request that contains a resolvable private address for the scanner's device address (ScanA field) and address resolution is enabled, the Link Layer shall resolve the private address (see Section 1.3.2.3). The advertising filter policy (see Section 4.3.2) shall then determine if the advertiser processes the scan request.

When an advertiser receives a scan request that contains a device Identity Address for the scanner's device address (ScanA field), and if that device is in the Resolving List with a non-zero peer IRK for which the Host has specified device privacy mode, then the advertising filter policy (see Section 4.3.2) shall determine if the advertiser processes the scan request.

When an advertiser receives a scan or connection request that contains a non-resolvable private address, the advertising filter policy (see Section 4.3.2) shall determine if the advertiser processes the scan or connection request.

If the advertiser processes the scan request, the advertiser's device address (AdvA field) in the SCAN_RSP PDU shall be the same as the advertiser's device address (AdvA field) in the SCAN_REQ PDU to which it is responding.

6.2.2 Connectable directed event type

The Link Layer shall use resolvable private addresses for the advertiser's device address (AdvA field). If an IRK is available in the Link Layer Resolving List for the peer device, then the target's device address (TargetA field) shall use a resolvable private address. If an IRK is not available in the Link Layer Resolving List or the IRK is set to zero for the peer device, then the target's device address (TargetA field) shall use the Identity Address when entering the Advertising State and using connectable directed events.

The AdvA field of the connectable directed advertising event PDU is generated using the resolving list's Local IRK value and the Resolvable Private Address Generation procedure (see Section 1.3.2.2).

The TargetA field of the connectable directed advertising event PDU is generated using the Peer IRK value and the Resolvable Private Address Generation procedure (see

Section 1.3.2.2). The TargetA field uses the public or static device address of the peer device if no peer IRK is available.

When an advertiser receives a connection request that contains a resolvable private address for the initiator's address (InitA field) and address resolution is enabled, the Link Layer shall resolve the private address (see Section 1.3.2.3).

When an advertiser receives a connection request that contains a device Identity Address for the initiator's address field (InitA field), and if that device is in the Resolving List with a non-zero peer IRK for which the Host has specified device privacy mode, then the advertiser shall establish a connection. When responding with an AUX_CONNECT_RSP, the Link Layer should not set the TargetA field to the same value as the InitA field in the received PDU.

6.2.3 Non-connectable and non-scannable undirected and scannable undirected event types

The Link Layer may use resolvable private addresses or non-resolvable private addresses for the advertiser's device address (AdvA field) when entering the Advertising State and using the following event types:

- non-connectable and non-scannable undirected event
- scannable undirected event

The AdvA field of the non-connectable and non-scannable undirected advertising event PDU and scannable undirected event PDU are generated using the resolving list's Local IRK value and the Resolvable Private Address Generation procedure or Non-Resolvable Private Address Generation procedure (see Section 1.3.2.2).

When an advertiser receives a scan request that contains a resolvable private address for the scanner's device address (ScanA field) and address resolution is enabled, the Link Layer shall resolve the private address (see Section 1.3.2.3). The advertising filter policy (see Section 4.3.2) shall then determine if the advertiser processes the scan request.

When an advertiser receives a scan request that contains a device Identity Address for the scanner's device address (ScanA field), and if that device is in the Resolving List with a non-zero peer IRK for which the Host has specified device privacy mode, then the advertising filter policy (see Section 4.3.2) shall determine if the advertiser processes the scan request.

When an advertiser receives a scan request that contains a non-resolvable private address, the advertising filter policy (see Section 4.3.2) shall determine if the advertiser processes the scan request.

If the advertiser processes the scan request, the advertiser's device address (AdvA field) in the scan response PDU shall be the same as the advertiser's device address (AdvA field) in the scan request PDU to which it is responding.

6.2.4 Connectable undirected event type

The Link Layer may use resolvable private addresses or non-resolvable private addresses for the advertiser's device address (AdvA field) when entering the Advertising State and using connectable undirected events.

The AdvA field of the connectable undirected advertising event PDU is generated using the resolving list's Local IRK value and the Resolvable Private Address Generation procedure (see Section 1.3.2.2). If the Host has not provided any Resolving List IRK pairs for the peer to the Link Layer, then the AdvA field shall use a Host-provided address.

When an advertiser receives a connection request that contains a resolvable private address for the initiator's address (InitA field) and address resolution is enabled, the Link Layer shall resolve the private address (see Section 1.3.2.3). The advertising filter policy (see Section 4.3.2) shall then determine if the advertiser establishes a connection. If the advertiser was able to resolve the InitA field, then it should set the TargetA field of the AUX_CONNECT_RSP PDU to a new resolvable private address using the Resolvable Private Address Generation procedure. Otherwise the advertiser shall set the TargetA field to the same value as the InitA field in the AUX_CONNECT_REQ PDU.

The advertising filter policy (see Section 4.3.2) shall determine if the advertiser processes the connect request if an advertiser receives a connect request that contains a non-resolvable private address.

6.2.5 Non-connectable and non-scannable directed and scannable directed event types

The Link Layer may use resolvable private addresses or non-resolvable private addresses for the advertiser's device address (AdvA field) when entering the Advertising State and using the following event types:

- non-connectable and non-scannable directed event
- scannable directed event

If an IRK is available in the Link Layer Resolving List for the peer device, then the target's device address (TargetA field) shall use a resolvable private address. If an IRK is not available in the Link Layer Resolving List or the IRK is set to zero for the peer device, then the target's device address (TargetA field) shall use the Identity Address

when entering the Advertising State and using non-connectable and non-scannable directed and scannable directed events.

The AdvA field of the non-connectable and non-scannable directed advertising event PDU and scannable directed event PDU is generated using the resolving list's Local IRK value and the Resolvable Private Address Generation procedure or Non-Resolvable Private Address Generation procedure (see Section 1.3.2.2).

The TargetA field of the scannable directed advertising event PDU is generated using the Peer IRK value and the Resolvable Private Address Generation procedure (see Section 1.3.2.2). The TargetA field uses the public or static device address of the peer device if no peer IRK is available.

When an advertiser receives a scan request that contains a resolvable private address for the scanner's device address (ScanA field) and address resolution is enabled, the Link Layer shall resolve the private address (see Section 1.3.2.3).

If the advertiser processes the scan request, the advertiser's device address (AdvA field) in the AUX_SCAN_RSP PDU shall be the same as the advertiser's device address (AdvA field) in the AUX_SCAN_REQ PDU to which it is responding.

6.3 Privacy in the Scanning state

The requirements in this section apply in addition to those in Section 4.4.3 and Section 4.7.

The Link Layer may use resolvable private addresses or non-resolvable private addresses for the scanner's device address (ScanA field) when entering the Scanning State.

The ScanA field of the scanning PDU is generated using the Resolving List's Local IRK value and the Resolvable Private Address Generation procedure (see Section 1.3.2.2), or the address is provided by the Host.

The advertiser's device address (AdvA field) in the scan request PDU shall be the same as the advertiser's device address (AdvA field) received in the advertising PDU to which the scanner is responding.

When a scanner receives an advertising packet that contains a resolvable private address for the advertiser's device address (AdvA field) and address resolution is enabled, the Link Layer shall resolve the private address (see Section 1.3.2.3). The scanning filter policy (see Section 4.3.3) shall then determine if the scanner responds with a scan request.

When a scanner receives an advertising packet that contains a device Identity Address for the advertiser's device address (AdvA field), and if that device is in the Resolving List

with a non-zero peer IRK for which the Host has specified device privacy mode, then the scanning filter policy (see Section 4.3.3) shall determine if the scanner responds with a scan request. The Link Layer should not set the ScanA field to the same value as the TargetA field in the received advertising PDU.

When a scanner receives a directed scannable advertising packet that contains a resolvable private address for the target's address (TargetA field) and address resolution is enabled, the Link Layer shall resolve the private address using the Local IRK values (see Section 1.3.2.3). If the Link Layer is unable to resolve the address, the scanning filter policy shall determine if the Host is notified about this advertisement.

A scanner that has been instructed by the Host to use Resolvable Private Addresses (e.g., using the HCI_LE_Set_Scan_Parameters command; see [Vol 4] Part E, Section 7.8.10) shall not respond to directed scannable advertising events that contain public or static addresses for the target's address (TargetA field).

When a scanner receives an advertising packet that contains a non-resolvable private address, the scanning filter policy (see Section 4.3.3) shall determine if the scanner processes the advertising packet.

6.4 Privacy in the Initiating state

The requirements in this section apply in addition to those in Section 4.4.4 and Section 4.7.

The Link Layer may use resolvable private addresses, the public address, or an address provided by the Host for the initiator's device address (InitA field) when in the Initiating state.

When an initiator receives a connectable advertising event that contains a resolvable private address for the advertiser's address (AdvA field) and address resolution is enabled, the Link Layer shall resolve the private address using the resolving list's Peer IRK values (see Section 1.3.2.3). The initiator filter policy (see Section 4.3.4) shall determine if the initiator establishes a connection.

The advertiser's device address (AdvA field) in the initiating PDU shall be the same as the advertiser's device address (AdvA field) received in the advertising event PDU to which the initiator is responding.

When an initiator receives a directed connectable advertising event that contains a resolvable private address for the target's address (TargetA field) and address resolution is enabled, the Link Layer shall resolve the private address using the resolving list's Local IRK values (see Section 1.3.2.3). An initiator that has been instructed by the Host to use Resolvable Private Addresses (e.g., using the HCI_LE_Create_Connection command; see [Vol 4] Part E, Section 7.8.12) shall not

respond to directed connectable advertising events that contain Public or Static addresses for the target's address (TargetA field).

When an initiator receives a connectable advertising event that contains a device Identity Address for the advertiser's device address (AdvA field), and if that device is in the Resolving List with a non-zero peer IRK for which the Host has specified device privacy mode, then the initiator filter policy (see Section 4.3.4) shall determine if the initiator establishes a connection.

The Host may request that the Link Layer shall use resolvable private addresses for the initiator's device address (InitA field) when initiating connection establishment with an associated device that exists in the Resolving List. If so, then the initiator's device address (InitA field) in the initiating PDU is generated using the Resolving List Local IRK and the Resolvable Private Address Generation procedure (see Section 1.3.2.2). The Link Layer should not set the InitA field to the same value as the TargetA field in the received advertising PDU.

In all other circumstances, the Link Layer shall use the public address or the Host-provided address for the initiator's device address (InitA field) when initiating connection establishment.

6.5 Privacy of the device

A device wanting to maintain its privacy shall not use its Identity Address in any advertising PDU. The Host may command the Controller to advertise, scan, or initiate a connection using a Resolvable Private Address when the Controller is using the resolving list. If the local IRK in the resolving list associated with the peer Identity Address is all zeros, the Controller will use the Identity Address. If the peer IRK in the resolving list associated with the peer Identity Address is all zeros, the Controller will accept the Identity Address. If the Host has instructed the Controller to use device privacy mode with a peer Identity Address, the Controller will accept the peer's Identity Address. This implies that the device's network privacy is violated. To maintain a device's network privacy, the Controller's resolving list can only contain entries with non-zero IRKs and device privacy mode cannot be used.

6.6 Privacy in the Synchronization State

6.6.1 Periodic advertising trains

The requirements in this section apply when the Link Layer is directed by the Host to receive a periodic advertising train using the SyncInfo field of an AUX_ADV_IND PDU. The requirements in this section apply in addition to those in Section 4.4.5.1 and Section 4.7.

When a scanner receives an advertising packet that contains a resolvable private address for the advertiser's device address (AdvA field) and address resolution is

enabled, the Link Layer shall resolve the private address (see Section 1.3.2.3). The scanner's periodic sync establishment filter policy (see Section 4.3.5) shall determine if the scanner processes the advertising packet.

7 ISO TEST MODE

This section contains information on testing a CIS or BIS in the Controller without the protocols and profiles in the Host that use the CIS Central, CIS Peripheral, Isochronous Broadcaster, and Synchronized Receiver role features of this specification. The command that enters ISO Test mode takes the connection handle of a CIS or BIS as a parameter.

7.1 ISO Transmit test mode

When instructed by the Host, the Link Layer shall generate and transmit the payloads in SDUs as follows:

1. When Payload_Type = 0b00 (zero size SDU), the length of every SDU shall be set to zero.
2. When Payload_Type = 0b01 (variable size SDU), every SDU shall contain the value of the 4-octet SDU counter of the SDU padded with vendor-specific data as shown in Figure 7.1. The size of the SDU can be different in every SDU_Interval by an algorithm chosen by the transmitting device. The range shall be between 4 and Max_SDU.

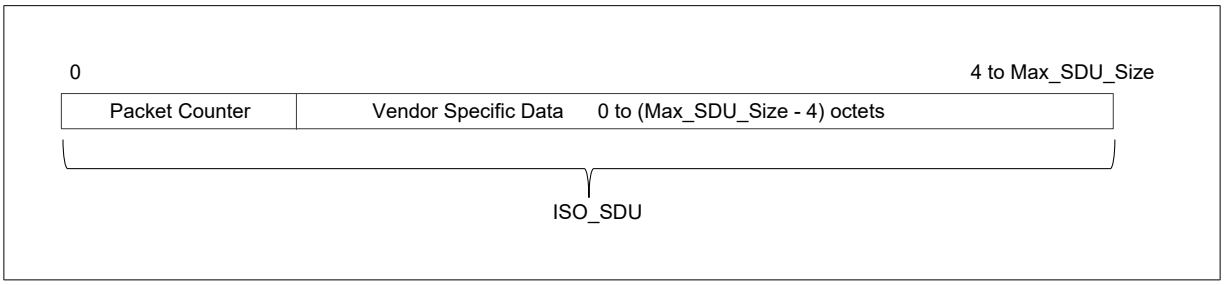

Figure 7.1: Payload_Type = 1 (variable size payloads)

3. When Payload_Type = 0b10 (maximum size SDU), every SDU shall contain the value of the 4-octet SDU counter of the SDU padded with vendor-specific data, as shown in Figure 7.2. The length of every SDU shall be equal to the value of the Max_SDU.

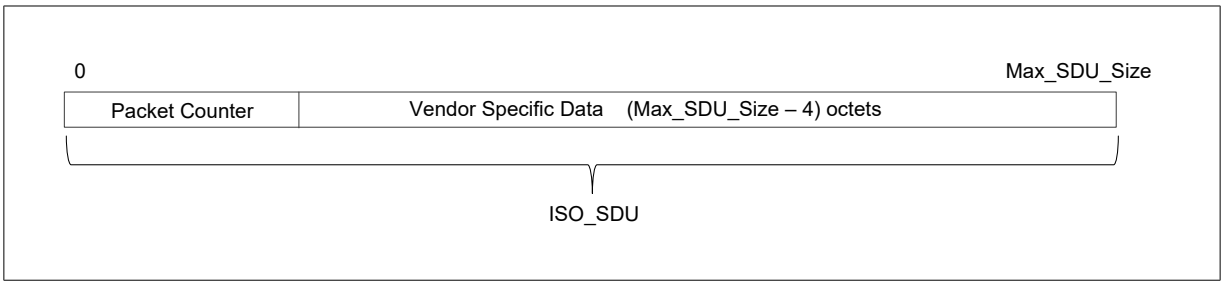

Figure 7.2: Payload_Type = 2 (maximum size payloads)

The ISO Transmit Test mode may be used in combination with the ISO Receive Test mode for a CIS configured for data flow from the Central to Peripheral and/or Peripheral to Central.

Note: For Payload_Type = 0b01 and 0b10, the minimum SDU size must be configured to be at least 4 octets, as described above in numbered paragraphs 2 and 3.

The SDU counter depends on the configuration (Max_SDU, SDU_Interval, or Max_PDU), of the logical link in the direction ISO Transmit Test mode is applied.

- When using unframed PDUs, the SDU counter shall be equal to the payload counter (i.e. the value of *bisPayloadCounter* in a BIS or of *cisPayloadCounter* in a CIS) of the PDU containing the first fragment from the SDU divided by UPPS (see [Vol 6] Part G, Section 2.1).

  Note: For UPPS=1 this results in the SDU counter being identical to the payload counter. The SDU counter is independent of the actual length of the SDUs when using variable length SDUs.
- When using framed PDUs the SDU counter cannot be derived from the payload counter of the PDU. It shall be initialized to 0 for the first test SDU transmitted and incremented by 1 for each additional SDU.

When instructed by the Host, the Link Layer shall stop generating test SDUs, exit the ISO Transmit Test mode, and notify the Host.

7.2 ISO Receive test mode

When instructed by the Host, the Link Layer shall initialize three 32-bit counters (Missed_SDU_Count, Received_SDU_Count, and Failed_SDU_Count) to zero and then increment these counters based on the received or missed test SDUs. Any vendor-specific data included in the SDU shall be ignored for the purpose of updating these counters.

When using framed PDUs the expected value of the SDU counter shall be initialized with the value of the SDU counter of the first valid received SDU. A valid SDU is one where all the PDUs composing the SDU are valid.

The counters shall be incremented as follows:

1. The Received_SDU_Count shall be incremented by one for every valid received test ISO Data SDU containing a size in the expected range and an SDU counter that matches the expected value as defined in Section 7.1. This includes empty SDUs when configured to zero size SDU.
2. The Missed_SDU_Count shall be incremented by one for each SDU that is made up of one or more invalid or missing PDUs.

3. The Failed_SDU_Count shall be incremented by one for each valid received test SDU where the size or SDU counter does not match the expected size or value as defined in Section 7.1.

Because the transmitter and receiver do not enter test mode simultaneously, it is not possible to determine whether the first test SDU received was the first one sent. As a consequence, at the moment the first valid test SDU is received (indicated by either Received_SDU_Count or Failed_SDU_Count being incremented), the value of Missed_SDU_Count is unpredictable. Once a valid test SDU has been received, any further changes in Missed_SDU_Count will be correct.

When instructed by the Host, the Link Layer shall exit the ISO Receive Test mode and notify the Host.

SAMPLE DATA

This Part contains sample data for Bluetooth Low Energy. All sample data are provided for reference purpose only. They can be used to check the behavior of an implementation and avoid misunderstandings.

CONTENTS

1 ENCRYPTION SAMPLE DATA

This section contains sample data for the Low Energy encryption process.

The following scenario describes the start of encryption, followed by the transfer of an encrypted data physical channel data packet in each direction. It describes:

- how the derived values are calculated (fixed values are given in red)
- which HCI command and events are exchanged if HCI is used (given in italic)
- which LL messages are exchanged over the air (given in green).

Note: CRCs are not shown because they depend on a random CRC init value. Scrambling is disabled.

The following parameters are set to the fixed values below:

```
LTK = 0x4C68384139F574D836BCF34E9DFB01BF (MSO to LSO)
EDIV = 0x2474 (MSO to LSO)

RAND = 0xABCDEF1234567890 (MSO to LSO)
SKD_C = 0xACBDCEDFE0F10213 (MSO to LSO)
SKD_P = 0x0213243546576879 (MSO to LSO)
IV_C = 0xBADCAB24 (MSO to LSO)
IV_P = 0xDEAFBABE (MSO to LSO)
```

```

2 LE CODED PHY SAMPLE DATA

Whenever bits are specified, they are in transmission order irrespective of spacing.

2.1 Reference information packet

The reference packet is described as bytes in transmission order (the leftmost byte in a line is transmitted first). Inside a byte, bits are transmitted LSB first.

```
Access address:     D6 BE 89 8E
PDU:                00 03 42 4C 45
CRC:                29 0A CE
```

2.2 Forward Error Correction encoder

This data shows the bits input to and output by the FEC encoder and its internal state.

The encoder state is expressed in octal notation where the LSB represents the rightmost bit store in Figure 3.6 of [Vol 6] Part B, Section 3.3.1. The state specified is that after the bits are output and the shift operations have taken place.

```
Access address
Input:   0   1   1   0   1   0   1   1   0   1   1   1   1   1   0   1

3 LE CHANNEL SELECTION ALGORITHM #2 SAMPLE DATA

This section contains two sets of sample data with different channel maps for the LE Channel Selection Algorithm #2.

The test access address is 0x8E89BED6, meaning the *channelIdentifier* is 0x305F.

3.1 Sample data 1 (37 used channels)

Channel map [36:0] = 0b11111_11111111_11111111_11111111_11111111.

The minimum channel distance d = 11.

	Event Counter	0	1	2	3
ACL or Periodic advertising event / CIS or BIS subevent 1	prn_e	56857	1685	38301	27475
	unmappedChannel	25	20	6	21
	mappedChannel[1]	25	20	6	21
Subevent 2	remappingIndexOfLastUsed-Channel	25	20	6	21
	prnSubEvent_se	11710	20925	6541	40400
	subEventIndex	1	36	18	4
	mappedSubEventChannel[1]	1	36	18	4
Subevent 3	prnSubEvent_se	16649	11081	14597	30015
	subEventIndex	16	12	32	22
	mappedSubEventChannel[1]	16	12	32	22
Subevent 4	prnSubEvent_se	38198	48920	62982	49818
	subEventIndex	36	34	21	8
	mappedSubEventChannel[1]	36	34	21	8

Table 3.1: Sample data 1 (37 used channels)

[1]These values are the general purpose channel indices actually used for transmitting and receiving the relevant event or subevent.

3.2 Sample data 2 (9 used channels)

Channel map [36:0] =0b11110_00000000_11100000_00000110_00000000.

The remapping table is [9, 10, 21, 22, 23, 33, 34, 35, 36].

Sample Data

The minimum channel distance d = 3.

	Event Counter	6	7	8
ACL or Periodic advertising event / CIS or BIS subevent 1	prn_e	10975	5490	46970
	unmappedChannel	23	14	17
	mappedChannel[1]	23	9	34
Subevent 2	remappingIndexOfLastUsed-Channel	4	0	6
	prnSubEvent_se	14383	4108	7196
	subEventIndex	7	3	0
	mappedSubEventChannel[1]	35	22	9
Subevent 3	prnSubEvent_se	28946	45462	33054
	subEventIndex	2	8	5
	mappedSubEventChannel[1]	21	36	33
Subevent 4	prnSubEvent_se	61038	64381	42590
	subEventIndex	8	5	1
	mappedSubEventChannel[1]	36	33	10

Table 3.2: Sample data (9 Used channels)

[1]These values are the general purpose channel indices actually used for transmitting and receiving the relevant event or subevent.

3.3 Sample data 3 (3 used channels)

Channel map [36:0] = 0b00000_00000000_00000000_00000001_00000110.

The remapping table is [1, 2, 8].

The minimum channel distance d = 1.

	Event Counter	11	12	13
ACL or Periodic advertising event / CIS or BIS subevent 1	prn_e	8628	34748	22072
	unmappedChannel	7	5	20
	mappedChannel[1]	1	2	2
Subevent 2	remappingIndexOfLastUsed-Channel	0	1	1
	prnSubEvent_se	30457	51913	13818
	subEventIndex	1	0	2
	mappedSubventChannel[1]	2	1	8

Sample Data

	Event Counter	11	12	13
Subevent 3	prnSubEvent_se	35147	46599	60171
	subEventIndex	0	2	1
	mappedSubventChannel[1]	1	8	2
Subevent 4	prnSubEvent_se	36952	37702	36470
	subEventIndex	2	1	0
	mappedSubventChannel[1]	8	2	1

Table 3.3: Sample data (3 Used channels)

[1]These values are the general purpose channel indices actually used for transmitting and receiving the relevant event or subevent.

4 COMPLETE PACKETS

Examples in this section assume use of the LE 1M PHY. For the LE 2M PHY, the packet will be identical except for the longer preamble and longer (in number of bits) Constant Tone Extension. For the LE Coded PHY, examples of converting from the form used on the uncoded PHYs to those used on the air are shown in Section 2.

Bit sequences are always in transmission order irrespective of spacing. Decimal and hexadecimal numbers are in their normal form.

4.1 Whitening sequences

The whitening sequence (see [Vol 6] Part B, Section 3.2) depends only on the physical channel index of the channel being used. The sequence repeats after 127 bits.

Channel	First 64 bits of the whitening sequence
0	00000010 01001101 00111101 11000011 11111000 11101100 01010010 11111010

4.2 Advertising Physical channel PDUs

4.2.1 Legacy advertising PDUs

Example: ADV_NONCONN_IND PDU

```
PDU Type: 2
ChSel: RFU
TxAdd: 1 (random)
RxAdd: RFU
AdvA: 0xC1A2A3A4A5A6 (a static device address)
AdvData: (3 octets) 0x01 0x02 0x03
Channel index: 38

PDU header: 0100 0 0 1 0 10010000
PDU body: 01100101 10100101 00100101 11000101 01000101 10000011
10000000 01000000 11000000
CRC: 10110101 00101101 11010111

PDU and CRC before whitening:
01000010 10010000 01100101 10100101 00100101 11000101 01000101
10000011 10000000 01000000 11000000 10110101 00101101 11010111

PDU and CRC after whitening:
00101001 00110011 01000111 10100001 10111111 10111110 11000010
01110010 01011000 11100101 00110101 11110111 11110011 10100101

Complete packet:
```

Sample Data

```
01010101
01101011 01111101 10010001 01110001
00101001 00110011 01000111 10100001 10111111 10111110 11000010
01110010 01011000 11100101 00110101 11110111 11110011 10100101
```

4.2.2 Extended advertising PDUs

Example: connectable undirected AUX_ADV_IND PDU with AdvA, ADI, TxPower, and AdvData fields.

```
PDU Type: 7
ChSel: RFU
TxAdd: 0 (public)
RxAdd: RFU
AdvA: 0xA9AAABACADAE (a public device address)
Advertising DID: 0xABC
Advertising SID: 0xE
TxPower: 0xD6 (-42 dBm)
AdvData: (5 octets) 0x05 0x07 0x09 0x0B 0x0D
Channel index: 7
PDU header: 1110 0 0 0 0 00001000

Extended header length: 010100
AdvMode: 10

Extended header:
    Flags: 1 0 0 1 0 0 1 0
    AdvA: 01110101 10110101 00110101 11010101 01010101 10010101
    ADI: 001111010101 0111
    TxPower: 01101011

AdvData: 10100000 11100000 10010000 11010000 10110000

PDU: 11100000 00001000 01010010 10010010 01110101 10110101 00110101
11010101 01010101 10010101 00111101 01010111 01101011 10100000
11100000 10010000 11010000 10110000

CRC: 00011011 11000100 01110101

PDU and CRC after whitening:
00011100 01111110 01111011 11101111 00100101 00000010 10101001
01111001 10010100 00100000 11101100 11000110 01101001 11101101
```

Sample Data

7 DETERMINISTIC RANDOM BIT GENERATOR SAMPLE DATA

This section contains sample data for the Deterministic Random Bit Generator.

The following scenarios provide sample entropy input for the h9() instantiation function, which then invokes several subordinate security toolbox functions described in [Vol 6] Part E, Section 3. After this, CS procedure counters, step counters, transaction IDs, and transaction counters are incremented for further iterations of sample data. The CS Backtracking procedure is also invoked to generate additional sample data.

Unless otherwise noted, all fields are displayed in leftmost (MSO) to rightmost (LSO) orientation as described in [Vol 6] Part E, Section 3.1.1.

8 CHANNEL SOUNDING PROCEDURE SAMPLE DATA

This section contains sample data for illustrative Channel Sounding procedures that make use of the Deterministic Random Bit Generator.

The data is generated as if the configuration and timing parameters listed in each subsection were negotiated or derived during the CS Configuration procedure ([Vol 6] Part B, Section 5.1.25 and [Vol 6] Part B, Section 2.4.2.45) and the CS Start procedure ([Vol 6] Part B, Section 5.1.26 and [Vol 6] Part B, Section 2.4.2.47).

The following scenarios provide sample entropy input for the h9() instantiation function, which then invokes several subordinate security toolbox functions described in [Vol 6] Part E, Section 3. After this, CS procedure counters, step counters, transaction IDs, and transaction counters are incremented for further iterations of sample data.

Unless otherwise noted, all fields are displayed in leftmost (MSO) to rightmost (LSO) orientation as described in [Vol 6] Part E, Section 3.1.1.

8.1 Channel Selection Algorithm #3b

8.1.1 Set 1

From the CS Configuration procedure:

- ChM = 0x00 00 00 00 00 00 00 1F FF FC
- ChM_Repetition = 2
- Main_Mode = 0x02
- Sub_Mode = 0x03
- Main_Mode_Min_Steps = 2
- Main_Mode_Max_Steps = 6
- Main_Mode_Repetition = 0
- Mode_0_Steps = 3
- RTT_Type = 0x01
- Role = 0b01
- ChSel = 0

Sample Data

From the CS Start procedure:

- Subevent_Len – setup to include at least 20 steps
- Procedure_Count = 1
- ACI = 7

8.1.4 Set 4

The sample data in this section includes CS scheduling considerations.

From the CS Configuration procedure:

- T_SW, Central and Peripheral = 10 µs, 10 µs

From the CS Configuration procedure:

- ChM = 0x00 00 00 00 00 00 00 1F 1F FC (Used: 2-12, 16-20, Unused: 0-1, 13-15, 21-79)
- ChM_Repetition = 2
- Main_Mode = 0x03 (Mode-3)
- Sub Mode = 0x02 (Mode-2)
- Main_Mode_Min_Steps = 1
- Main_Mode_Max_Steps = 6
- Main_Mode_Repetition = 2
- Mode_0_Steps = 1
- CS_SYNC_PHY = 0x02 (2M PHY)
- RTT_Type = 0x02 (96-bit sounding sequence)
- Role = 0b01 (Reflector)
- ChSel = 0 (Channel Selection Algorithm 3b)
- Ch3c Shape = 0
- Ch3c Jump = 2
- T IP1 = 0x07 (145 µs)
- T IP2 = 0x07 (145 µs)
- T FCS = 0x09 (150 µs)
- T PM = 0x00 (10 µs)

From the CS Start procedure:

- T_EVENT_OFFSET (from Offset_Min and Offset_Max) = 0 ns
- T_EVENT_INTERVAL (from Event_Interval) = 1

Sample Data

- N_SUBEVENTS_PER_EVENT (from Subvents_Per_Event) = 3
- T_SUBEVENT_INTERVAL (from Subevent_Interval) = 5.000 ms
- T_SUBEVENT_LEN (from Subevent_Len) = 4.000 ms
- T_MAX_PROCEDURE_LEN (from Max_Procedure_Len) = 40.4000 s
- ACI = 7 (ACI 7)

Other scheduling parameters:

- ACL connection interval = 40.000 ms

8.2 Channel Selection Algorithm #3c

The timing parameters provided with each set are used to actively calculate the number of steps included in each CS subevent.

8.2.1 Set 1

Time parameters:

Sync packet:	T_SY = 26
Frequency measurement:	T_FM = 80 µs
Guard Time:	T_GD = 10 µs
Time to hop:	T_FCS = 15 µs
Ramp down time:	T_RD = 5 µs

Sample Data

Interlude period 1: T_IP1 = 10 µs
Interlude period 2: T_IP2 = 10 µs
Phase measurement time: T_PM = 10 µs
Number of antenna path: N_AP = 1
Antenna switch time: T_SW = 0 µs

CSShapeSelection: X
CSChannelJump: 2
CSNumRepetitions: 1

Mode-0 duration: 177 µs
Main-mode (Mode-2) duration: 75 µs
Sub-Mode (Mode-3) duration: 147 µs
Minimum main mode steps: 2
Maximum main mode steps: 4
PHY: 2 Mbps
RTT Type: AA-only

Event duration: 5000 µs
Mode_0_Steps: 3
Main_Mode_Repetition: 3

```

Low Energy Controller
Part D

MESSAGE SEQUENCE CHARTS

Examples of message sequence charts showing the interactions of the Host Controller Interface with the Link Layer.

CONTENTS

1 INTRODUCTION

This section shows typical interactions between Host Controller interface (HCI) commands and events and the Link Layer (LL). It focuses on the message sequence charts (MSCs) for the procedures specified in “Bluetooth Host Controller Interface Functional Specification” with regard to Link Layer control procedures from “Link Layer”. This section illustrates only the most useful scenarios; it does not cover all possible alternatives. Furthermore, the message sequence charts do not consider errors over the air interface or Host interface. In all message sequence charts it is assumed that all events are not masked, so the Controller will not filter out any events.

The sequence of messages in these message sequence charts is for illustrative purposes. The messages may be sent in a different order where allowed by the Link Layer or HCI. If any of these charts differ with text in the Link Layer or HCI Parts, the text in those Parts overrides these charts.

1.1 Notation

The notation used in the message sequence charts (MSCs) consists of ovals, elongated hexagons, boxes, lines, and arrows. The vertical lines terminated on the top by a shadow box and at the bottom by solid oval indicate a protocol entity that resides in a device. MSCs describe interactions between these entities and states those entities may be in.

The following symbols represent interactions and states:

Oval	Defines the context for the message sequence chart
Hexagon	Indicates a condition needed to start the transactions below this hexagon. The location and width of the Hexagon indicates which entity or entities make this decision.
Box	Replaces a group of transactions. May indicate a user action, or a procedure in the Link Layer.
Dashed Box	Optional group of transactions.
Solid Arrow	Represents a message, signal or transaction. Can be used to show Link Layer and HCI traffic.
Dashed Arrow	Represents an optional message, signal or transaction. Can be used to show Link Layer and HCI traffic.

1.2 Control flow

Some message sequences are split into several charts. In these charts, numbers indicate normal or required ordering and letters represent alternative paths. For example, Step 4 is after Step 3, and Step 5a could be executed instead of Step 5b.

1.3 Example MSC

The protocol entities represented in the example shown in Figure 1.1 illustrate the interactions of two devices named A and B; each device includes a Host and a LL entity in this example. Other MSCs in this section may show the interactions of more than two devices.

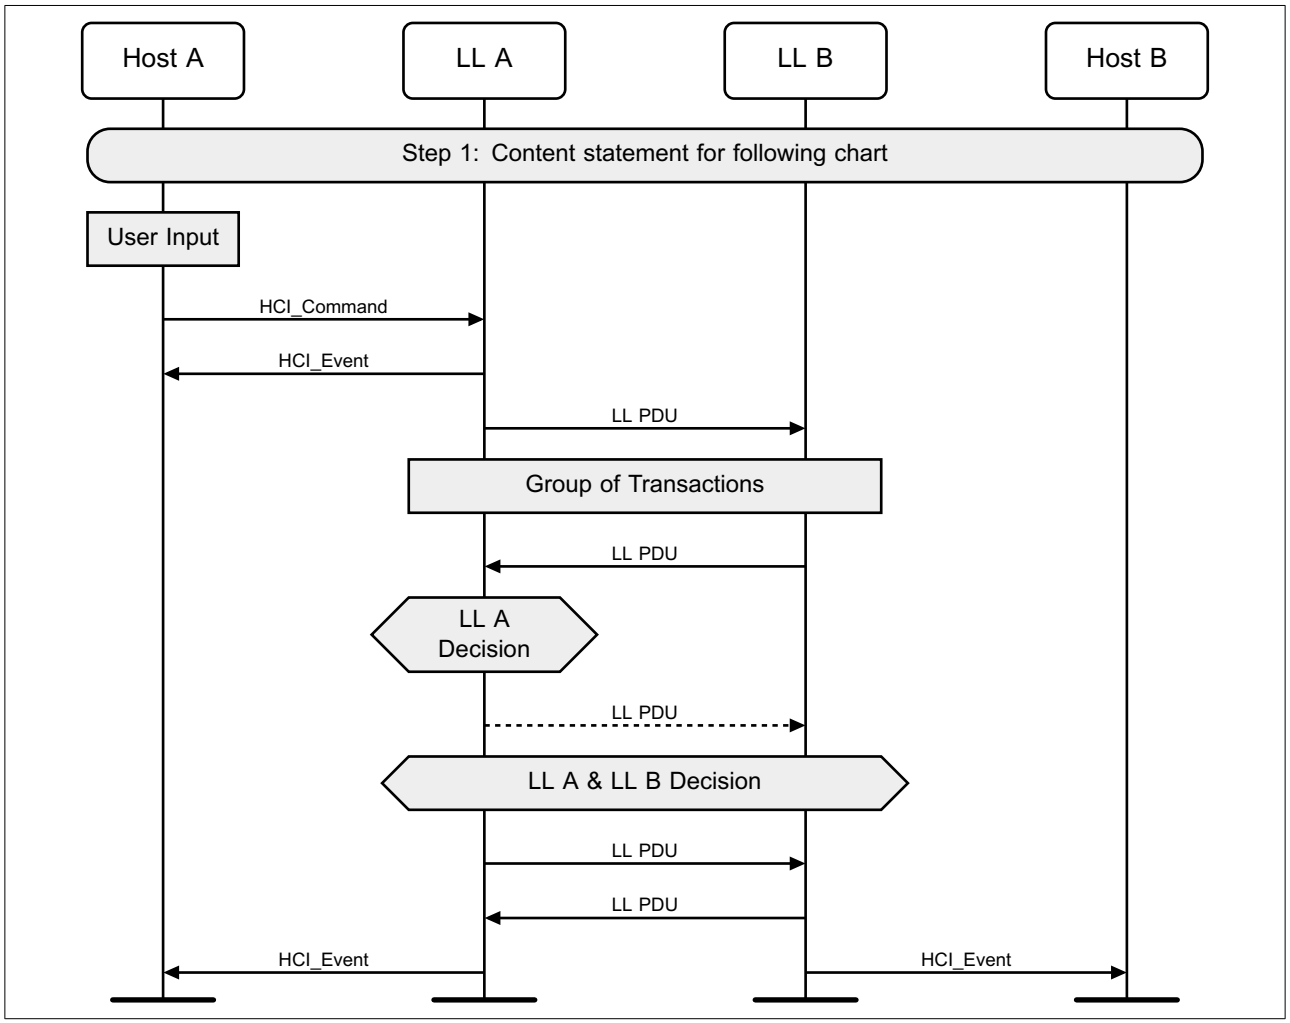

Figure 1.1: Example MSC

1.4 Forward compatibility

Many of the message sequences in this Part use HCI commands or events that have enhanced or extended variants that were added to the specification later than the relevant sequence. Such variants can be related commands or events with different names (e.g,. HCI_LE_Advertising_Report and HCI_LE_Extended_Advertising_Report events) or commands or events with multiple versions (e.g., HCI_LE_Generate_DHKey command). In some instances (for example, see [Vol 4] Part E, Section 3.1.1), a Host is

required to use the new variant rather than the one shown in the MSC. Even when this is not a requirement, Host implementers may prefer to use the newer variants.

In these circumstances, the MSCs have not been rewritten to use newer features but have been left unchanged. In general, the new commands and events will directly replace the old ones, but this is not always the case and readers should not assume it.

2 STANDBY STATE

2.1 Initial setup

To perform initial setup of a LE Controller, the following sequence of actions may be required.

First, the Host would wait for the Controller to indicate the number of HCI Command packets the Host is currently allowed to send using a Command Complete event on a No OPeration command opcode. Then it would reset the Controller to a known state. Then it needs to read the local supported features to check that low energy is supported on this Controller. It would then set the event mask and LE event mask to enable the events that it wants the Controller to generate to the Host. Next, it will check the buffers that are available for data flow, using the Read Buffer Size and LE Read Buffer Size commands. Then it would read the locally supported LE features and select the features

that it wishes to use. Finally, it will read the public device address if the Controller has one (see Figure 2.1).

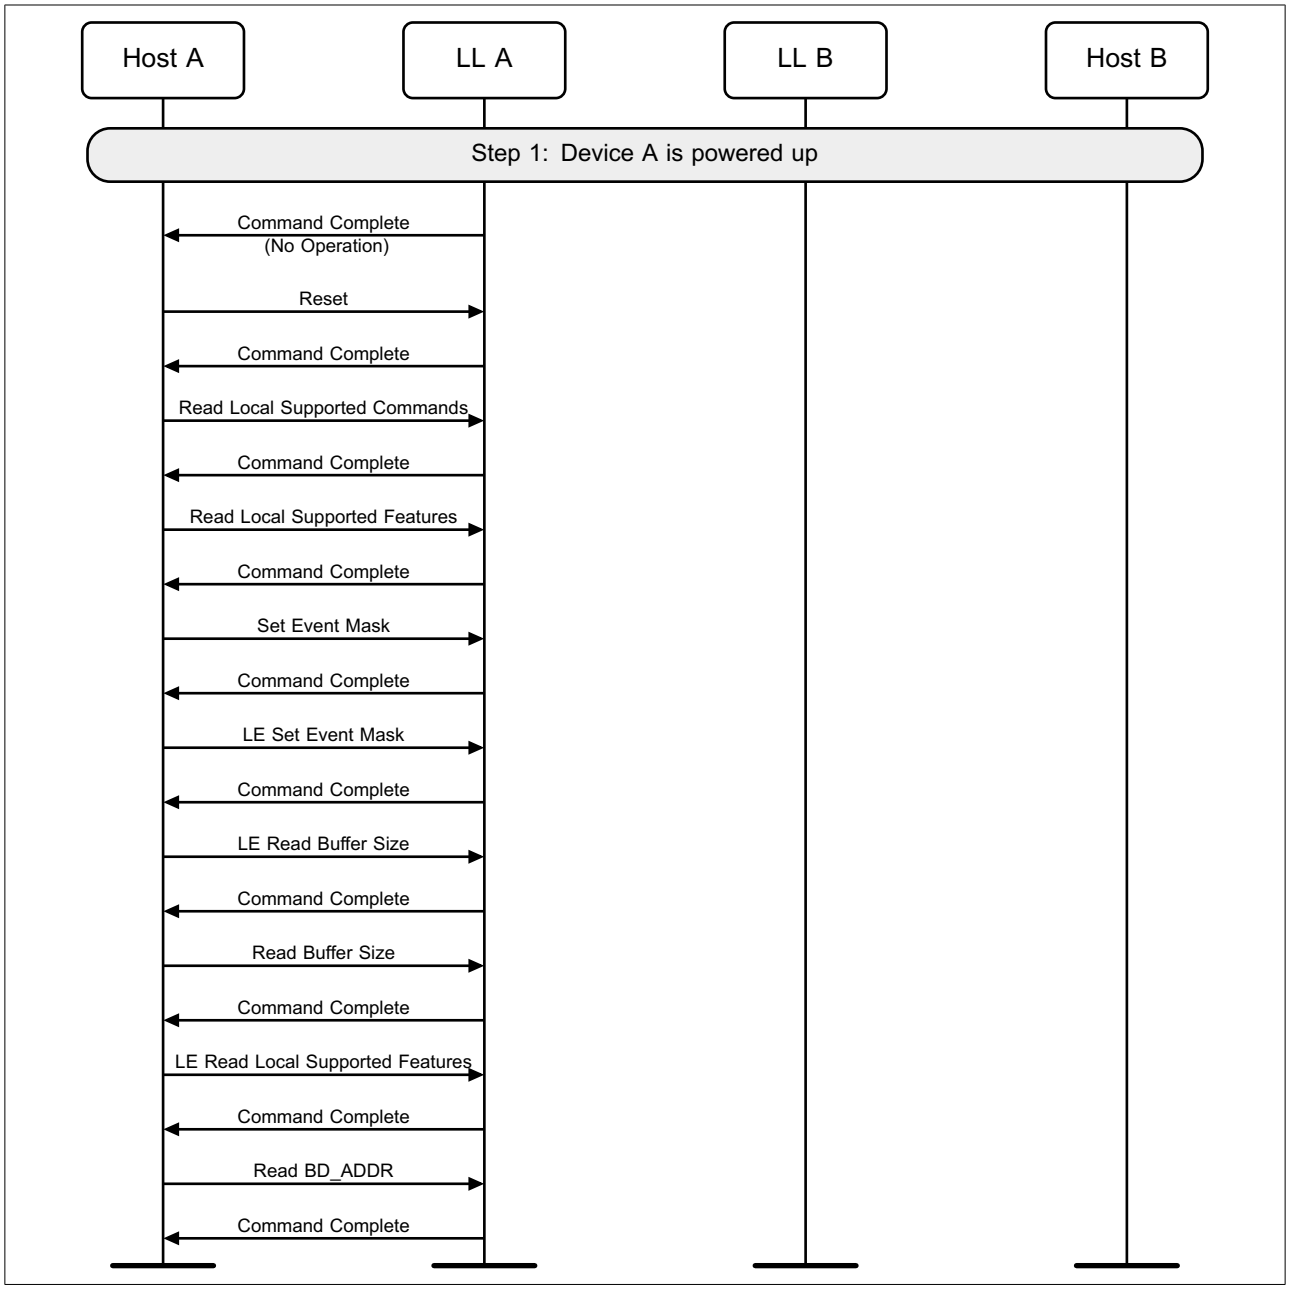

Figure 2.1: Initial setup

2.2 Random Device address

A device may use a random device address, but this address has to be configured before being used during advertising, scanning or initiating (see Figure 2.2).

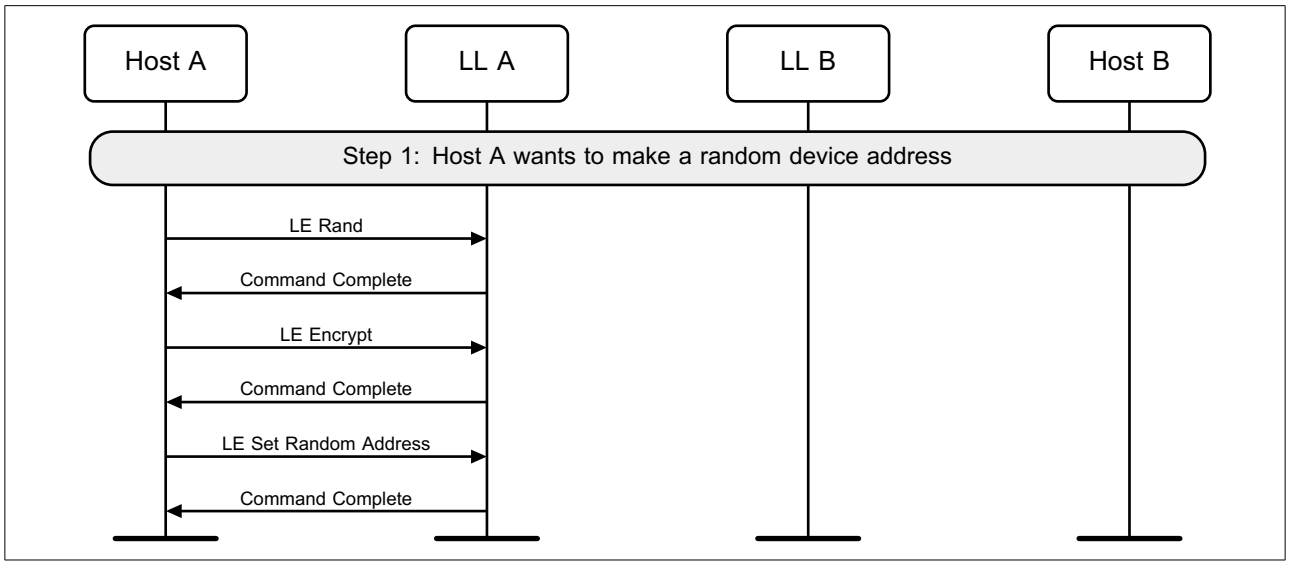

Figure 2.2: Random device address

2.3 Filter Accept List

Before advertising, scanning or initiating can use a Filter Accept List, the Filter Accept List may be cleared and devices added in as required (see Figure 2.3).

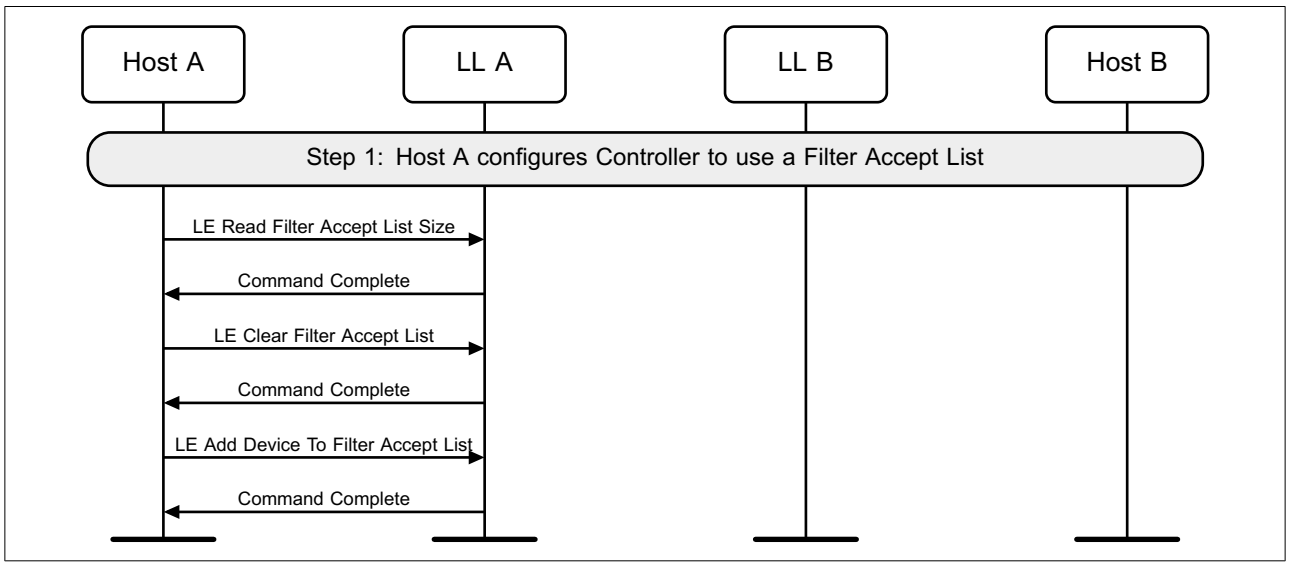

Figure 2.3: Filter Accept List

2.4 Adding IRK to resolving list

Before advertising, scanning or initiating can use resolving lists, the resolving list may be cleared and devices added in as required (see Figure 2.4).

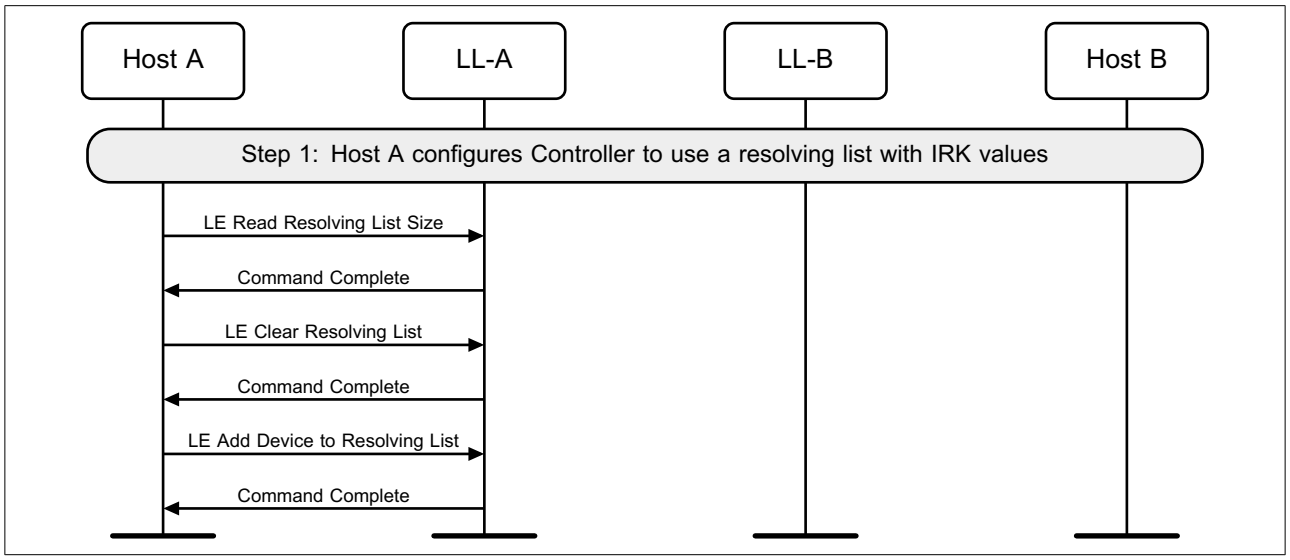

Figure 2.4: Resolving lists

2.5 Default data length

Before creating a connection, the Host may specify its preferred values for the Controller's maximum transmission packet size and maximum packet transmission time to be used for new connections. This may be done on either the Central or the Peripheral.

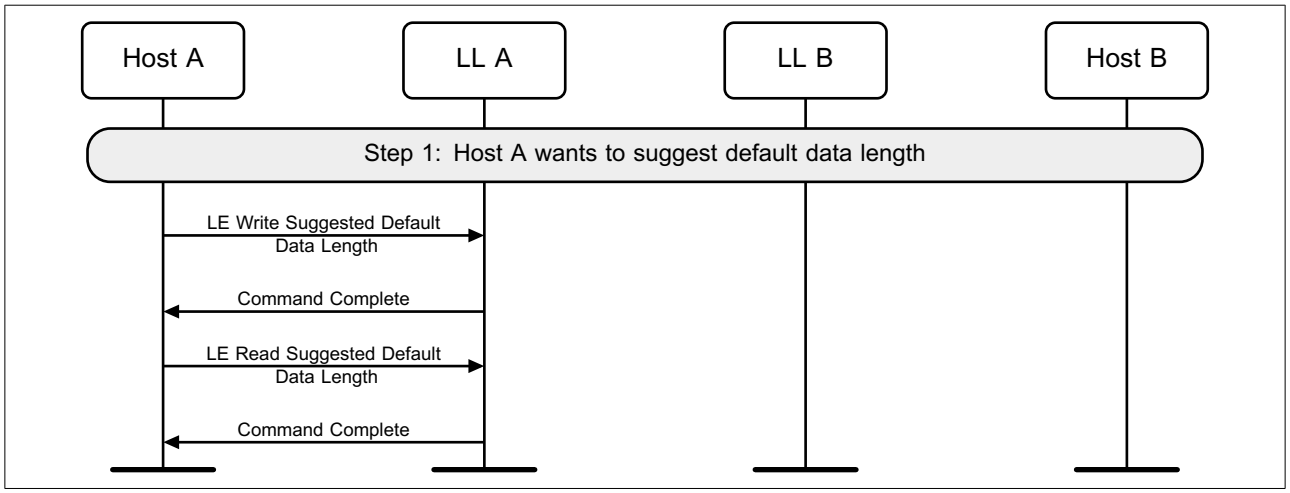

Figure 2.5: Default data length

2.6 Periodic Advertiser List

The Periodic Advertiser List may be cleared and entries added as required, before it is made use of (see Figure 2.6).

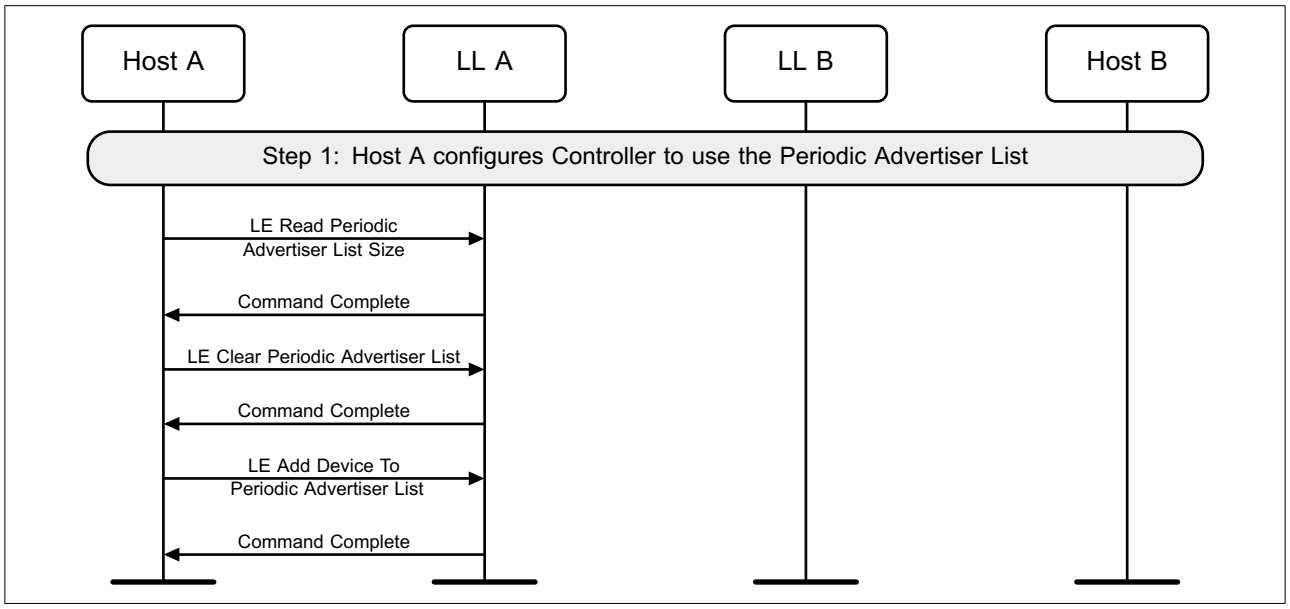

Figure 2.6: Periodic Advertiser List

3 ADVERTISING STATE

3.1 Undirected advertising

A device may enter the Advertising state by enabling advertising. It should also configure the advertising parameters before doing this (see Figure 3.1).

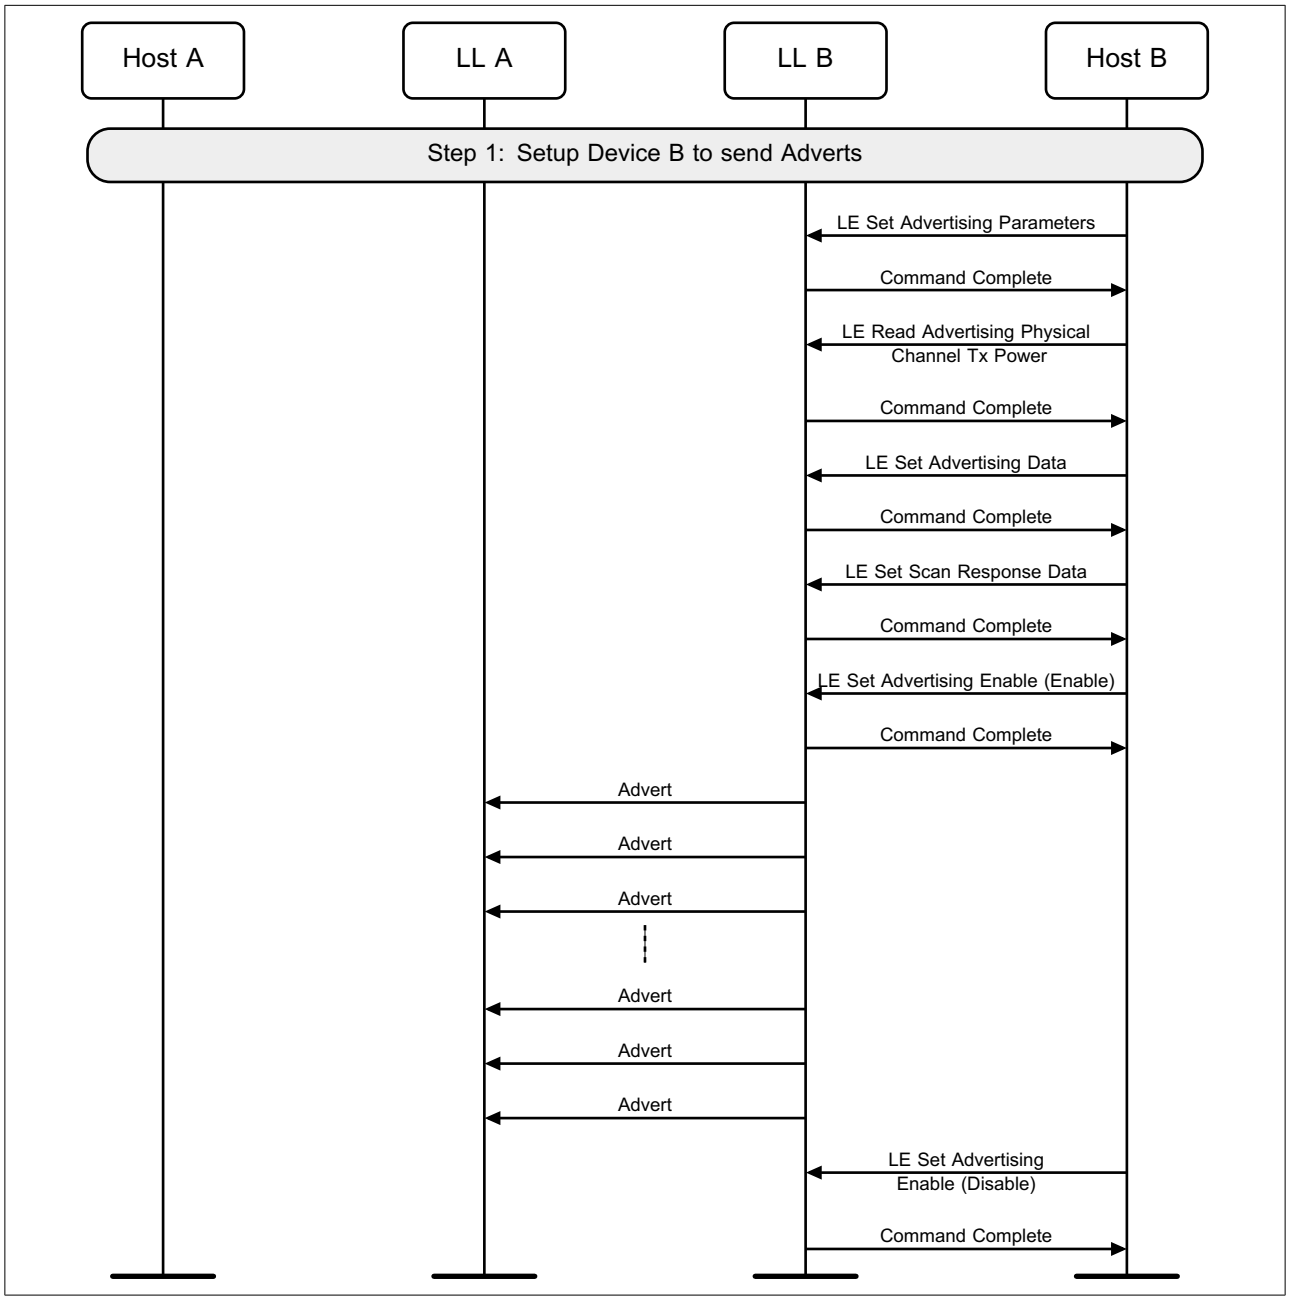

Figure 3.1: Undirected advertising

3.2 Directed advertising

A device may use directed advertising to allow an initiator to connect to it. High duty cycle directed advertising is time limited in the Controller and therefore this may fail before a connection is created. This example only shows the failure case (see Figure 3.2).

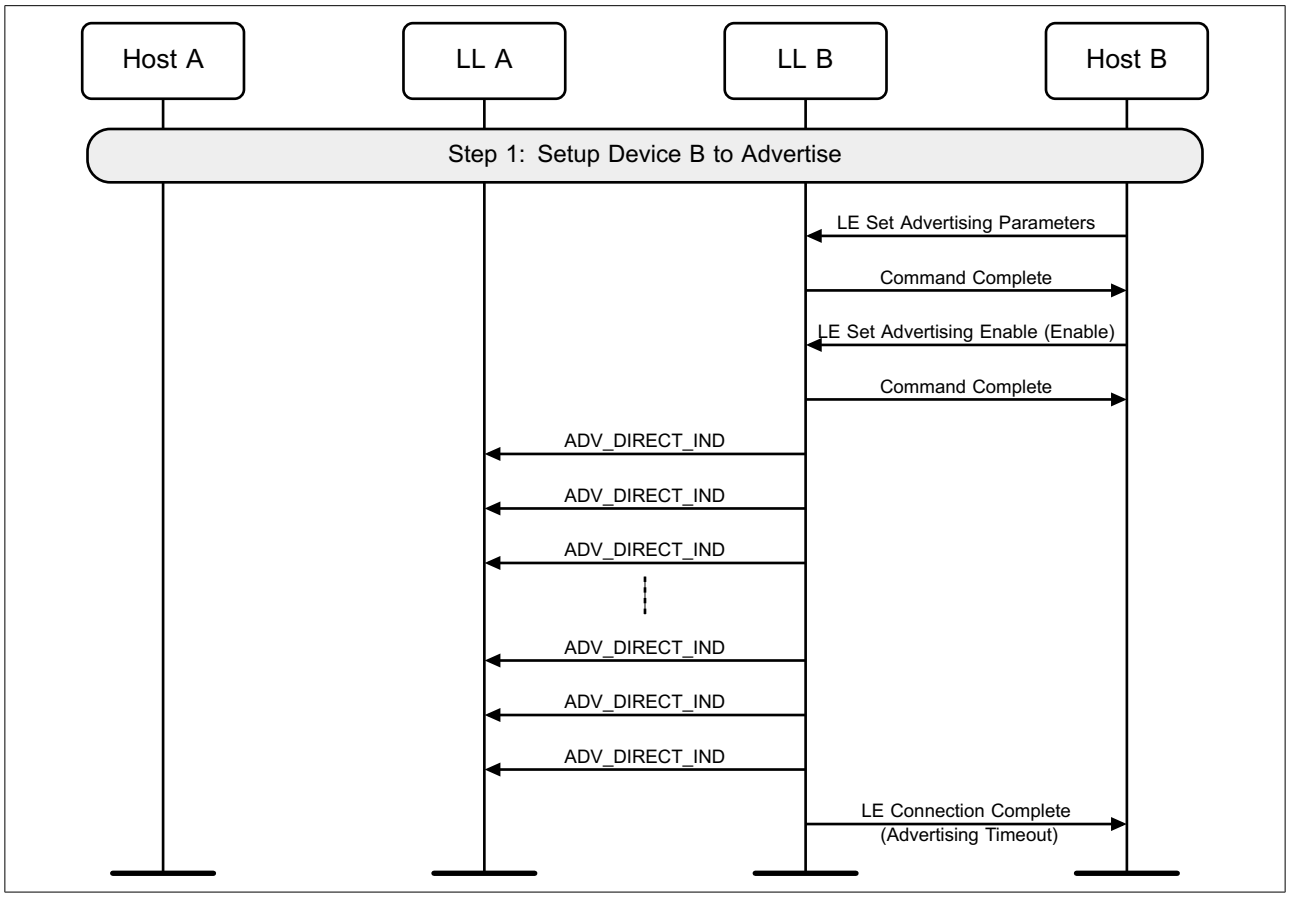

Figure 3.2: High duty cycle directed advertising showing failure case

Low duty cycle directed advertising is not time-limited. This example shows the case where no connection is made. A device should also configure the advertising parameters before doing this (see Figure 3.3).

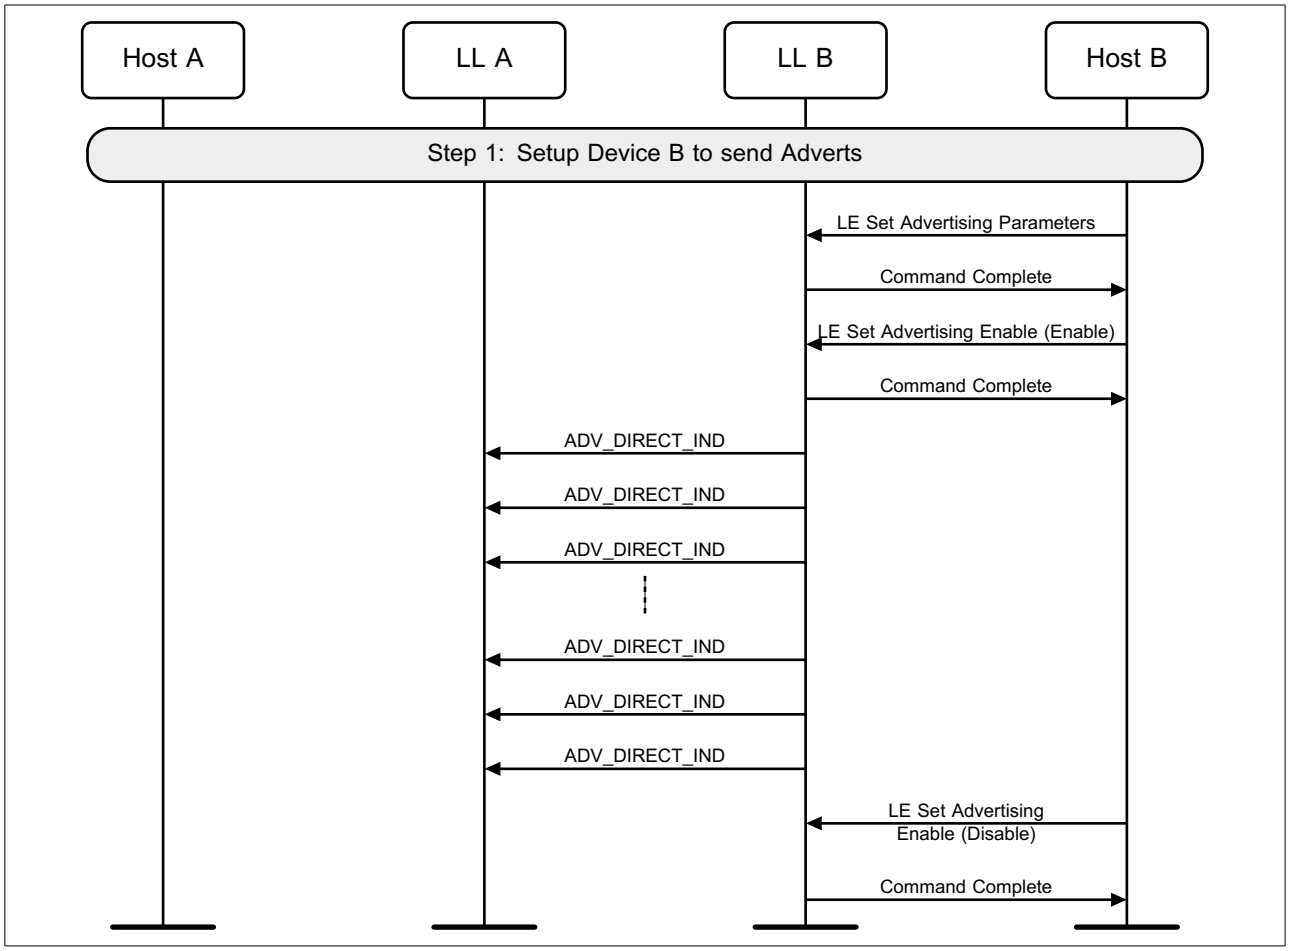

Figure 3.3: Low duty cycle directed advertising

3.3 Advertising using ADV_EXT_IND

A device may enter the Advertising state by enabling advertising a set. It should also configure the advertising set parameters before doing this (see Figure 3.4).

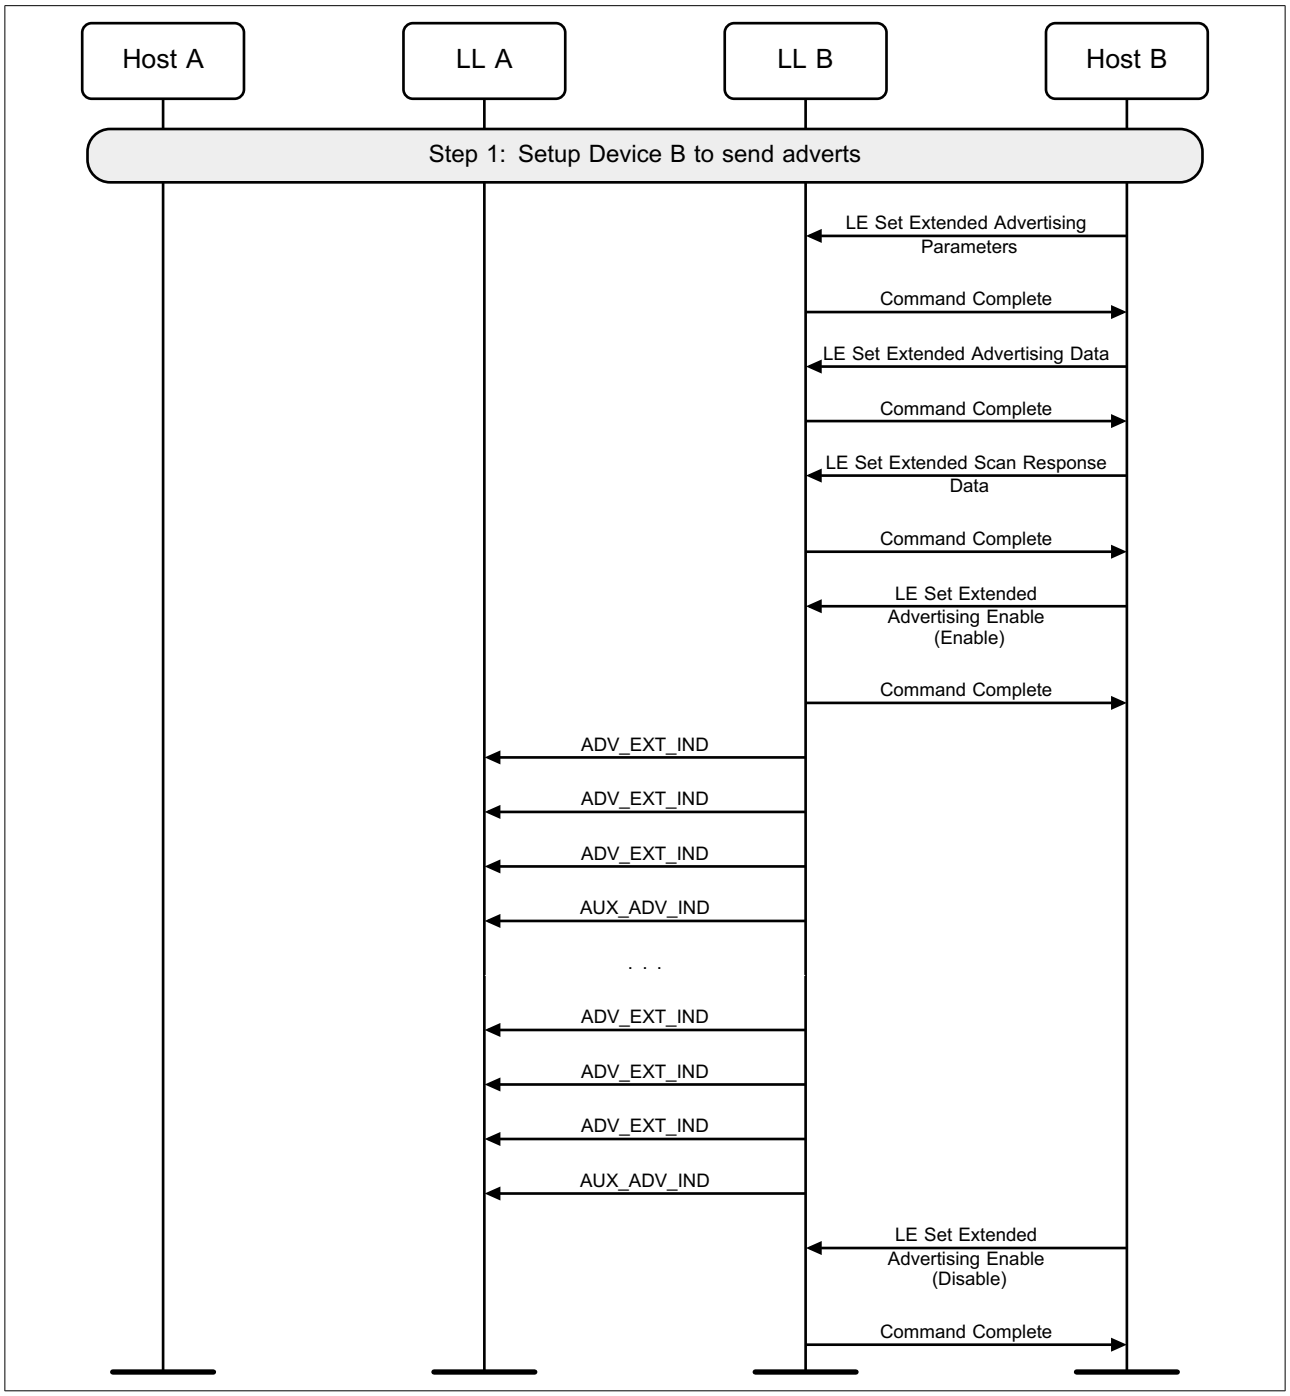

Figure 3.4: Advertising using ADV_EXT_IND

3.4 Scan request notifications

A device may enable scan request notifications in an advertising set (see Figure 3.5).

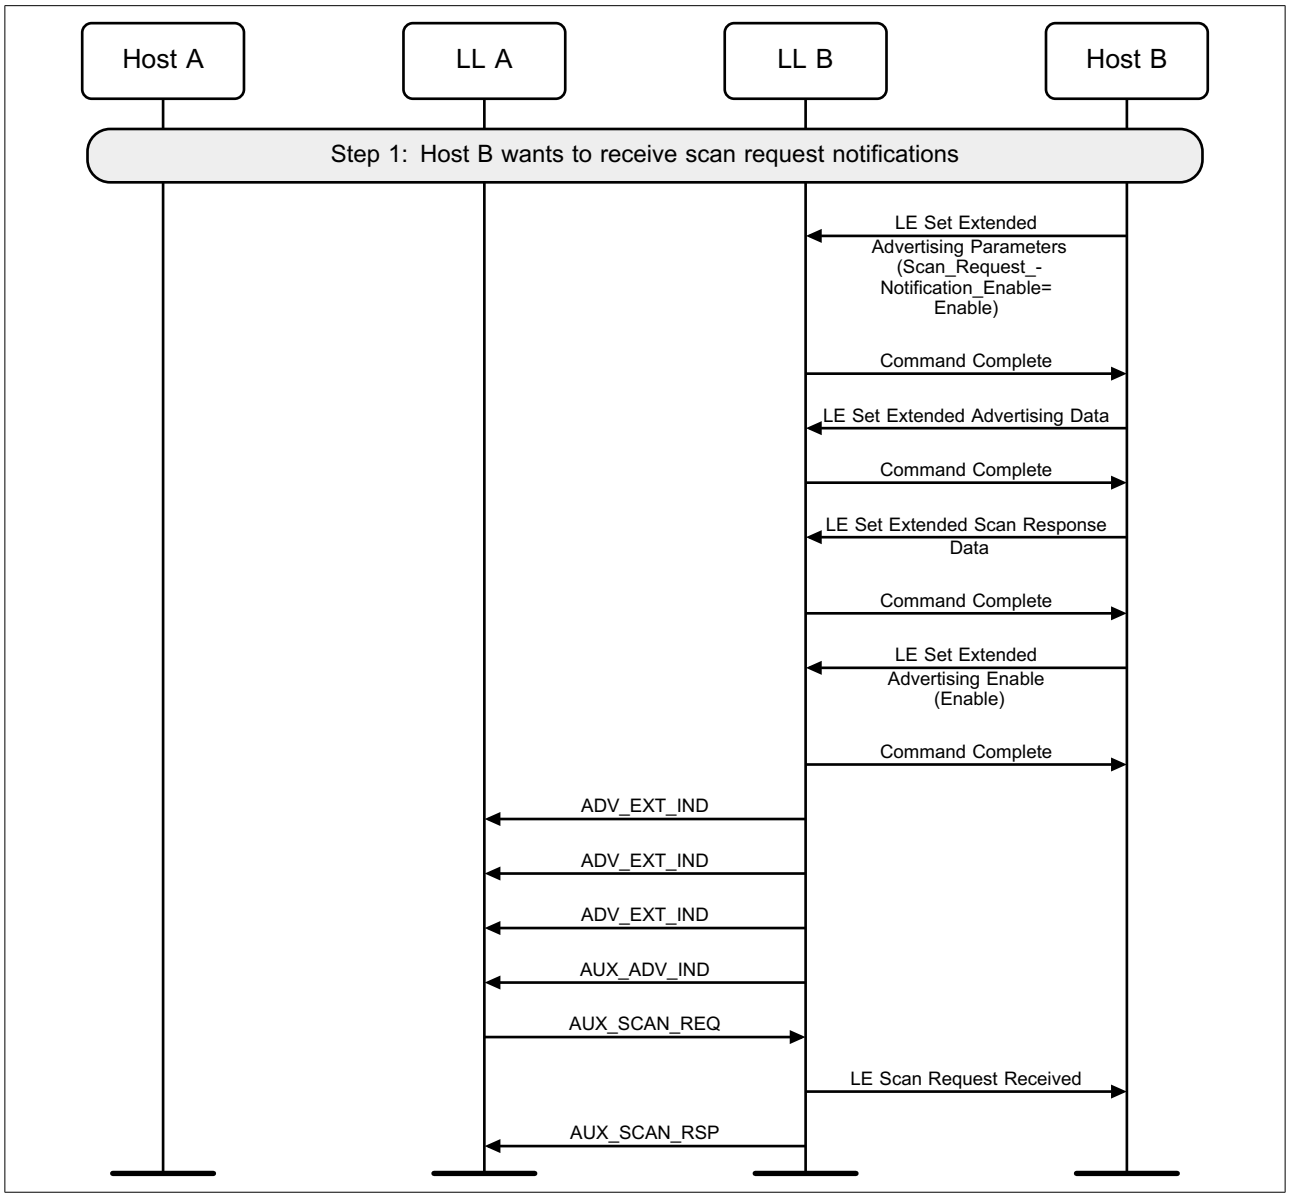

Figure 3.5: Scan request notifications

3.5 Advertising duration ended

A device may enter the Advertising State by enabling advertising a set for a limited duration of time (see Figure 3.6).

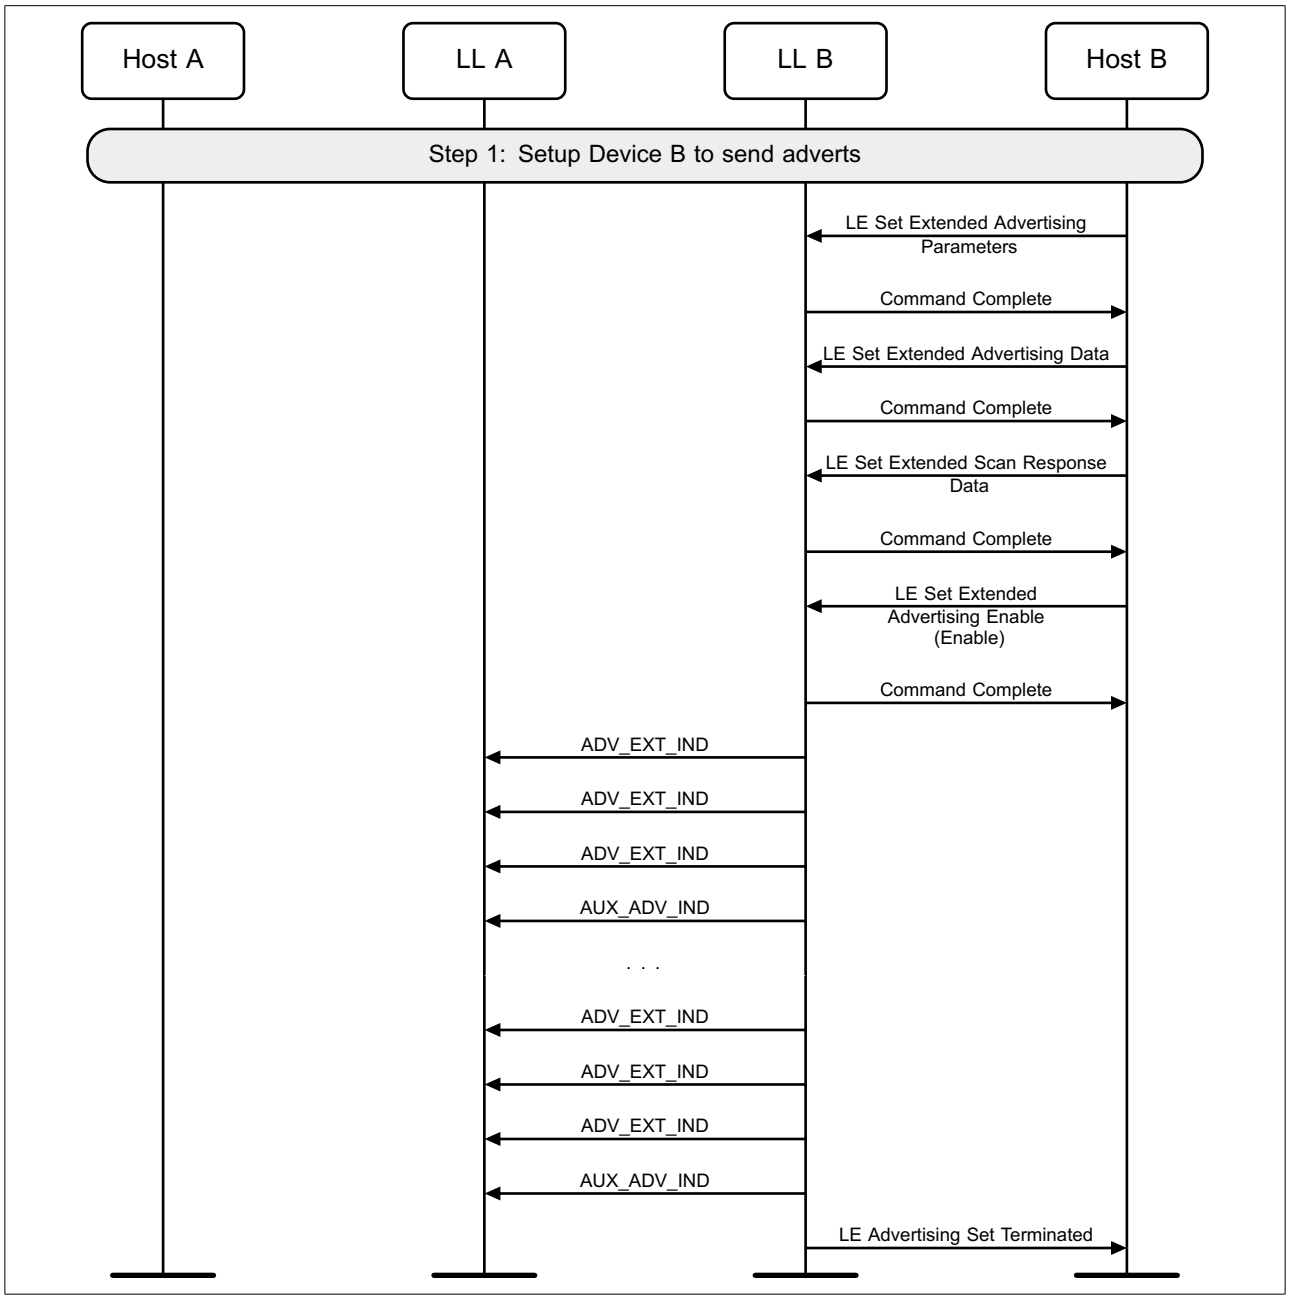

Figure 3.6: Advertising duration ended

3.6 Periodic advertising

A device may enter the Advertising State by enabling periodic advertising in a set. It should also configure the advertising set parameters before doing this (see Figure 3.7).

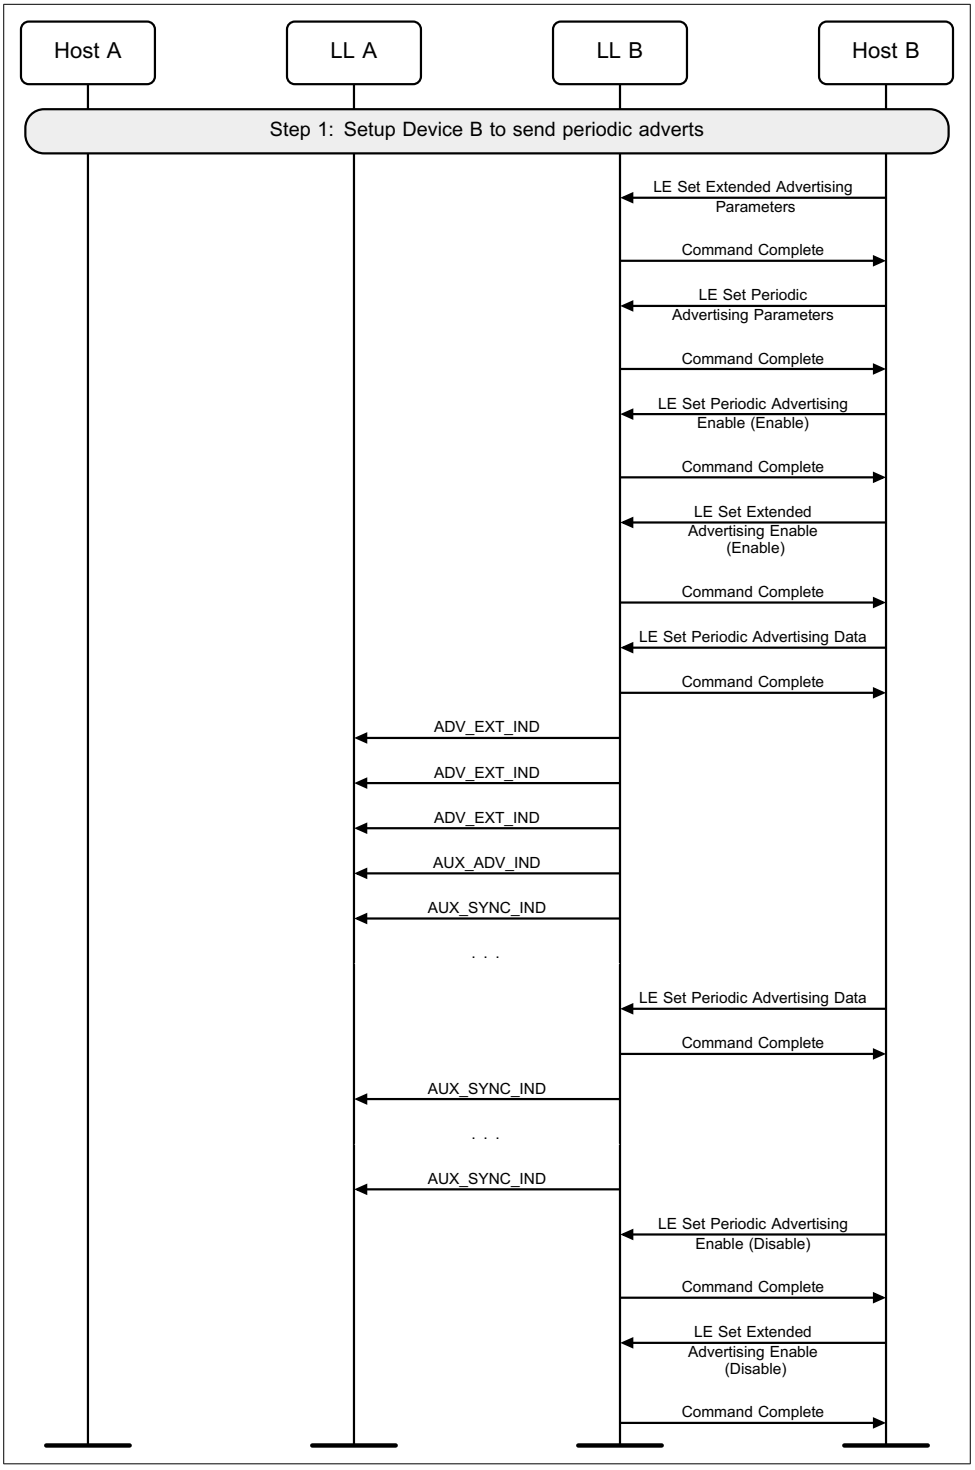

Figure 3.7: Periodic advertising

3.7 Connectionless Constant Tone Extension transmission

A device may send periodic advertising packets containing a Constant Tone Extension (see Figure 3.8).

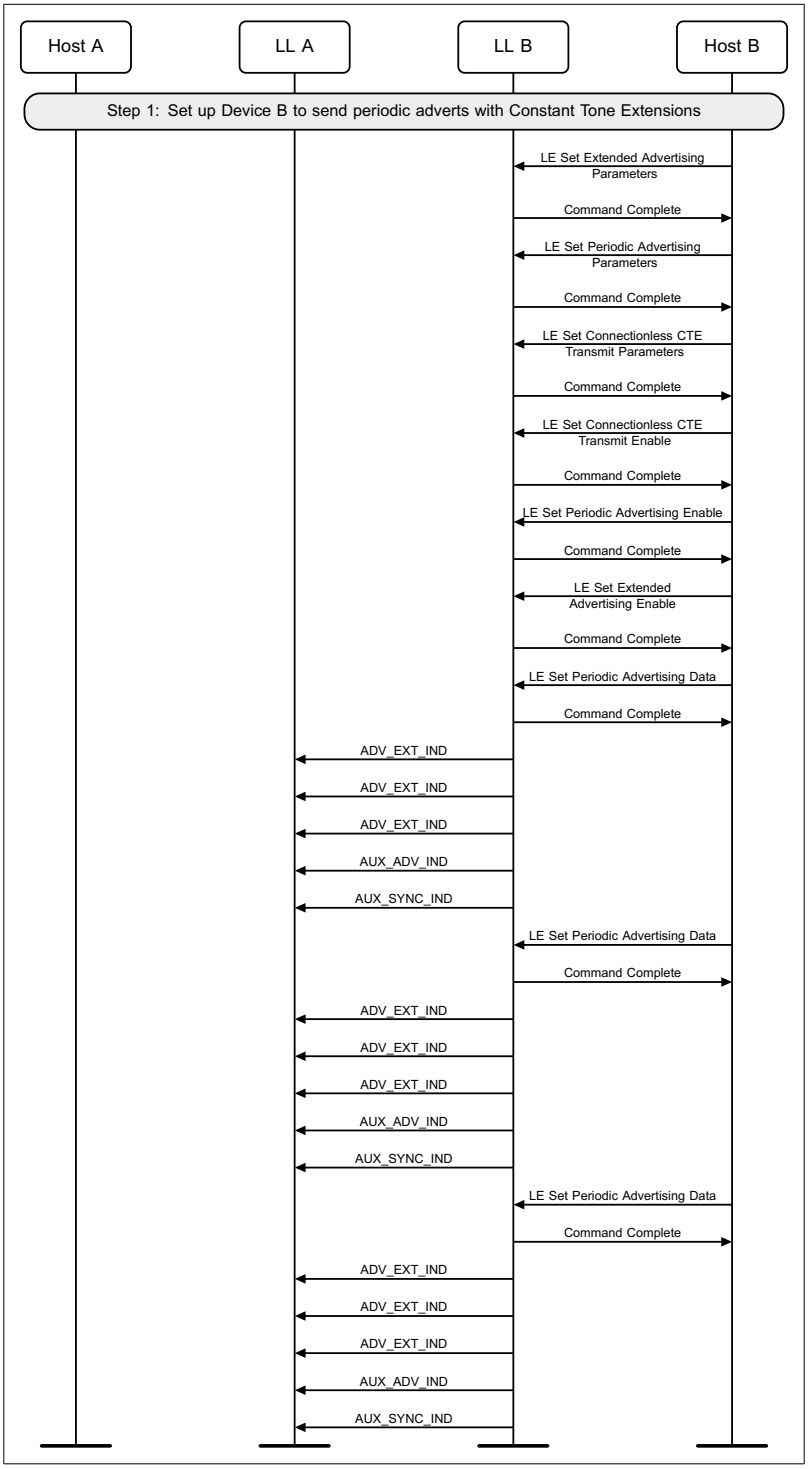

Figure 3.8: Connectionless CTE transmission

3.8 Isochronous Broadcasting State

3.8.1 Create a Broadcast Isochronous Group

A device enters the Isochronous Broadcasting State and enables the periodic advertising associated with the BIG. The device then creates the BIG and sends isochronous data using the isochronous data paths (see Figure 3.9).

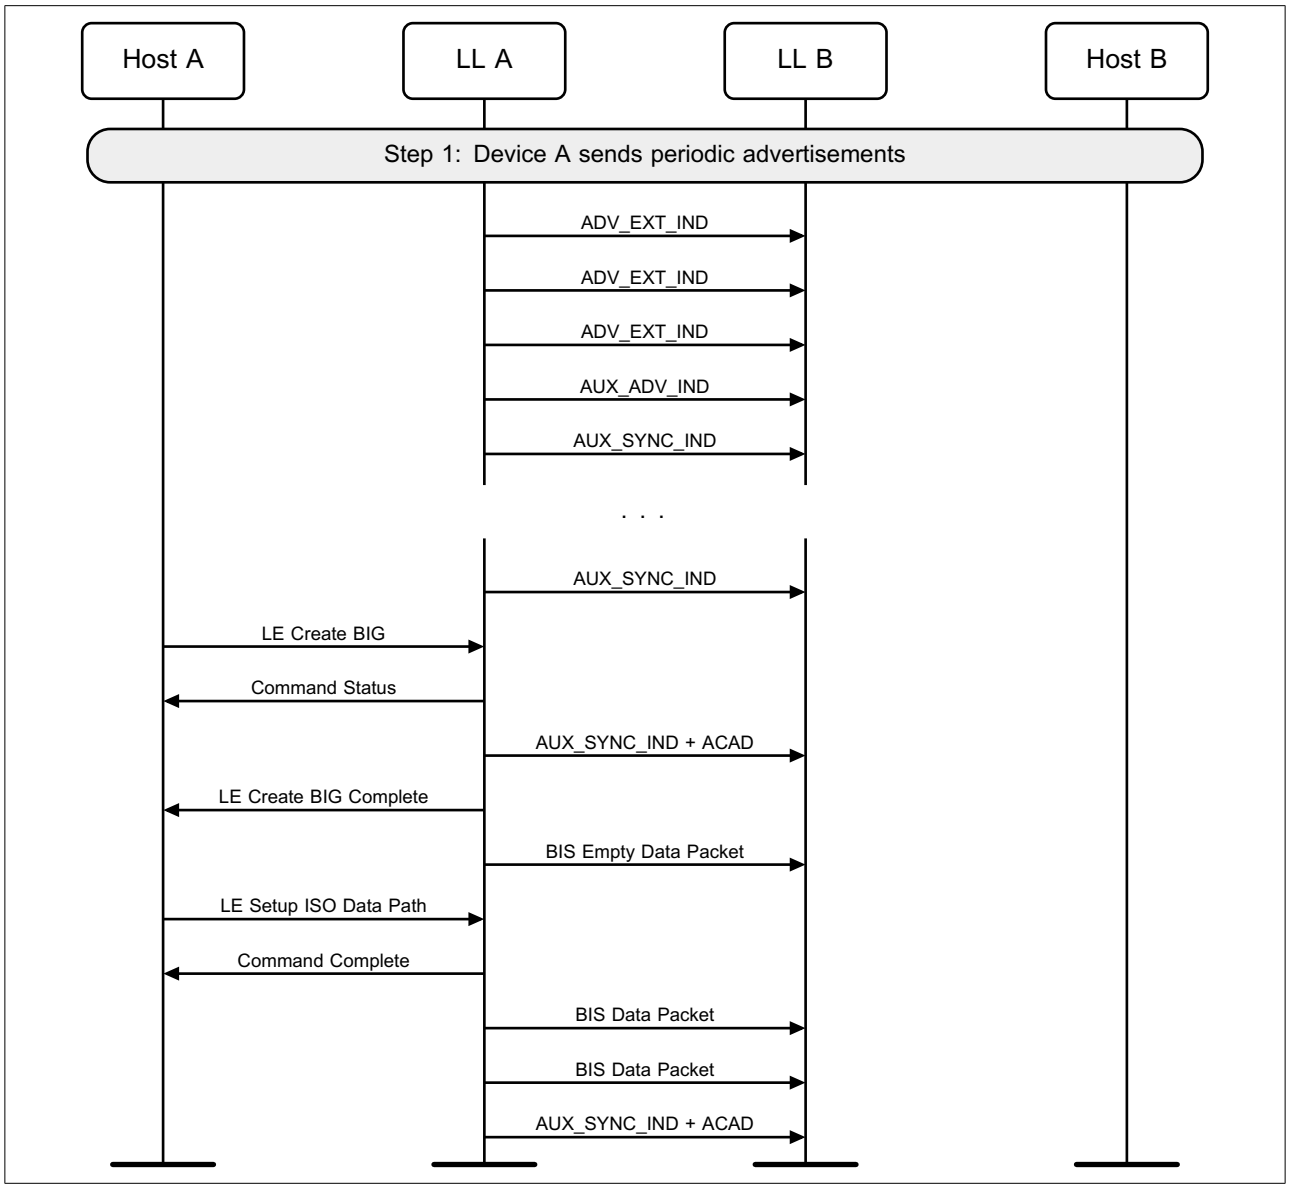

Figure 3.9: Device A creates a BIG

3.8.2 Terminate a Broadcast Isochronous Group

A device terminates a BIG (see Figure 3.10).

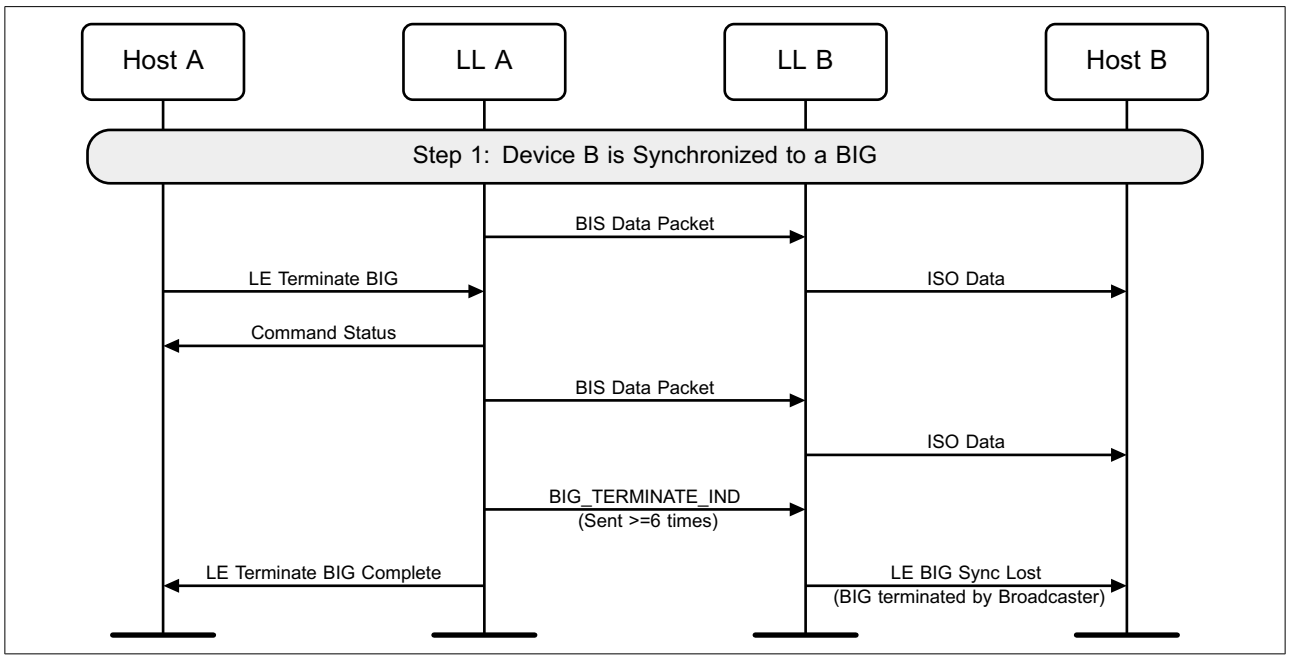

Figure 3.10: Device A terminates a BIG

3.9 Periodic advertising with responses (PAwR)

A device may enter the Advertising state by enabling PAwR in a set. The device should configure the advertising set parameters before doing this (see Figure 3.11).

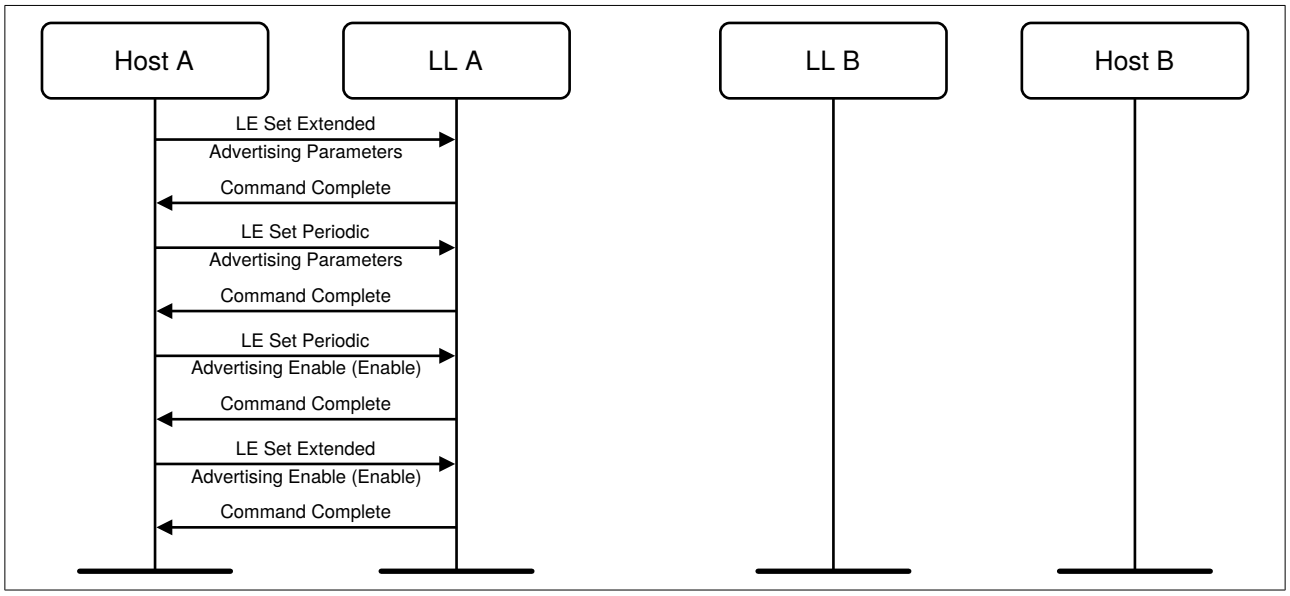

Figure 3.11: Configuring PAwR

3.10 Transmitting PAwR subevents

A Controller may request data to be sent in one or more subevents of a PAwR advertising set. The Host can send this data to the Controller ahead of when the subevents are scheduled.

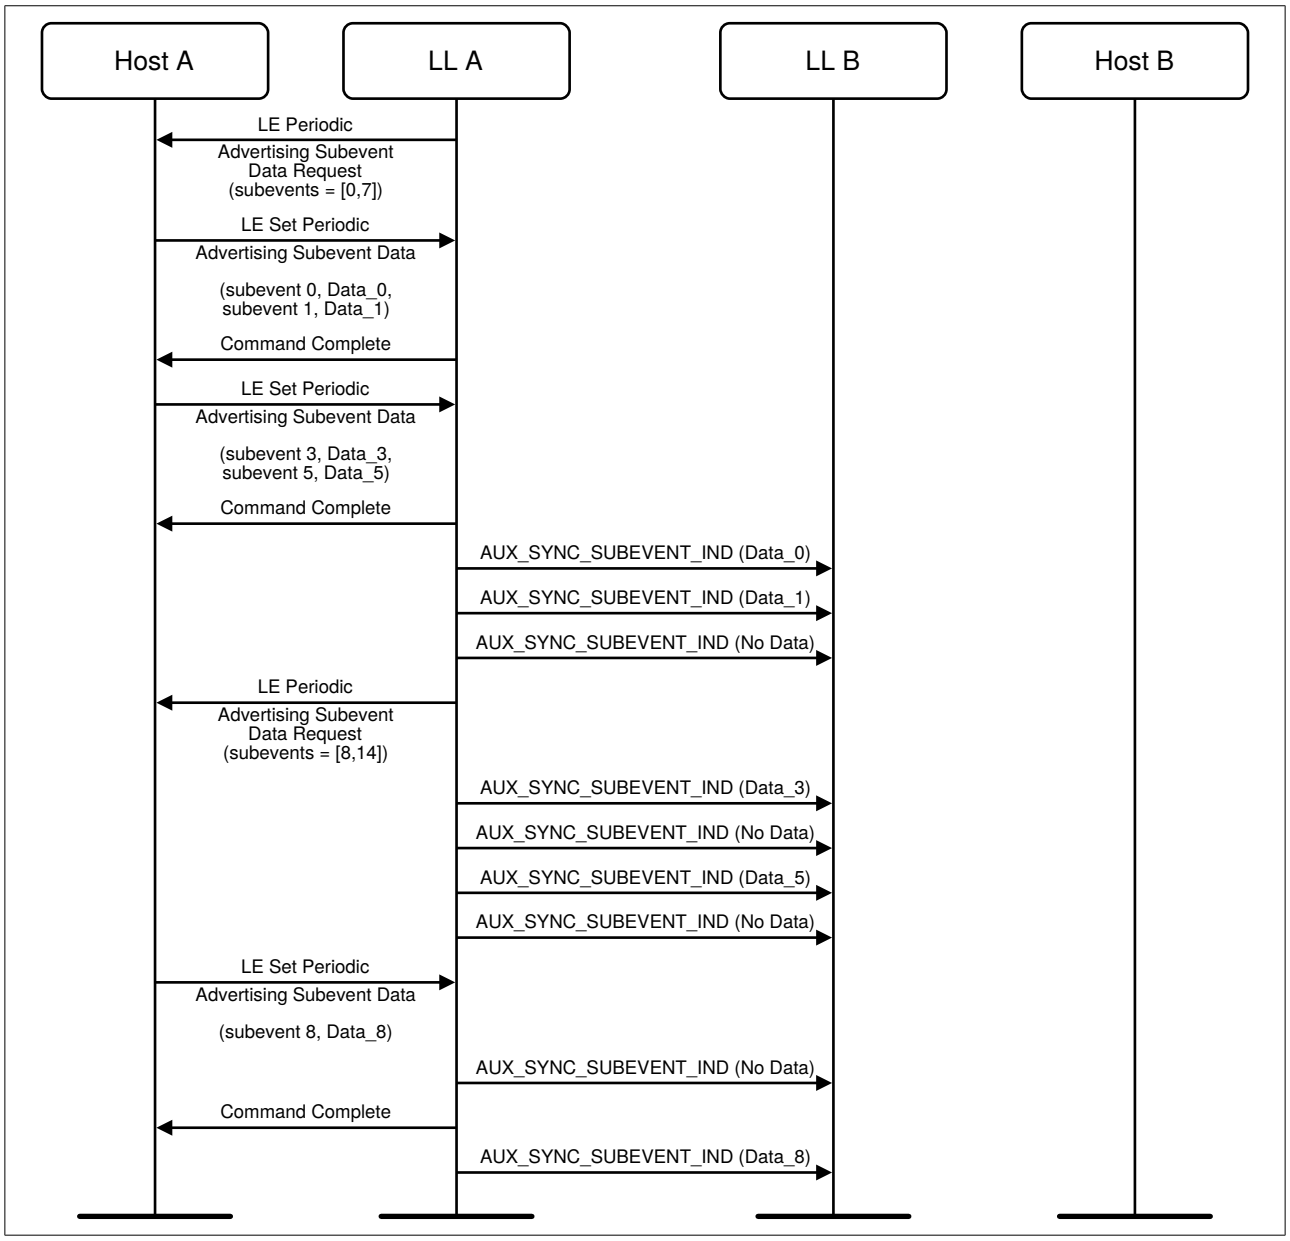

Figure 3.12: Transmitting PAwR subevents

3.11 Using a response slot in PAwR

A device can send a response to a PAwR advertisement packet. The timing of the response is determined by the Host using information from the advertisement packet.

The Host can send a response by indicating the response slot and data to be sent in that response slot.

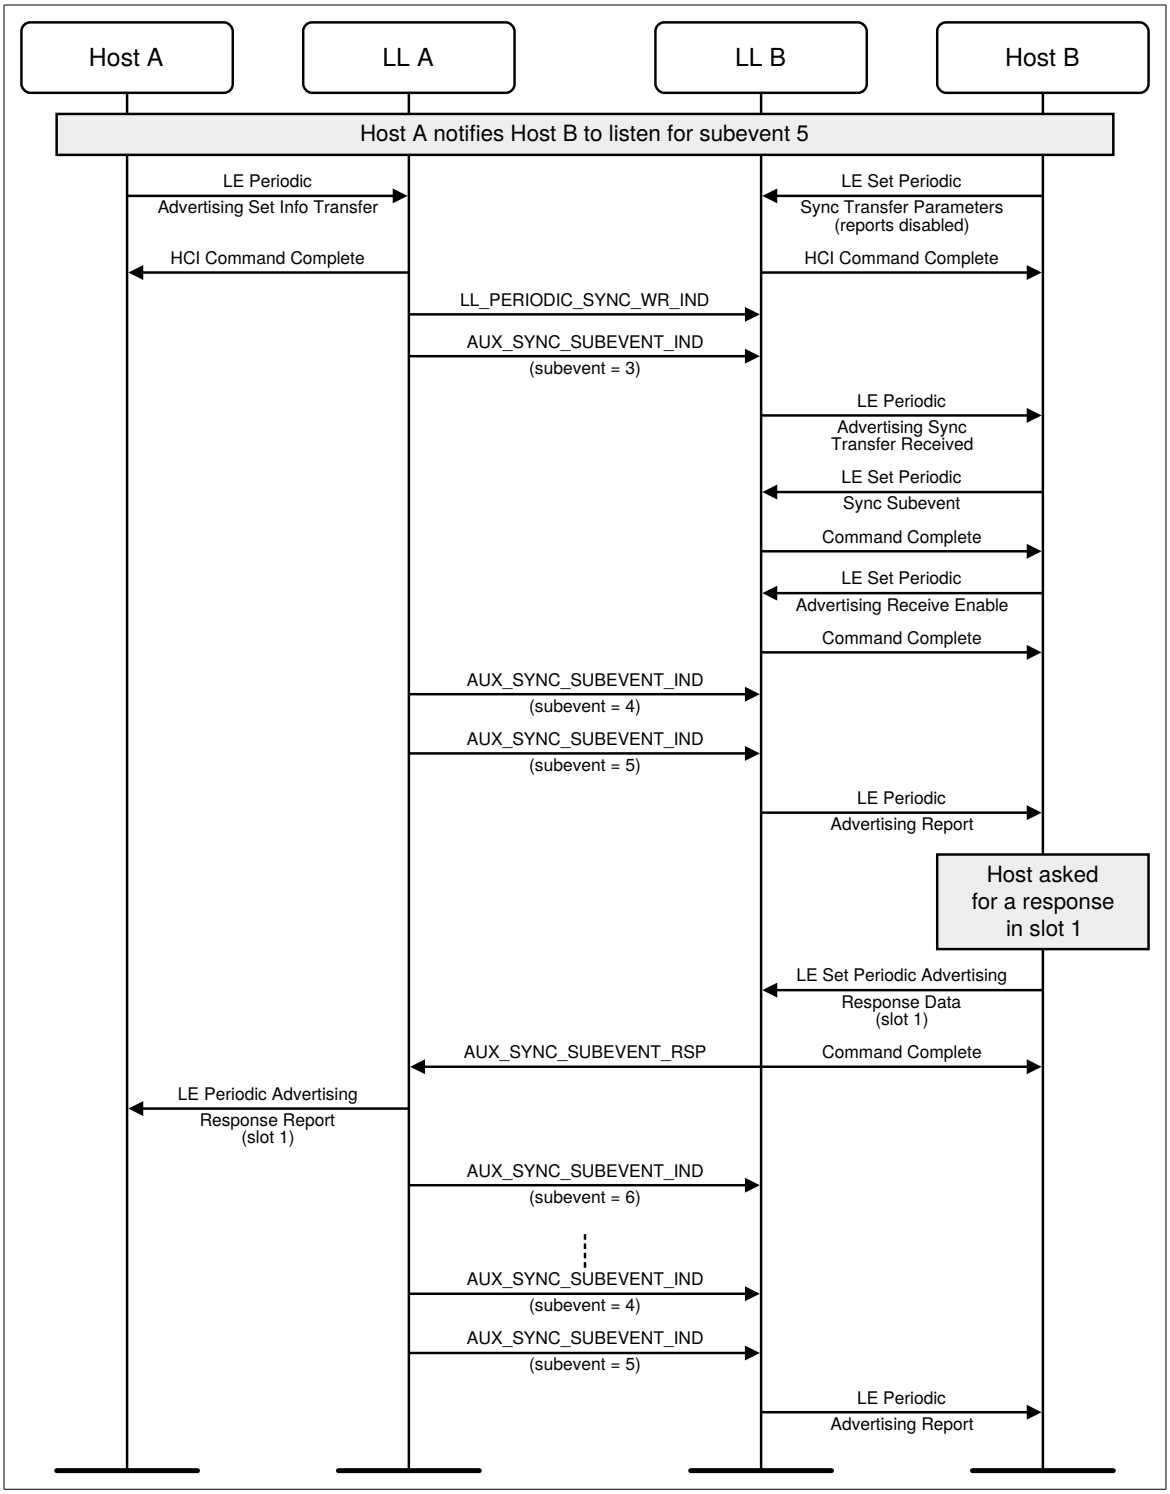

Figure 3.13: Using a response slot in PAwR

3.12 Connecting from PAwR

A device may initiate a connection with a synchronized device by using the LE Extended Create Connection command which indicates the subevent and BD_ADDR of the peer device. This initiates a connection by sending an AUX_CONNECT_REQ PDU in that subevent.

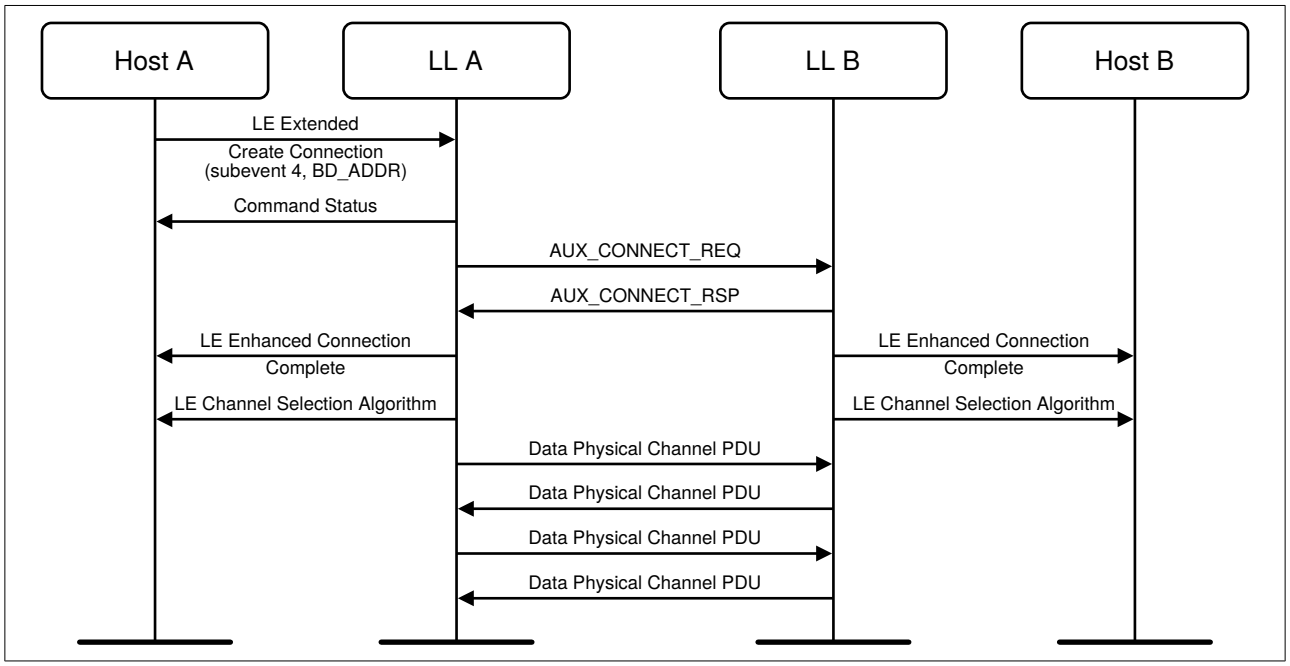

Figure 3.14: Connecting from PAwR

3.13 Failed Connection Attempts From PAWR

A synchronized device can miss an AUX_CONNECT_REQ PDU sent by the periodic advertiser.

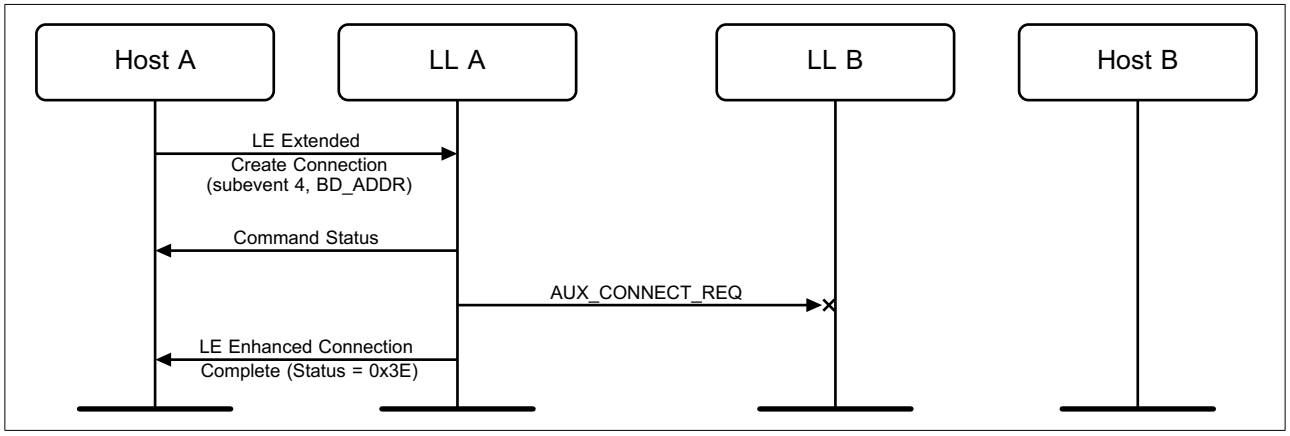

Figure 3.15: Synchronized device misses the AUX_CONNECT_REQ PDU

The periodic advertiser can miss an AUX_CONNECT_RSP PDU sent by a synchronized device.

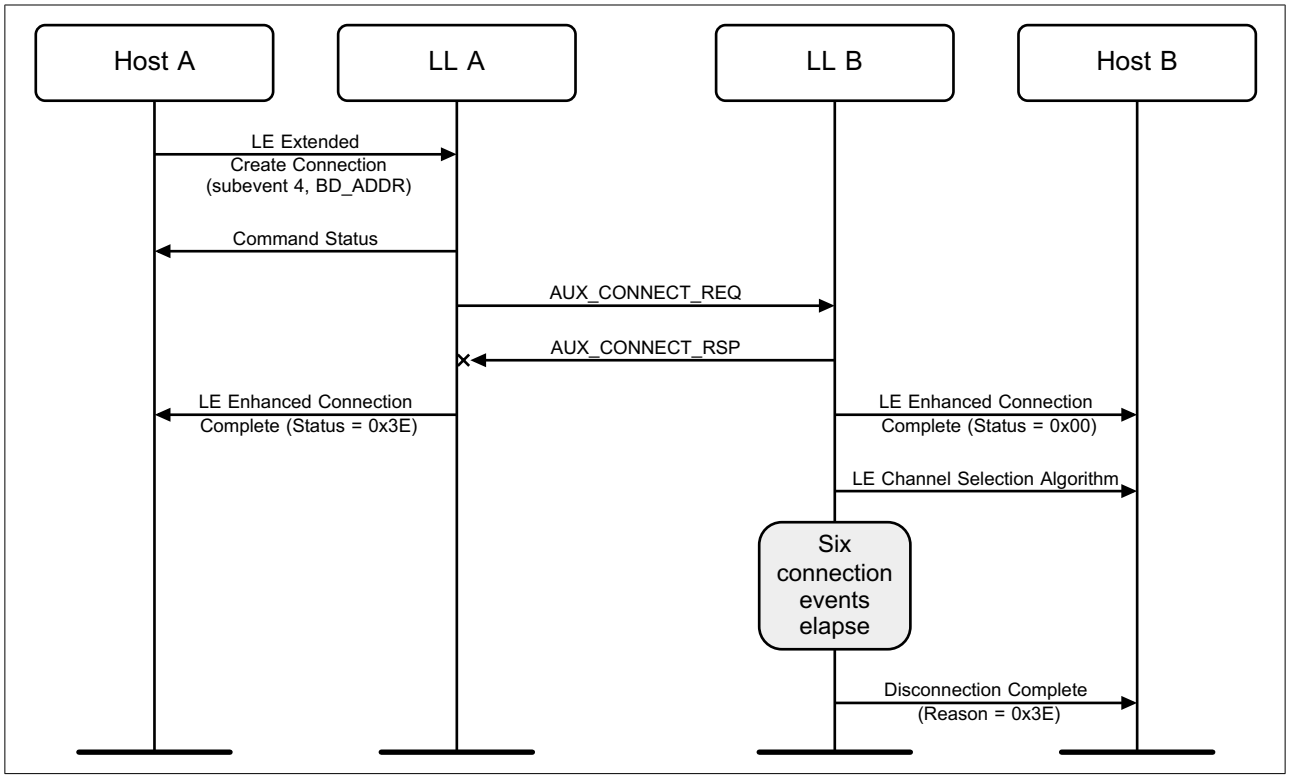

Figure 3.16: Periodic advertiser misses the AUX_CONNECT_RSP PDU

4 SCANNING STATE

4.1 Passive scanning

A device can use passive scanning to find advertising devices in the area. This would receive advertising packets from peer devices and report these to the Host (see Figure 4.1).

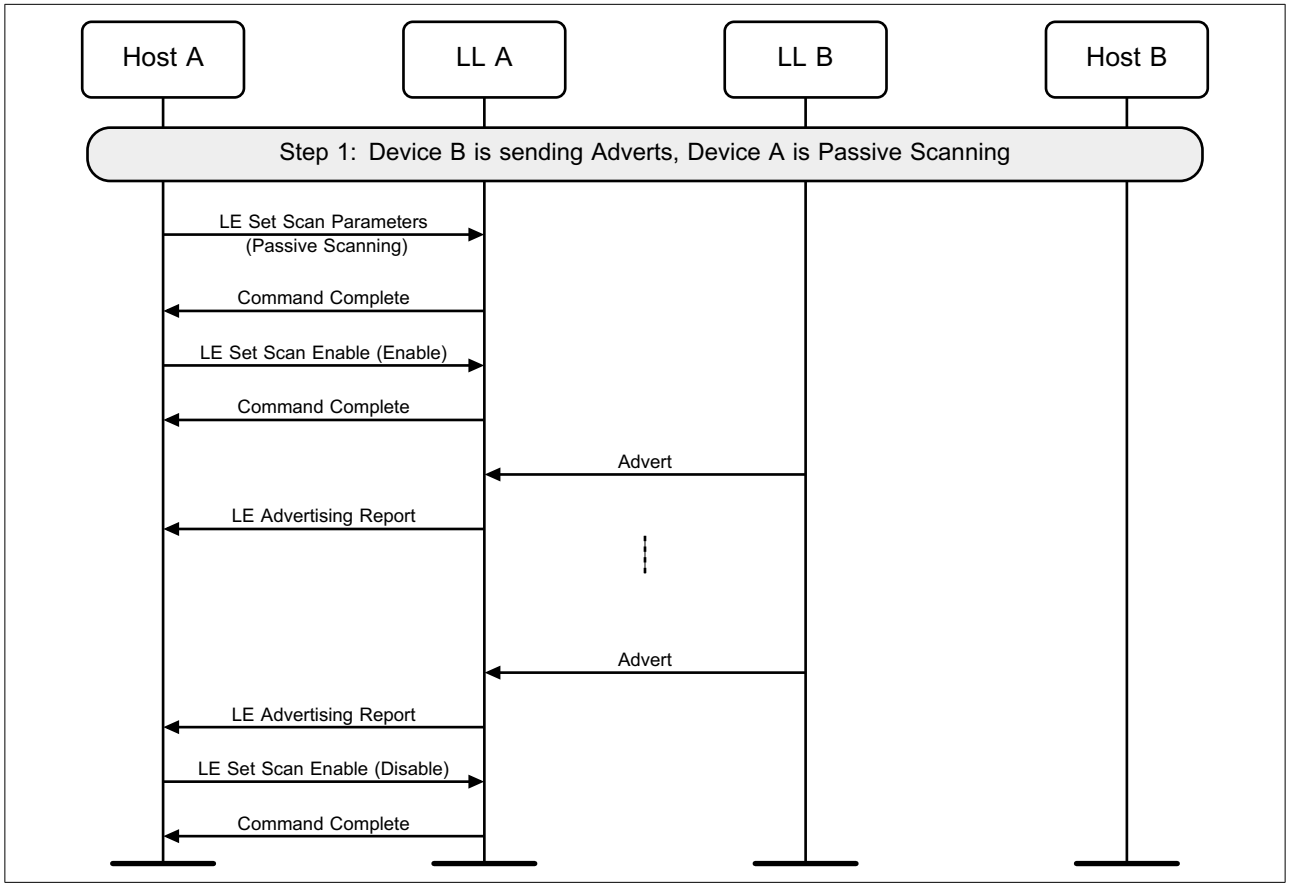

Figure 4.1: Passive scanning

4.2 Active scanning

A device may use active scanning to obtain more information about devices that may be useful to populate a user interface. Active scanning involves more Link Layer advertising messages (see Figure 4.2).

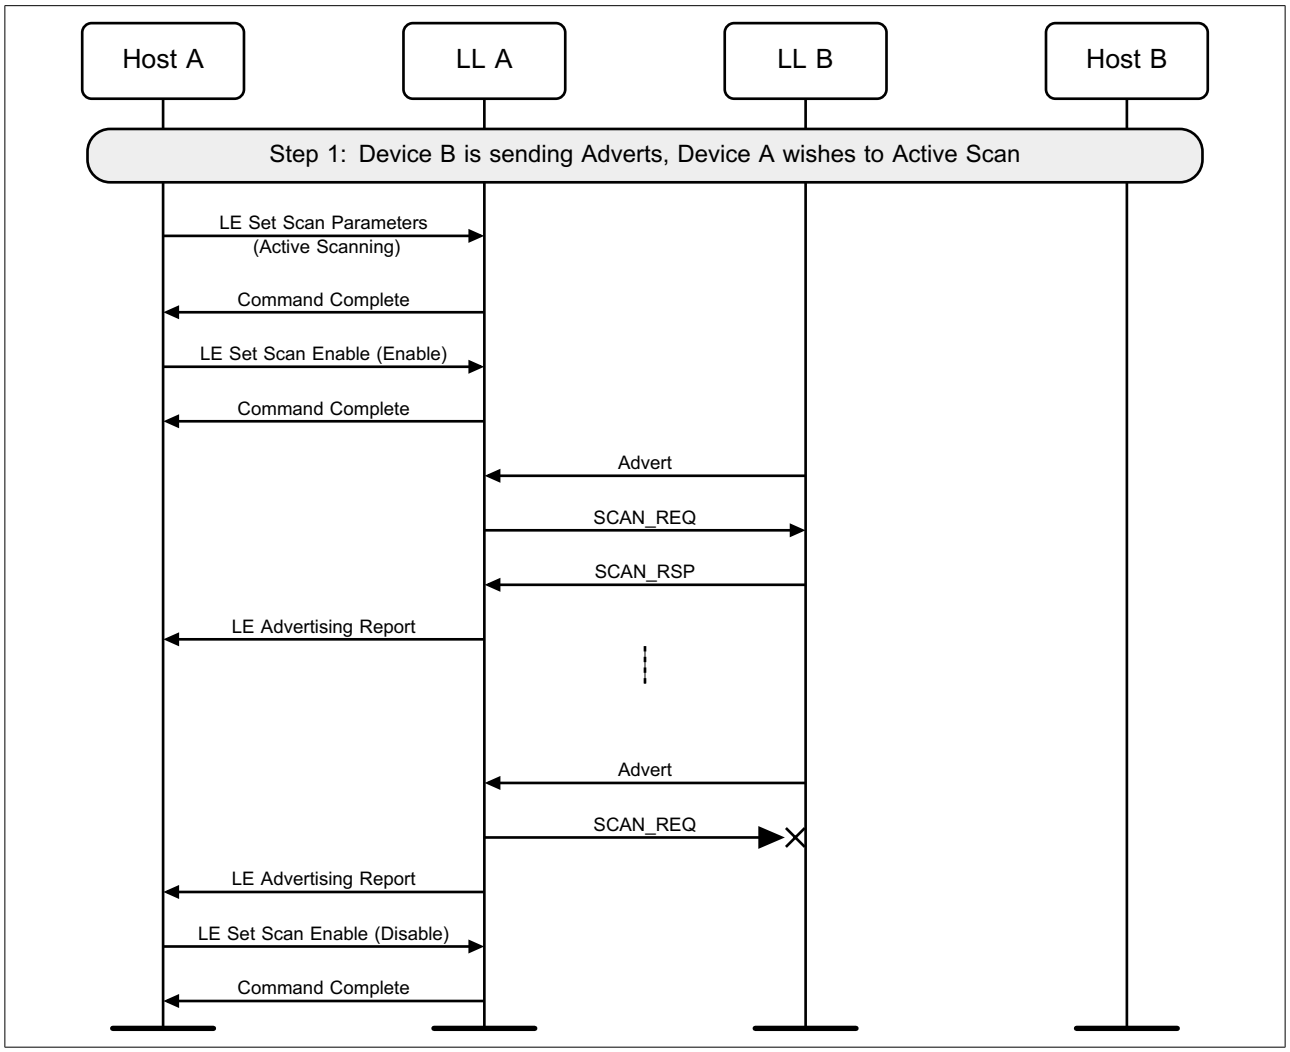

Figure 4.2: Active scanning

4.3 Passive scanning for directed advertisements with Privacy

If a device does not support Privacy in the Controller, it may choose to forward LE Directed Advertising Report events from devices supporting Privacy without requiring filtering through the Controller Resolving List.

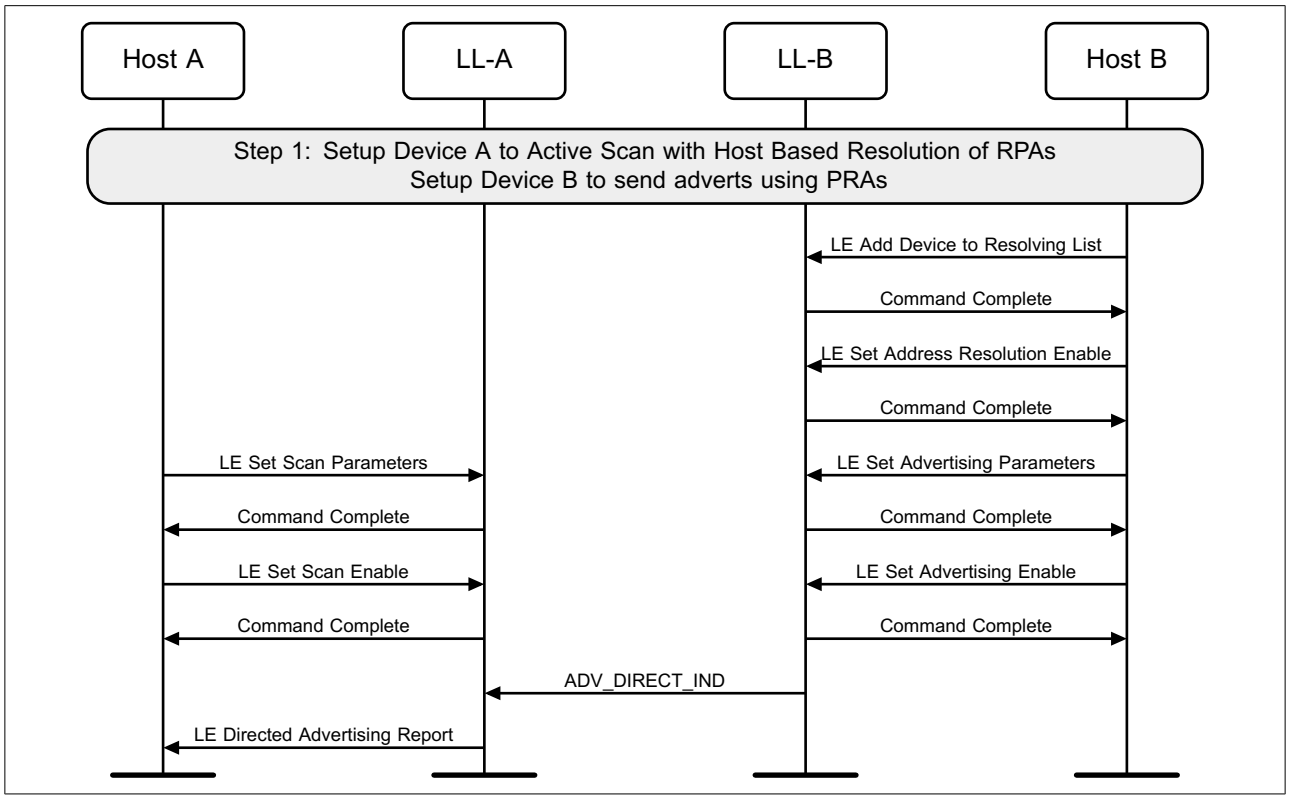

Figure 4.3: Directed advertising with Privacy

4.4 Active scanning with Privacy

A device may use active scanning to obtain more information about devices that may be useful to populate a user interface. Privacy may be used during active scanning to make it more difficult to track either device during active scanning (see Figure 4.4).

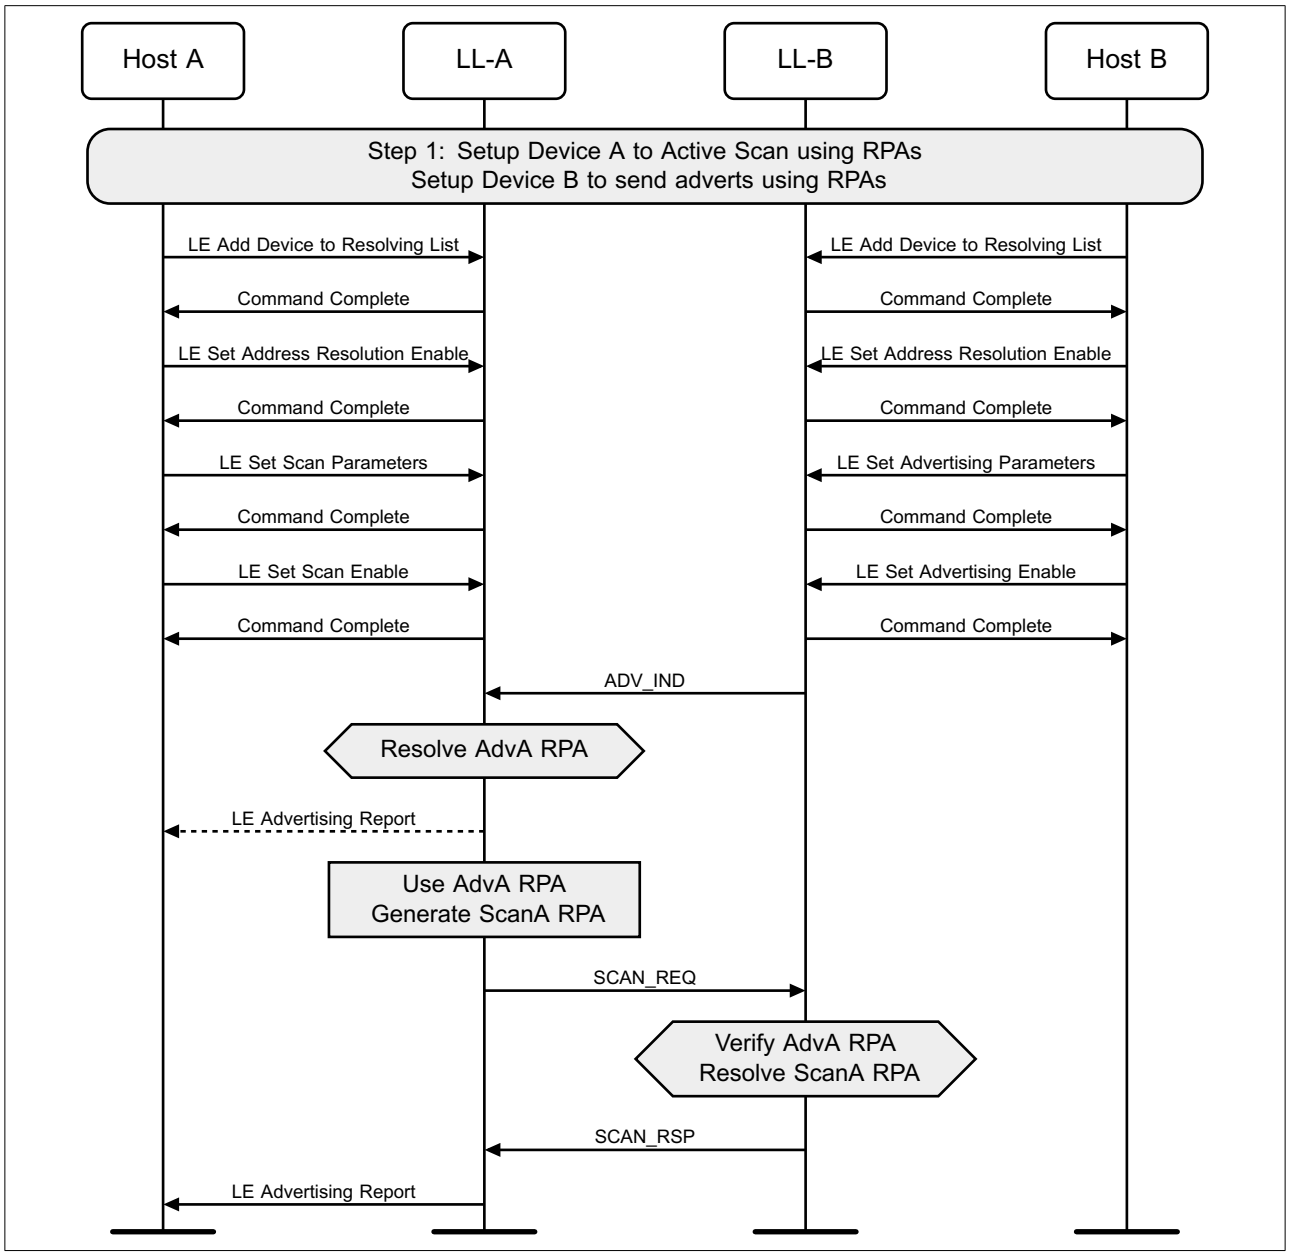

Figure 4.4: Active scanning with Privacy

4.5 Active scanning with Privacy and Controller based resolvable private address generation

A Controller will periodically update the resolvable private addresses used on both devices if the devices use active scanning and advertising with Privacy. A Host may at anytime retrieve the read from the Controller the current addresses being used (see Figure 4.5).

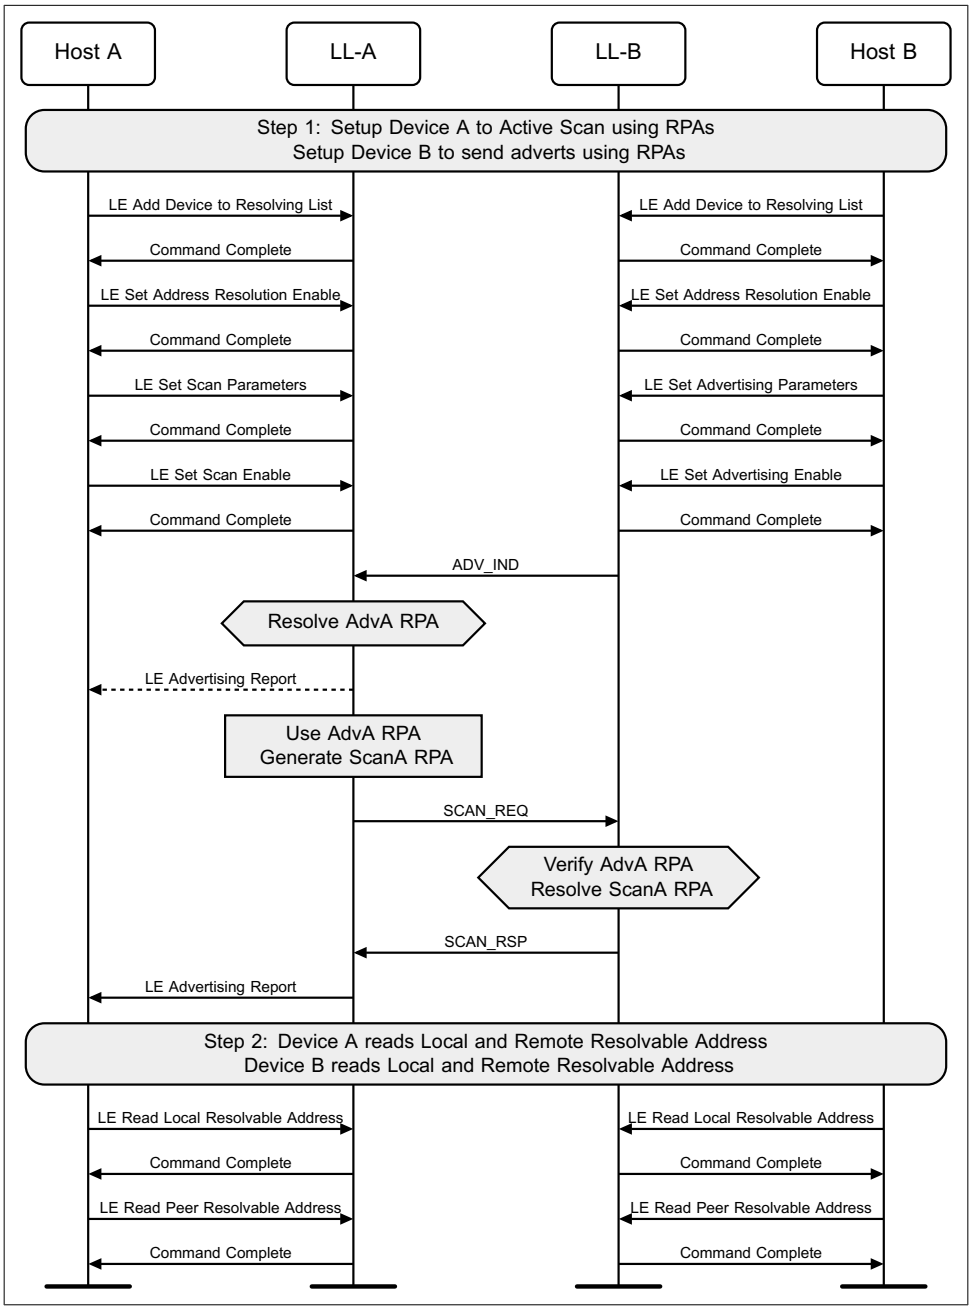

Figure 4.5: Retrieving local and remote resolvable address updates from the Controller

4.6 Active scanning on the secondary advertising Physical channel

A device may use active scanning on the secondary advertising physical channel in order to obtain more information about devices that may be useful to populate a user interface (see Figure 4.6).

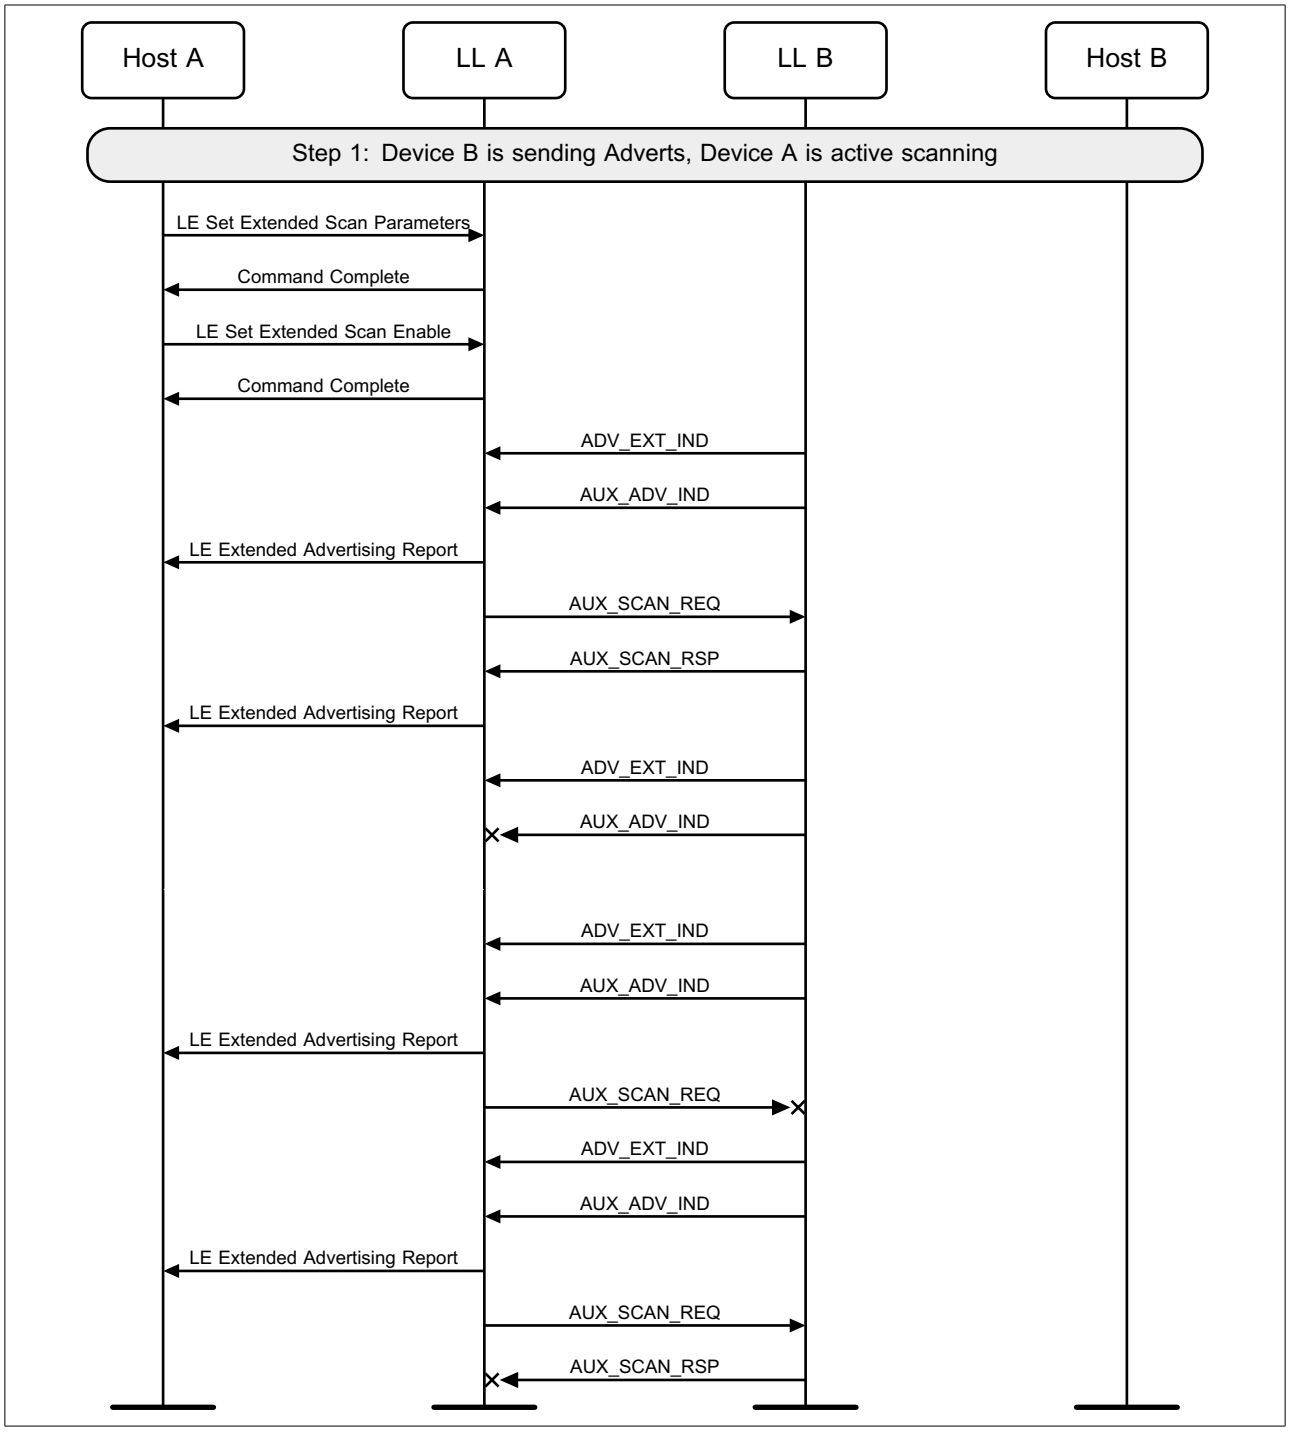

Figure 4.6: Extended active scanning on the secondary advertising physical channel

4.7 Scan timeout

A device may scan for a limited duration of time (see Figure 4.7).

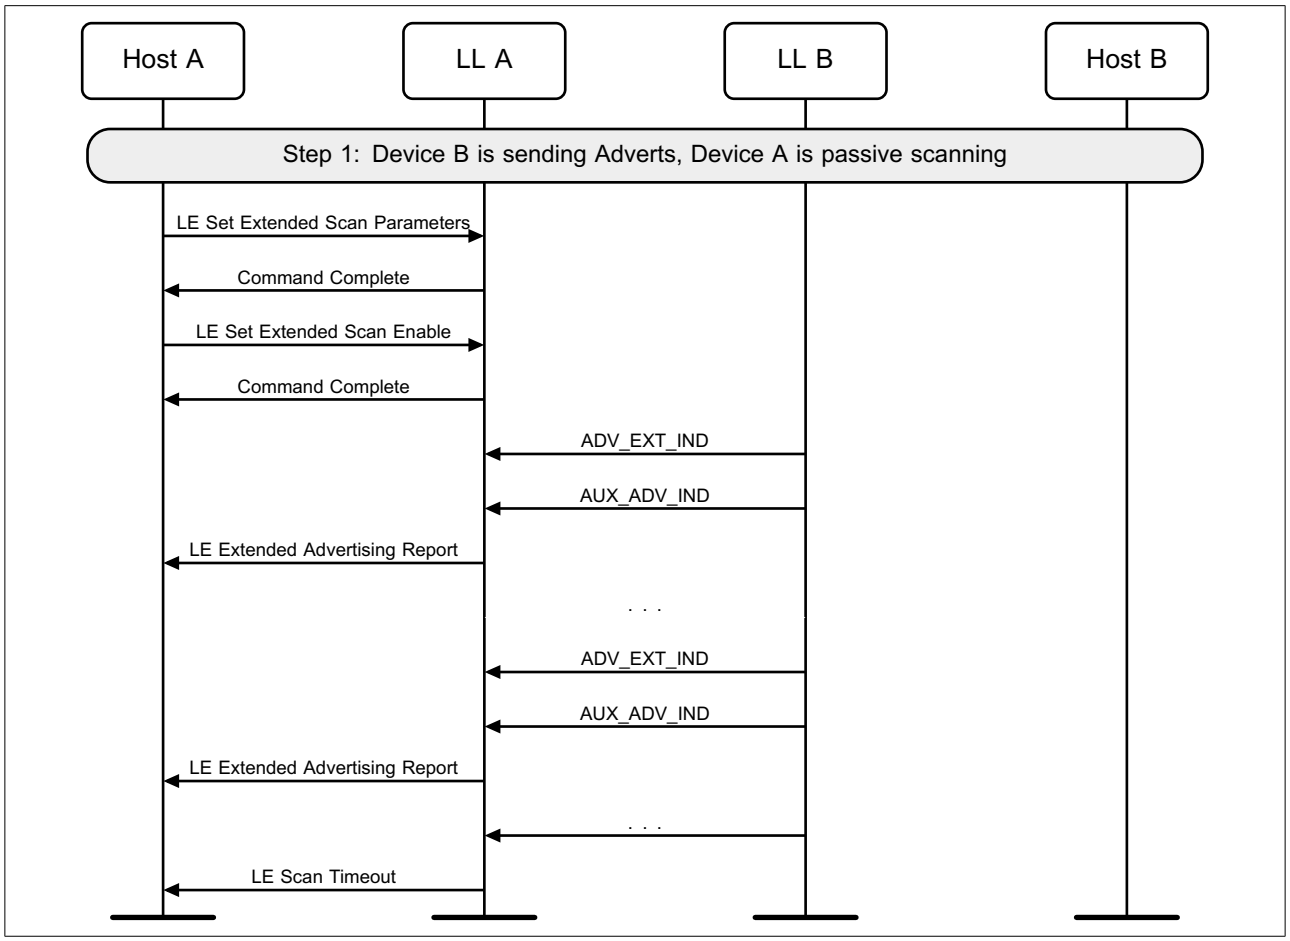

Figure 4.7: Scan timeout

4.8 Scanning for periodic advertisements

A device may establish synchronization with a periodic advertiser and report periodic advertising packets to the Host (see Figure 4.8).

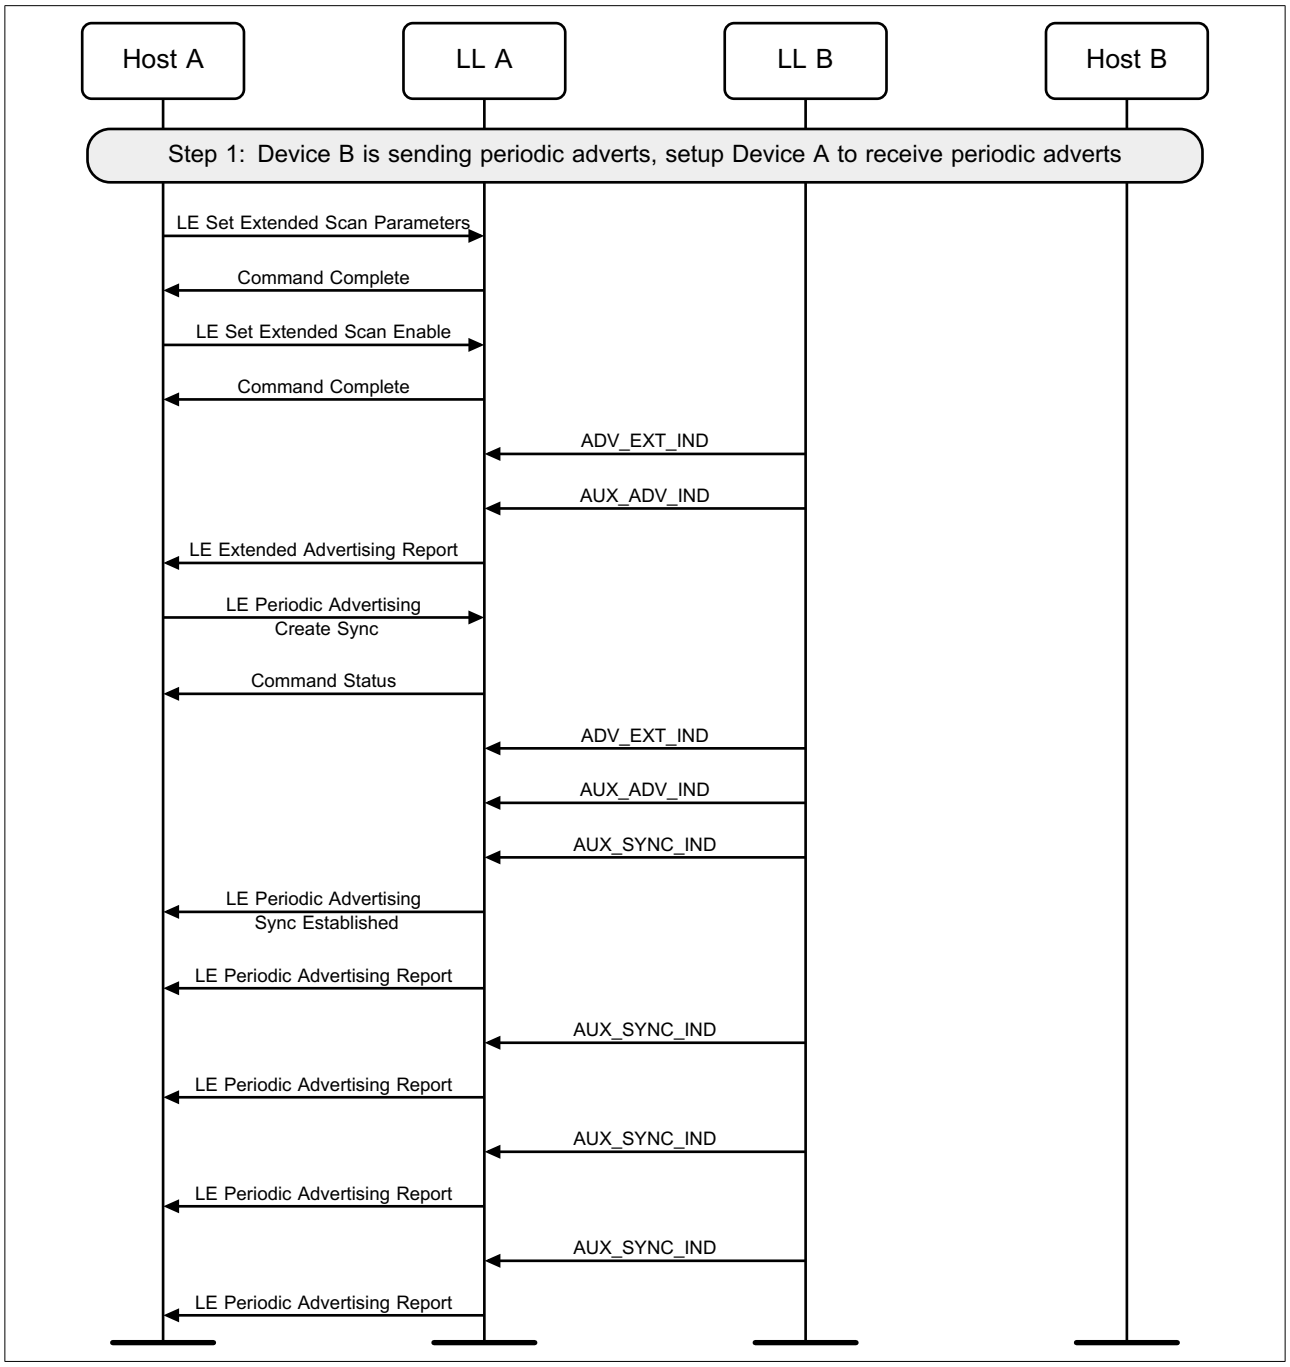

Figure 4.8: Periodic scanning

4.9 Cancel scanning for periodic advertisements

A device may cancel a pending request to establish synchronization with a periodic advertiser. This example shows an unsuccessful synchronization, followed by cancellation of the synchronization (see Figure 4.9).

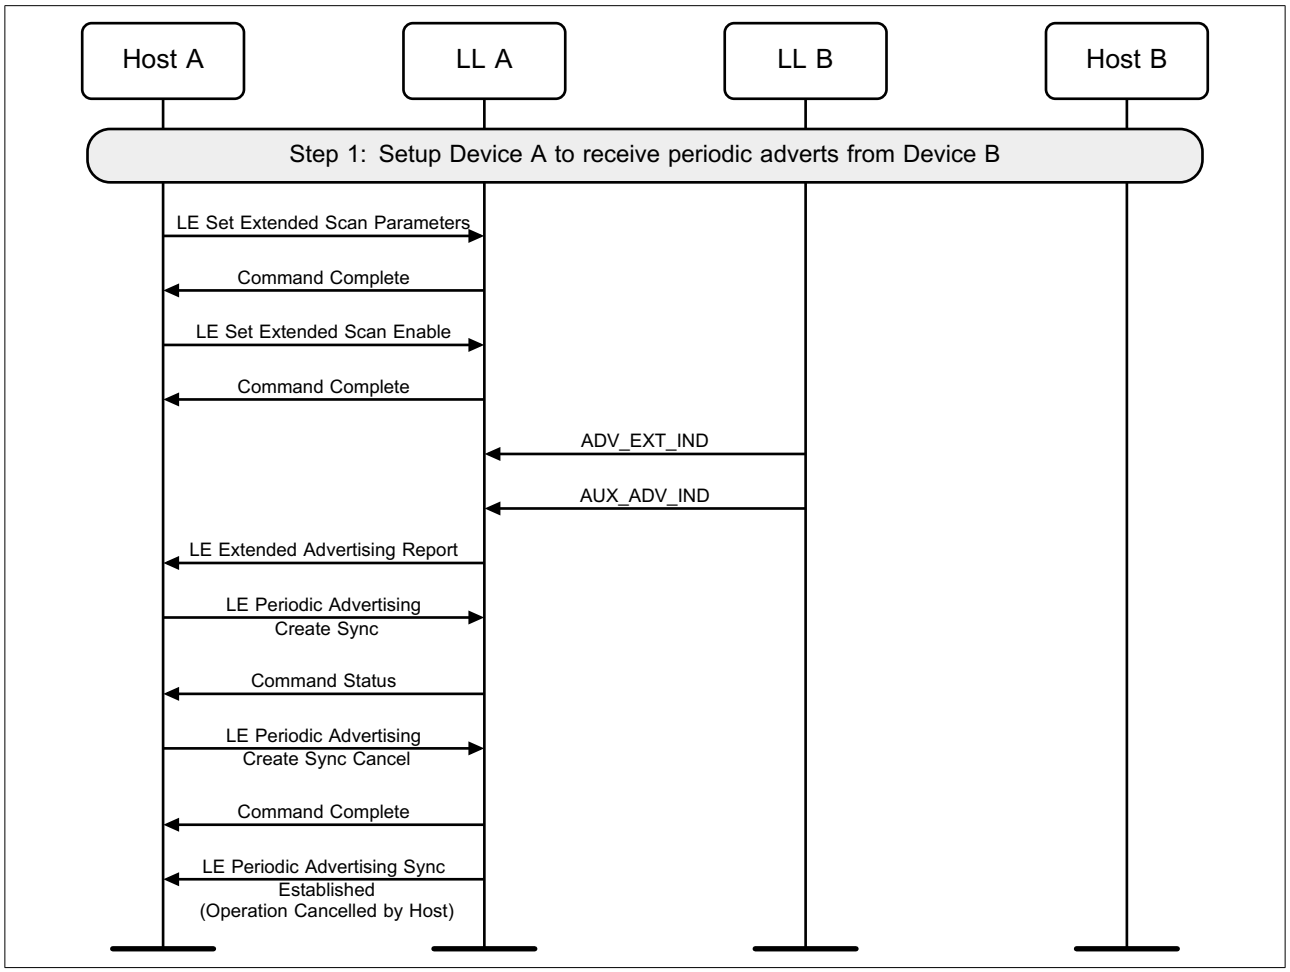

Figure 4.9: Periodic scanning cancel

4.10 Periodic advertising synchronization timeout

A device may lose synchronization with a periodic advertiser (see Figure 4.10).

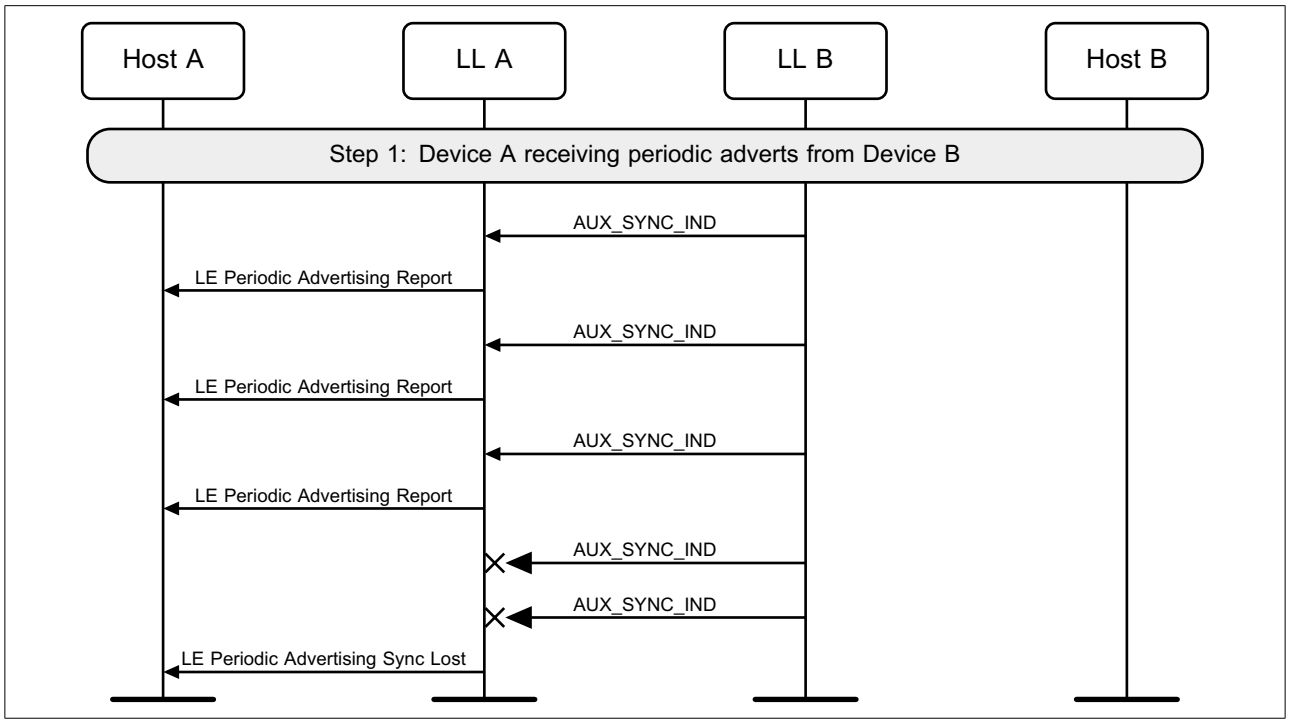

Figure 4.10: Periodic scanning timeout

4.11 Terminate reception of periodic advertising

Once synchronized with a periodic advertiser, the Host can terminate the synchronization (see Figure 4.11).

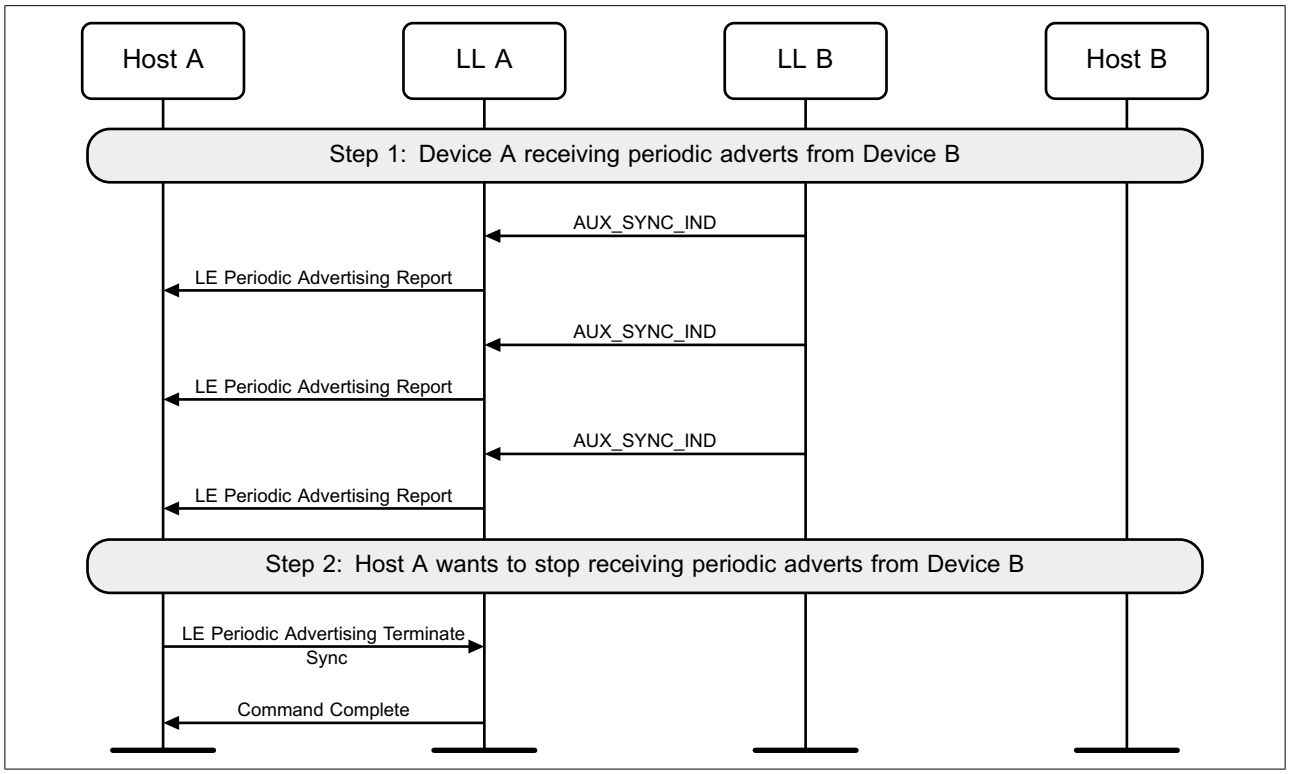

Figure 4.11: Periodic scanning terminate

4.12 Connectionless Constant Tone Extension reception

A device may receive periodic advertising packets containing a Constant Tone Extension and send IQ samples to the Host (see Figure 4.12).

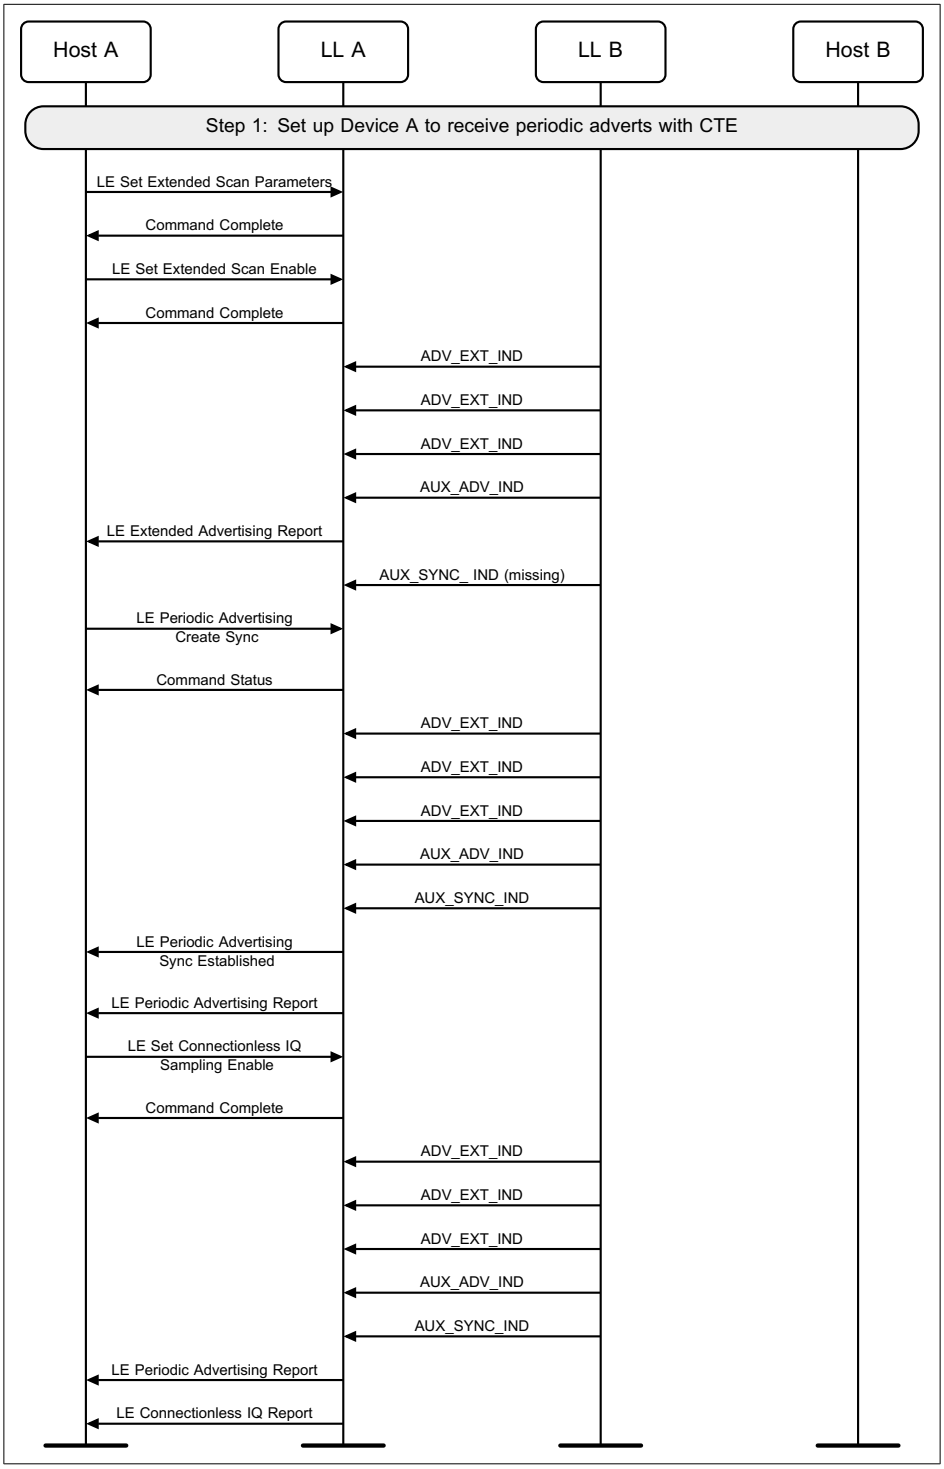

Figure 4.12: Connectionless Constant Tone Extension reception

4.13 Synchronization with separate enable of reports

A device may enable or disable reports after establishing synchronization with a periodic advertising train.

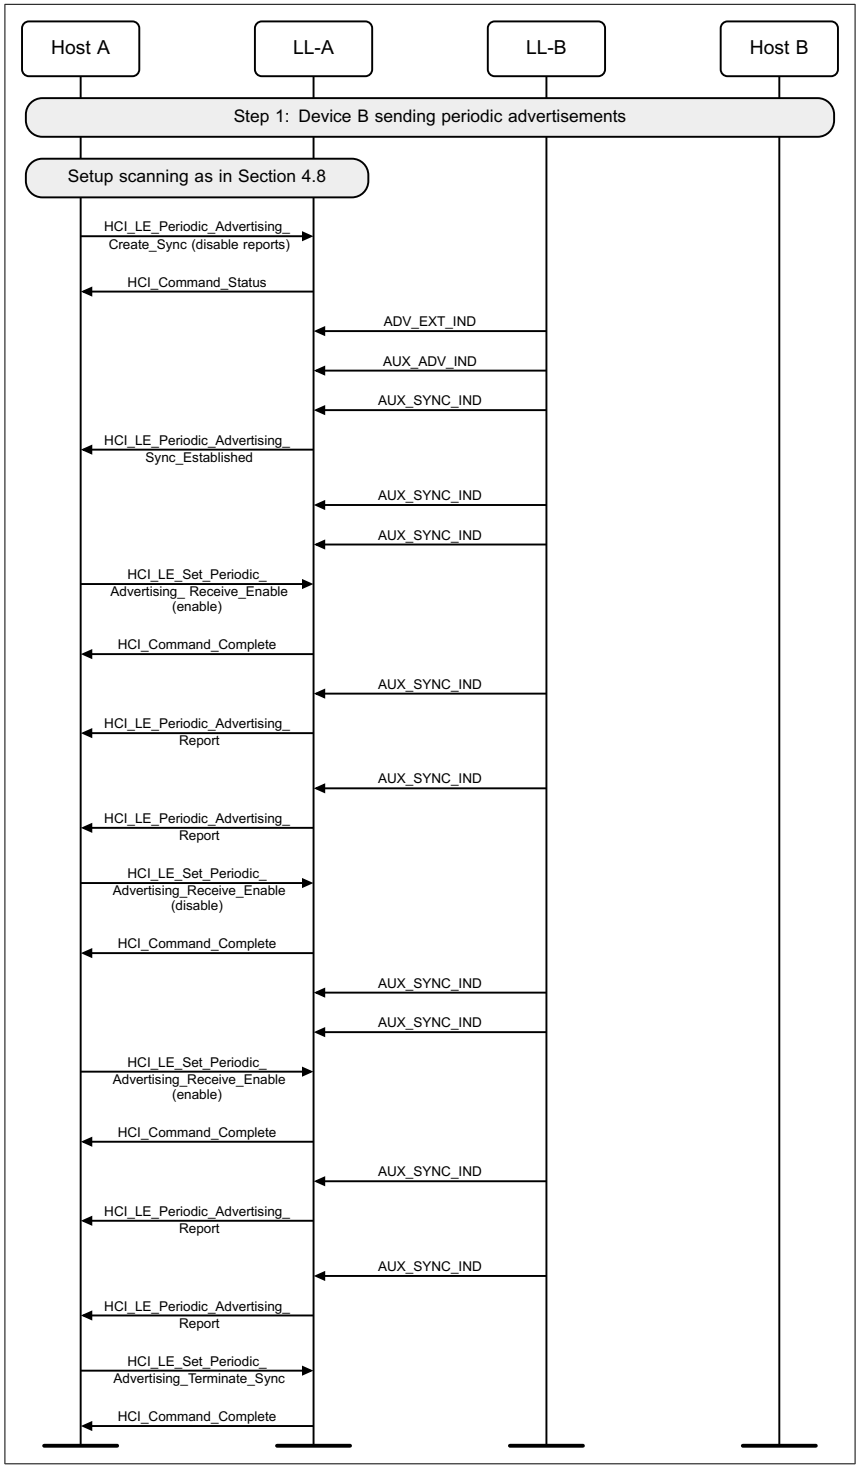

Figure 4.13: Periodic scanning with separate enable

5 INITIATING STATE

5.1 Initiating a connection

A device can initiate a connection to an advertiser. This example shows a successful initiation, resulting in both devices able to send application data (see Figure 5.1).

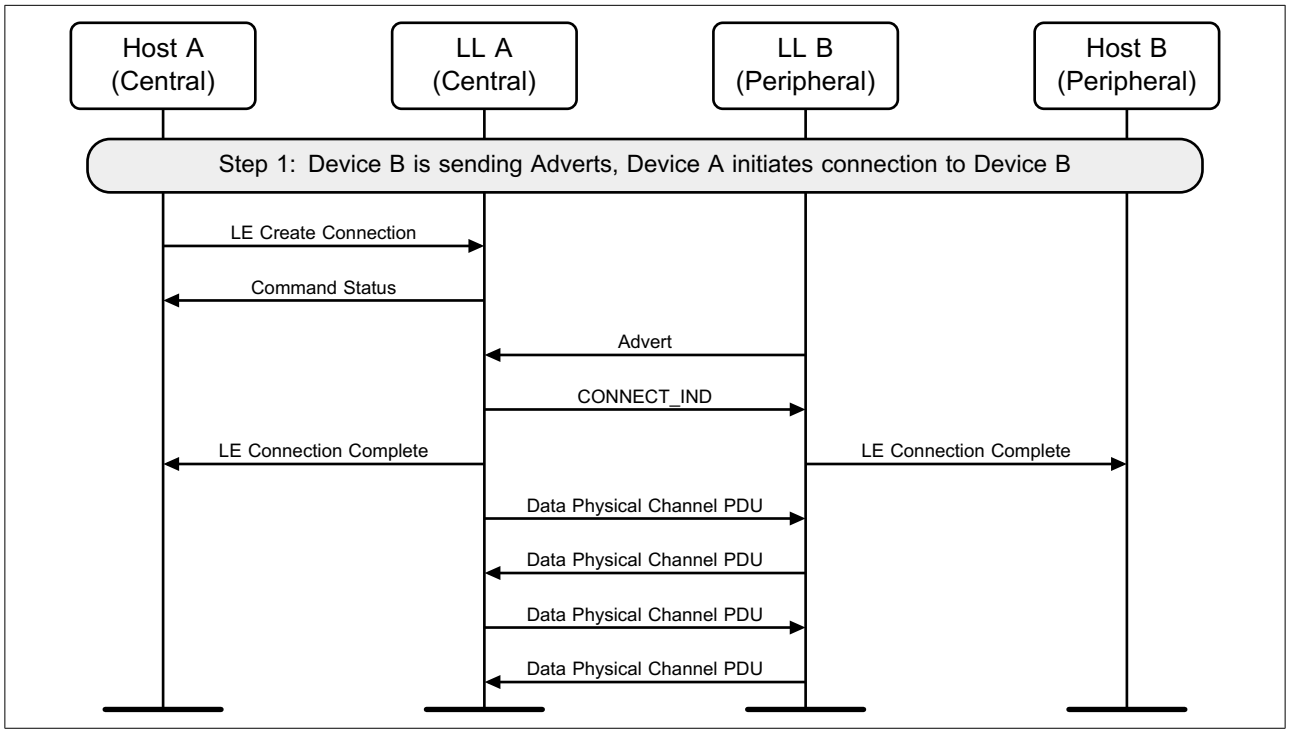

Figure 5.1: Initiating a connection

5.2 Canceling an initiation

A device can cancel a pending connection creation. This example shows an unsuccessful initiation, followed by a cancellation of the initiation (see Figure 5.2).

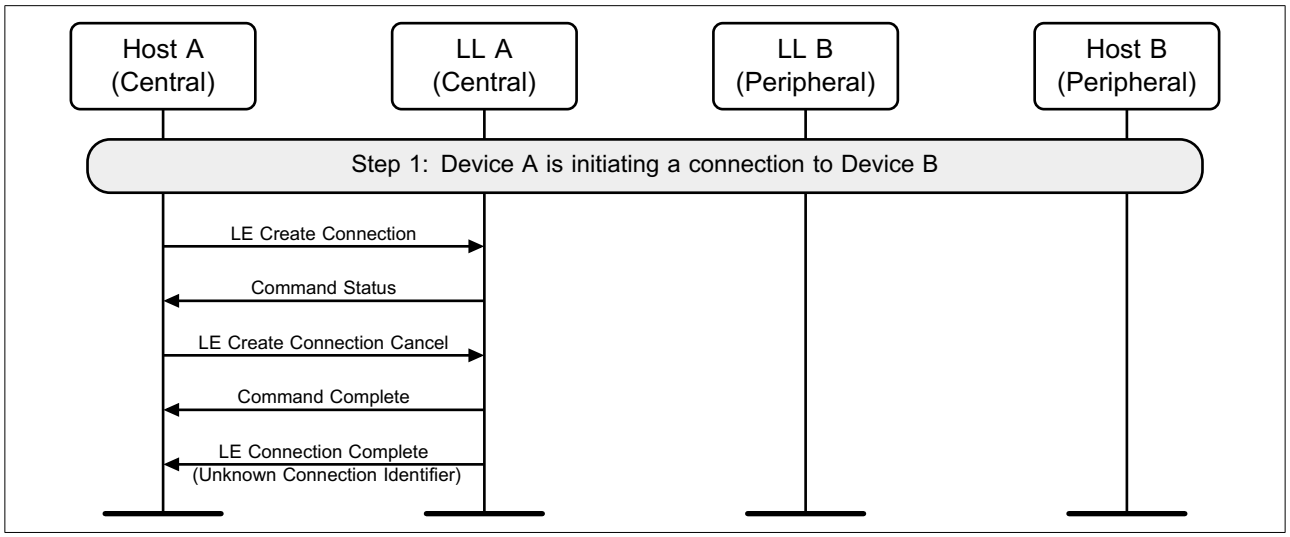

Figure 5.2: Canceling an initiation

5.3 Initiating a connection using undirected advertising with Privacy

A device can initiate a connection to an advertiser. Privacy may be used during connection initiation to make it more difficult to track either device during connection

setup. The example shows a successful initiation, resulting in both devices able to send application data (see Figure 5.3).

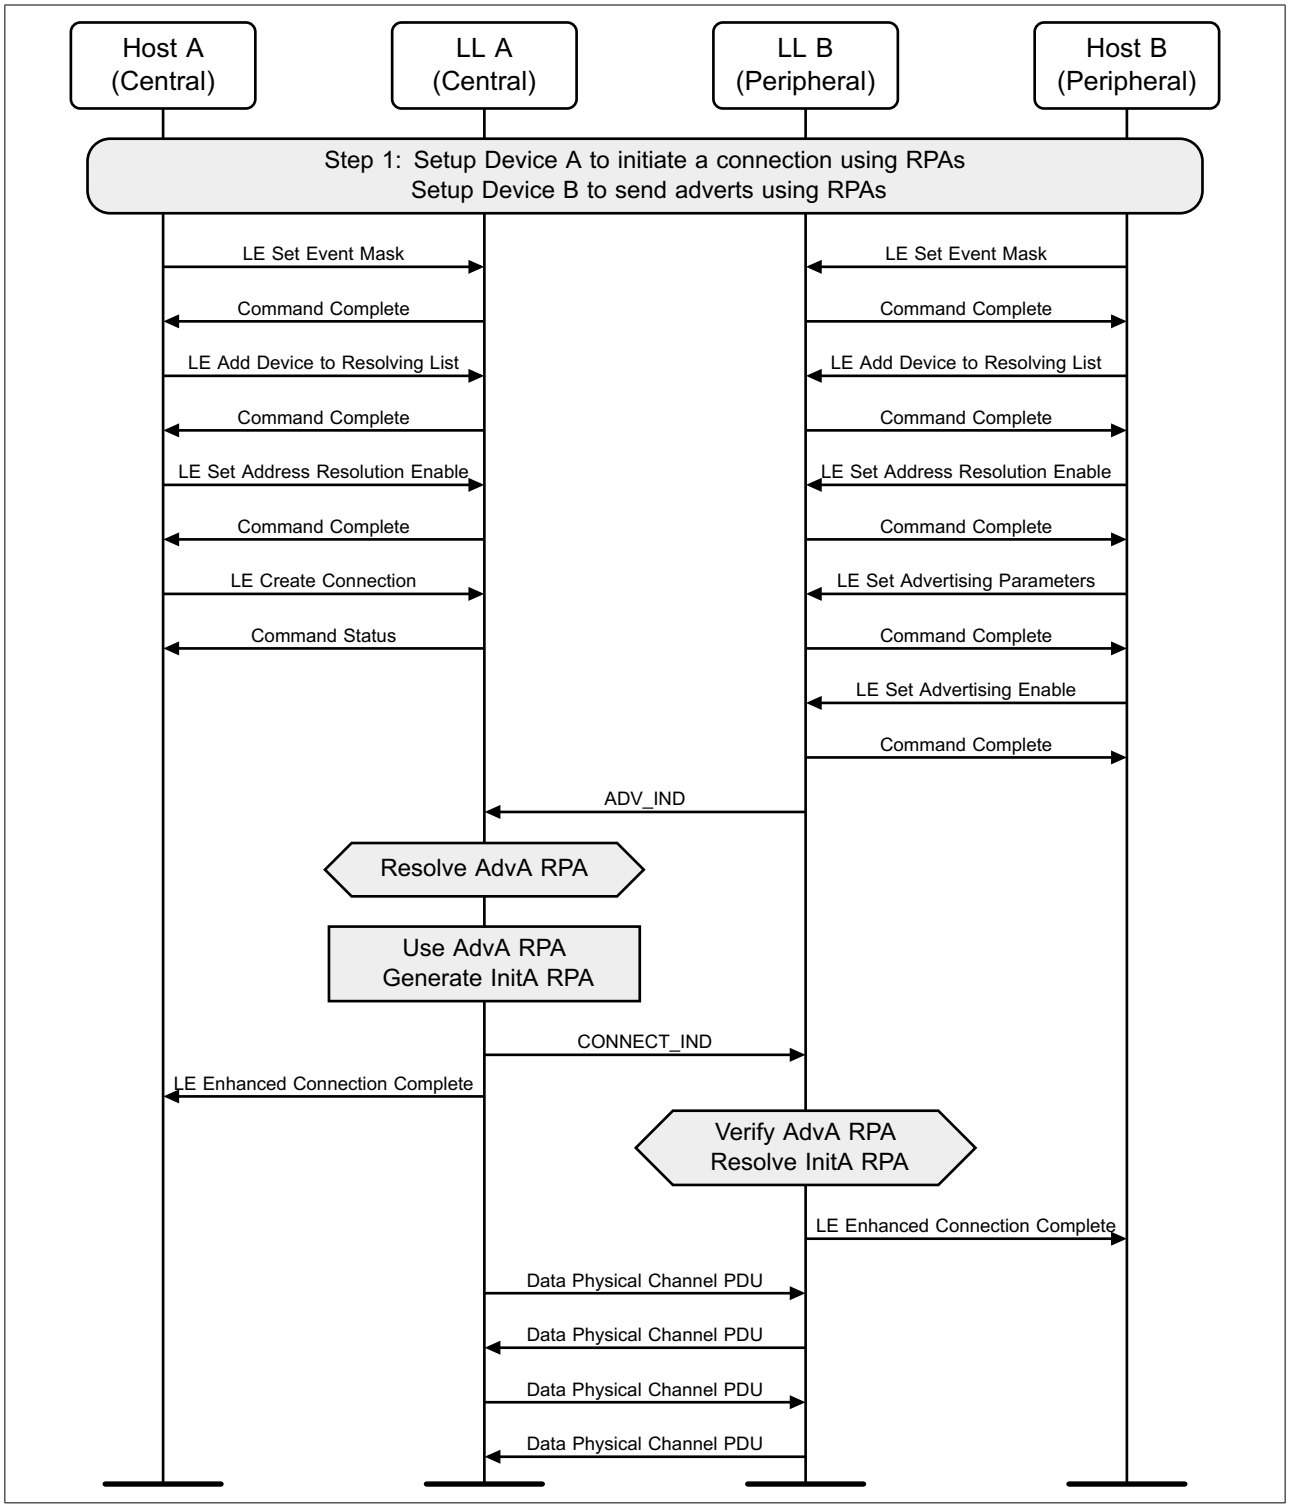

Figure 5.3: Initiating a connection using undirected advertising with Privacy

5.4 Initiating a connection using directed advertising with Privacy

A device can initiate a connection to an advertiser who is using Directed Advertising. Privacy may be used during connection initiation to make it more difficult to track either device during connection setup as well as target a single initiator. The example shows a successful initiation, resulting in both devices able to send application data (see Figure 5.4).

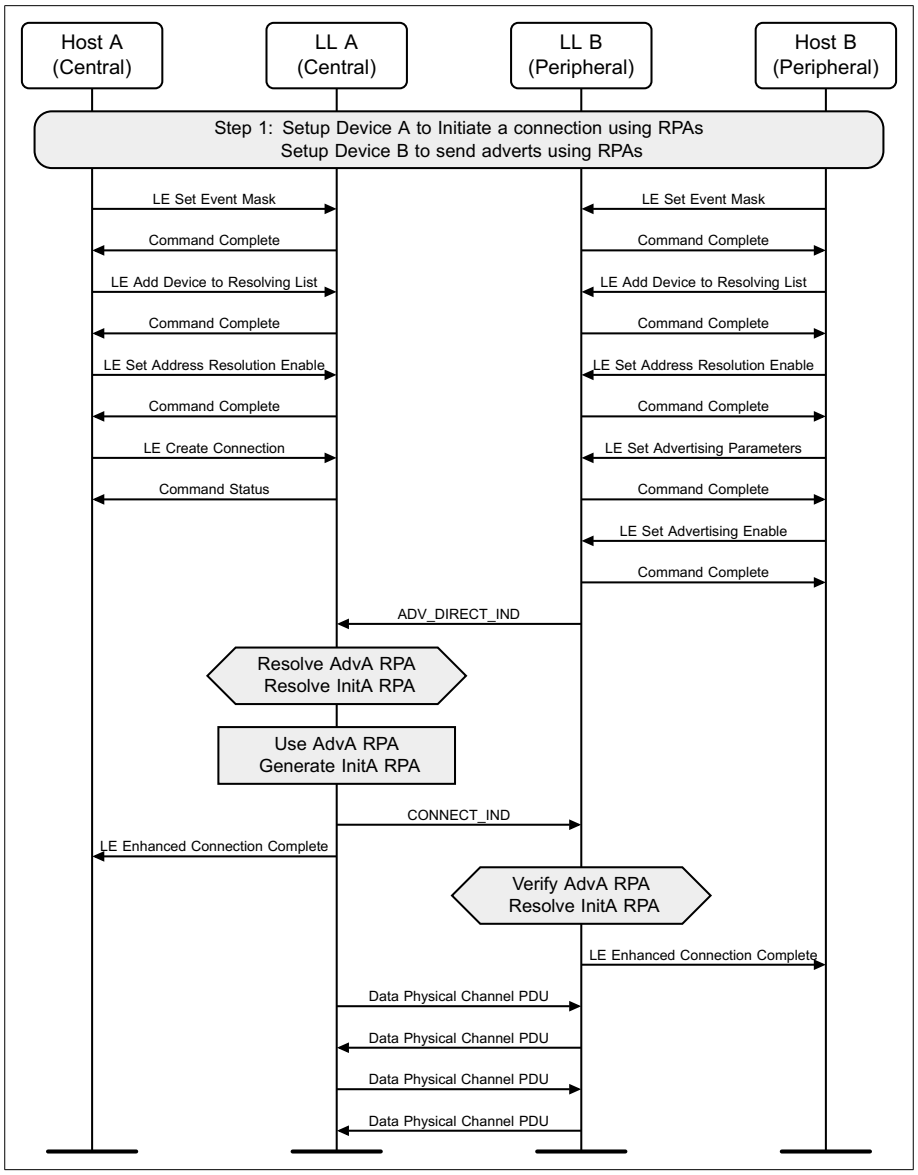

Figure 5.4: Initiating a connection using directed advertising with Privacy

5.5 Initiating a connection that fails to establish

This example shows an initiation that fails to establish because Device B (the advertiser) fails to respond to the Data Physical Channel PDUs sent by Device A.

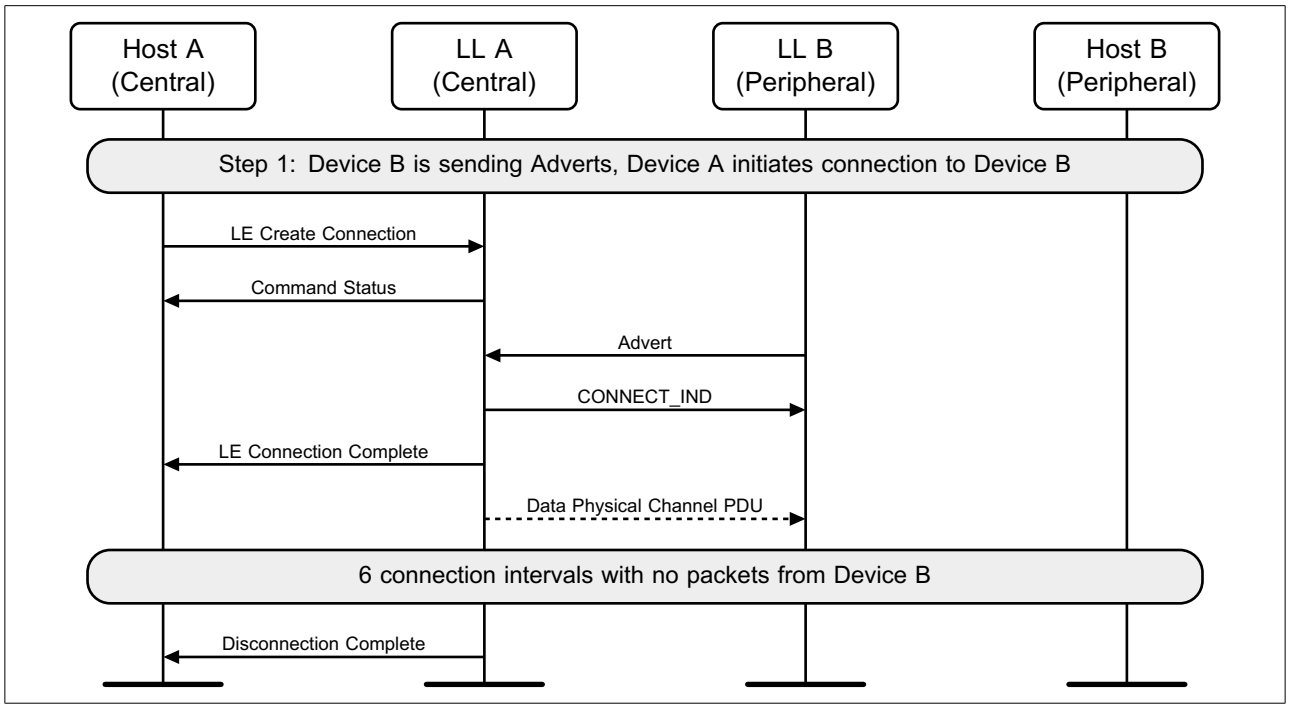

Figure 5.5: Initiating a connection that fails to establish

Device A is not required to send Data Channel PDUs in the 6 connection intervals before establishment fails. However, if it does not do so, Device B is unable to respond.

5.6 Initiating a connection on the secondary advertising physical channel

A device can initiate a connection to an advertiser on the secondary channel. This example shows a successful initiation, resulting in both devices able to send application data (see Figure 5.6).

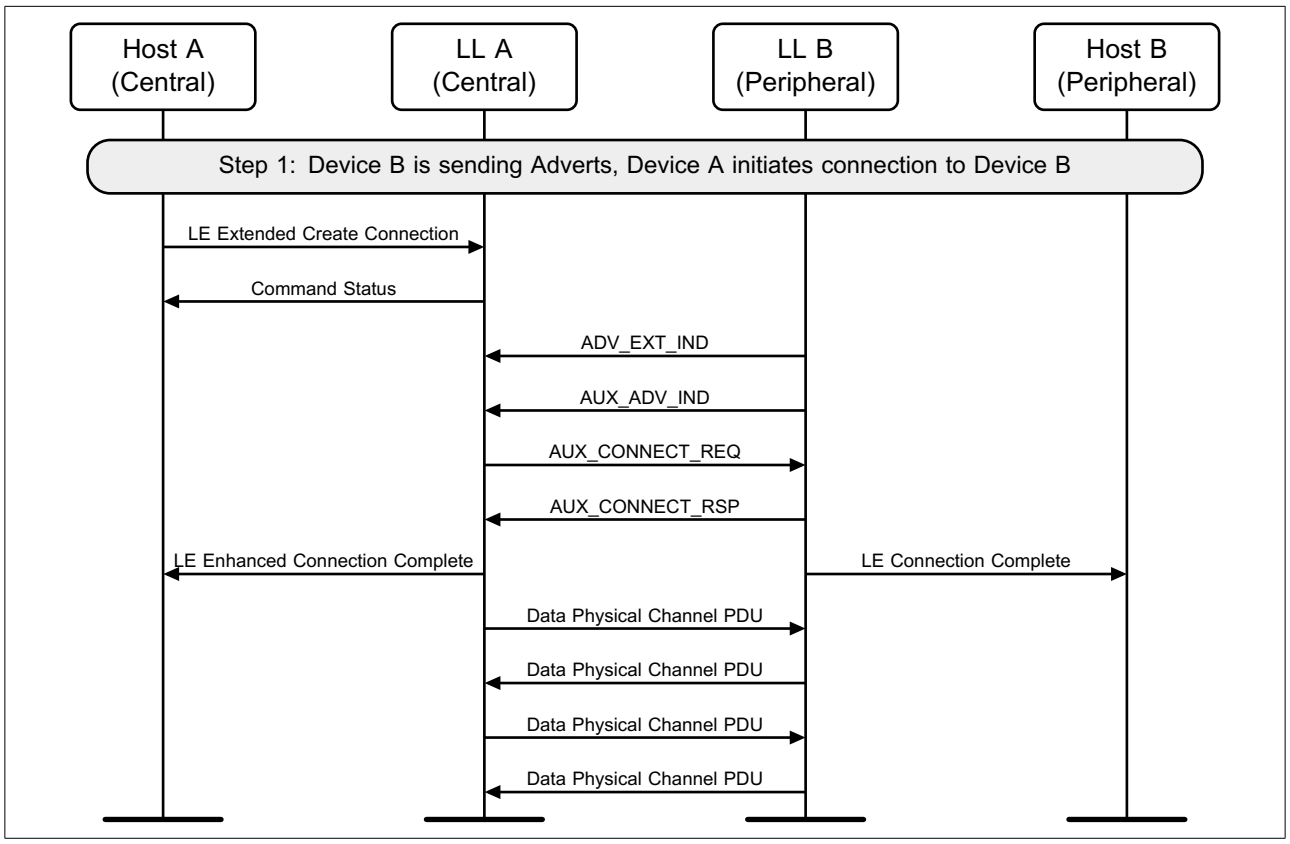

Figure 5.6: Initiating a connection on the secondary advertising physical channel

5.7 Initiating a Channel Selection algorithm #2 connection

Where a device supports the Channel Selection Algorithm #2 feature, it can initiate a connection which will use Channel Selection Algorithm #2 to an advertiser who has the

ChSel field of the advertising physical channel PDU set to 1. The example shows a successful initiation, resulting in the connection using Channel Selection Algorithm #2.

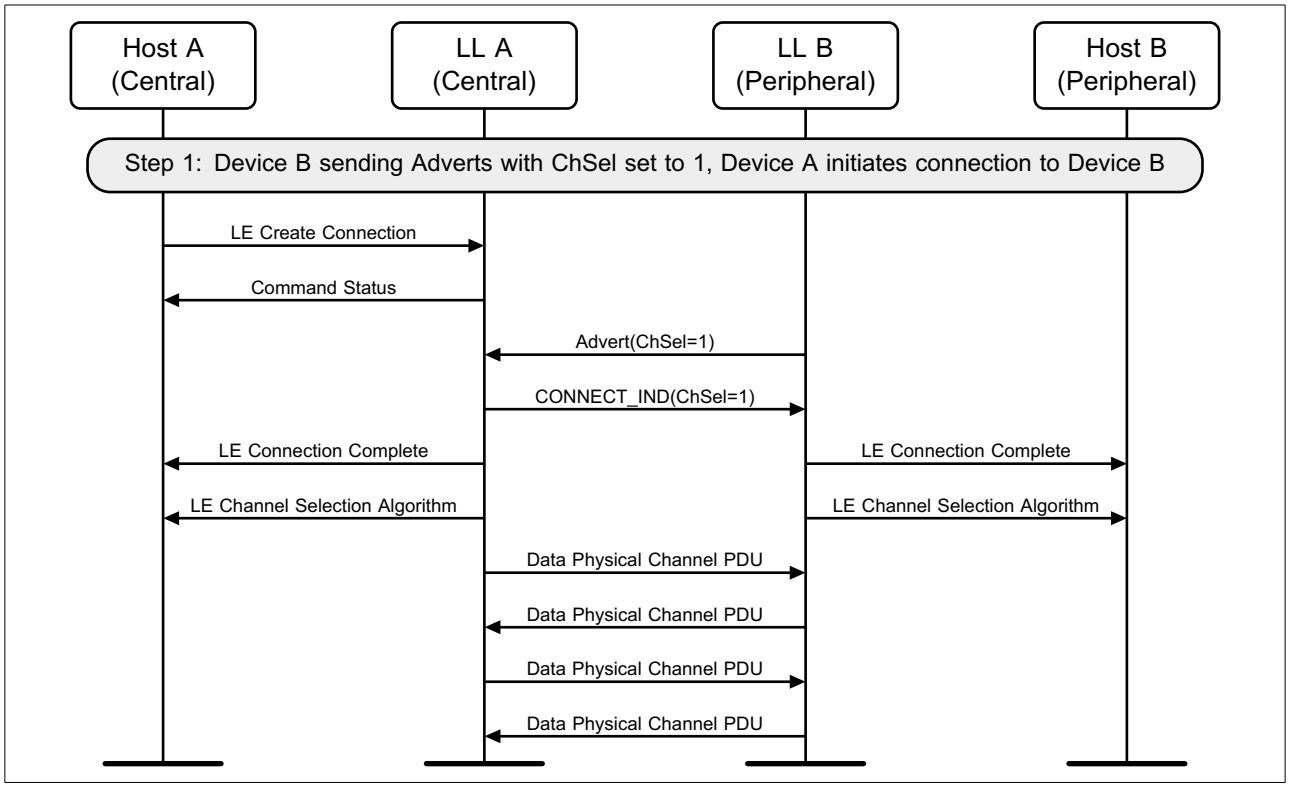

Figure 5.7: Initiating a Channel Selection algorithm #2 connection

5.8 Initiating a connection using an advertising set

A device can initiate a connection to an advertiser using an Extended Advertising advertising set. This causes additional events to be generated (see Figure 5.8). The LE Channel Selection Algorithm event can be generated irrespective of which algorithm is used by the connection.

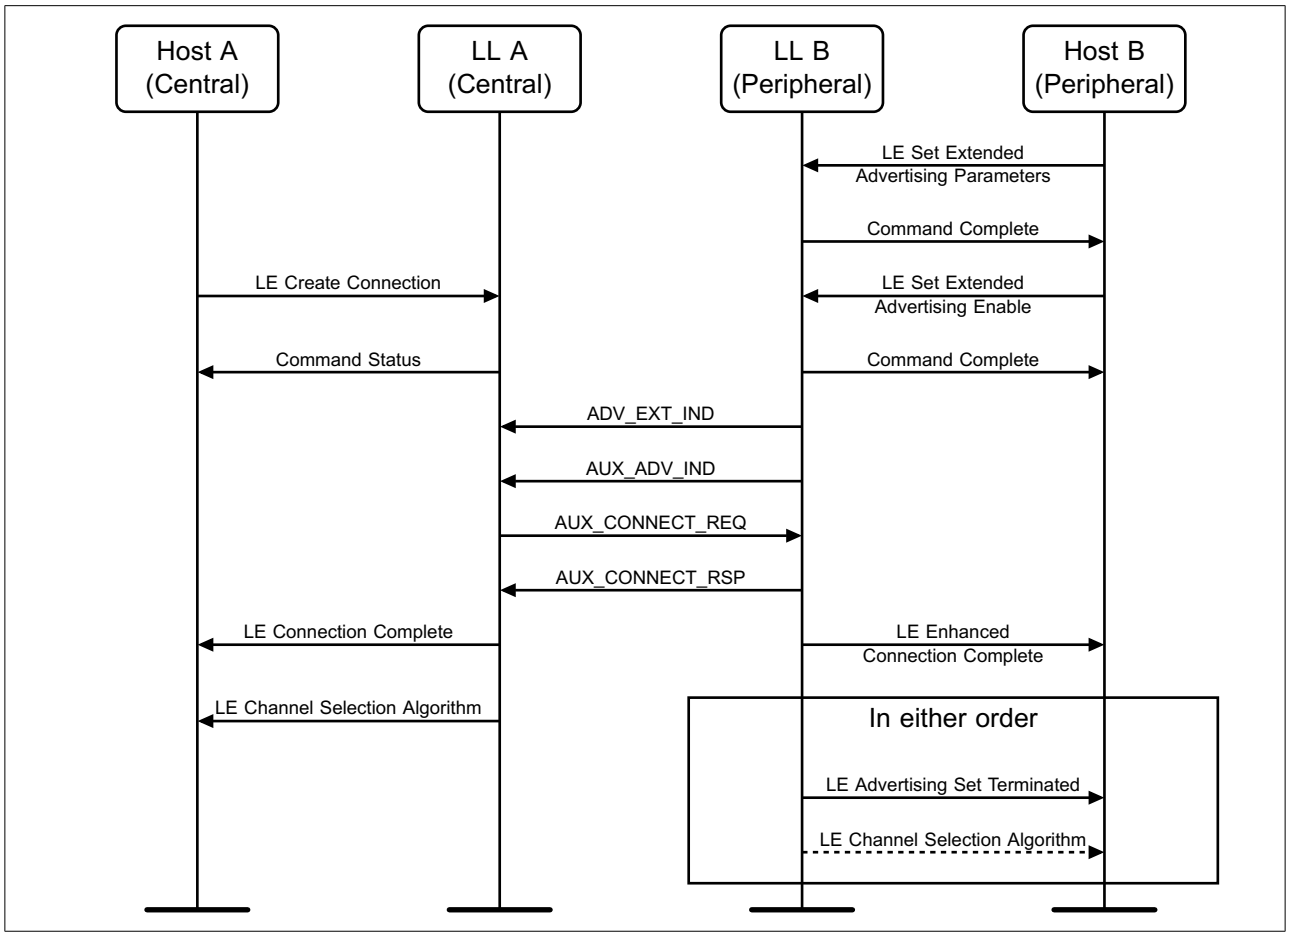

Figure 5.8: Initiating a connection using an advertising set

6 CONNECTION STATE

6.1 Sending data

Once two devices are in a connection, either device can send data. This example shows both devices sending data, for example when the Attribute Protocol does a read request and a read response is returned (see Figure 6.1).

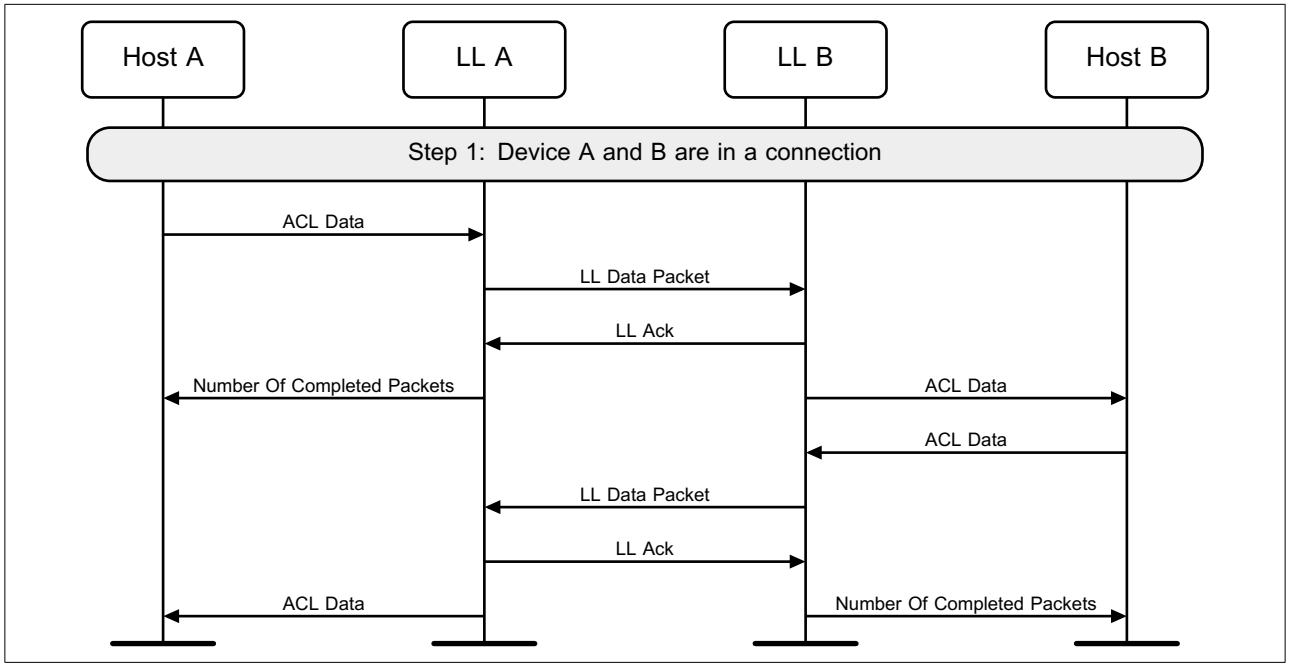

Figure 6.1: Sending data

6.2 Connection update

The Central of the connection may request a connection update using a Link Layer control procedure (see Figure 6.2).

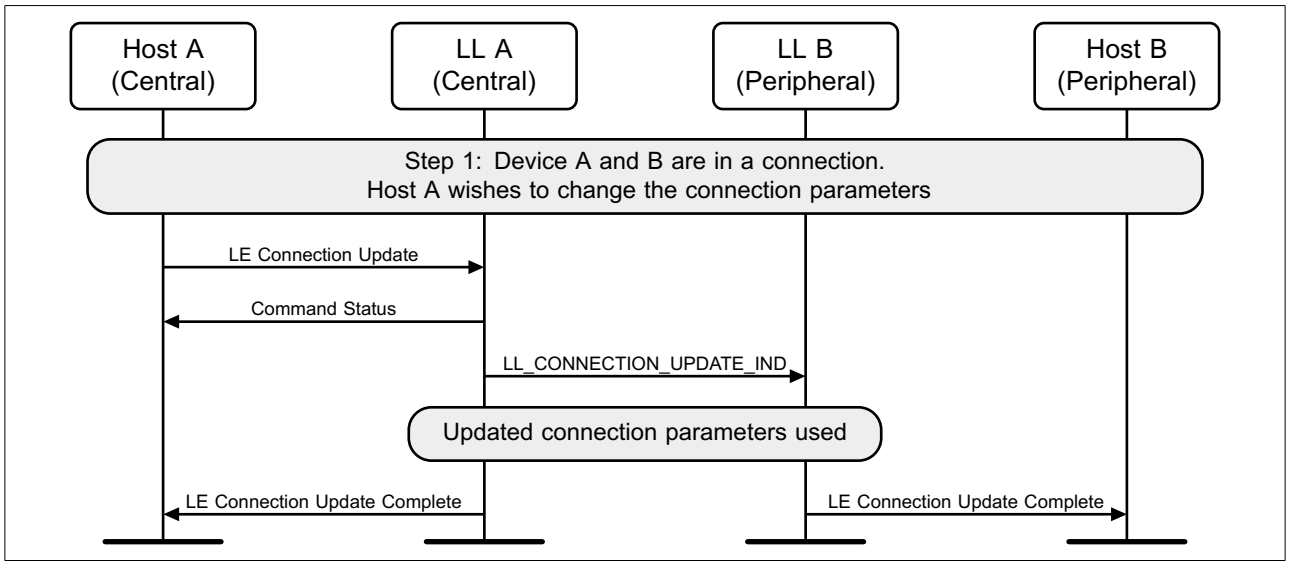

Figure 6.2: Connection update

6.3 Channel map update

The Controller of the Central may receive some channel classification data from the Host and then perform the Channel Update Link Layer Control procedure (see Figure 6.3).

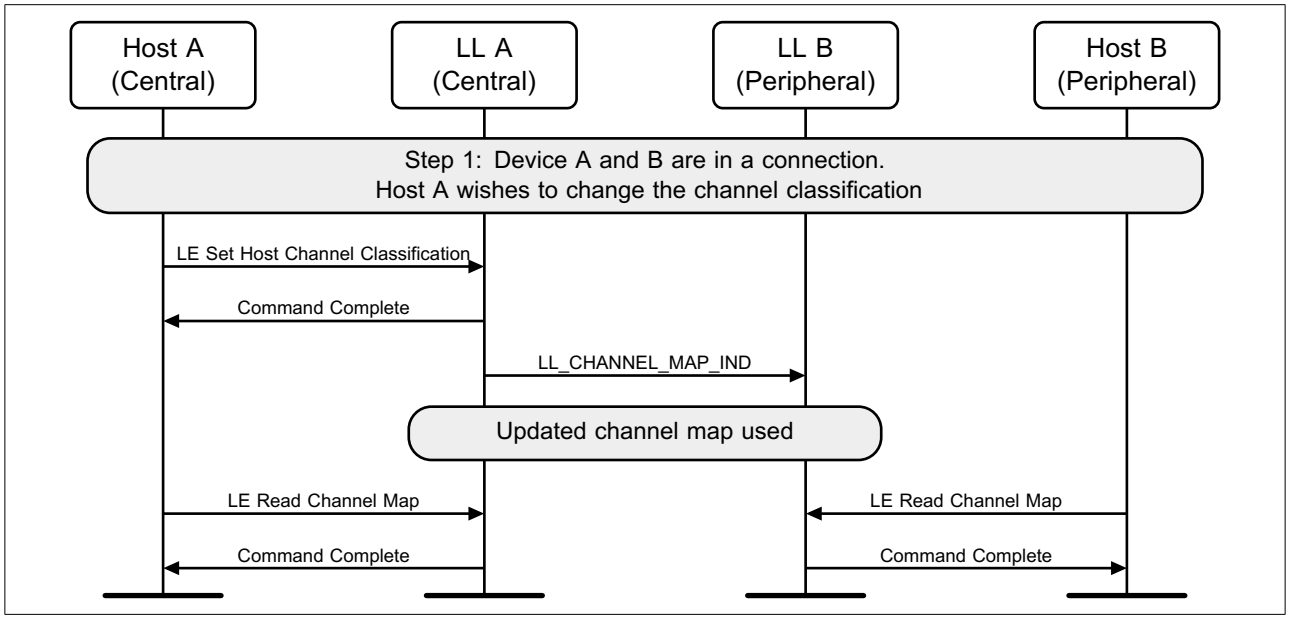

Figure 6.3: Channel map update

6.4 Features exchange

Both the Central and Peripheral can discover the set of features available on the remote device. To just fetch page 0, the Feature Exchange Link Layer Control procedure is used (see Figure 6.4 and Figure 6.5).

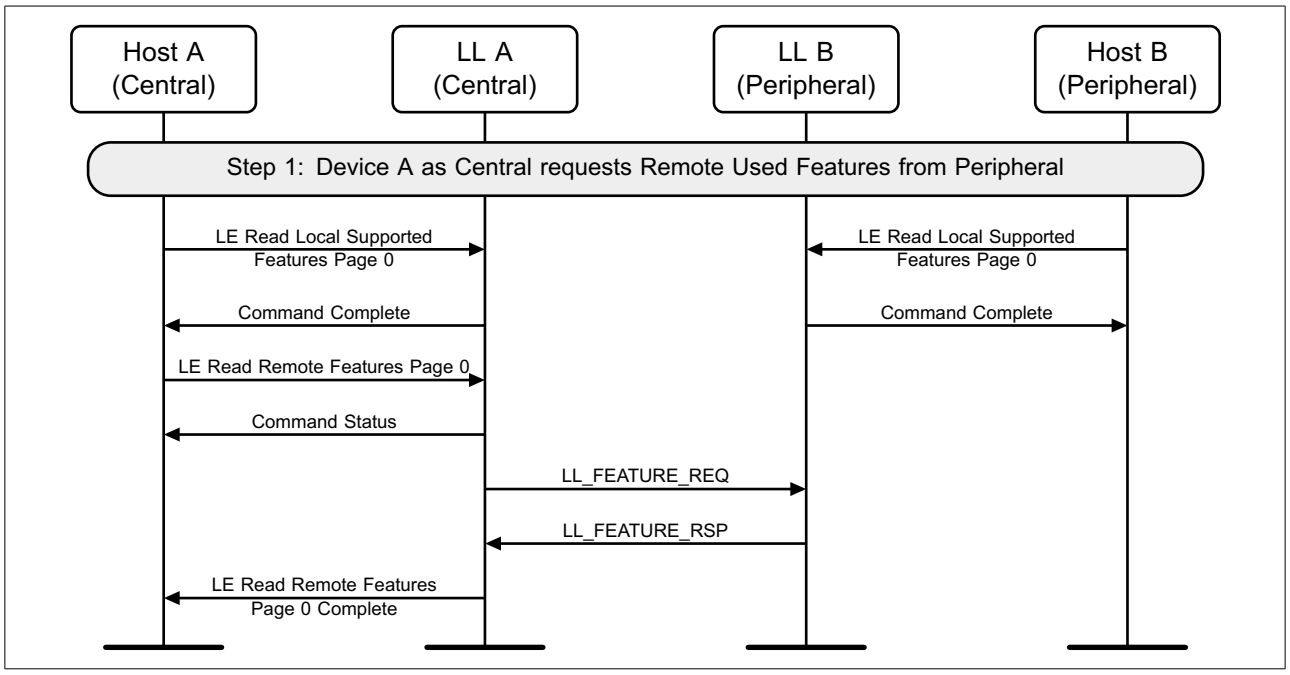

Figure 6.4: Central-initiated features exchange

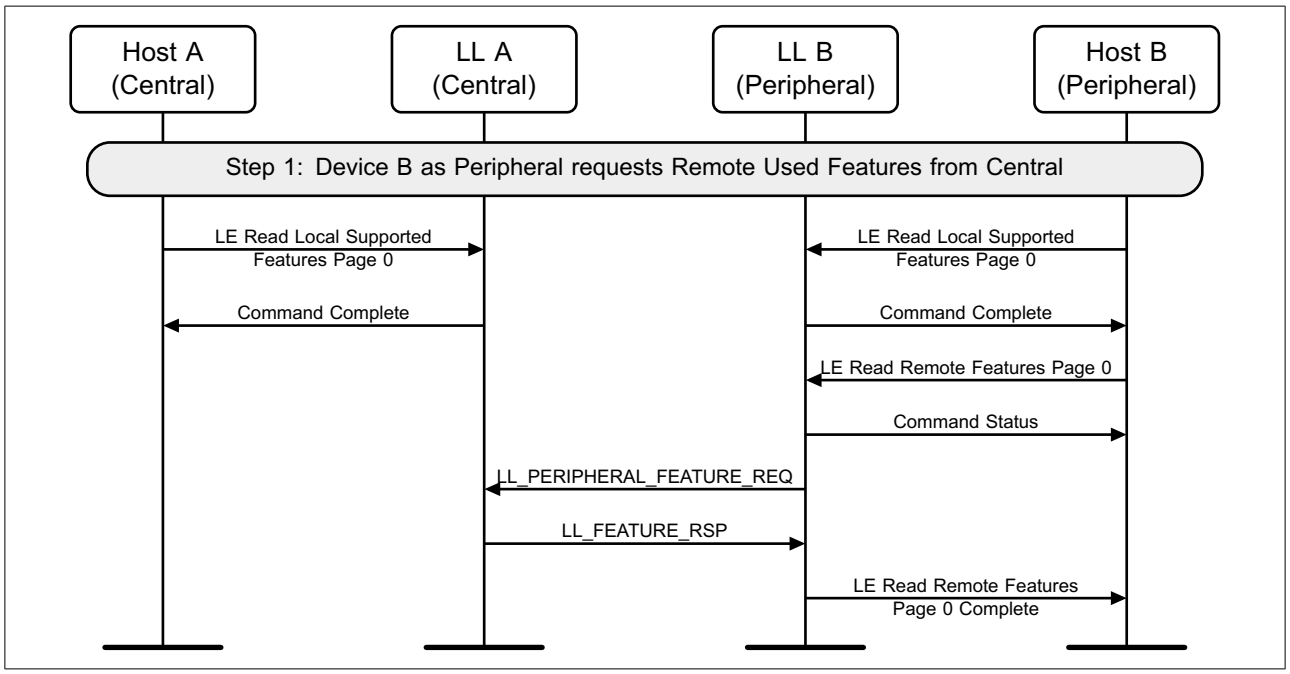

Figure 6.5: Peripheral-initiated features exchange

To fetch the entire feature list, this procedure is combined with 10 uses of the Feature Page Exchange procedure (see Figure 6.6).

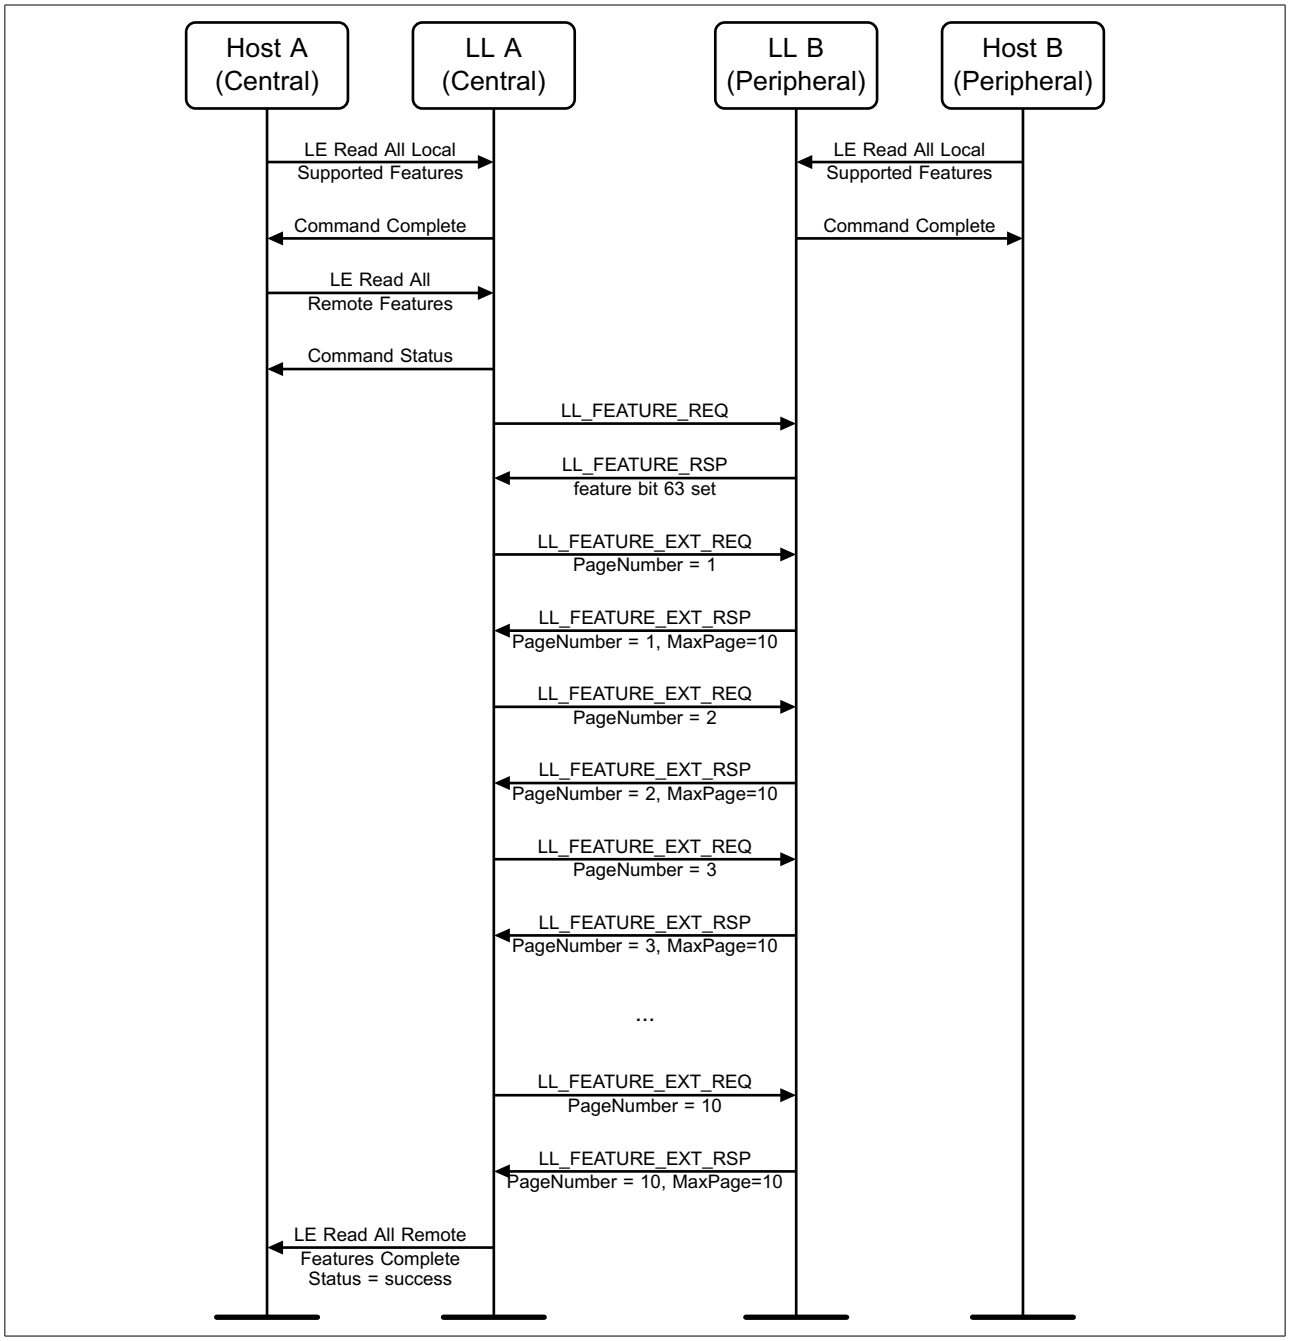

Figure 6.6: Complete feature exchange

If the peer only supports features in pages 0 to 2, then the Feature Page Exchange procedure need only be used twice (see Figure 6.7).

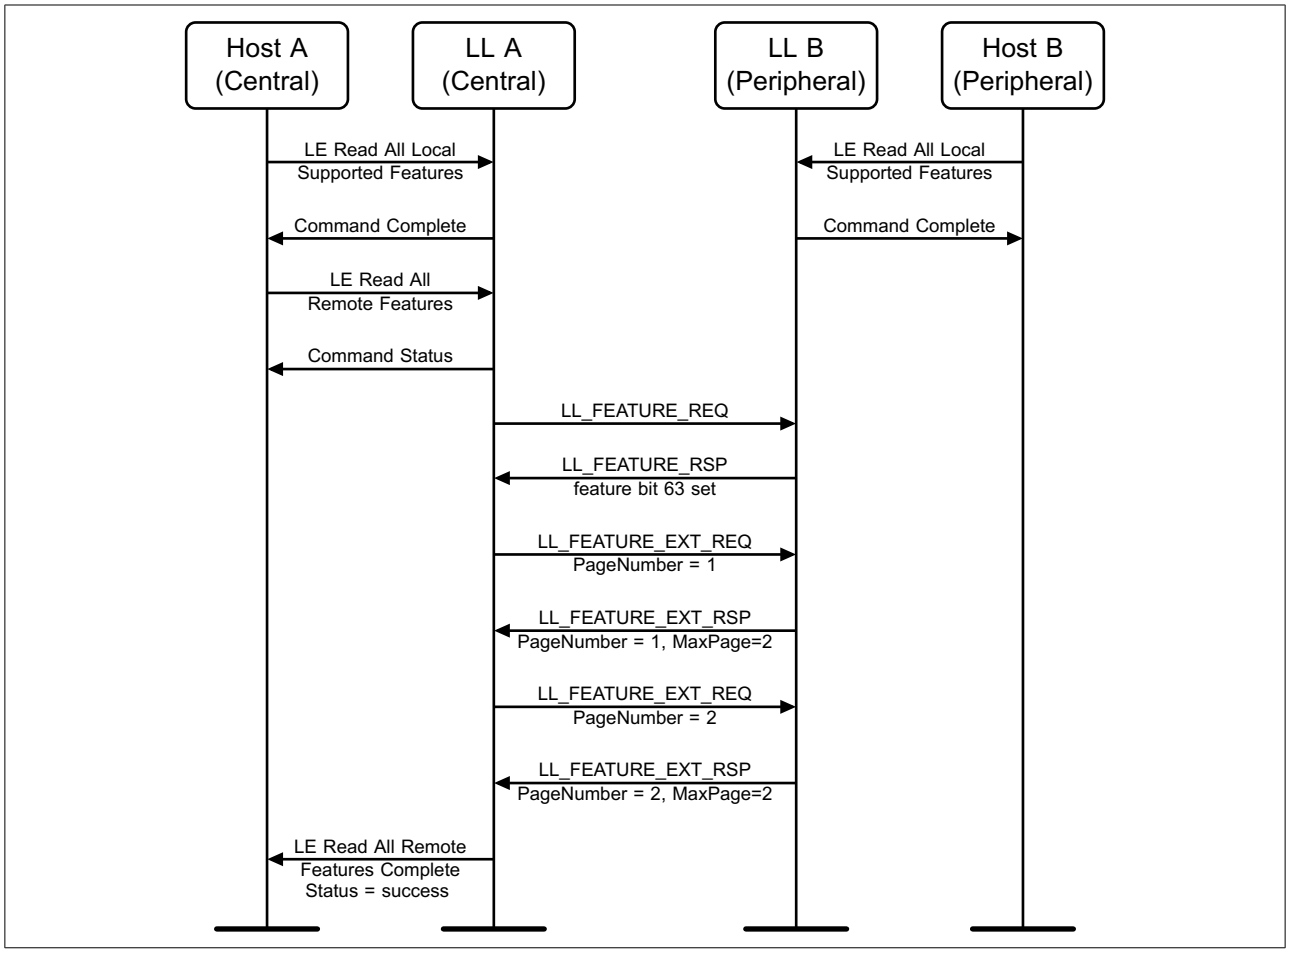

Figure 6.7: Complete feature exchange where only pages 0 to 2 are used

If the Peripheral does not support the Feature Page Exchange procedure, then the command has finished successfully as soon as it determines that it does not support the new procedure (see Figure 6.8).

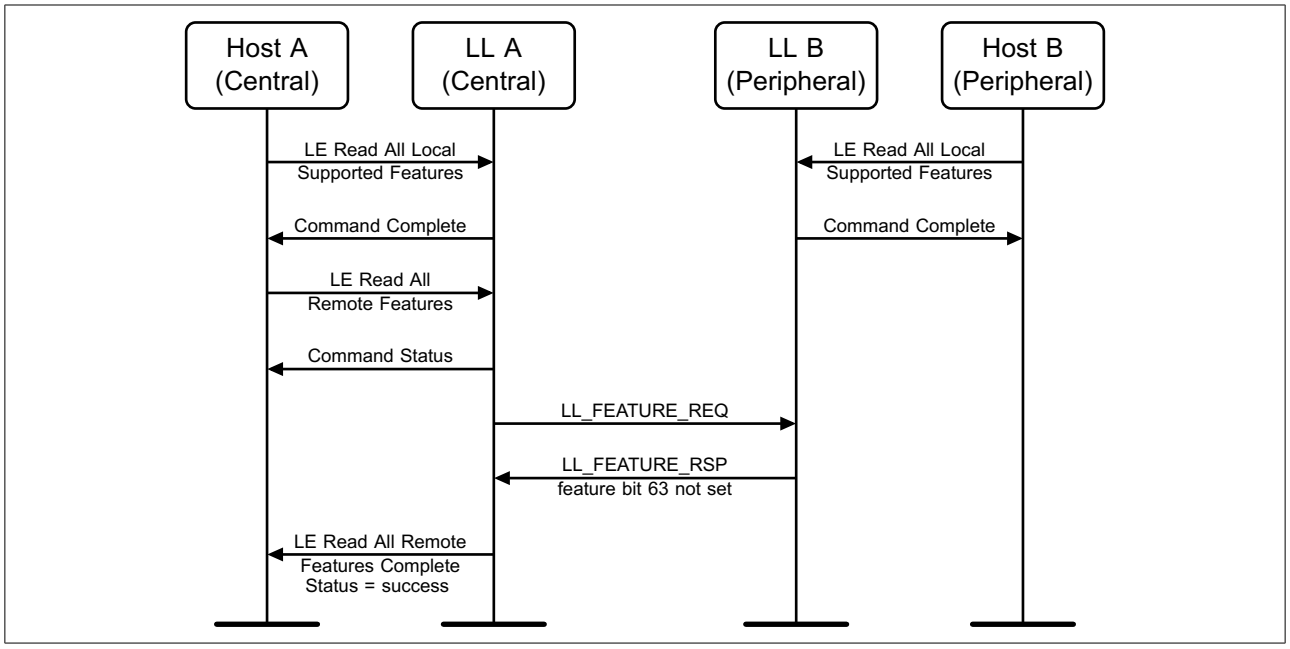

Figure 6.8: Complete feature exchange where the Peripheral does not support the new procedure

6.5 Version exchange

Either device may perform a Version Exchange procedure (see Figure 6.9 and Figure 6.10).

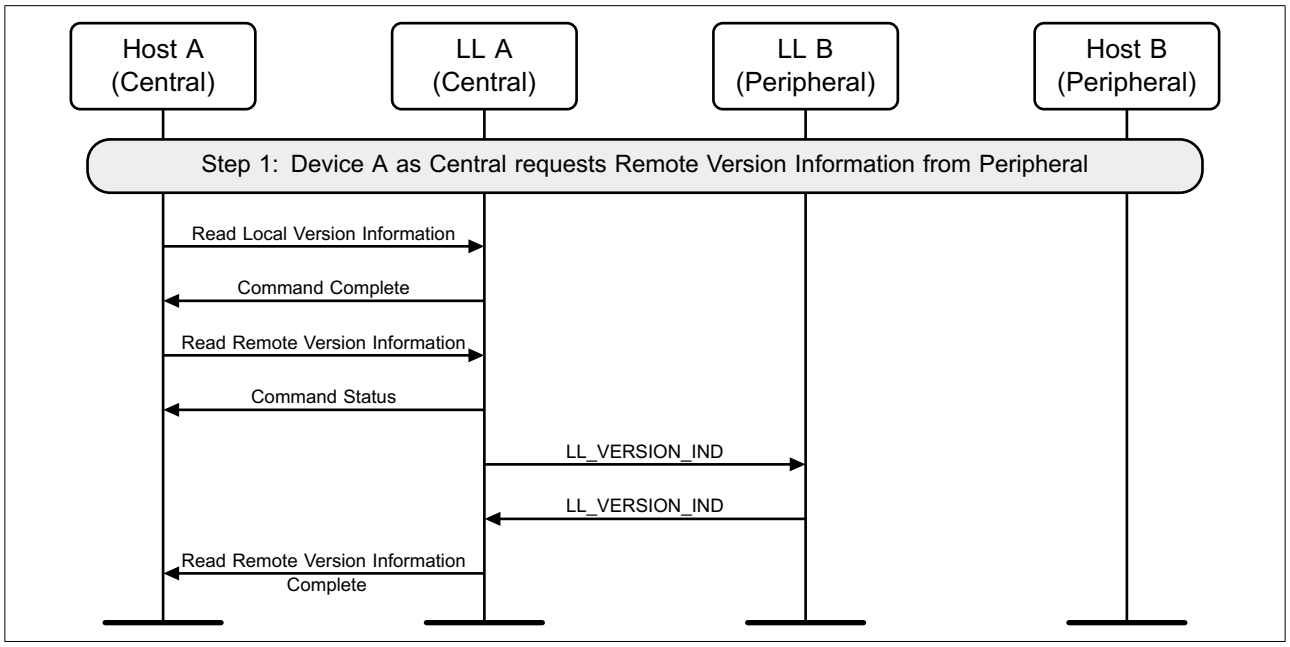

Figure 6.9: Version exchange from Central

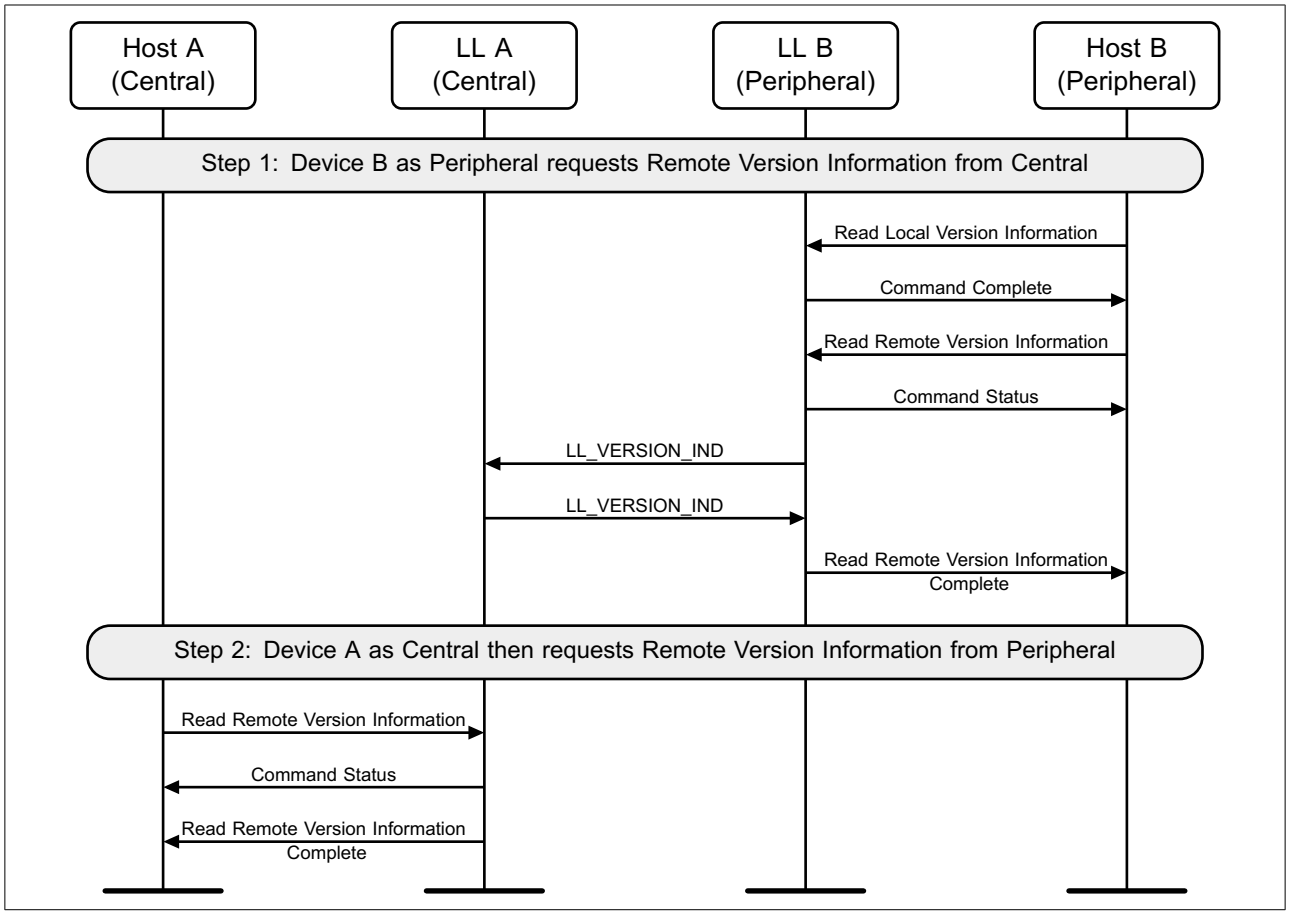

Figure 6.10: Version exchange from Peripheral

6.6 Start encryption

If encryption has not been started on a connection, it may be started by the Central (see Figure 6.11).

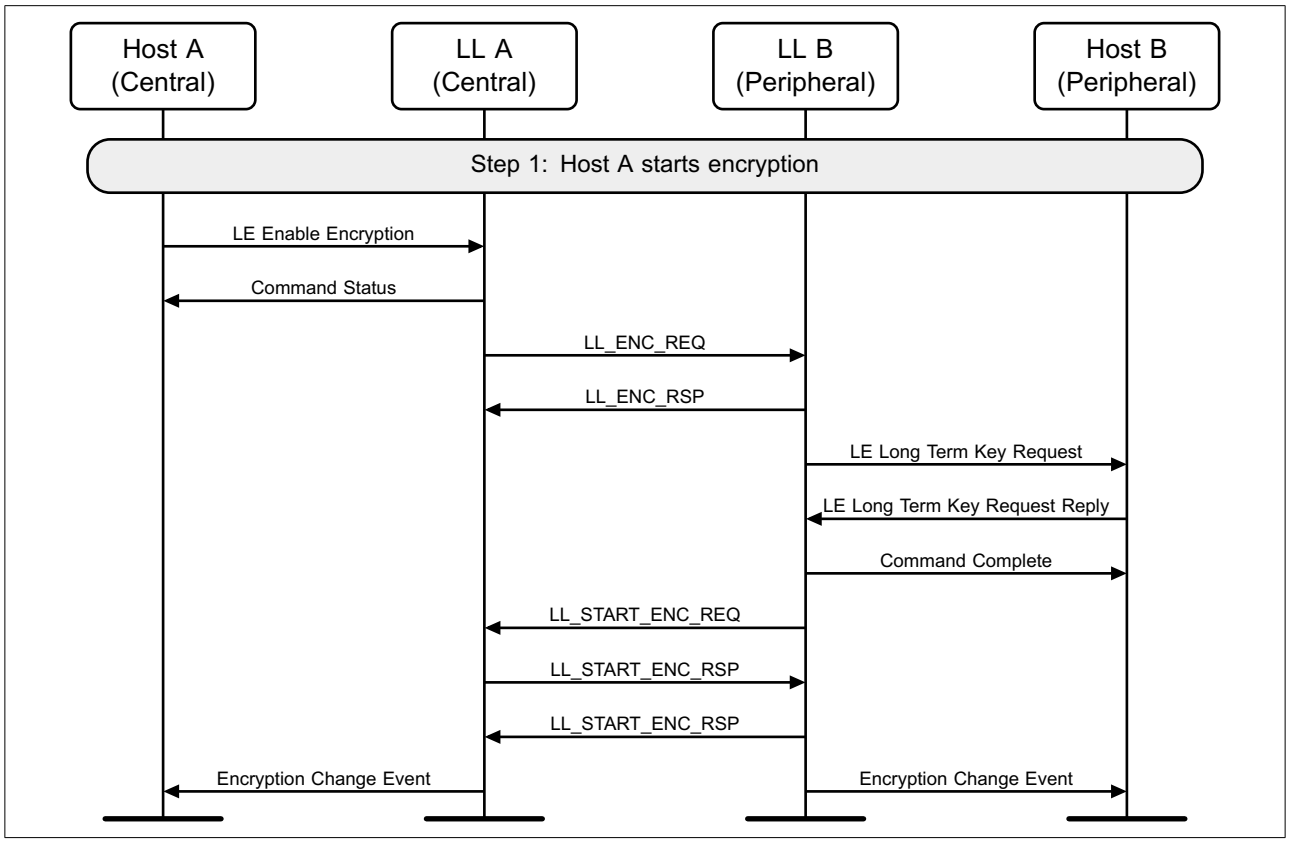

Figure 6.11: Start encryption

6.7 Start encryption without long-term key

If encryption has not been started on a connection, it may be started by the Central. Figure 6.12 shows the failure case of the Peripheral not having the long term key for the Central.

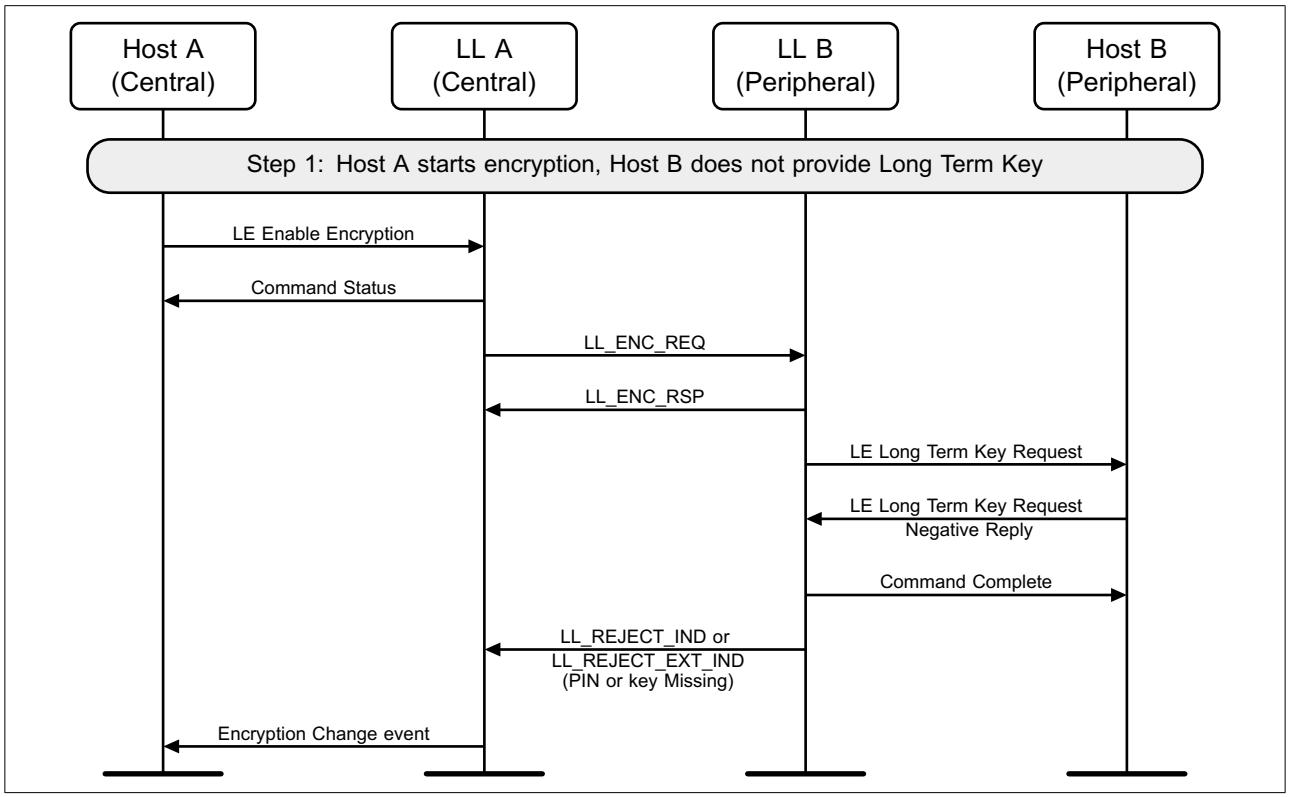

Figure 6.12: Start encryption without long-term key

6.8 Start encryption with event masked

If encryption has not been started on a connection, it may be started by the Central. Figure 6.13 shows the failure case when the Peripheral has masked out the HCI_LE_Long_Term_Key_Request event.

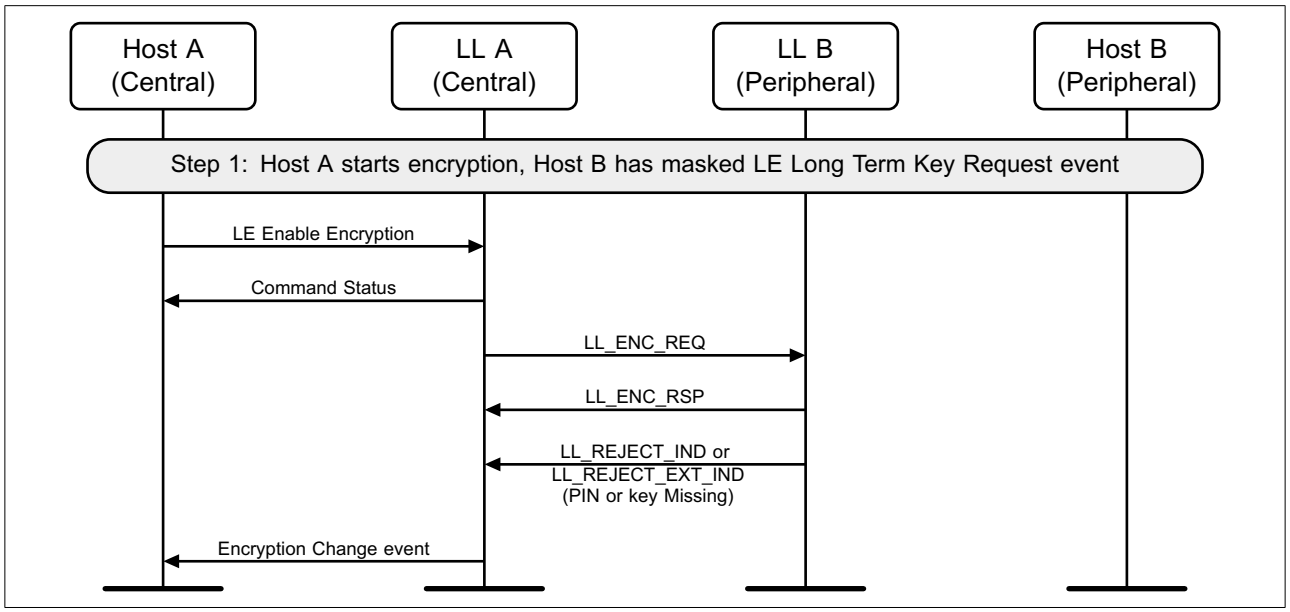

Figure 6.13: Start encryption with Peripheral masking out event

6.9 Start encryption without Peripheral supporting encryption

If encryption has not been started on a connection, it may be started by the Central. Figure 6.14 shows the failure case of the Peripheral that does not support the encryption feature.

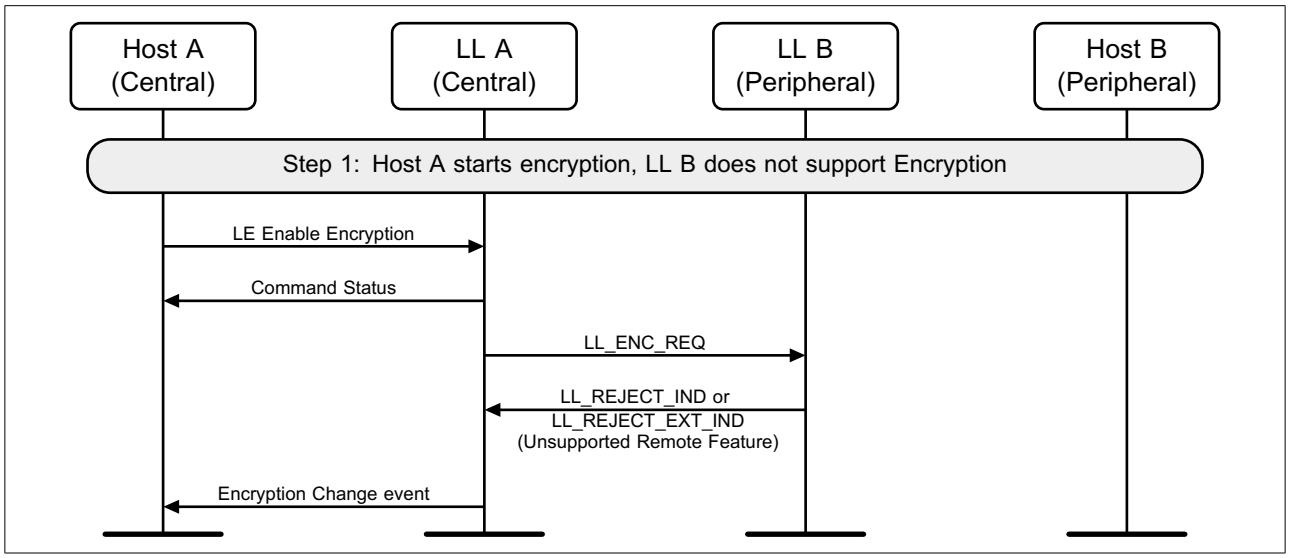

Figure 6.14: Start encryption failure when Peripheral does not support encryption

6.10 Restart encryption

If encryption has already been started on a connection, it may be restarted by the Central. This may be required to use a stronger encryption as negotiated by the Security Manager Protocol (see Figure 6.15).

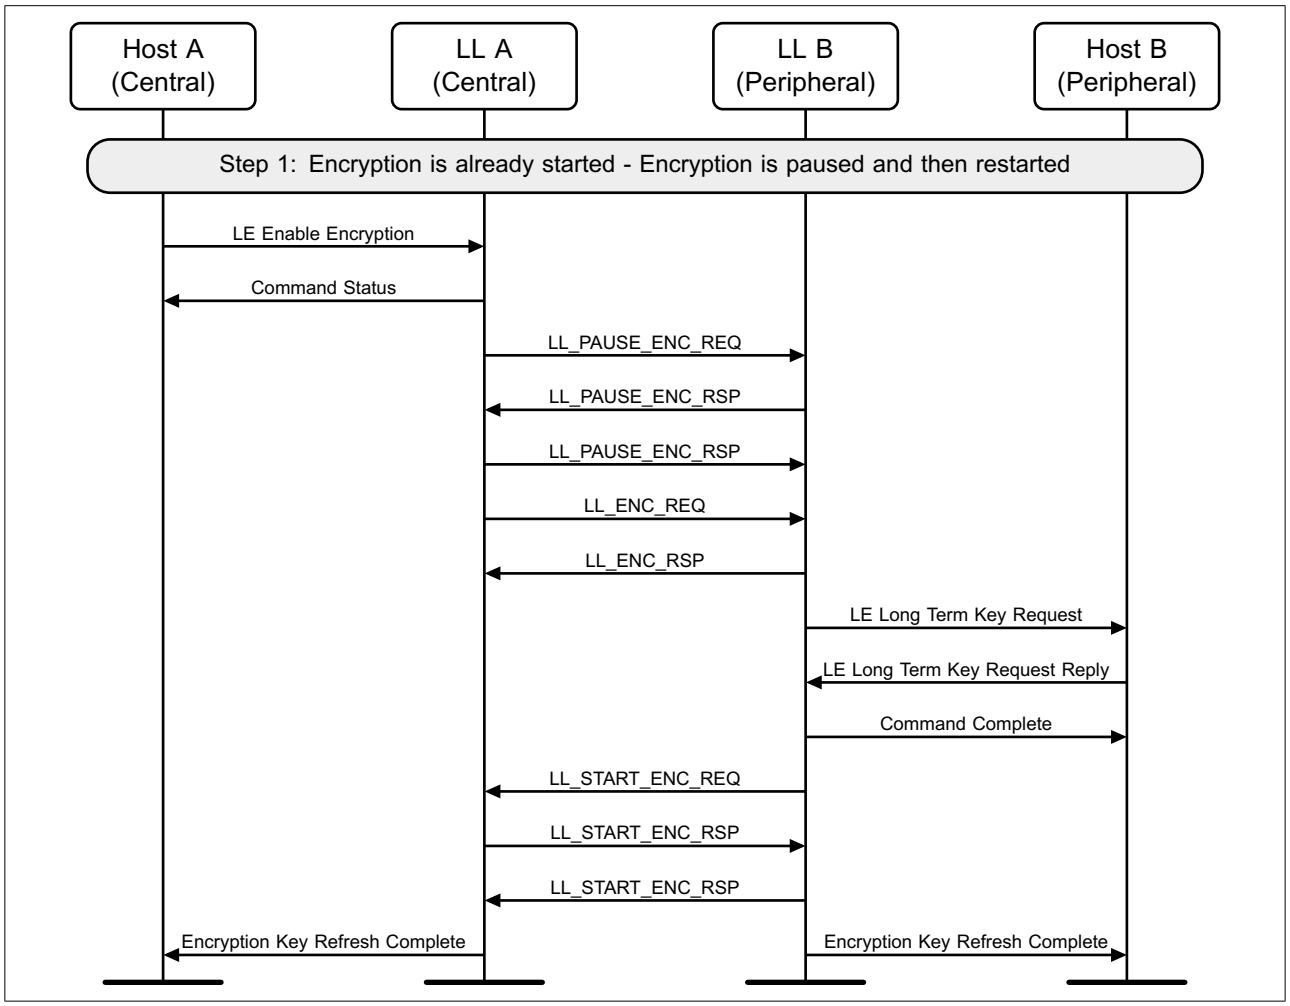

Figure 6.15: Restart encryption

6.11 Disconnect

Once a connection has no need to be kept active, the Host can disconnect it. This can be done by either device (see Figure 6.16 and Figure 6.17).

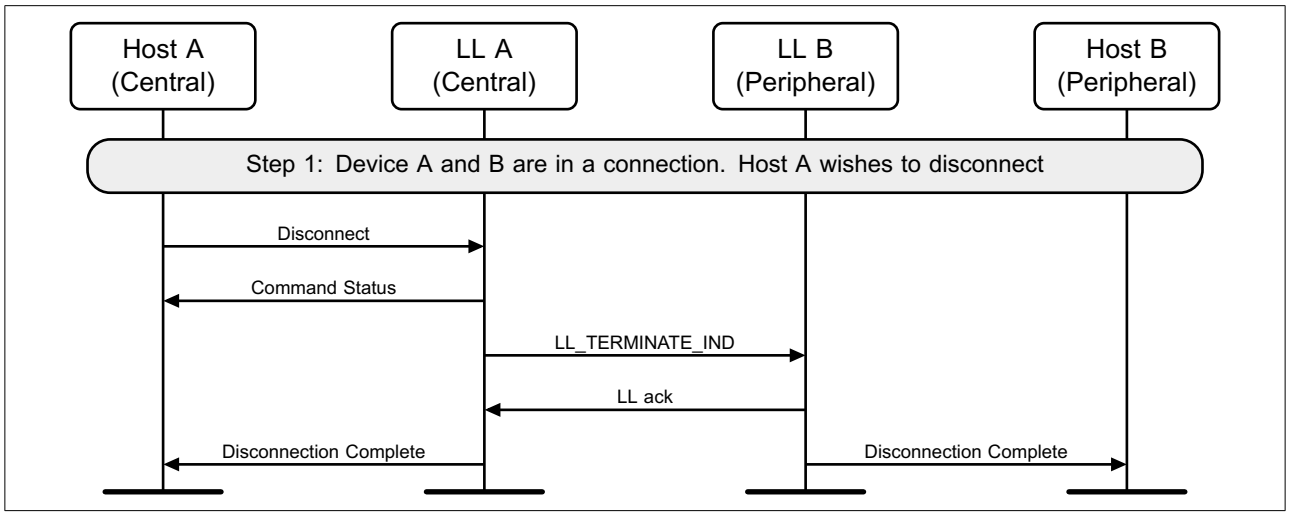

Figure 6.16: Disconnect from Central

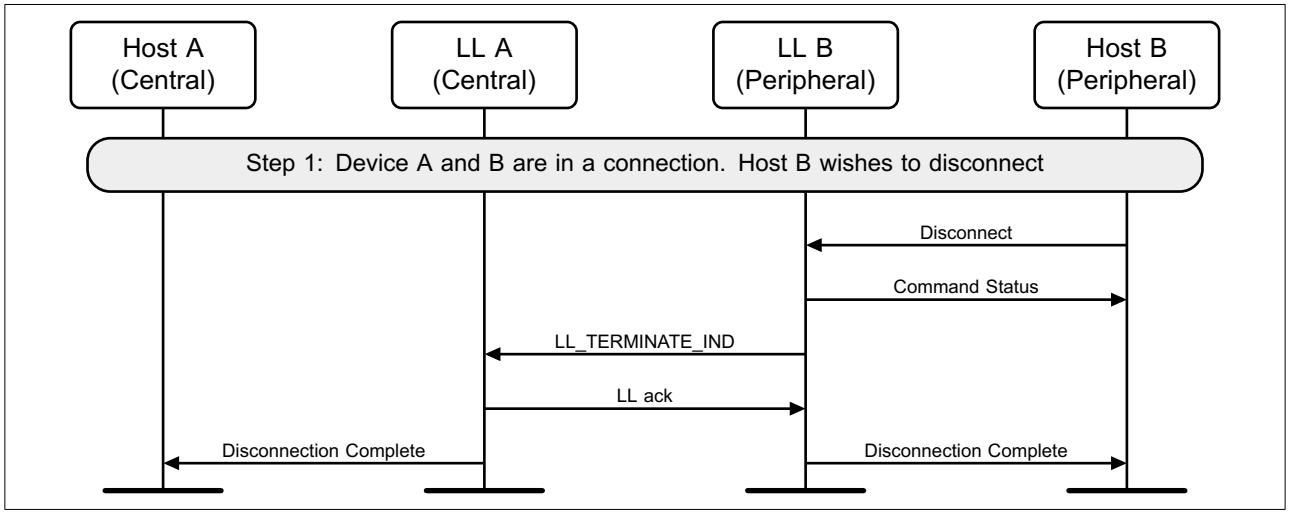

Figure 6.17: Disconnect from Peripheral

6.12 Connection parameters request

The Central or the Peripheral of the connection may request change in connection parameters using a Link Layer control procedure (see Figure 6.18 to Figure 6.25).

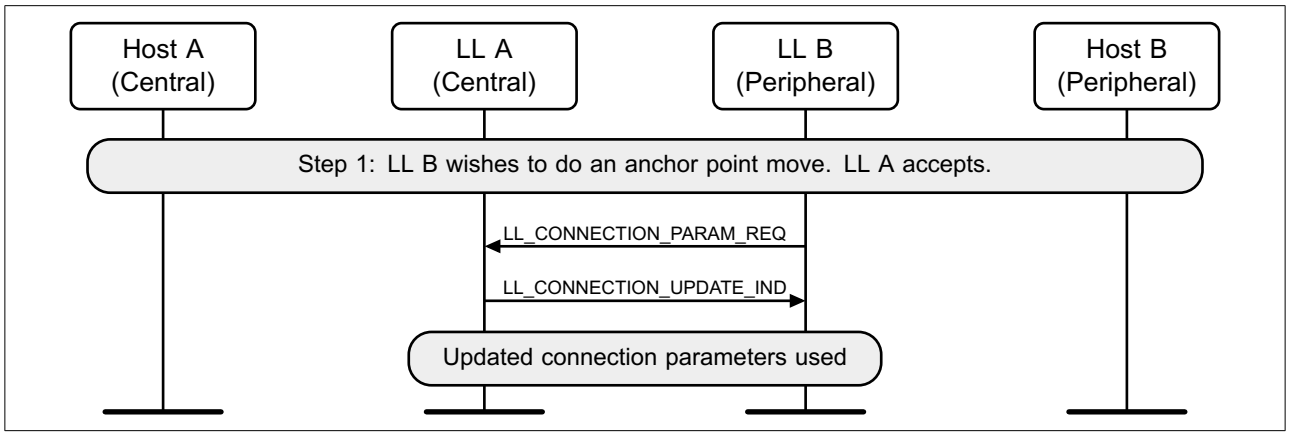

Figure 6.18: Peripheral-initiated Connection Parameters Request procedure - Peripheral requests a change in anchor points, Central accepts

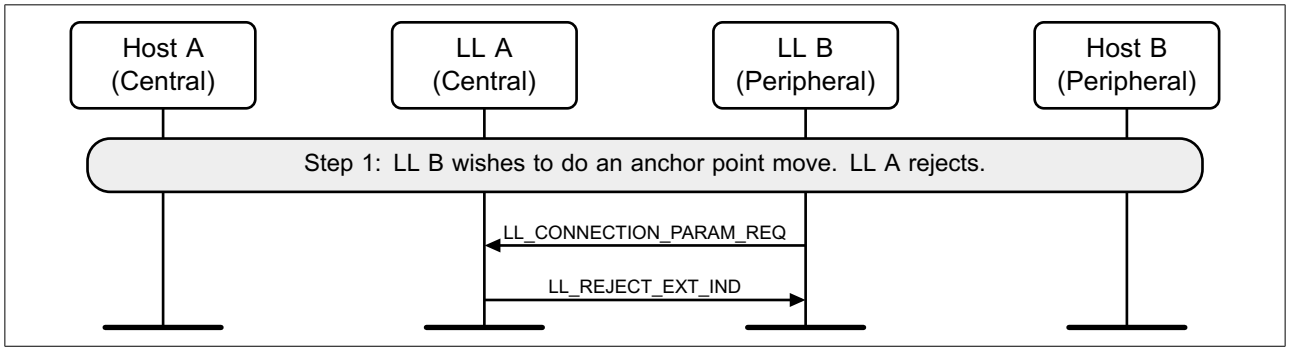

Figure 6.19: Peripheral-initiated Connection Parameters Request procedure – Peripheral requests a change in anchor points, Central rejects

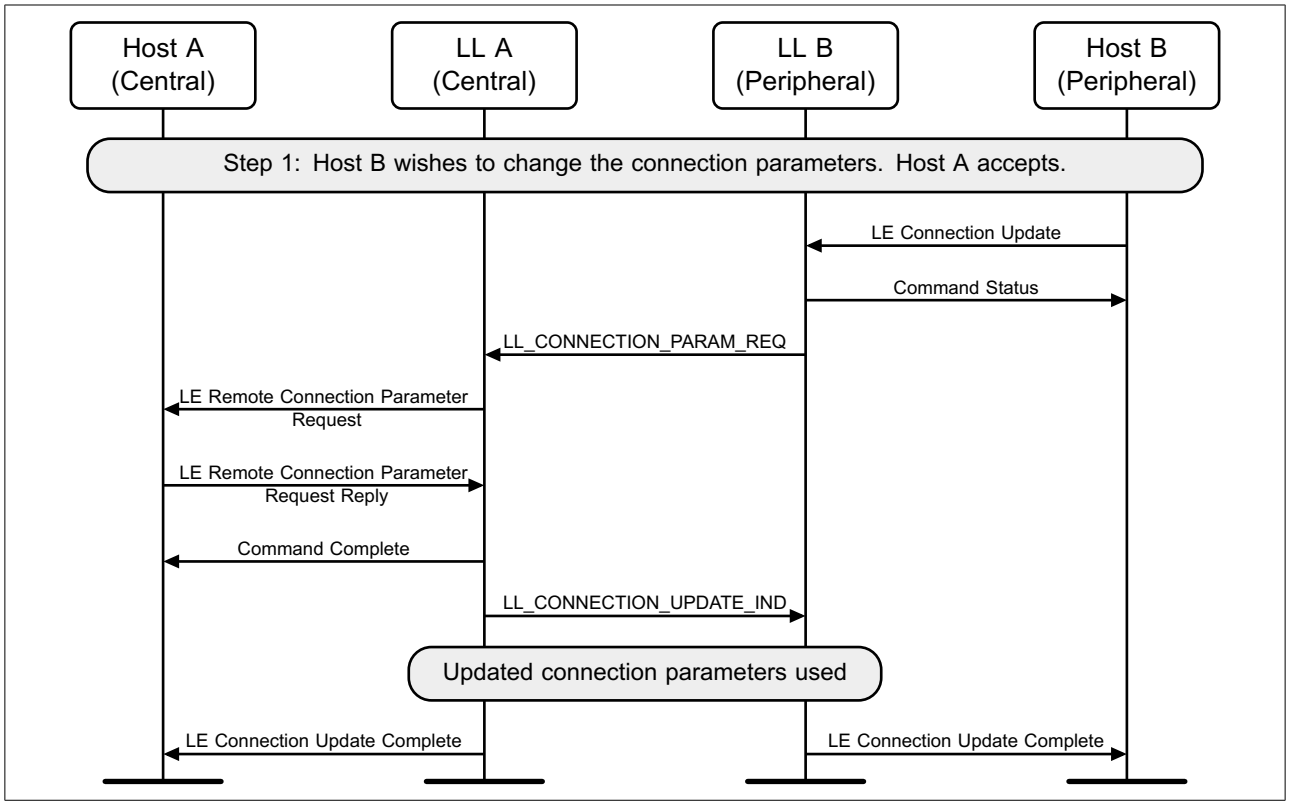

Figure 6.20: Peripheral-initiated Connection Parameters Request procedure – Peripheral requests change in LE connection parameters, Central's Host accepts

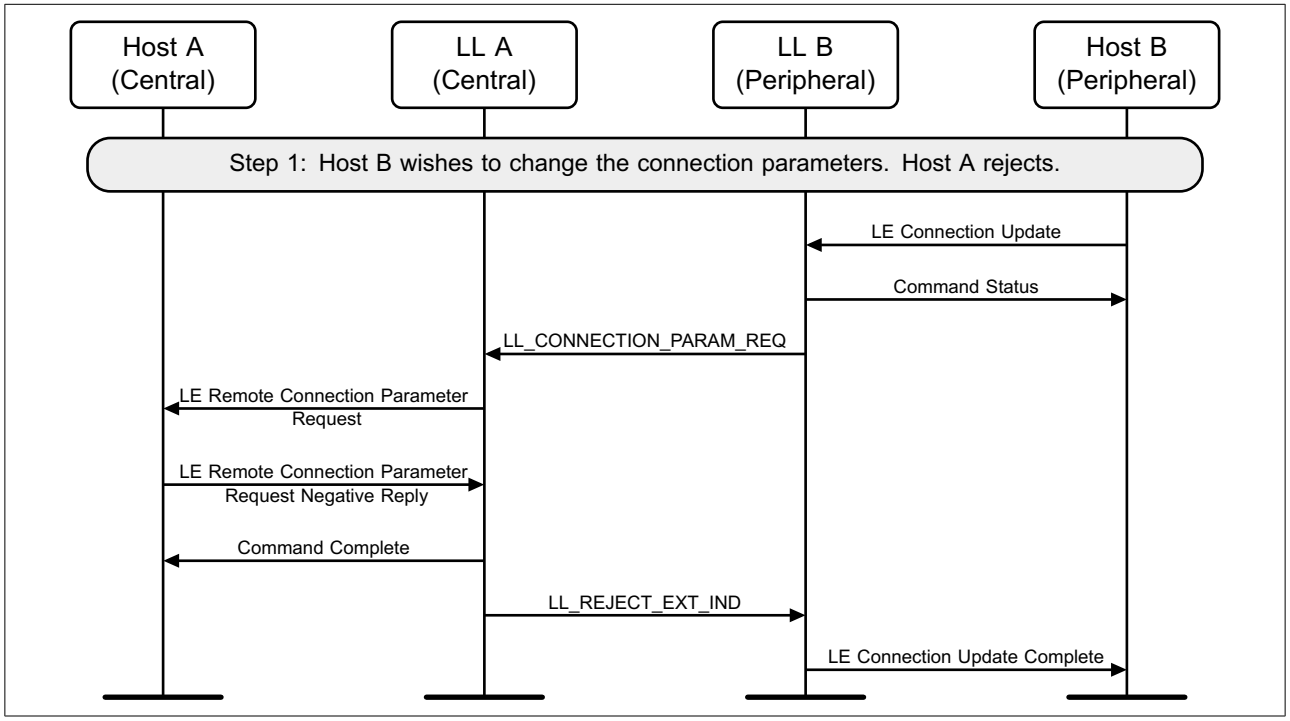

Figure 6.21: Peripheral-initiated Connection Parameters Request procedure – Peripheral requests change in LE connection parameters, Central's Host rejects

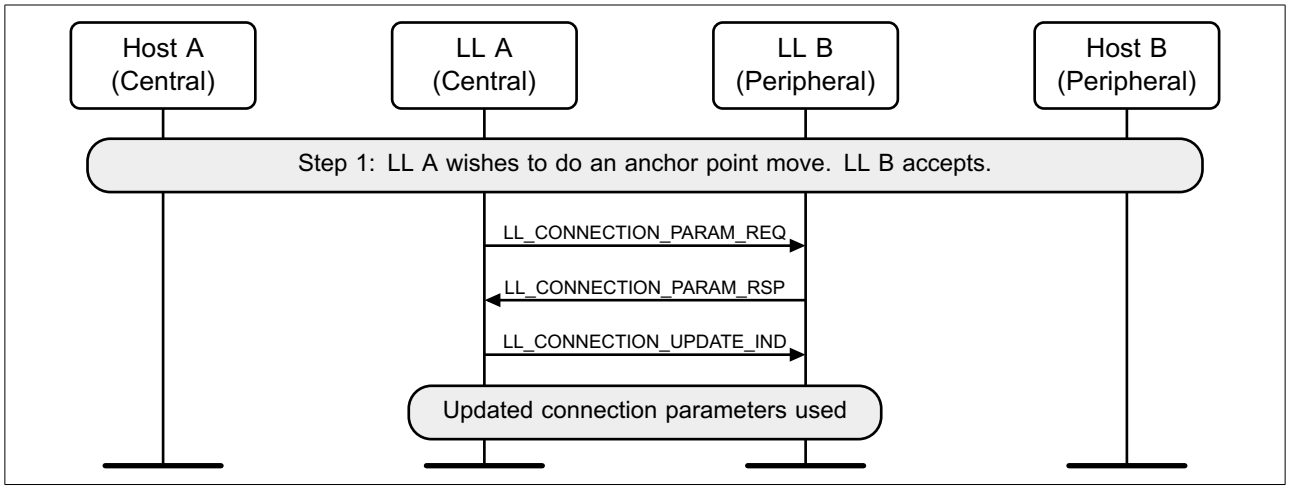

Figure 6.22: Central-initiated Connection Parameters Request procedure – Central requests a change in anchor points, Peripheral accepts

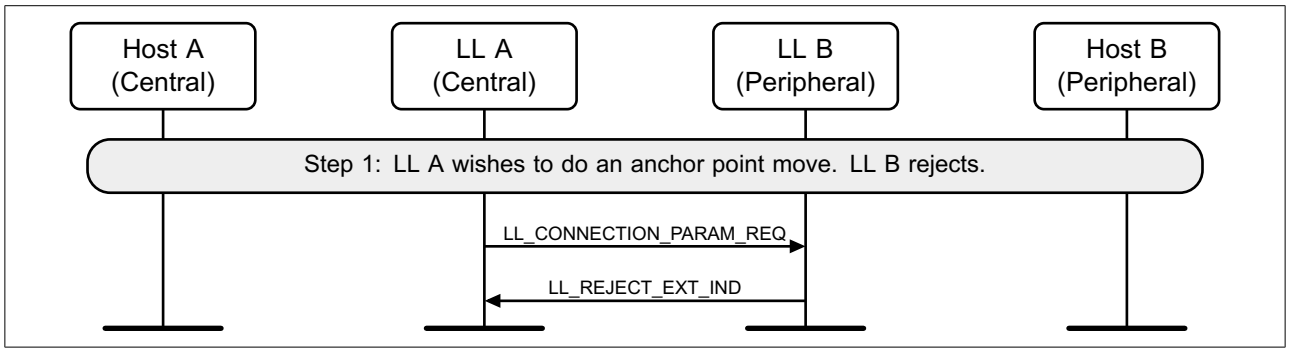

Figure 6.23: Central-initiated Connection Parameters Request procedure – Central requests a change in anchor points, Peripheral rejects

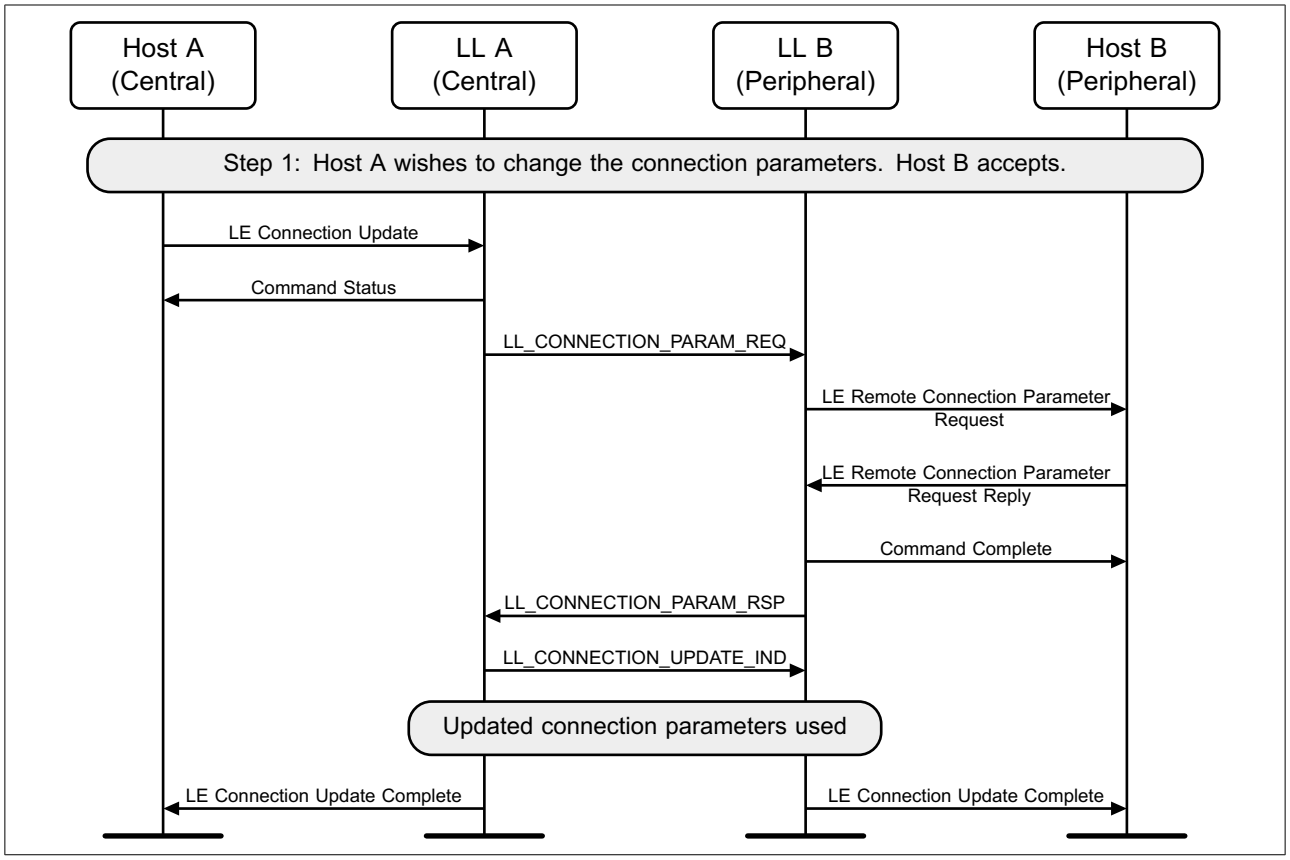

Figure 6.24: Central-initiated Connection Parameters Request procedure – Central requests change in LE connection parameters, Peripheral's Host accepts

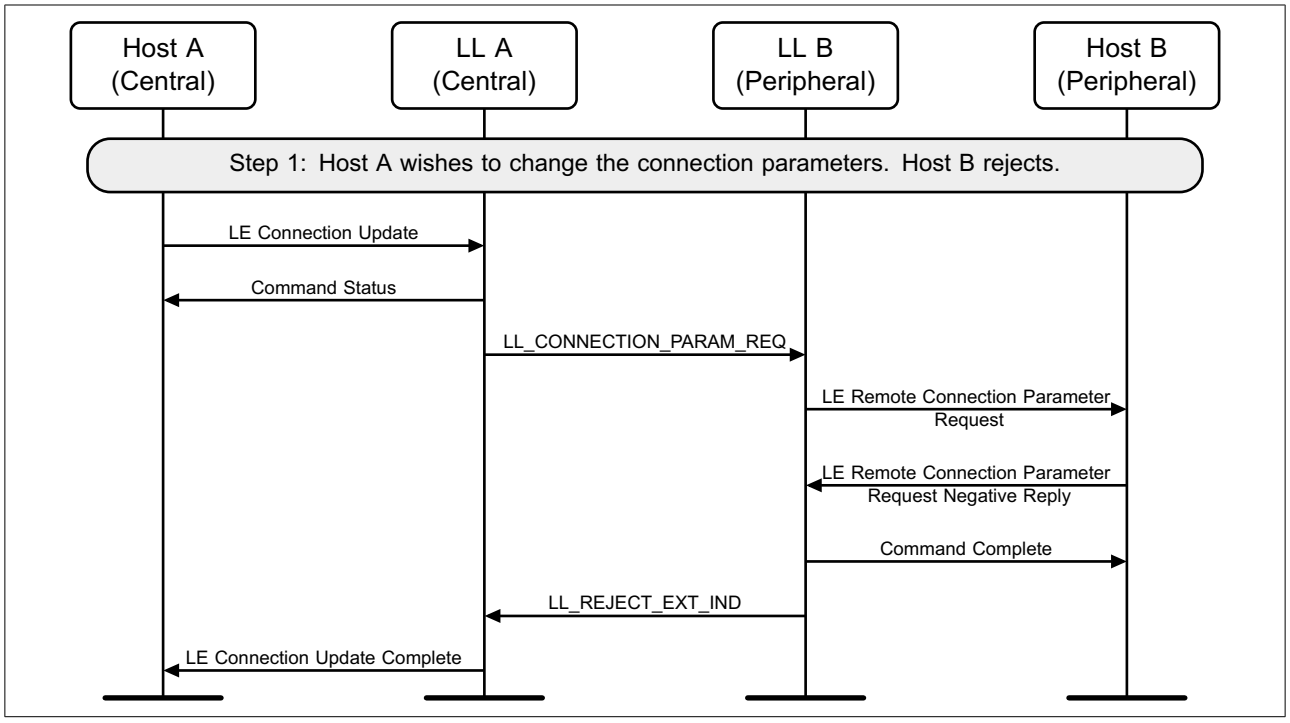

Figure 6.25: Central-initiated Connection Parameters Request procedure – Central requests change in LE connection parameters, Peripheral's Host rejects

6.13 LE Ping

A Host may use the HCI_Write_Authenticated_Payload_Timeout command to change the maximum interval between packets containing a valid MIC that the Link Layer will enforce when encryption is used.

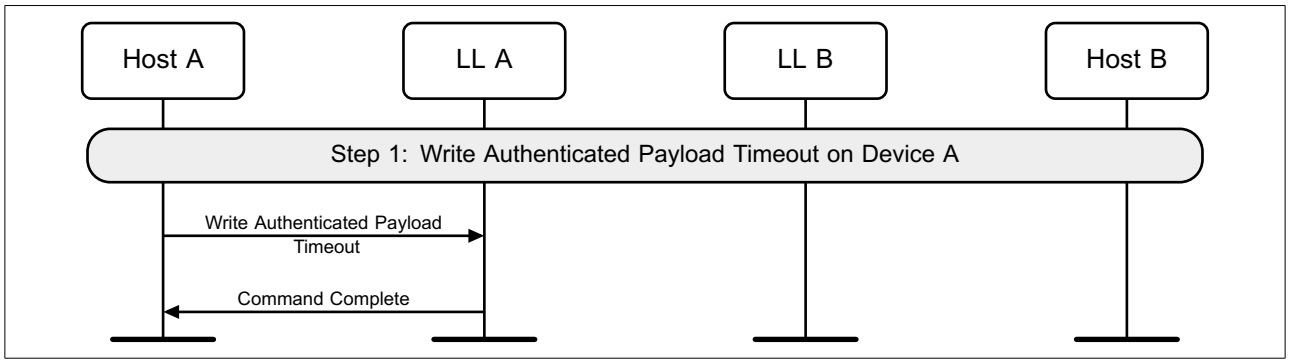

Figure 6.26: Set LE authenticated payload timeout

Either Link Layer can authenticate the remote device using the LE Ping procedure even if the remote device does not support the LE Ping feature. This procedure can also be

used for soliciting a packet from the remote device containing a valid MIC. LL A may be a Central or a Peripheral.

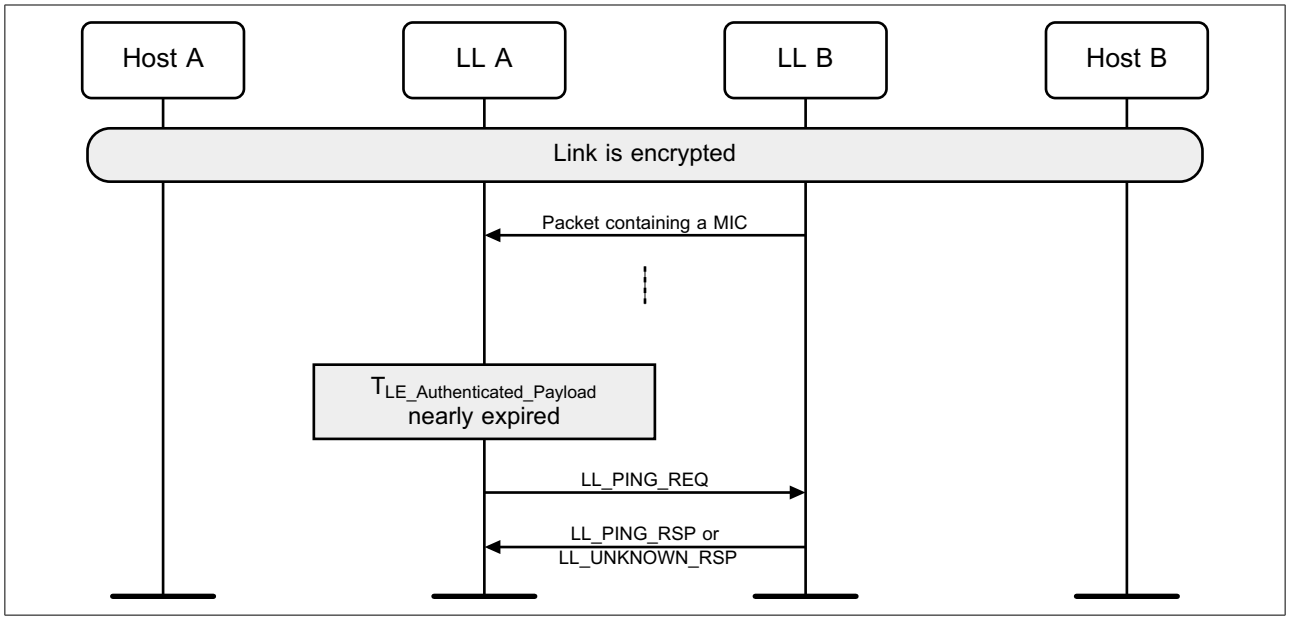

Figure 6.27: Successful LE Ping

When a packet with a valid MIC has not been received within the LE Authenticated Payload Timeout, the Host is notified that the timer has expired.

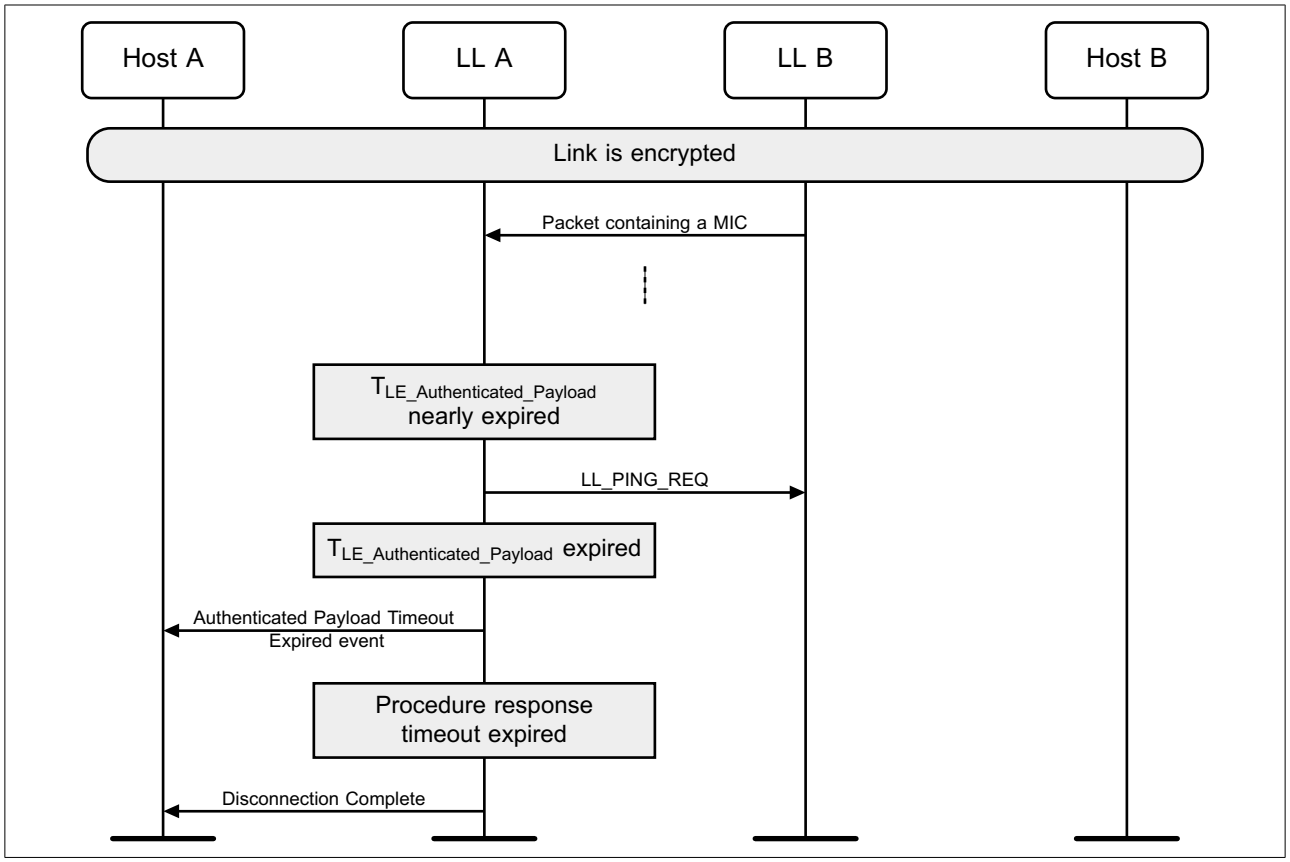

Figure 6.28: Unsuccessful LE Ping

The $T_{LE\_Authenticated\_Payload}$ Timer gets reset when the Host sets the Authenticated Payload Timeout.

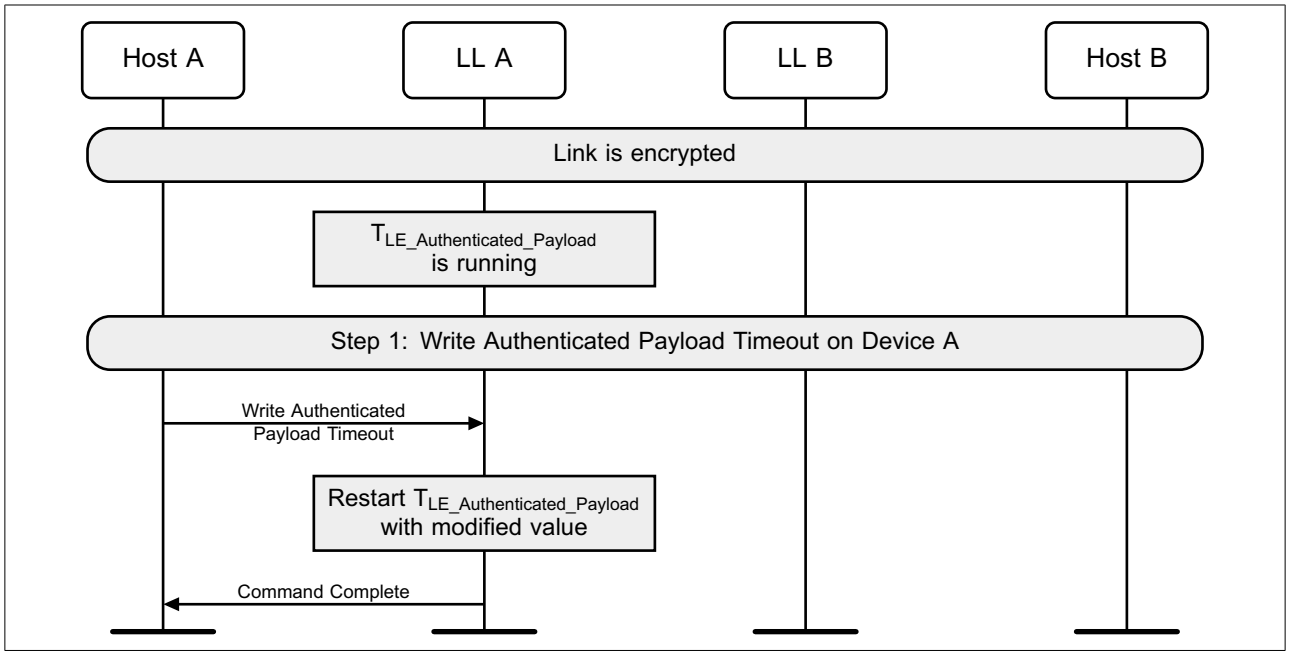

Figure 6.29: $T_{LE\_Authenticated\_Payload}$ Timer reset

6.14 Data length update

Once a connection has been created, the Host may suggest maximum transmission packet size and maximum packet transmission time to be used for the connection. This may be done on either the Central or the Peripheral.

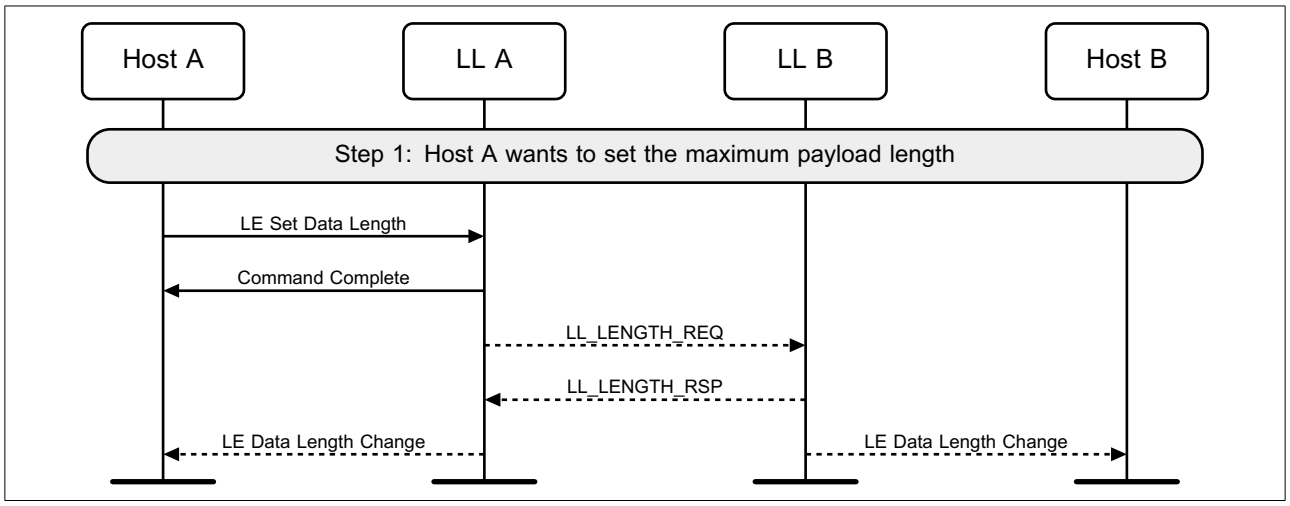

Figure 6.30: Data length update

6.15 PHY update

The Central or Peripheral of the connection may request a change in the PHY using a Link Layer control procedure (see Figure 6.31 to Figure 6.39).

The sequence of events shown in Figure 6.33 and Figure 6.36 can only happen before feature exchange and can only happen once per connection, because a Link Layer must not use a procedure that it knows the peer does not support as required by [Vol 6] Part B, Section 4.6.

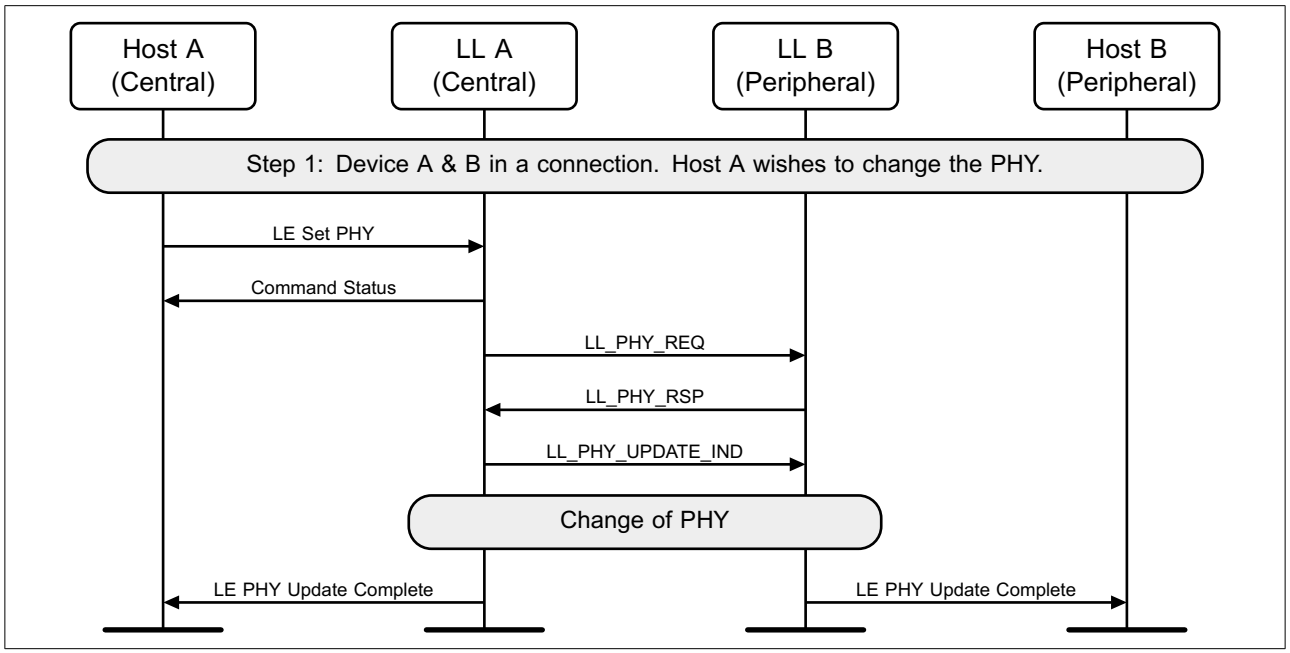

Figure 6.31: Central-initiated PHY Update procedure – Central requests a change of PHY, PHY changed in at least one direction

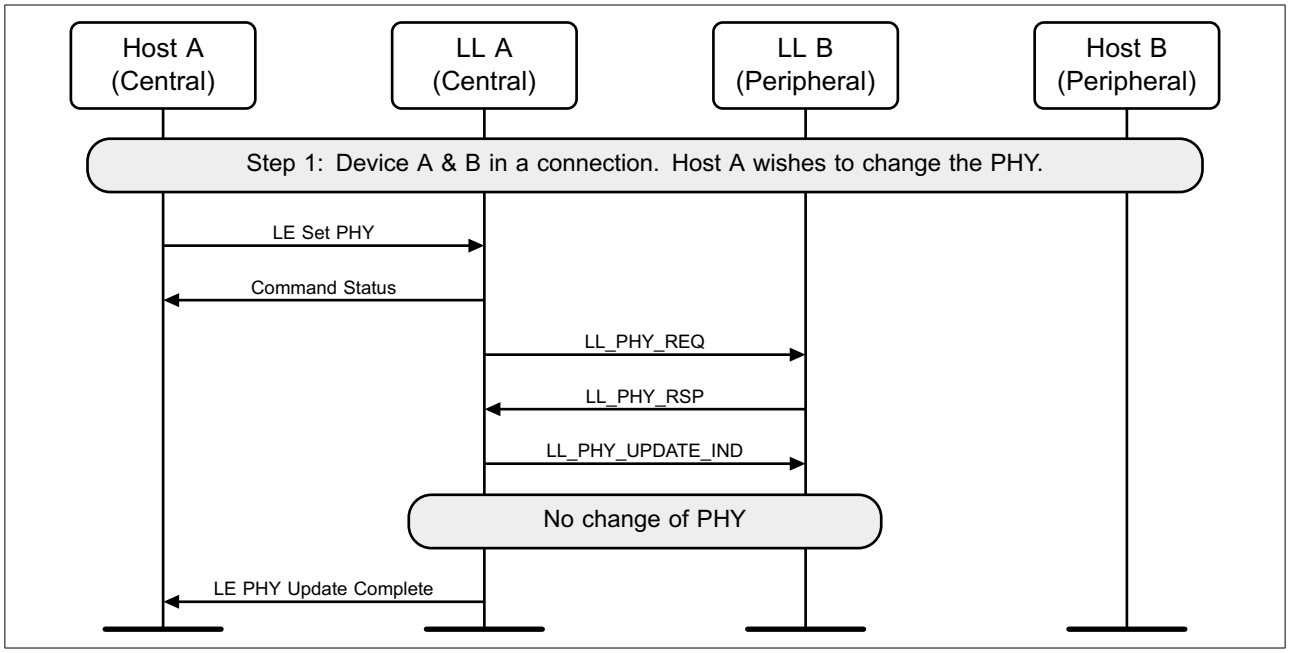

Figure 6.32: Central-initiated PHY Update procedure – PHY not changed (either because Peripheral doesn't specify PHYs that the Central prefers, or because the Central concludes that the current PHYs are still best)

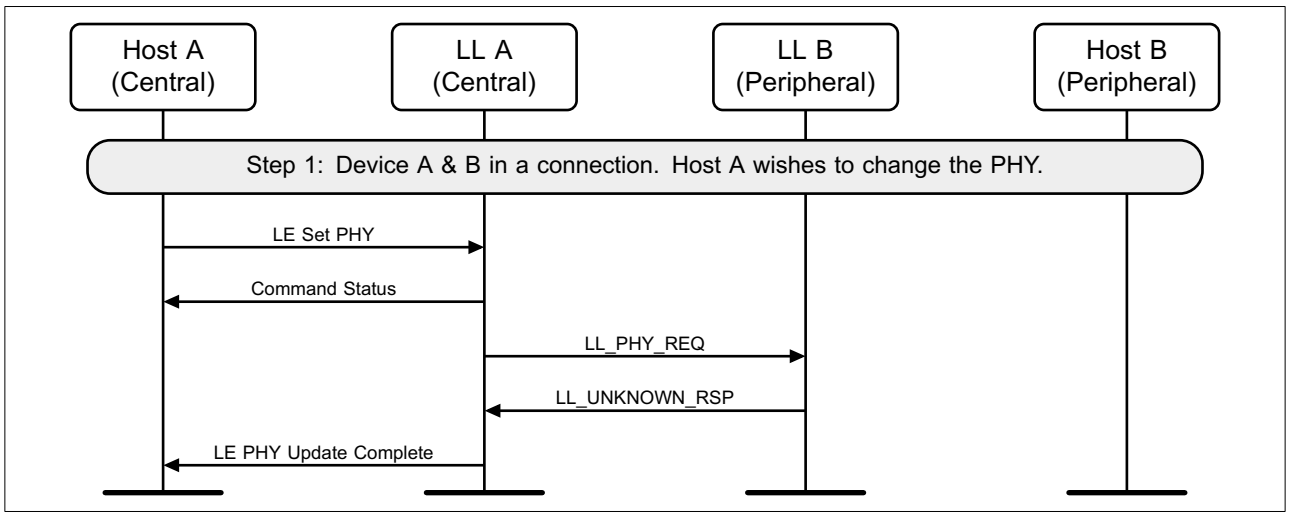

Figure 6.33: Central-initiated PHY Update procedure – Central requests a change of PHY, Peripheral does not support the feature

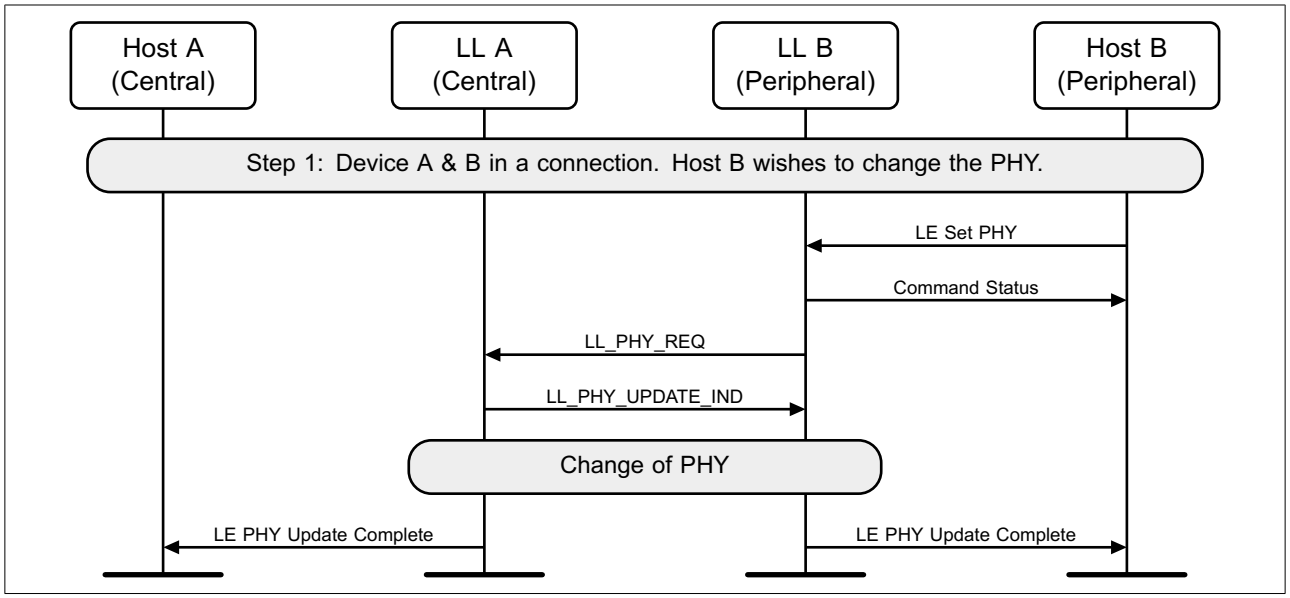

Figure 6.34: Peripheral-initiated PHY Update procedure – Peripheral requests a change of PHY, PHY changed in at least one direction

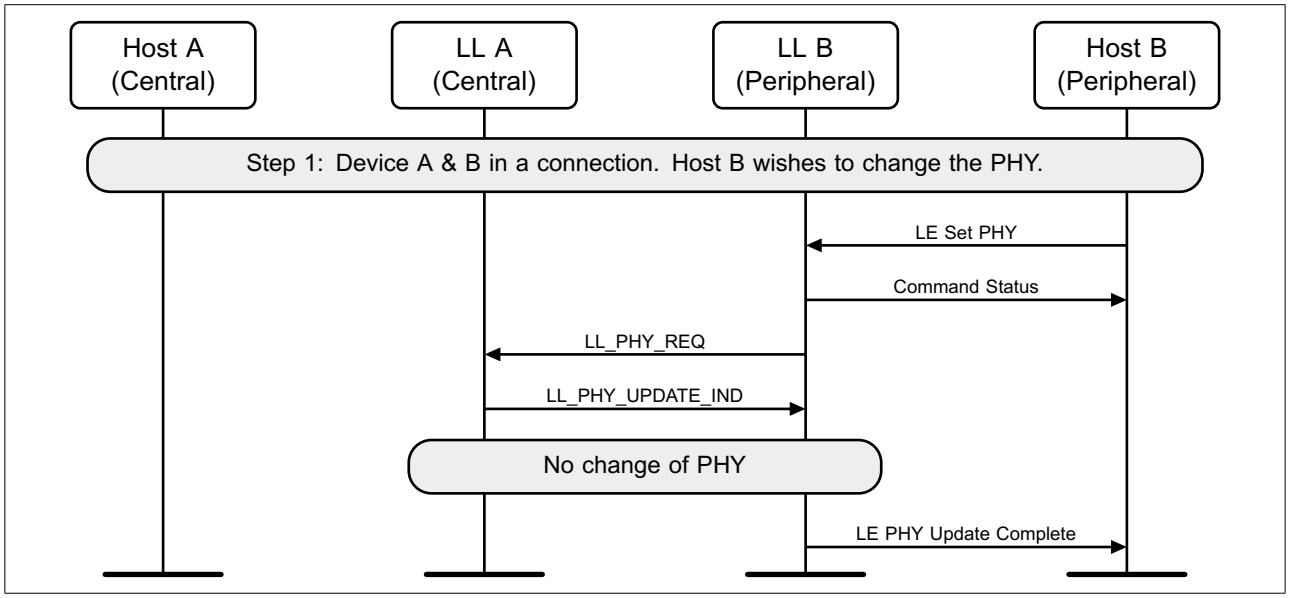

Figure 6.35: Peripheral-initiated PHY Update procedure – PHY not changed (either because Peripheral doesn't specify PHYs that the Central prefers, or because the Central concludes that the current PHYs are still best)

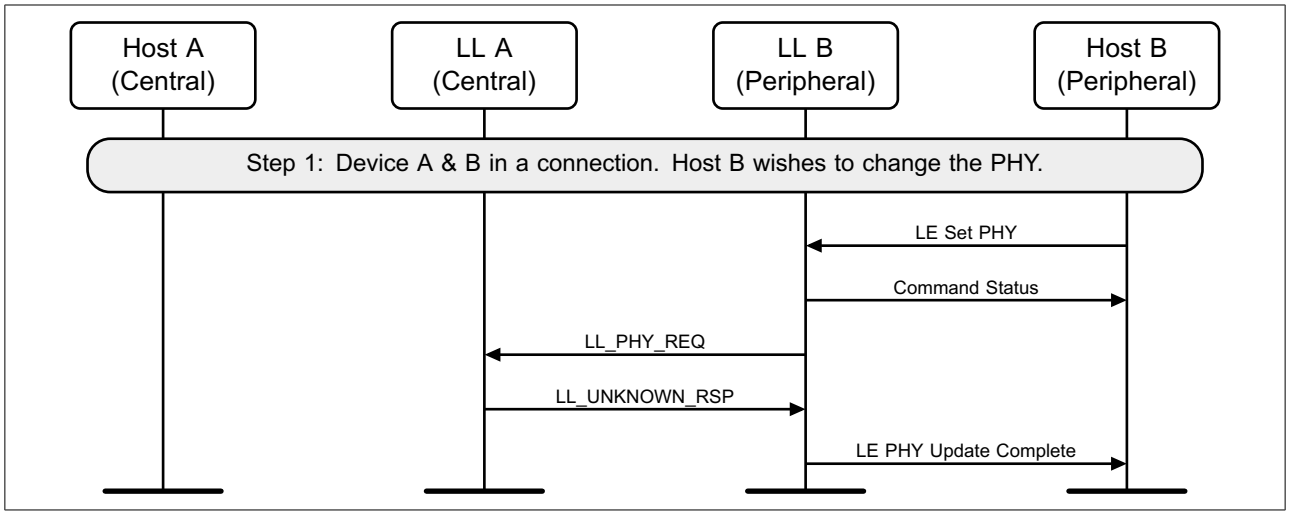

Figure 6.36: Peripheral-initiated PHY Update procedure – Peripheral requests a change of PHY, Central does not support the feature

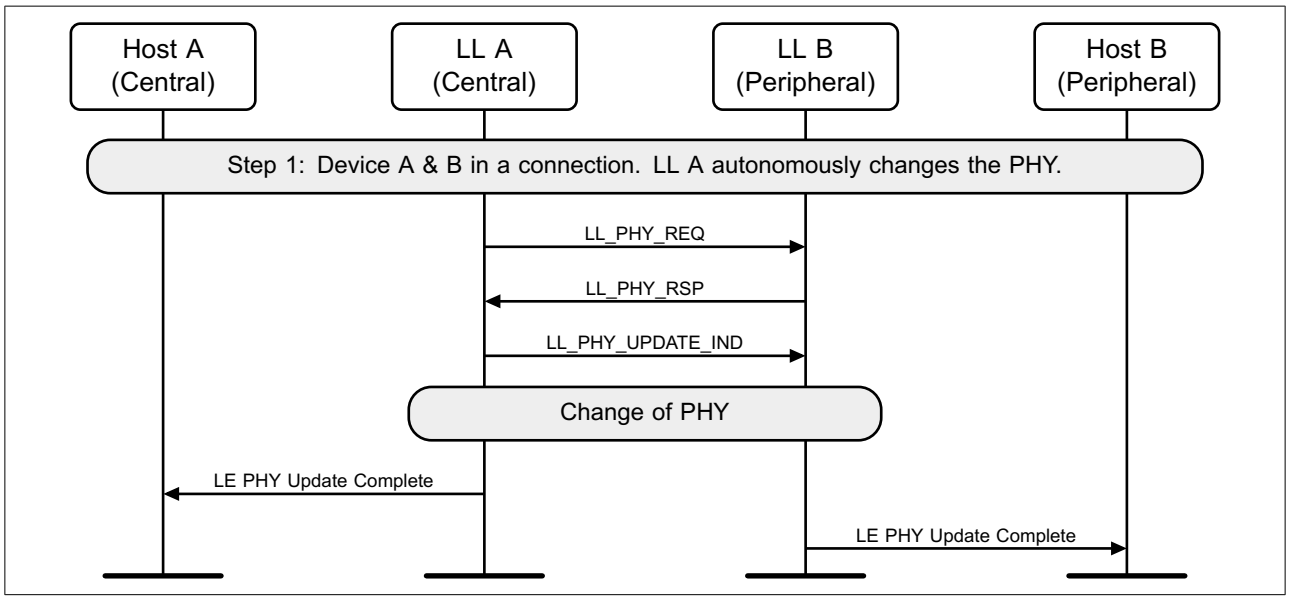

Figure 6.37: Autonomous Central-initiated PHY Update procedure – Central requests a change of PHY, Peripheral accepts, PHY changed in at least one direction

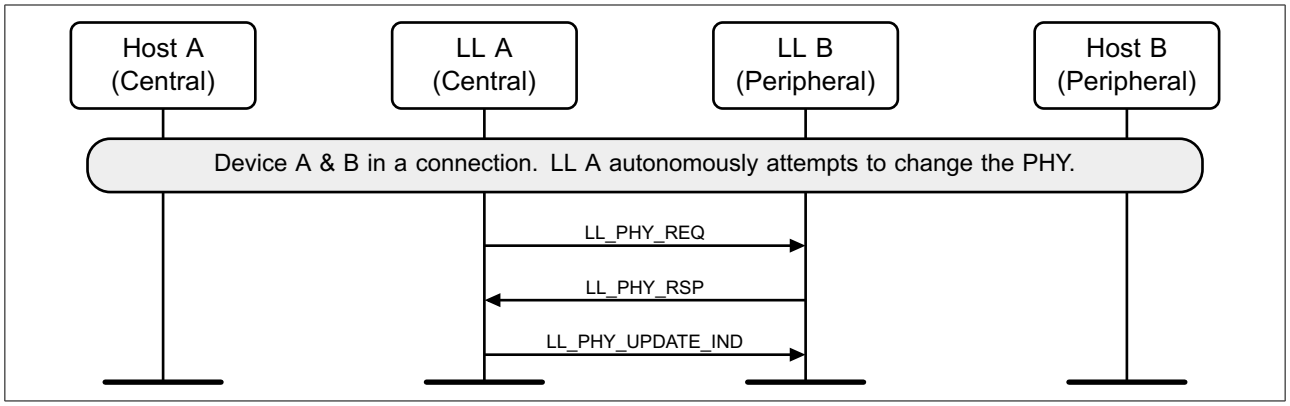

Figure 6.38: Autonomous Central-initiated PHY Update procedure – Central requests a change of PHY, PHY not changed (either because Peripheral doesn't specify PHYs that the Central prefers, or because the Central concludes that the current PHYs are still best)

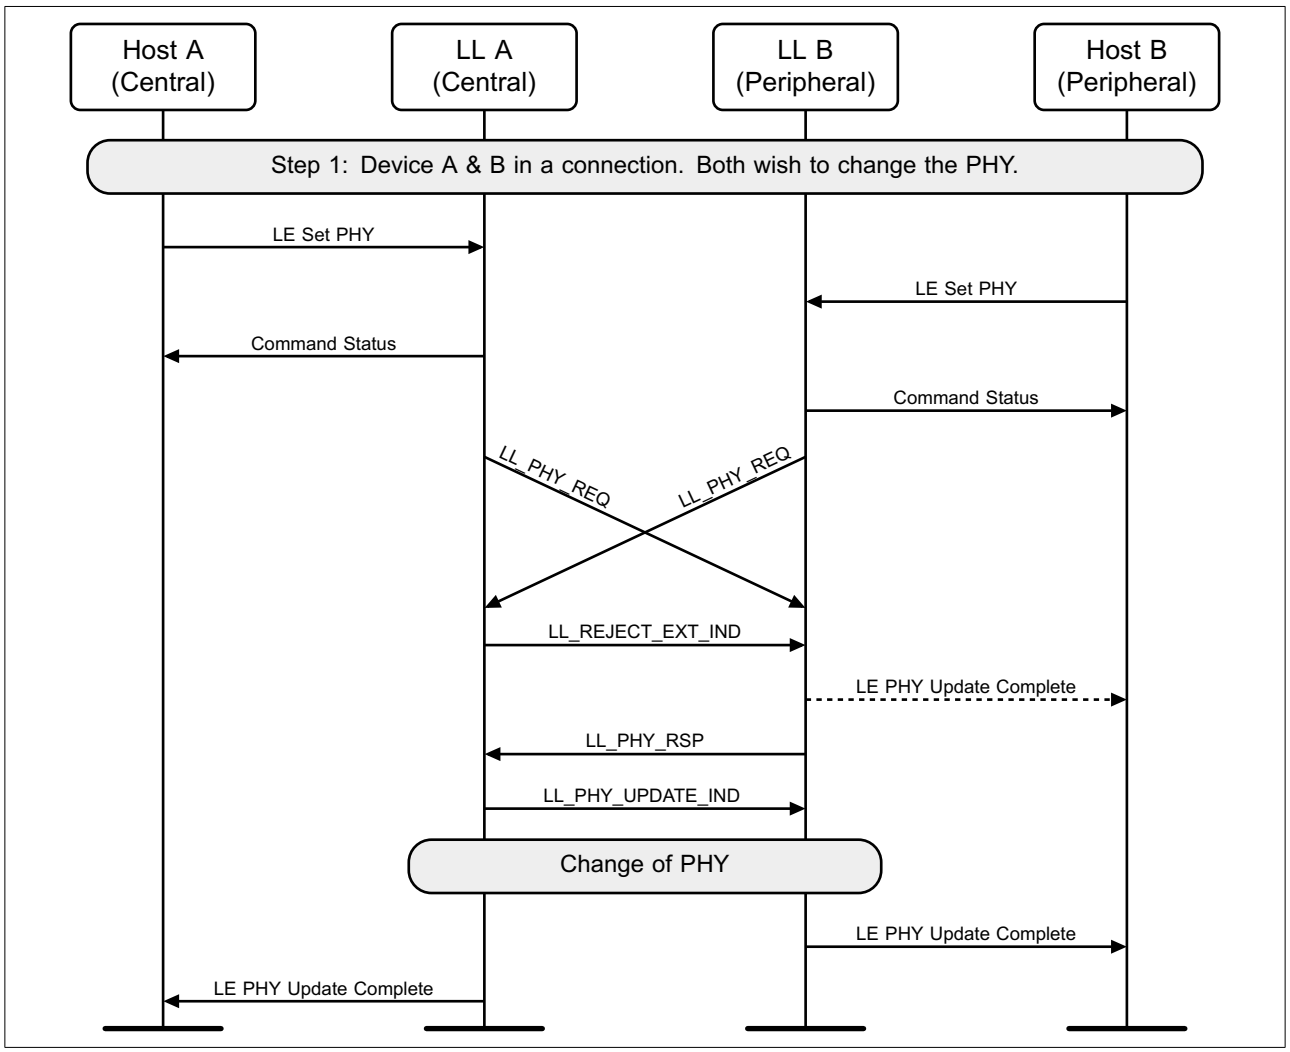

Figure 6.39: Central and Peripheral crossover PHY Update procedure – Central and Peripheral request a change of PHY concurrently

6.16 Minimum number of used channels request

Where a Peripheral supports the Minimum Number of Used Channels procedure, it can request that a certain minimum number of channels be used on the indicated PHY. The example shows a successful request, resulting in a channel map update with the requested minimum number of channels used for the connection.

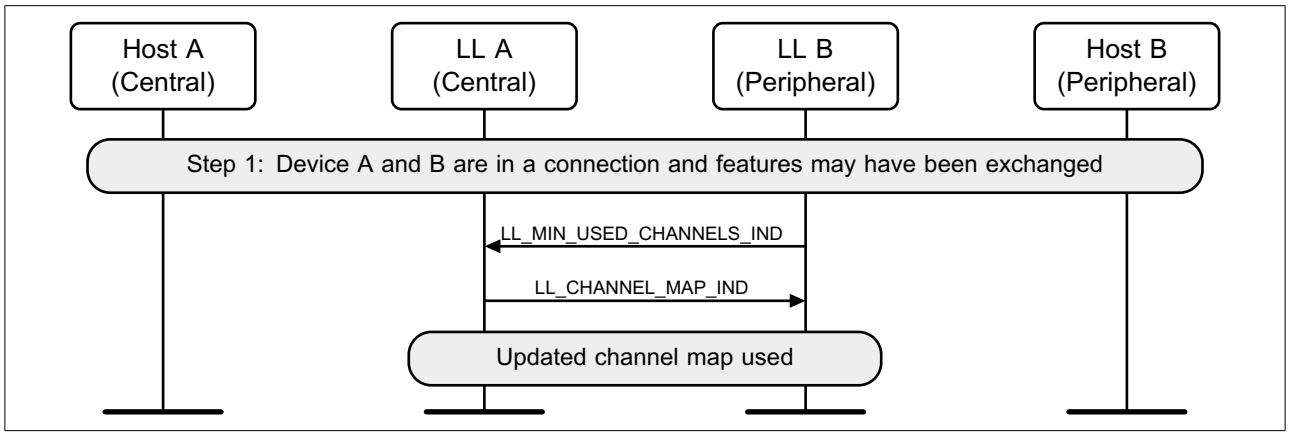

Figure 6.40: Requesting minimum number of used channels

6.17 LL procedure collision

The Link Layers of both the Central and Peripheral may initiate the same LL procedure at the same time.

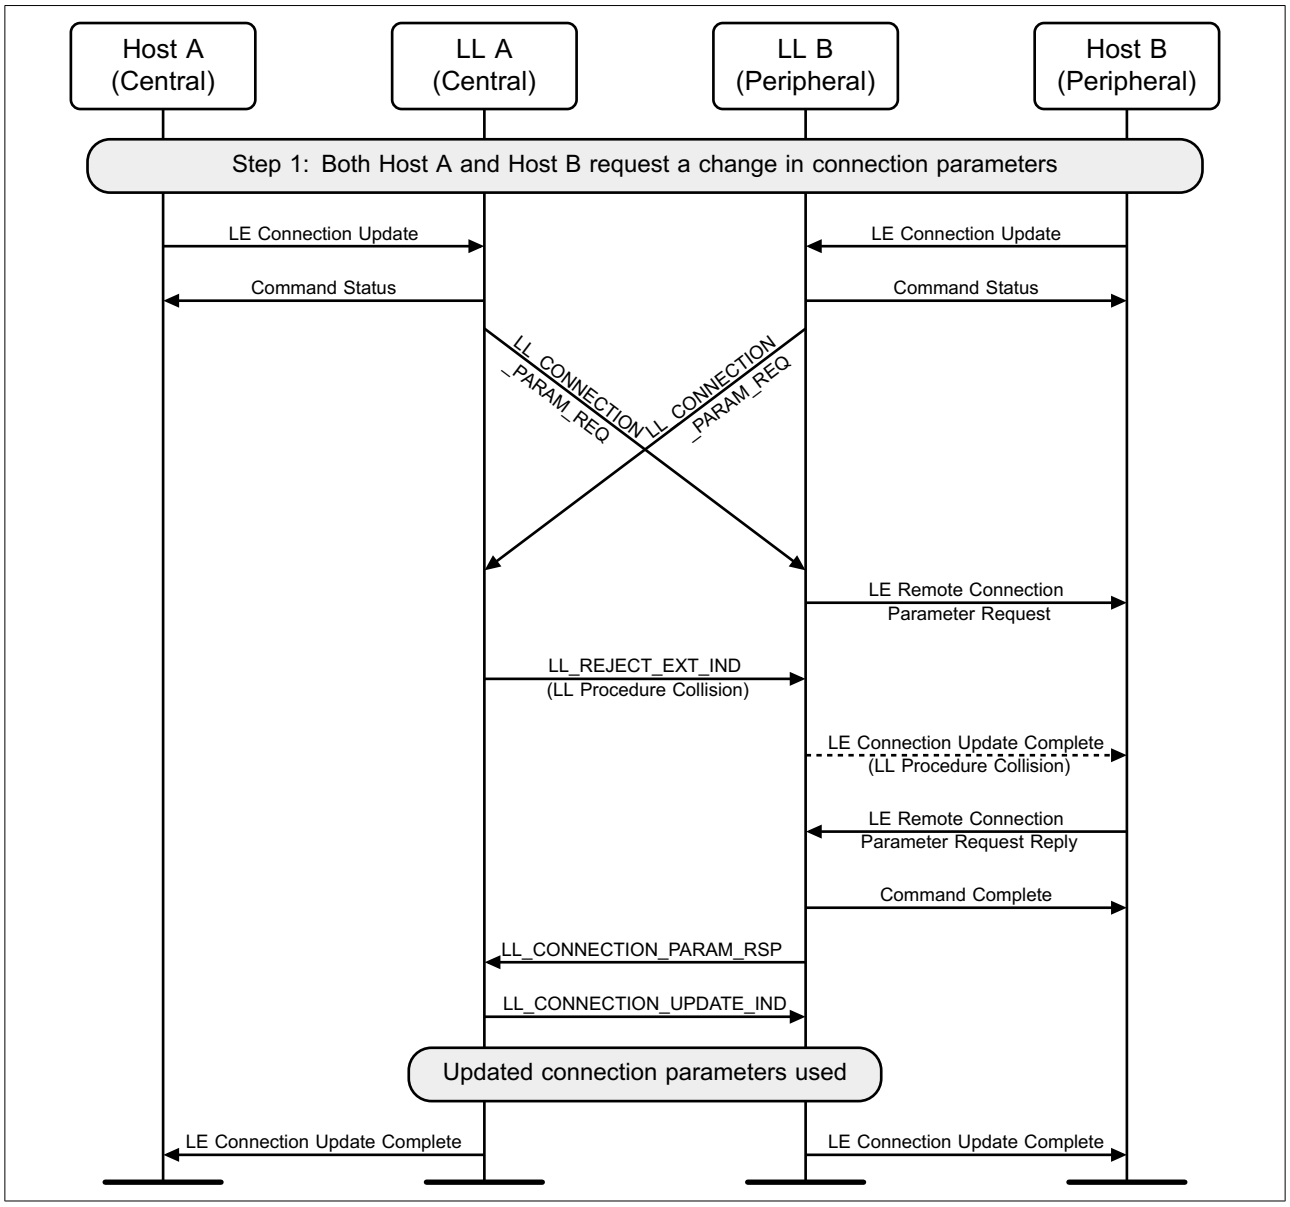

Figure 6.41: LL procedure collision

6.18 Constant Tone Extension Request

The Central or Peripheral of the connection may request the remote device to send an LL_CTE_RSP PDU with a Constant Tone Extension (see Figure 6.42 to Figure 6.44).

The sequence of events shown in figure 6.40 can only happen before feature exchange and can only happen once per connection, because a Link Layer must not use a

procedure that it knows the peer does not support as required by [Vol 6] Part B, Section 4.6.

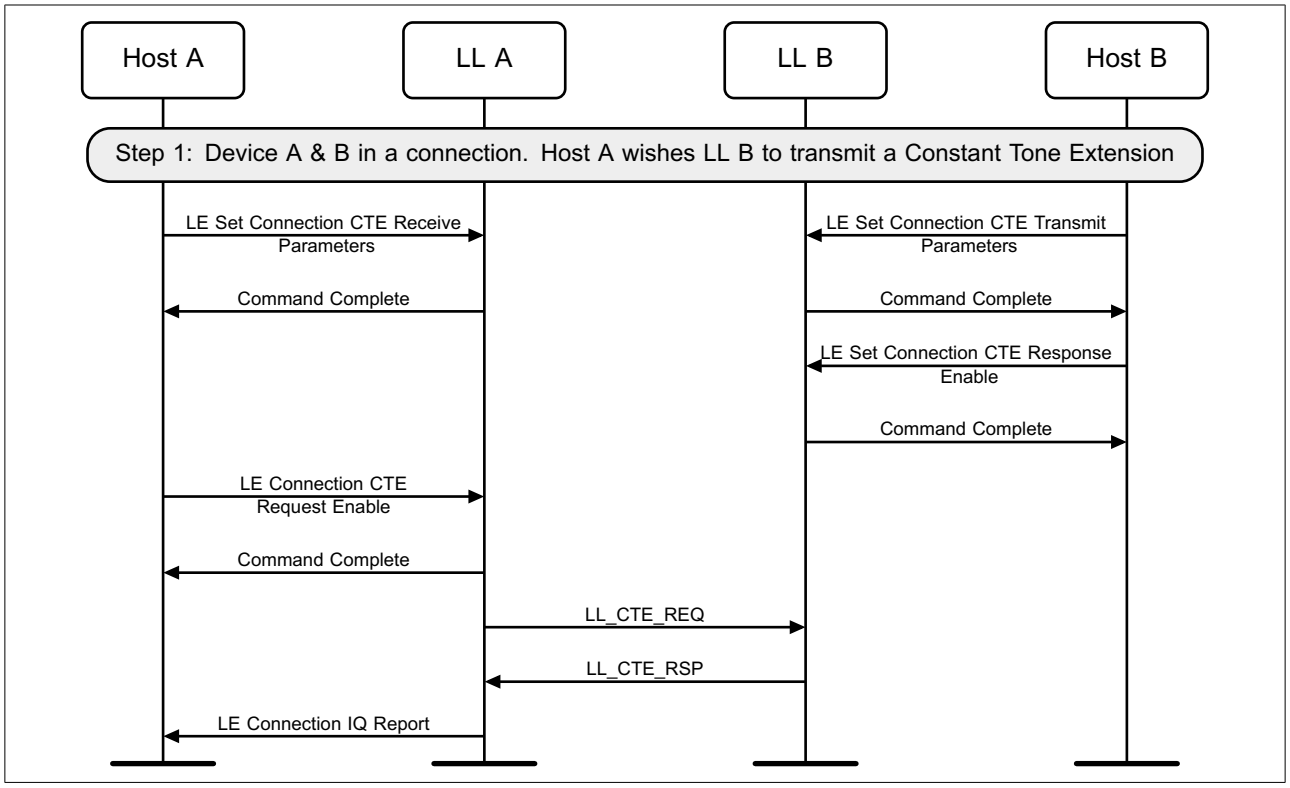

Figure 6.42: Central or Peripheral-initiated Constant Tone Extension Request procedure – remote device responds successfully

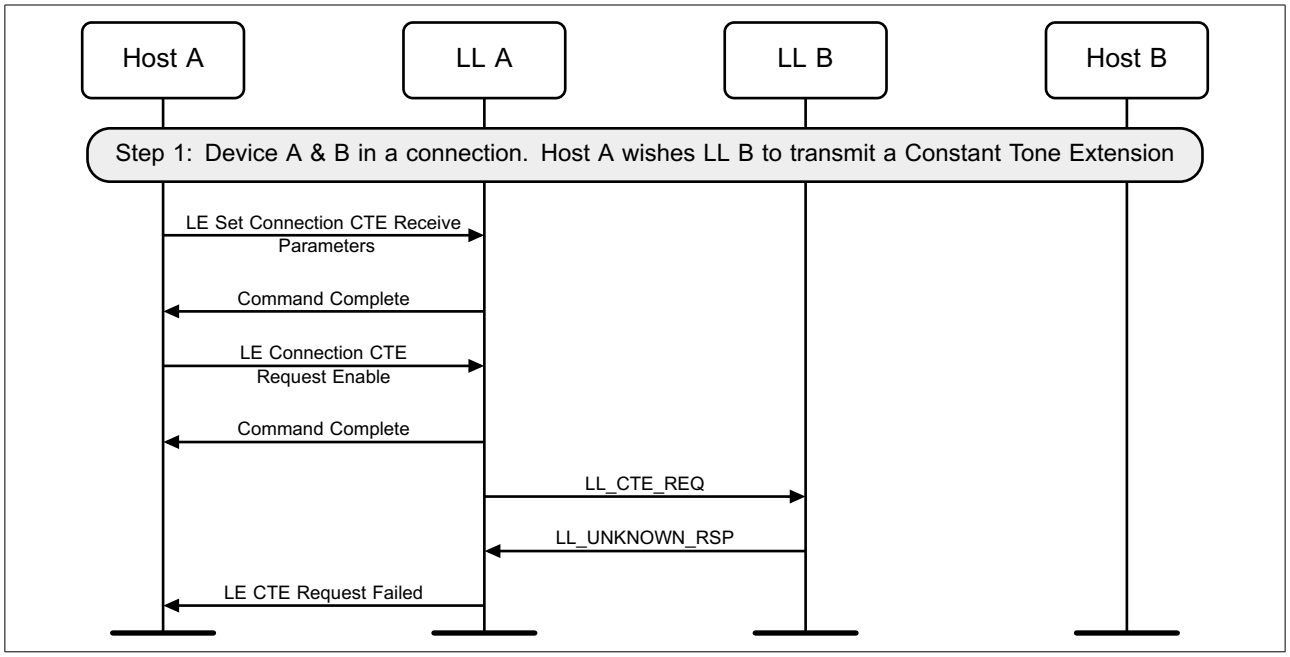

Figure 6.43: Central or Peripheral-initiated Constant Tone Extension Request procedure – remote device does not support the feature

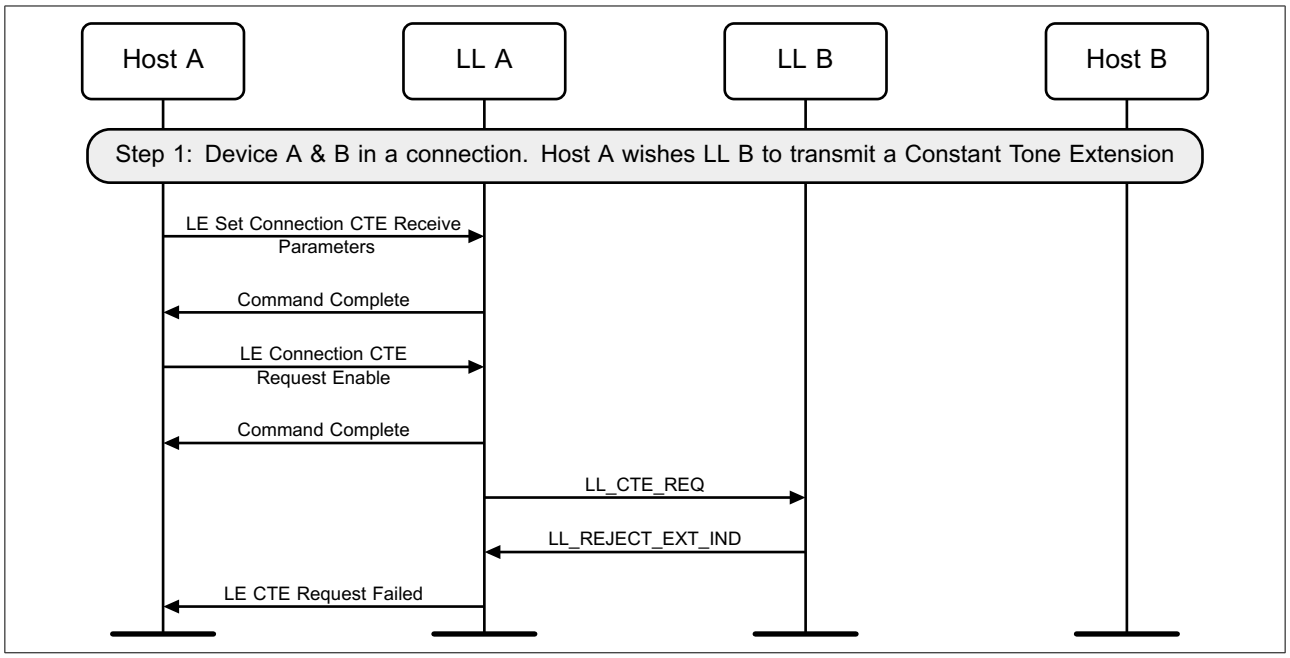

Figure 6.44: Central or Peripheral-initiated Constant Tone Extension Request procedure – remote device rejects

6.19 Connected Isochronous Group Setup

A Central sets up a CIG with parameters for one or more CISes, then establishes a CIS with a Peripheral (see Figure 6.45).

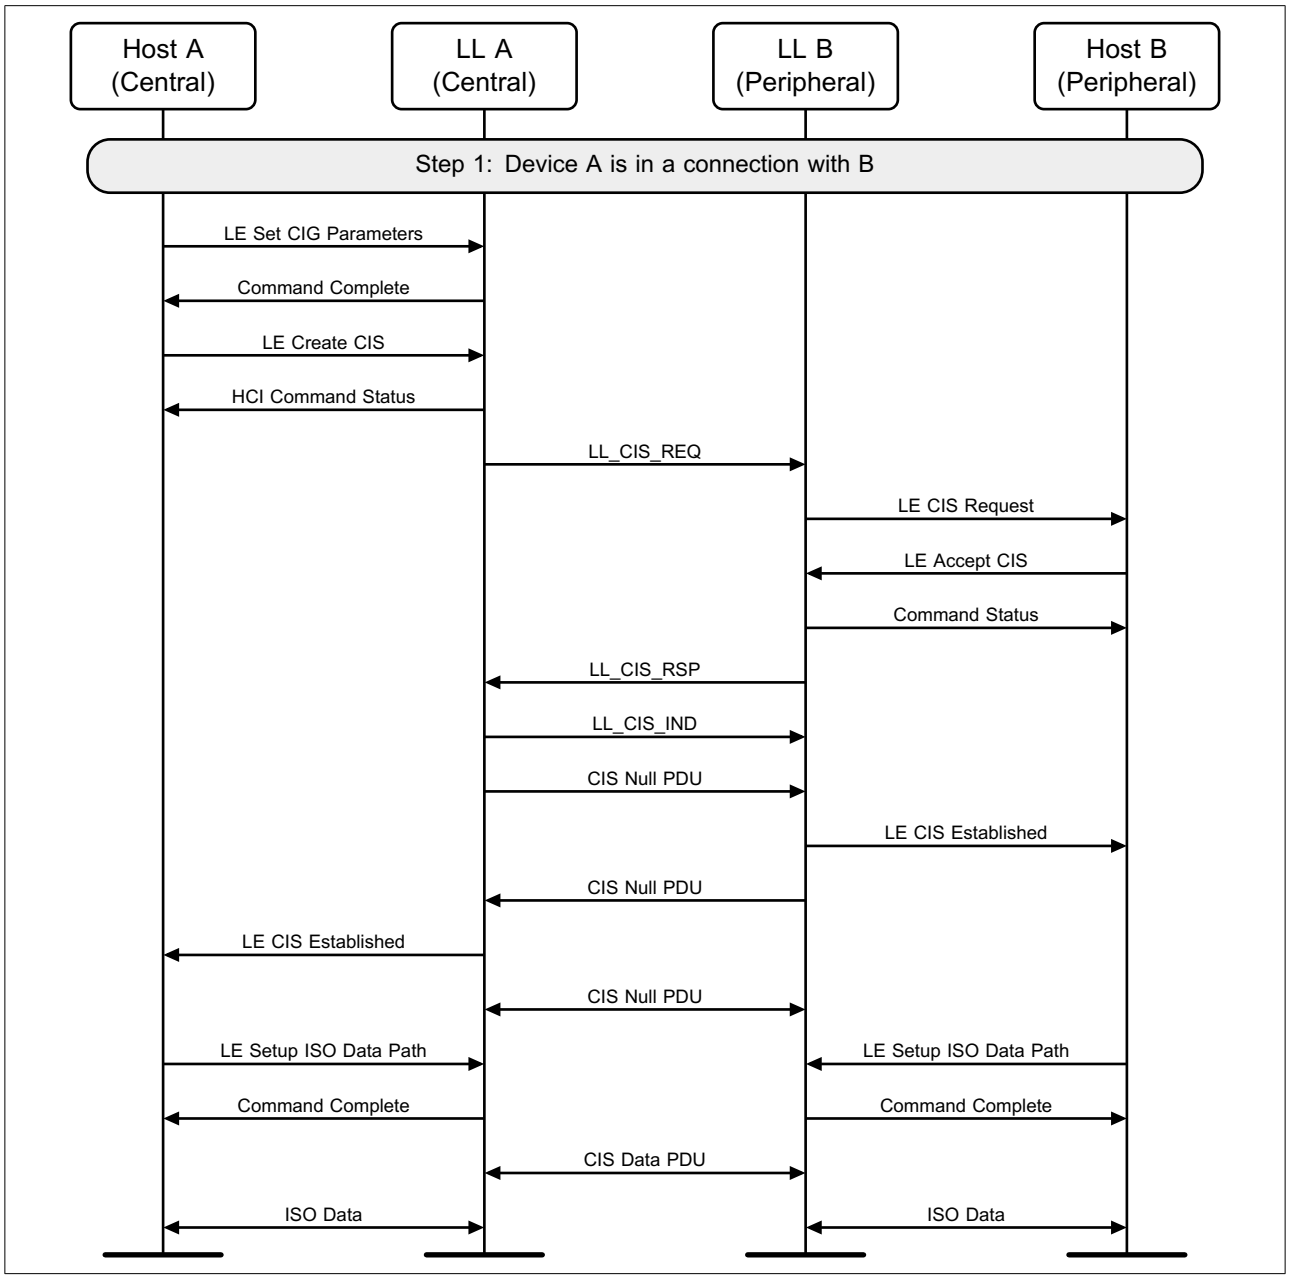

Figure 6.45: Device A establishes a CIS with a Peripheral

A Central sets up CIG parameters and establishes a CIS with two Peripherals (see Figure 6.46).

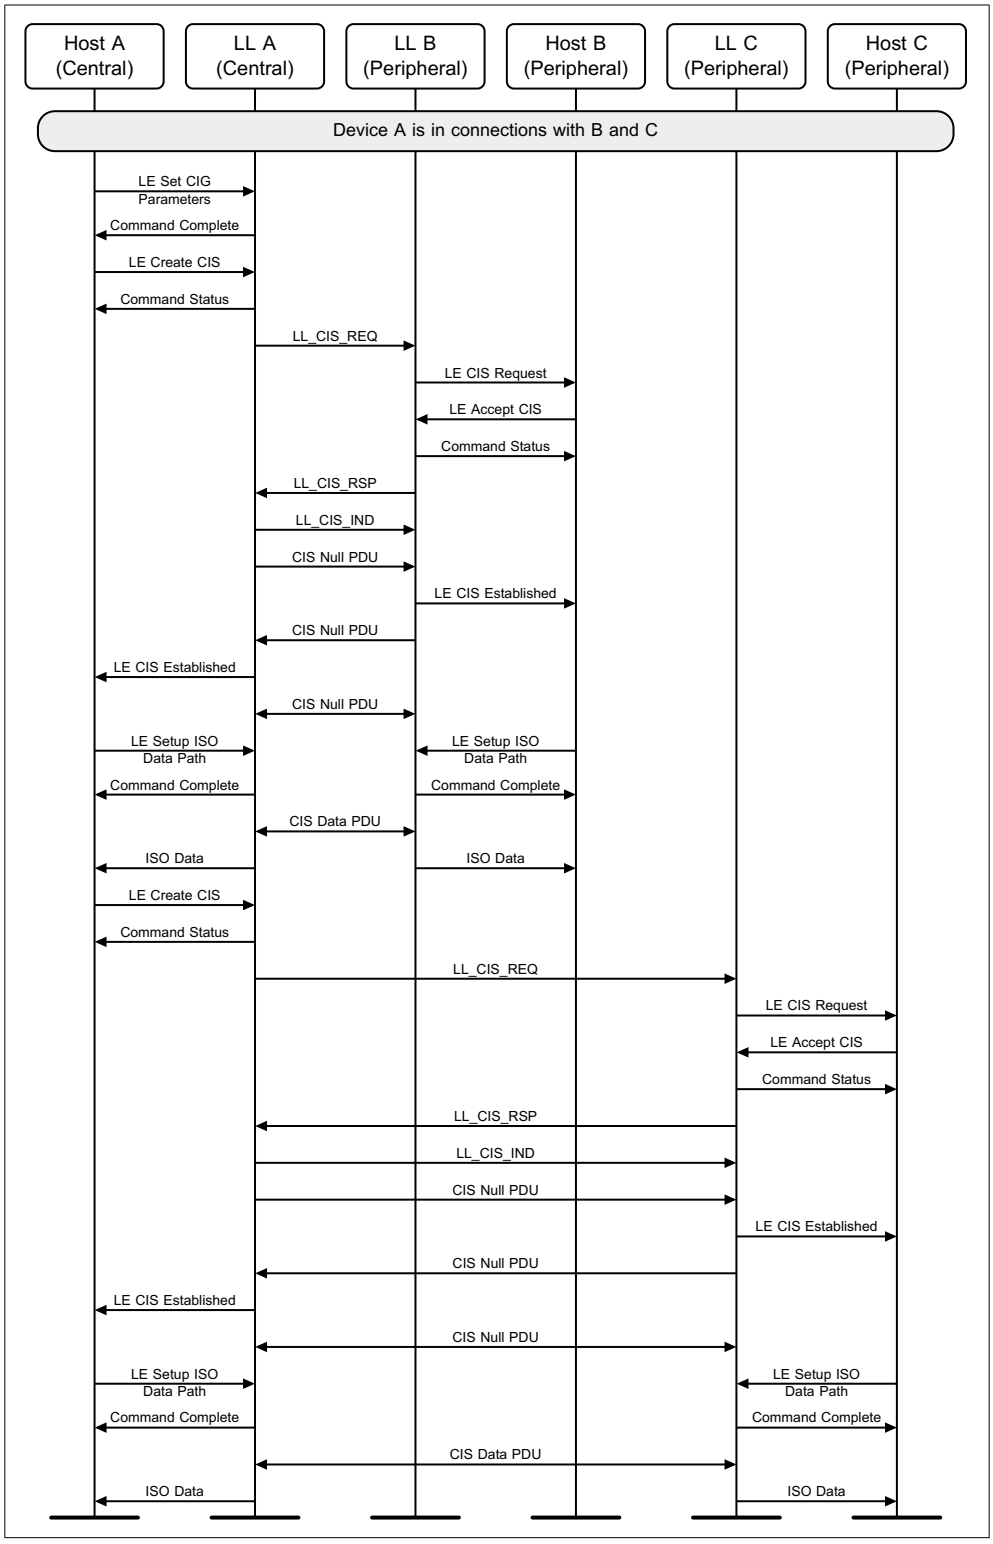

Figure 6.46: Device A establishes CISes with two Peripherals

6.20 Host Rejects Connected Isochronous Stream

The Peripheral's Host rejects the request to establish a CIS with the Central (see Figure 6.47).

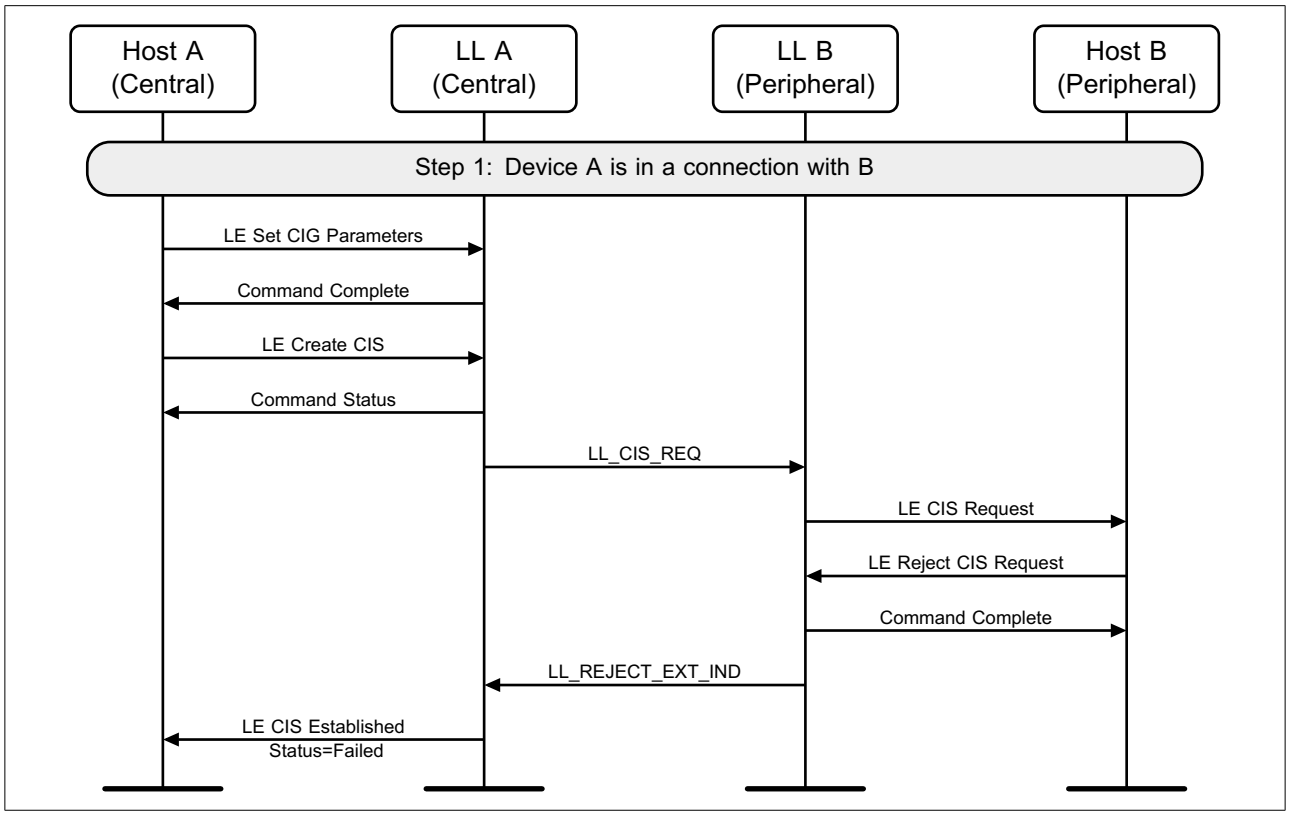

Figure 6.47: The Host in Device B rejects a CIS from Device A

While setting up CISes with two Peripherals, the Host of one of the Peripherals rejects the request to establish a CIS with the Central (see Figure 6.48).

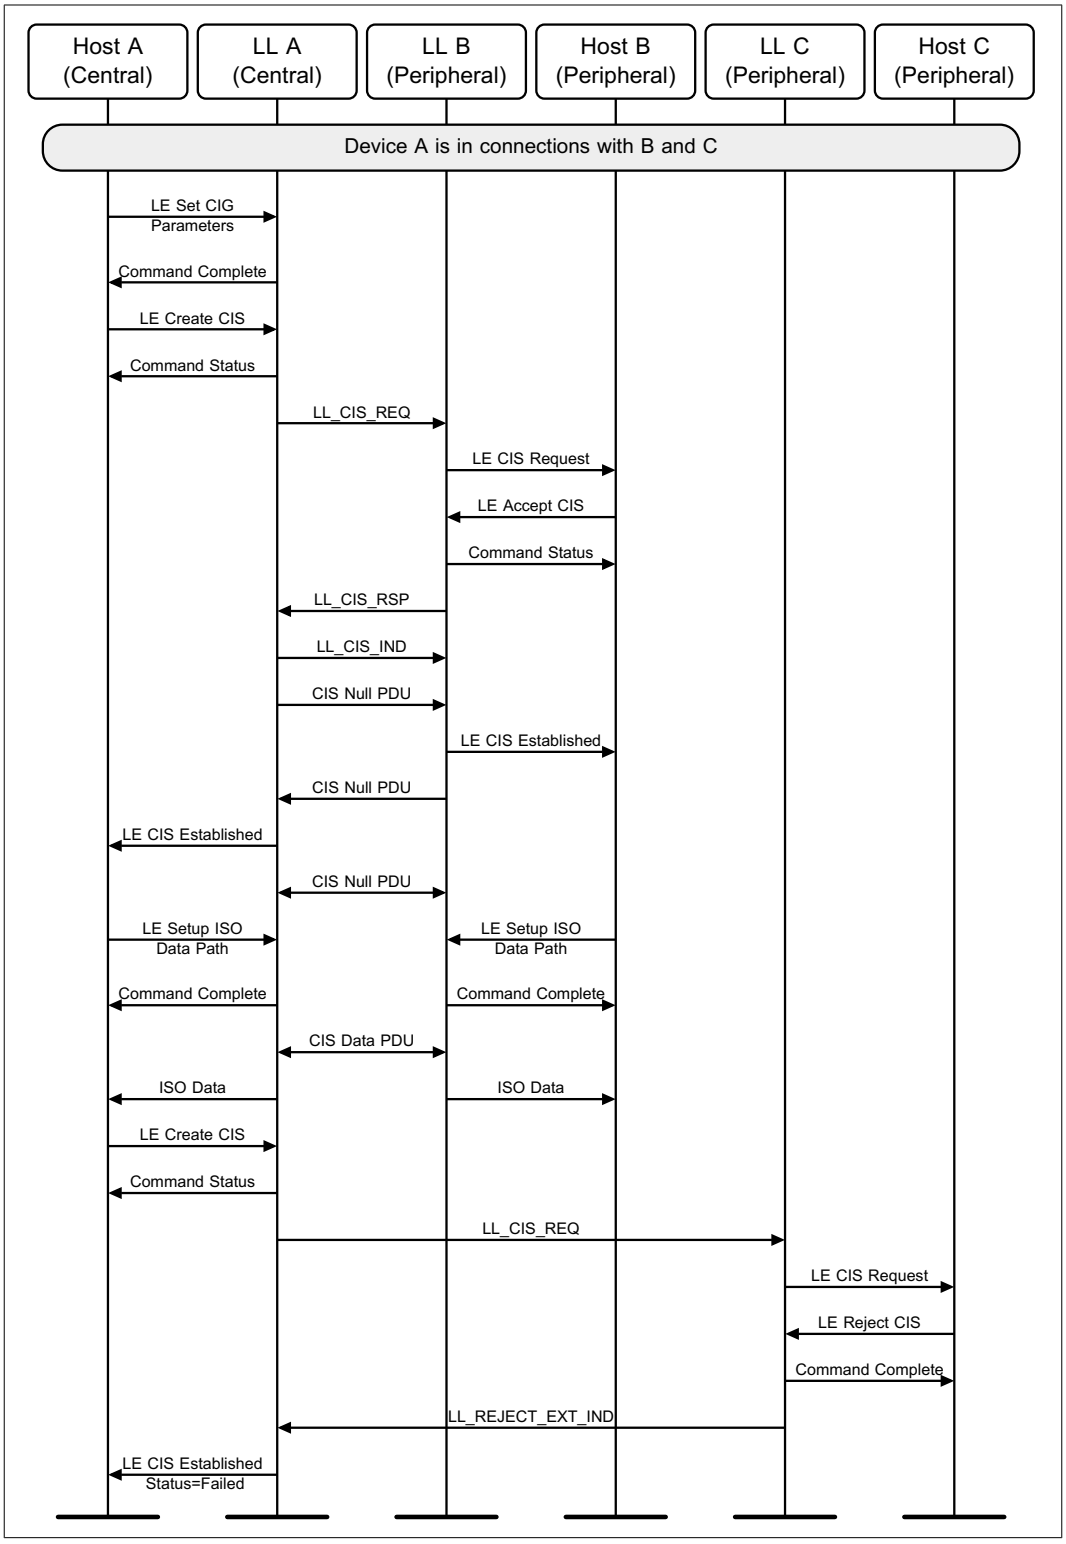

Figure 6.48: The Host in Device C rejects a CIS from Device A

6.21 Link Layer Rejects Connected Isochronous Stream

The Link Layer of the Peripheral rejects the request to establish a CIS with a Central (see Figure 6.49).

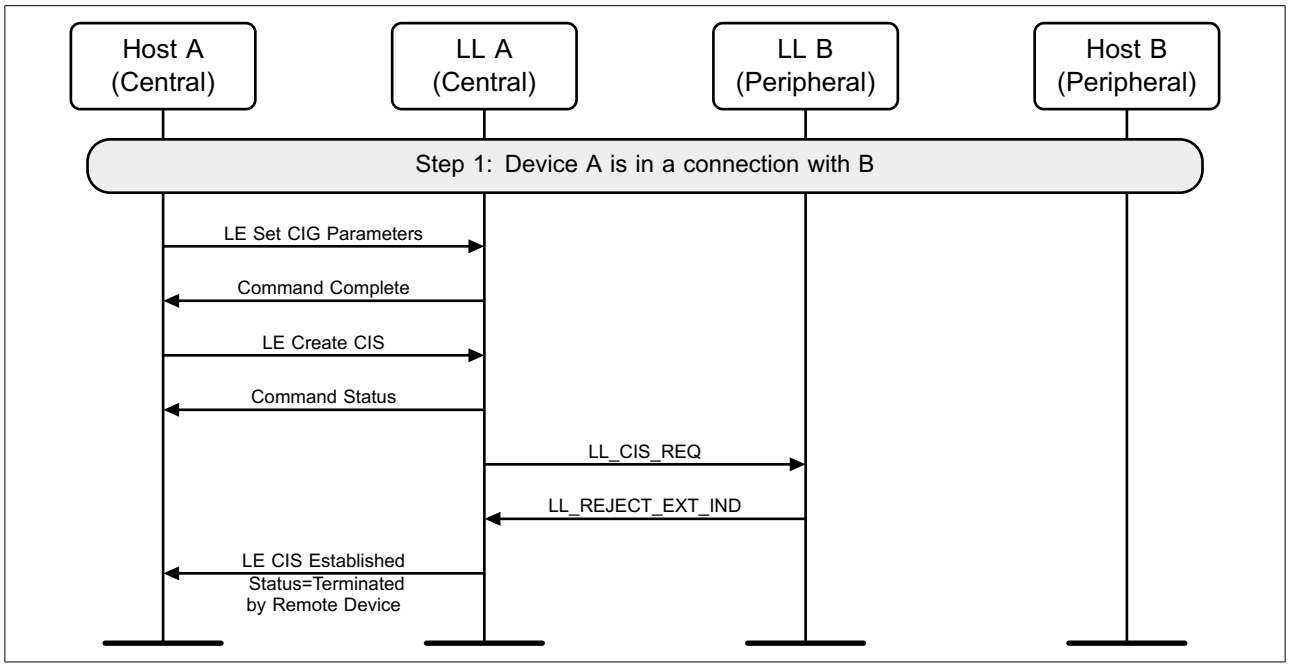

Figure 6.49: The Link Layer in Device B rejects a CIS request from Device A

While setting up CISes with two Peripherals, the Link Layer of one of the Peripherals rejects the request to establish a CIS with the Central (see Figure 6.50).

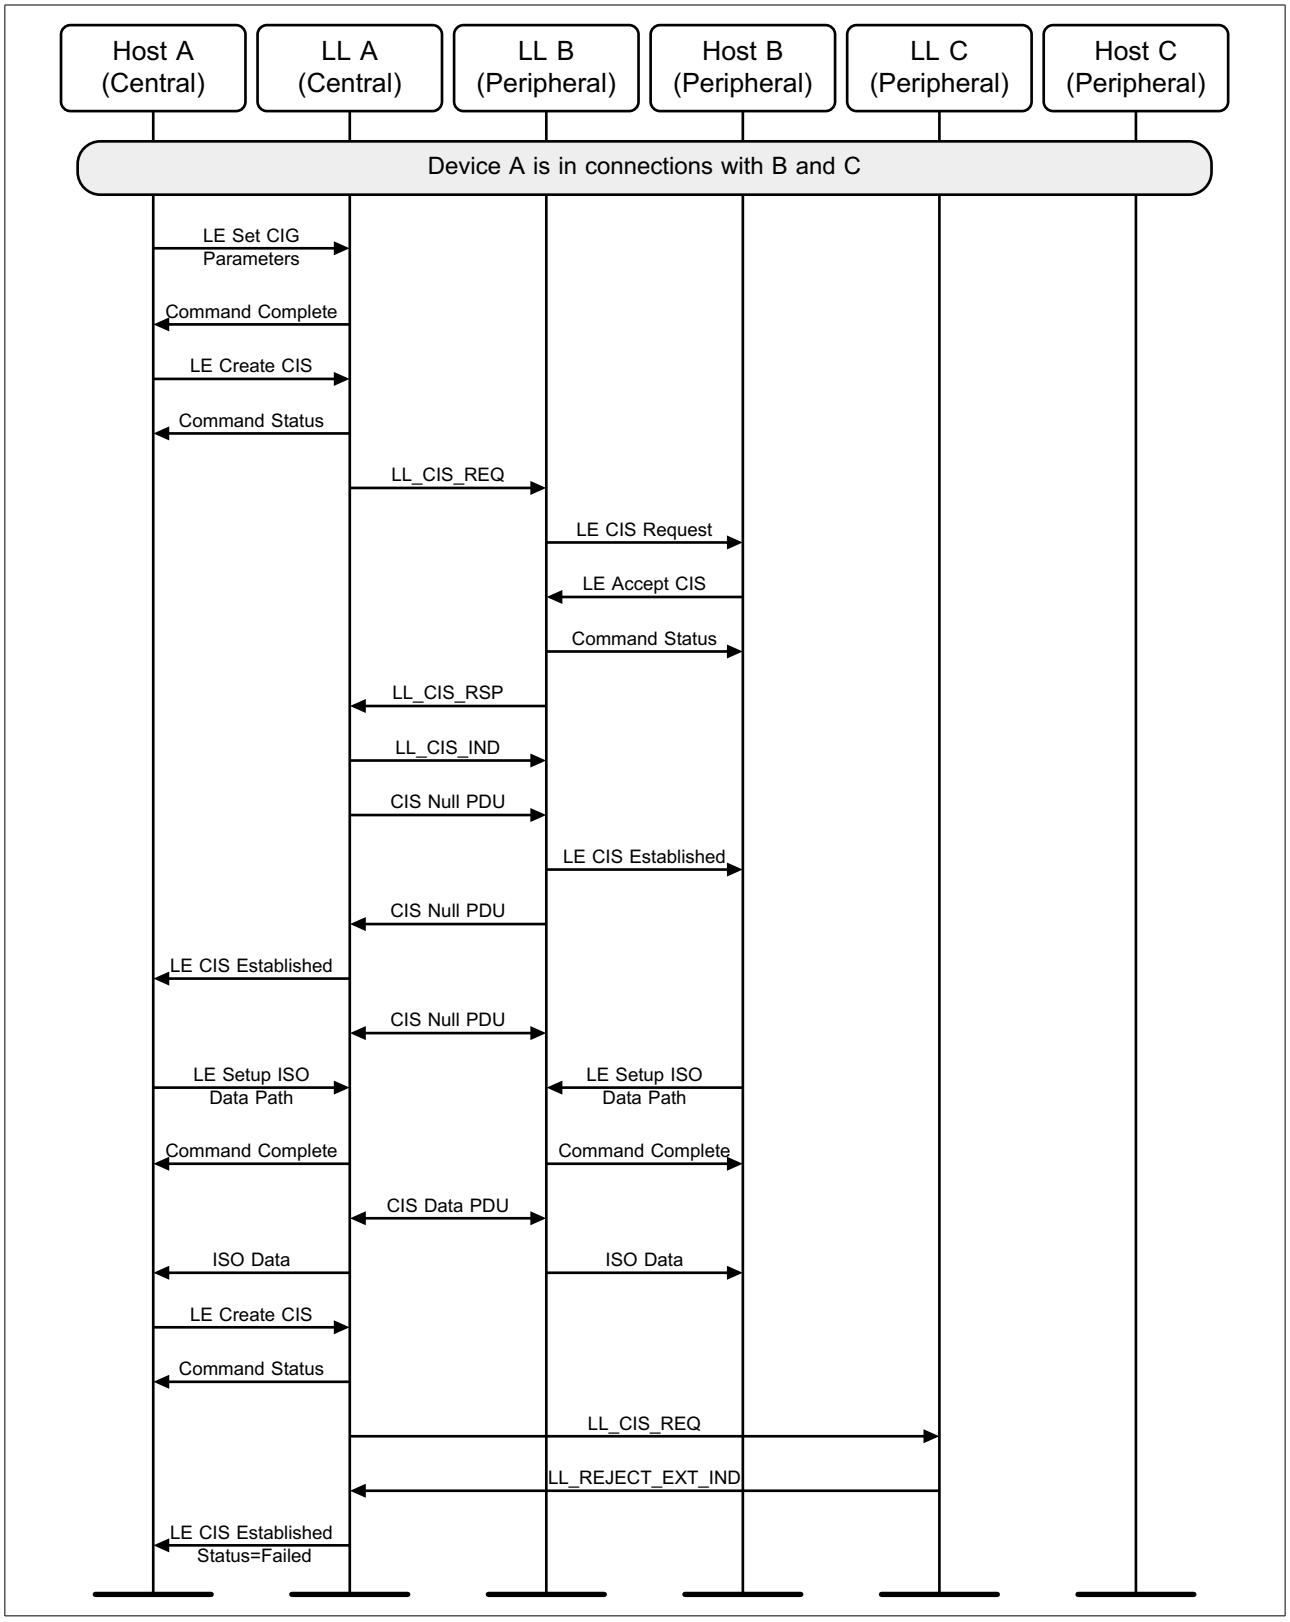

Figure 6.50: The Link Layer in Device C rejects a CIS from Device A

6.22 Link Layer Rejects Connected Isochronous Stream

The Link Layer of the Central rejects the request to create a CIS (see Figure 6.51).

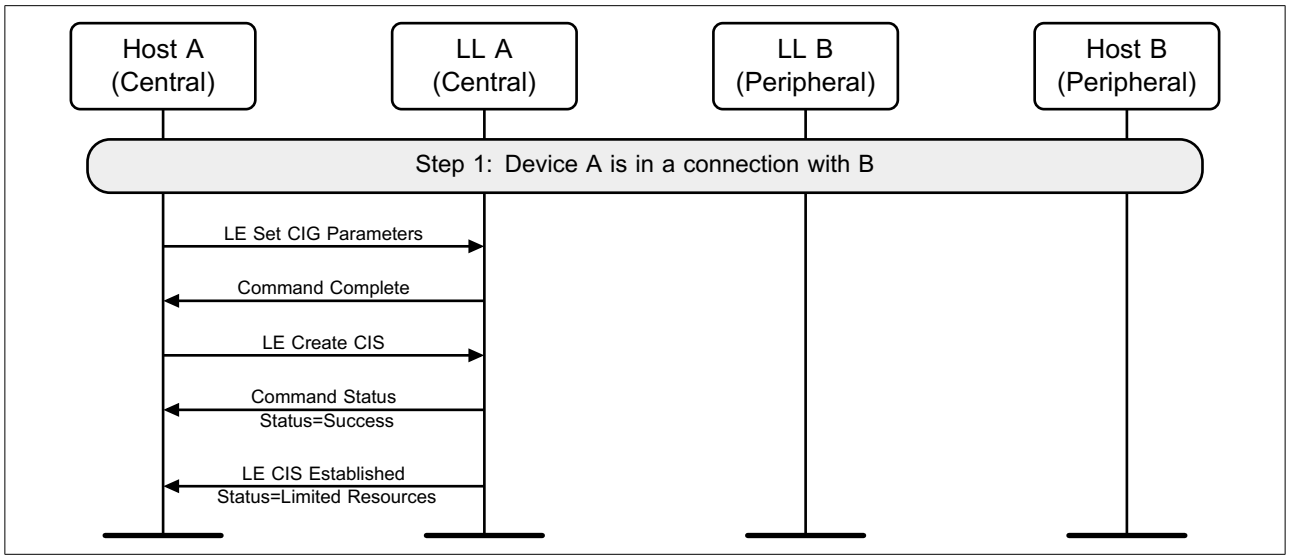

Figure 6.51: Link Layer in Device A rejects a request to create a CIS

6.23 Host A Terminates Connected Isochronous Stream

The Host of the Central terminates a Connected Isochronous Stream (see Figure 6.52). Either A or B can be the Central.

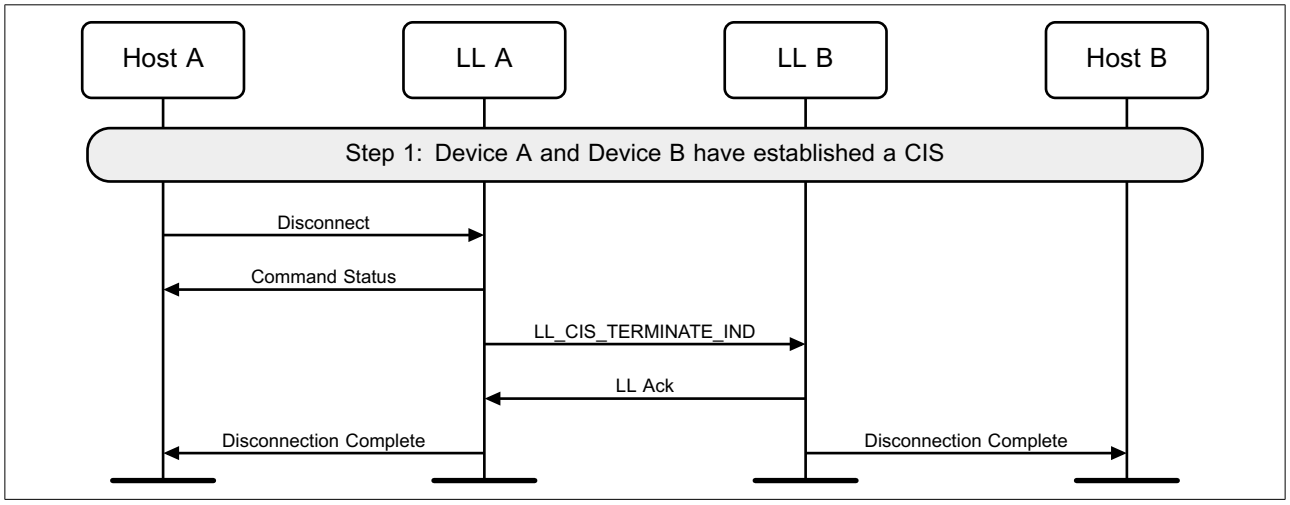

Figure 6.52: Device A terminates an established CIS

The Host of device A, which is the Central, terminates a Connected Isochronous Stream either before the Link Layer starts creating that CIS (see Figure 6.53) or during the creation process (see Figure 6.54).

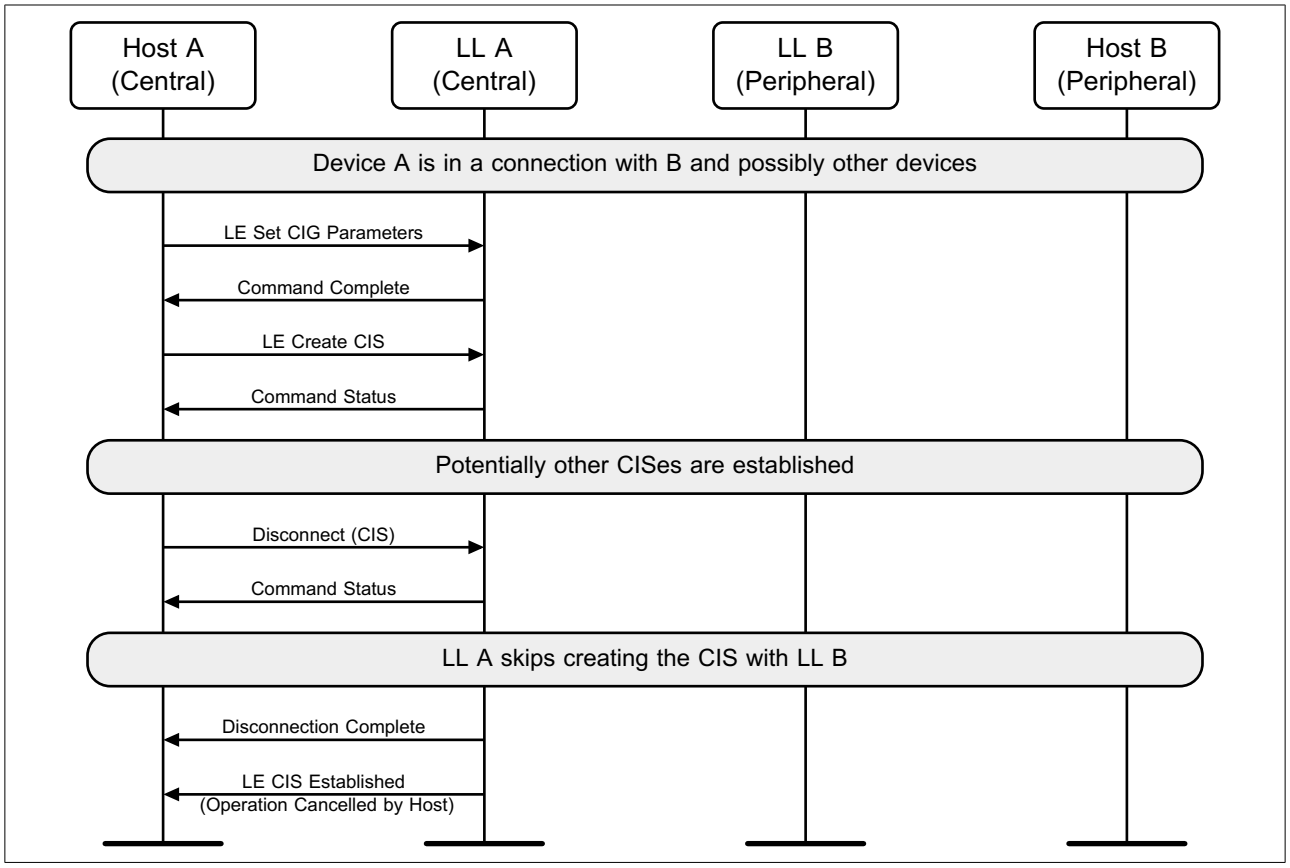

Figure 6.53: Device A terminates a CIS before the Link Layer starts creating it

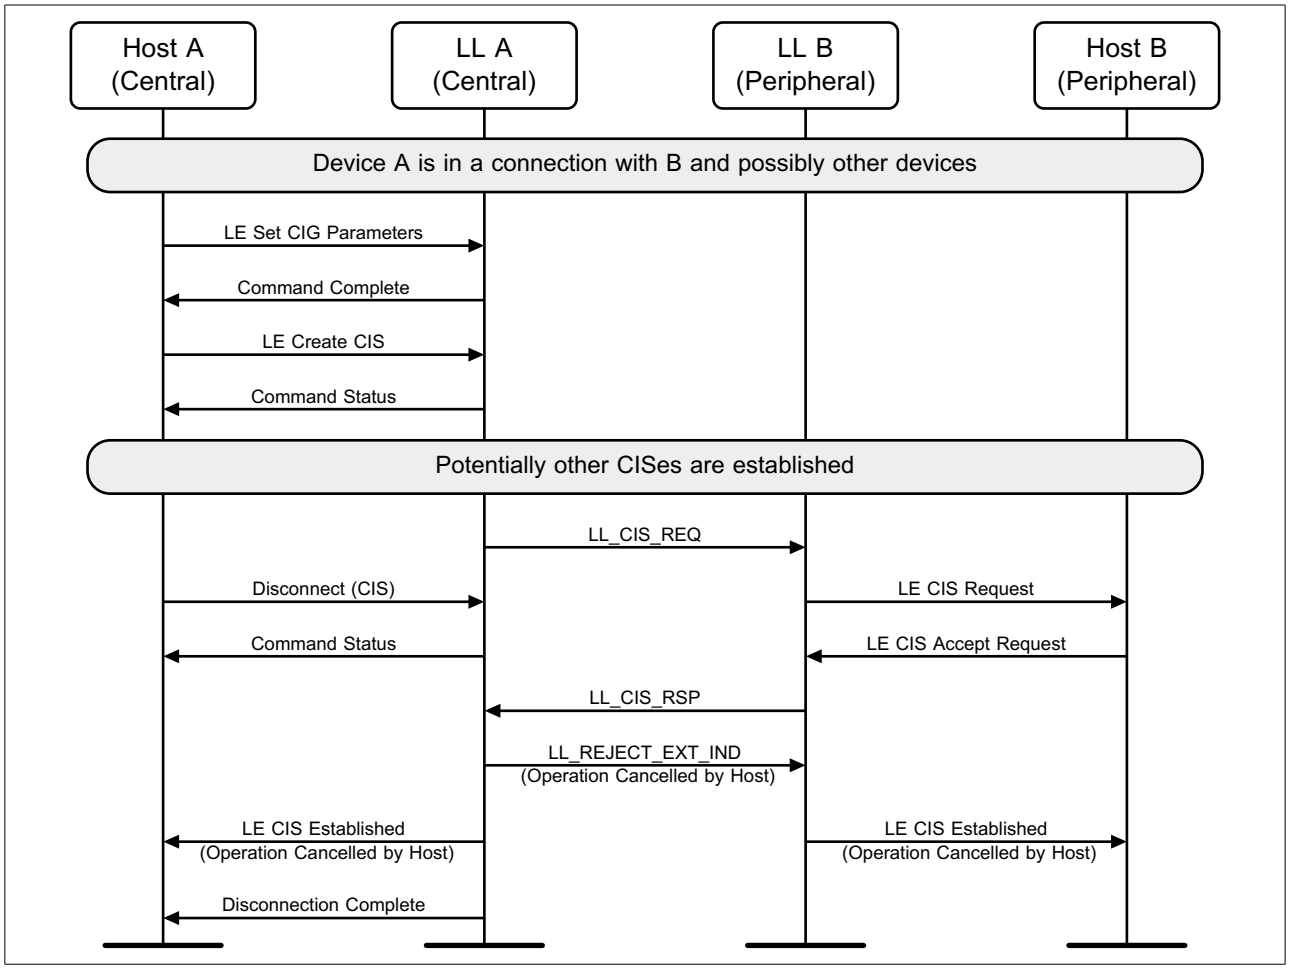

Figure 6.54: Device A terminates a CIS during the creation process

6.24 ACL disconnected

The disconnection of the ACL causes the disconnections of CISes (see Figure 6.55).

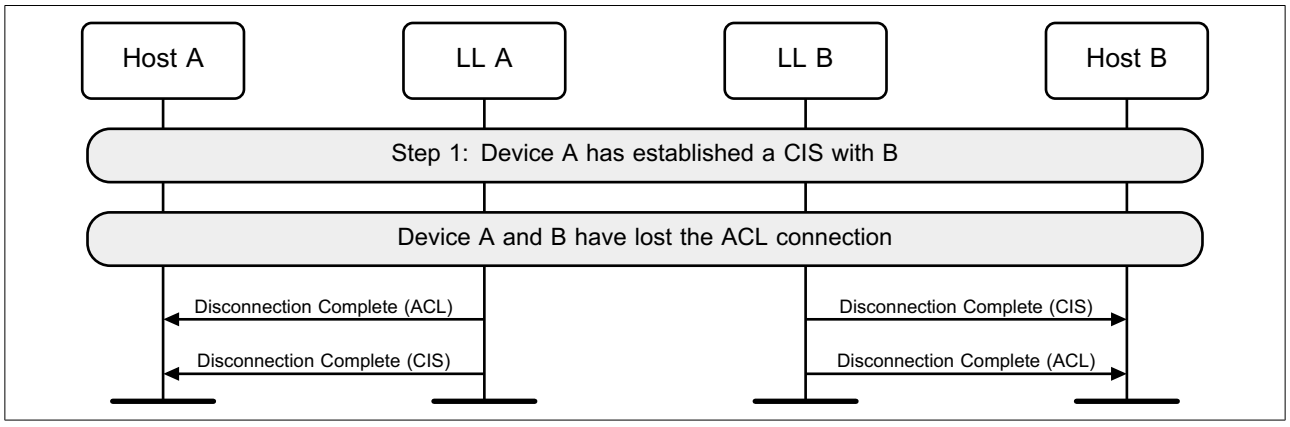

Figure 6.55: ACL connection Terminated

6.25 Host A Removes Connected Isochronous Group

A Host of the Central terminates the CIS and removes the CIG from the Link Layer (see Figure 6.56).

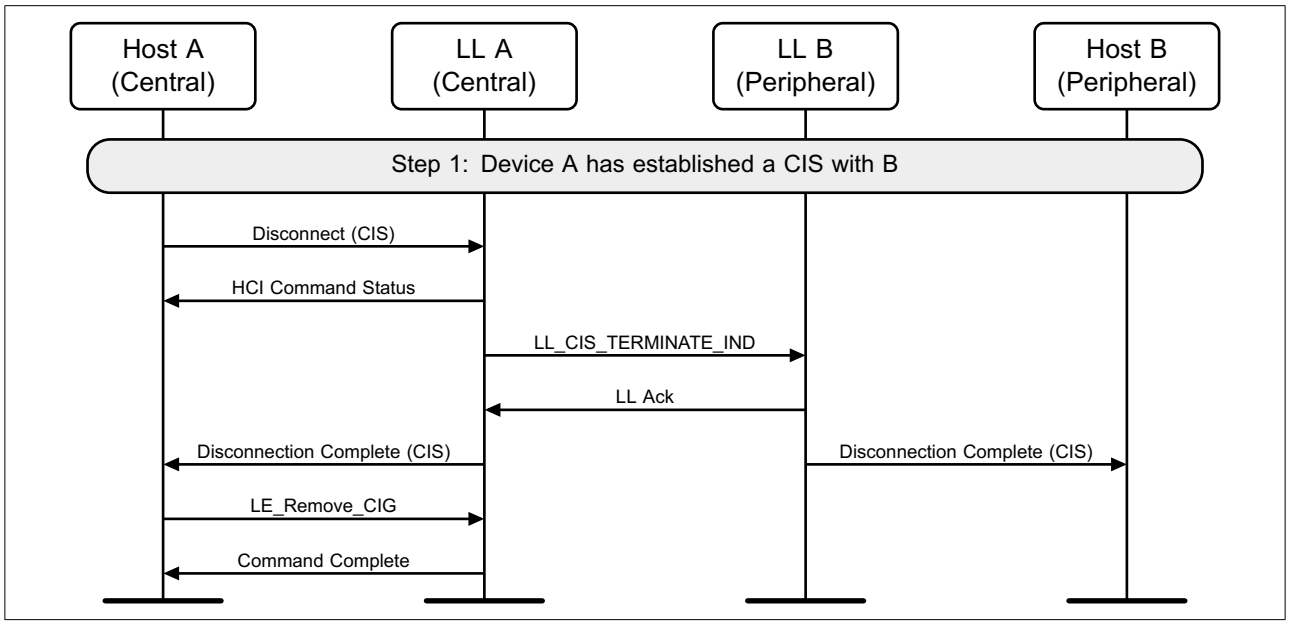

Figure 6.56: Device A terminates a CIS and removes a CIG

The Host of the Central terminates both the CISes in the CIG and removes the CIG from the Controller (see Figure 6.57).

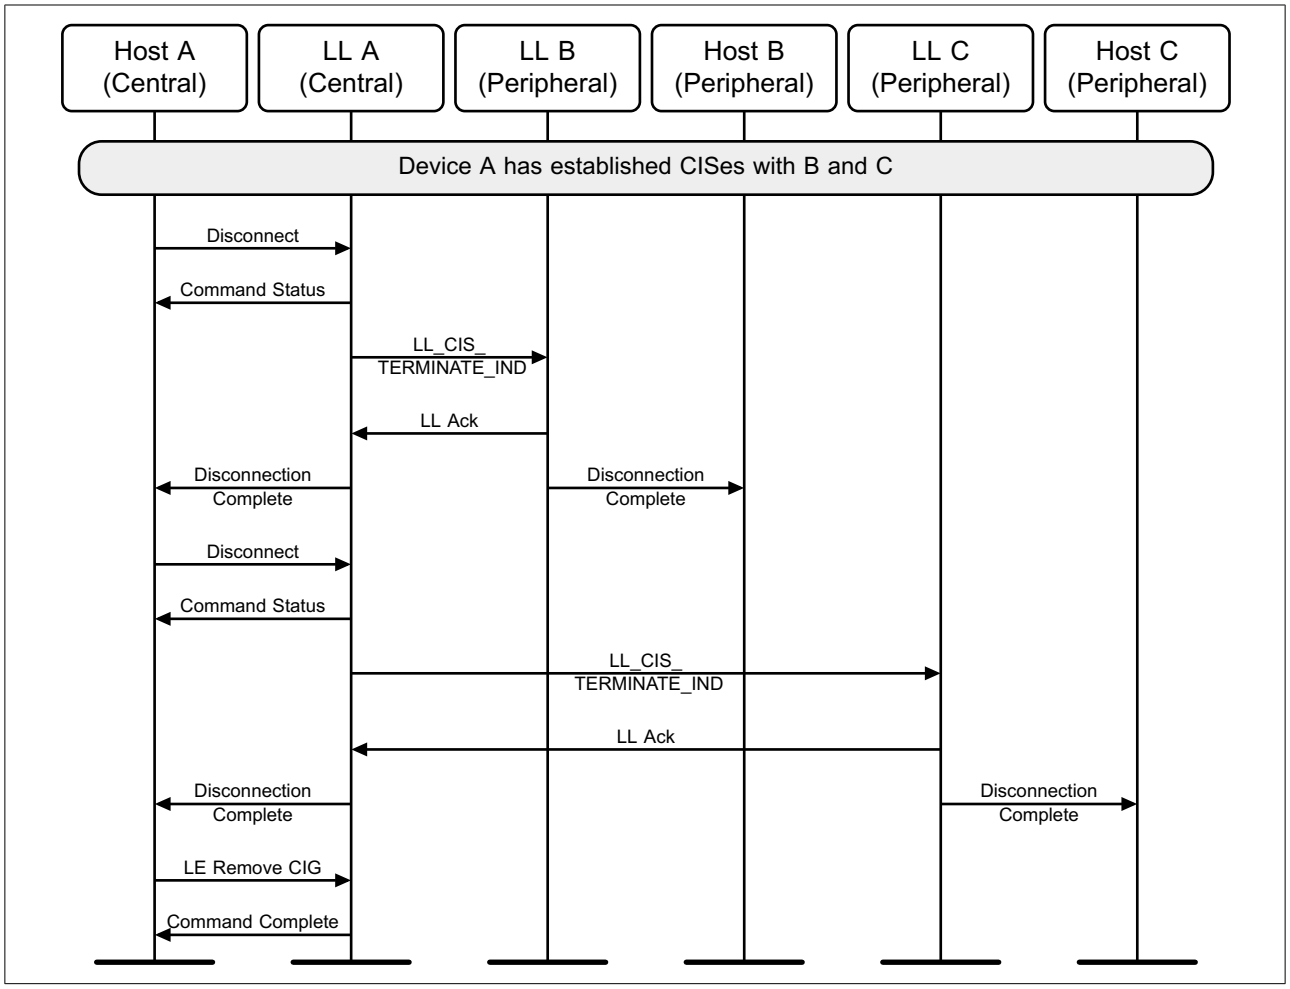

Figure 6.57: Device A terminates both CISes and removes the CIG

6.26 Request Sleep Clock Accuracy

Either device can initiate a Sleep Clock Accuracy Update procedure to query the sleep clock accuracy of the peer device (see Figure 6.58).

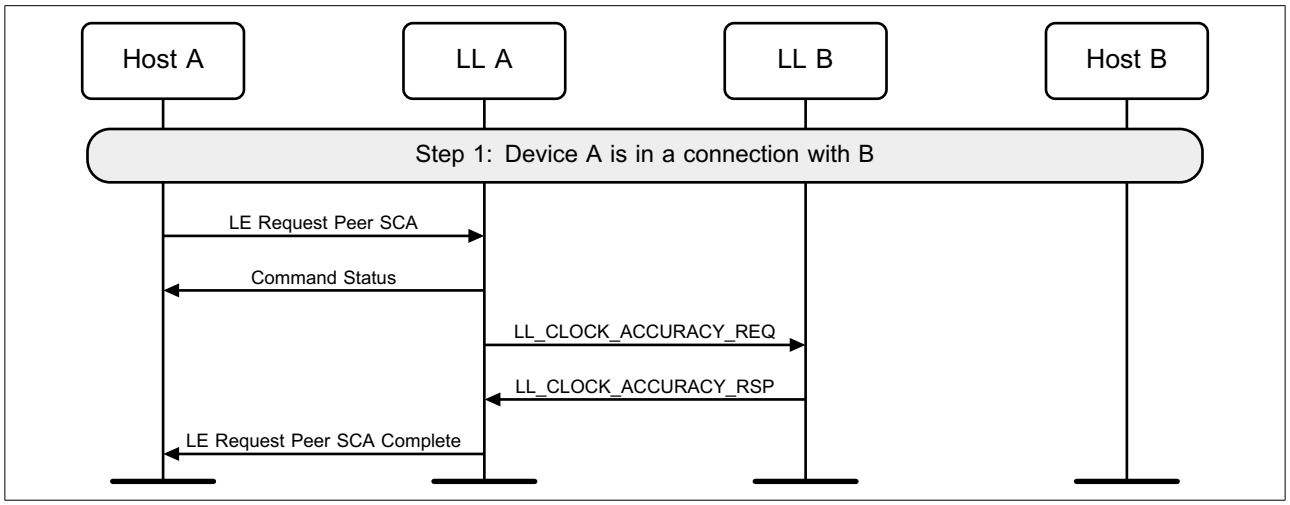

Figure 6.58: Device A requests SCA from Device B

6.27 Power Control

Either device can initiate a Power Control Request procedure to request the peer device to adjust its transmit power level (see Figure 6.59).

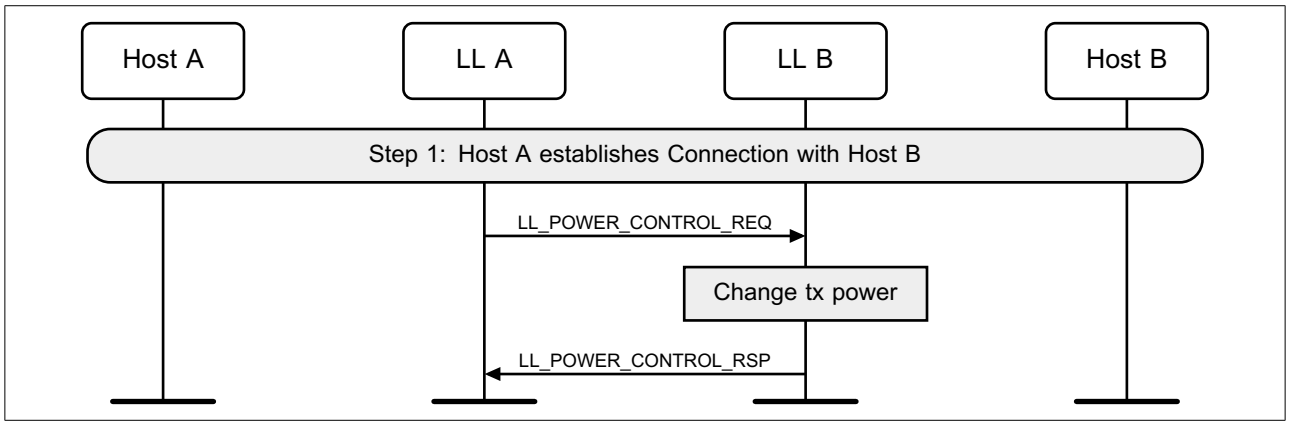

Figure 6.59: Power Control Request procedure to request remote transmit power update

Either device can use the Power Control Request procedure to query the Acceptable Power Reduction (APR) value from the peer device and adjust its transmit power based on the response (see Figure 6.60).

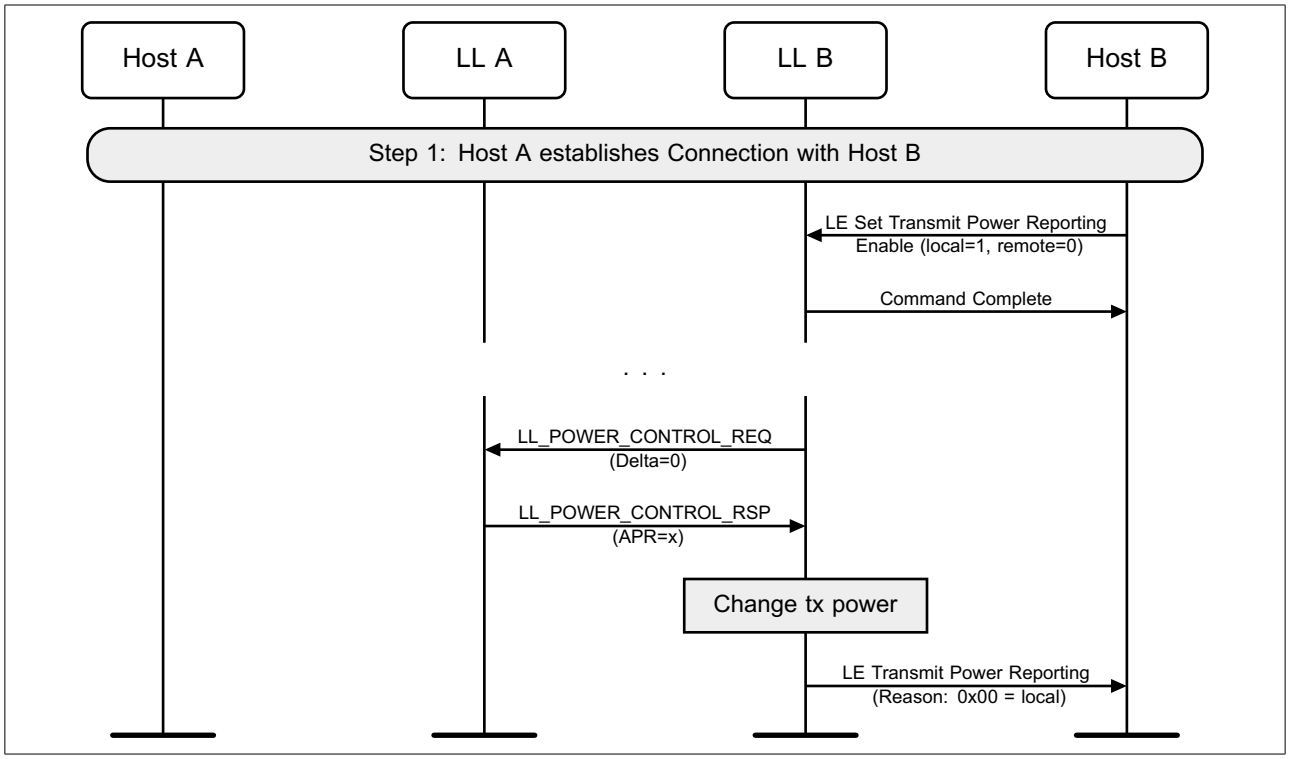

Figure 6.60: Power Control Request procedure to query Acceptable Power Reduction (APR) and transmitter Update

When the Host issues a command to enable reporting of remote power level changes, the Controller may initiate a Power Control Request procedure to request the remote device to start power level management (see [Vol 6] Part B, Section 4.5.15). When the remote Controller changes its transmit power level, it sends an indication to the peer device (see Figure 6.61). If reporting of remote transmit power level changes is enabled, the Controller sends an LE Transmit Power Reporting event to the Host.

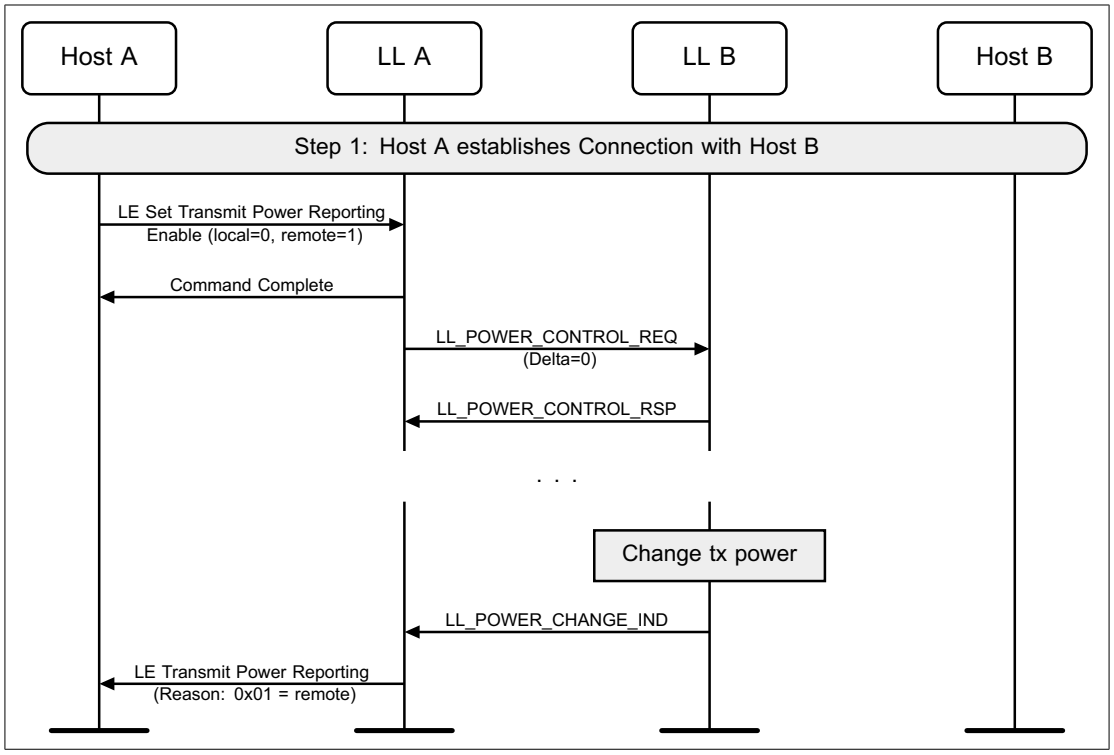

Figure 6.61: LL Power Change Indication procedure when device adjusts TX power autonomously

When a Host issues a command to read the transmit power level of a remote device, the Controller can initiate an LL Power Control Request procedure to query the transmit power level of the remote device (see Figure 6.62).

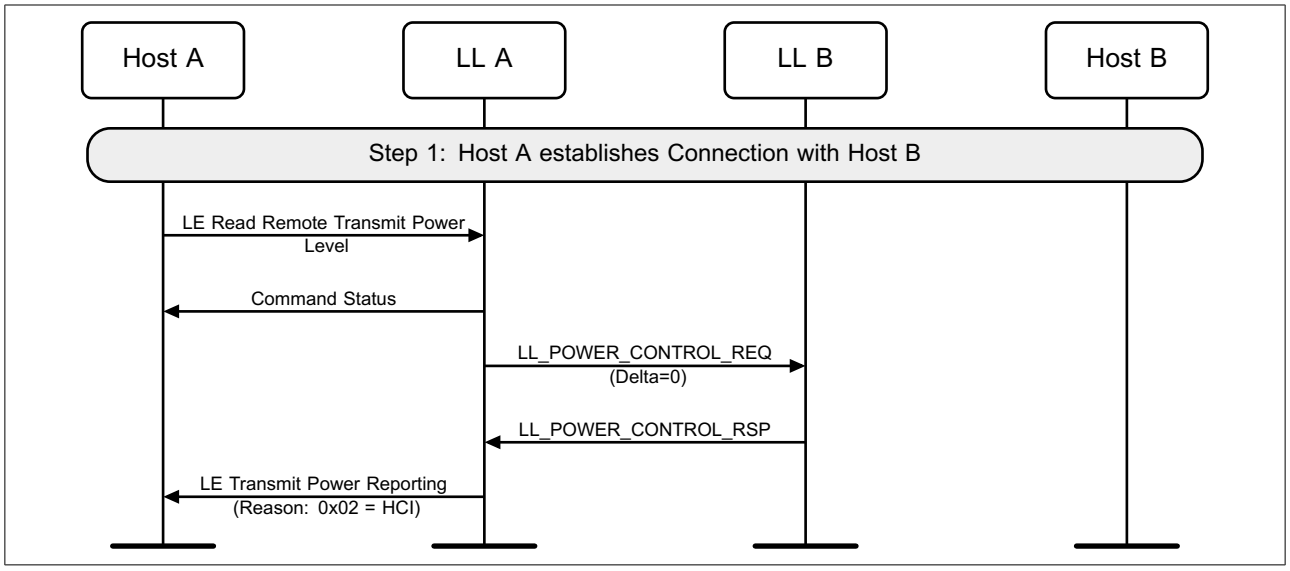

Figure 6.62: HCI command to read remote transmit power level

Before a PHY Update procedure is performed, the Link Layer may request a preferred transmit power level for the new PHY to be used by the remote device (see Figure 6.63).

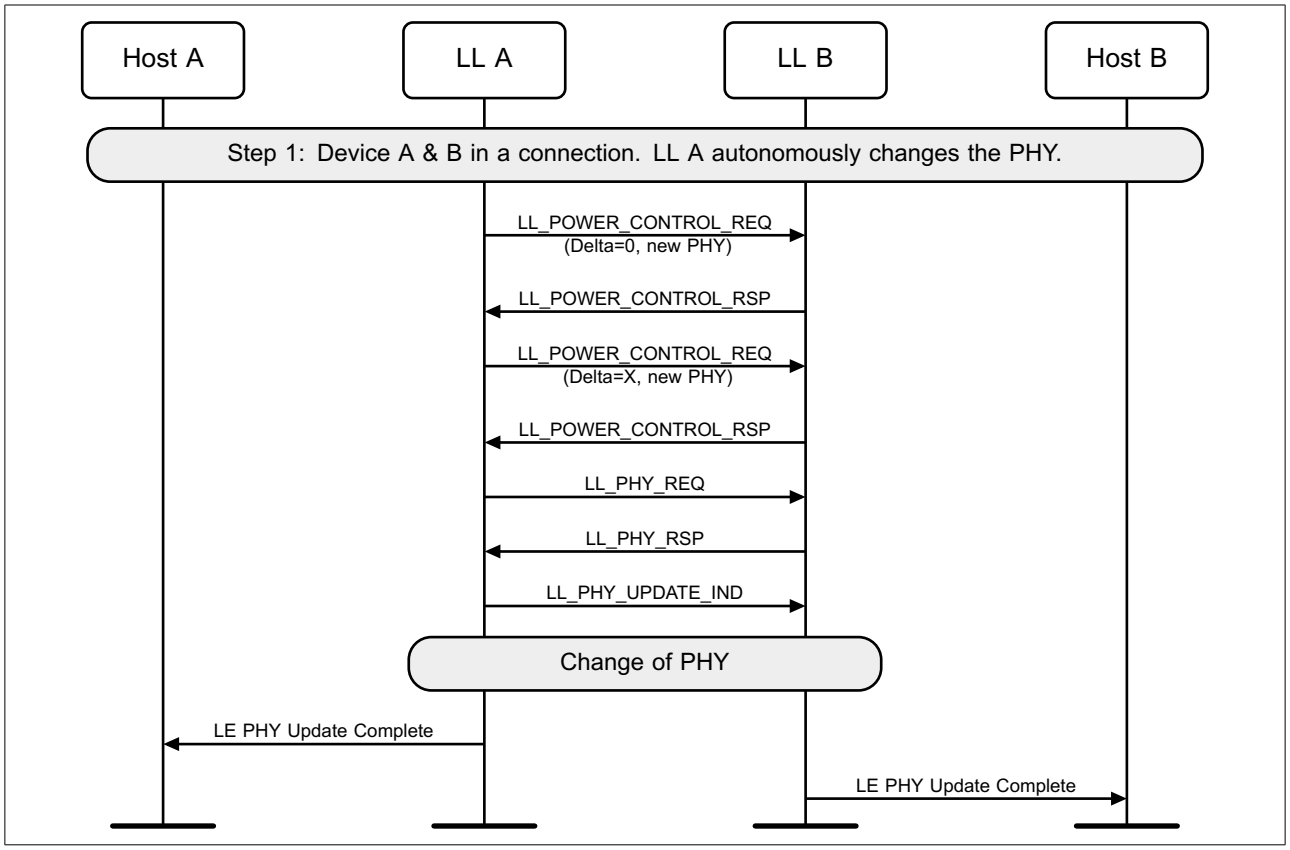

Figure 6.63: Autonomous Central-initiated PHY Update procedure with preferred transmit power level. PHY changed in both directions.

An implementation may choose to manage transmit power levels only on active PHYs and could reject a request for preferred transmit power level on the new PHY before a PHY Update procedure is performed (see Figure 6.64).

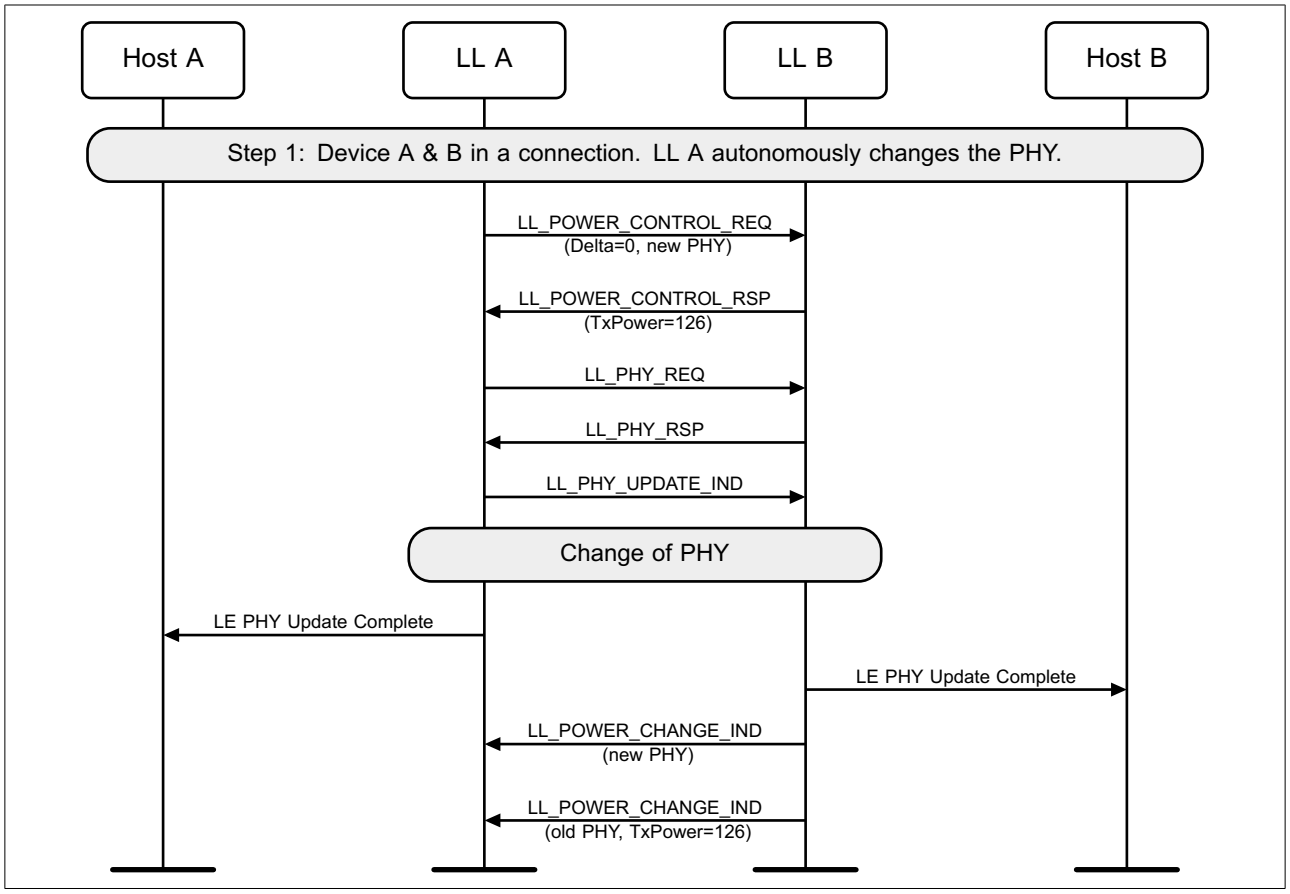

Figure 6.64: Autonomous Central-initiated PHY Update procedure with remote device maintaining only a single transmit power level. PHY changed in both directions.

When a PHY Update procedure is performed to switch to the LE Coded PHY, where the local and remote devices can use both S=8 and S=2 coding, the Controller treats them as separate PHYs for the purpose of Power Control (see Figure 6.65).

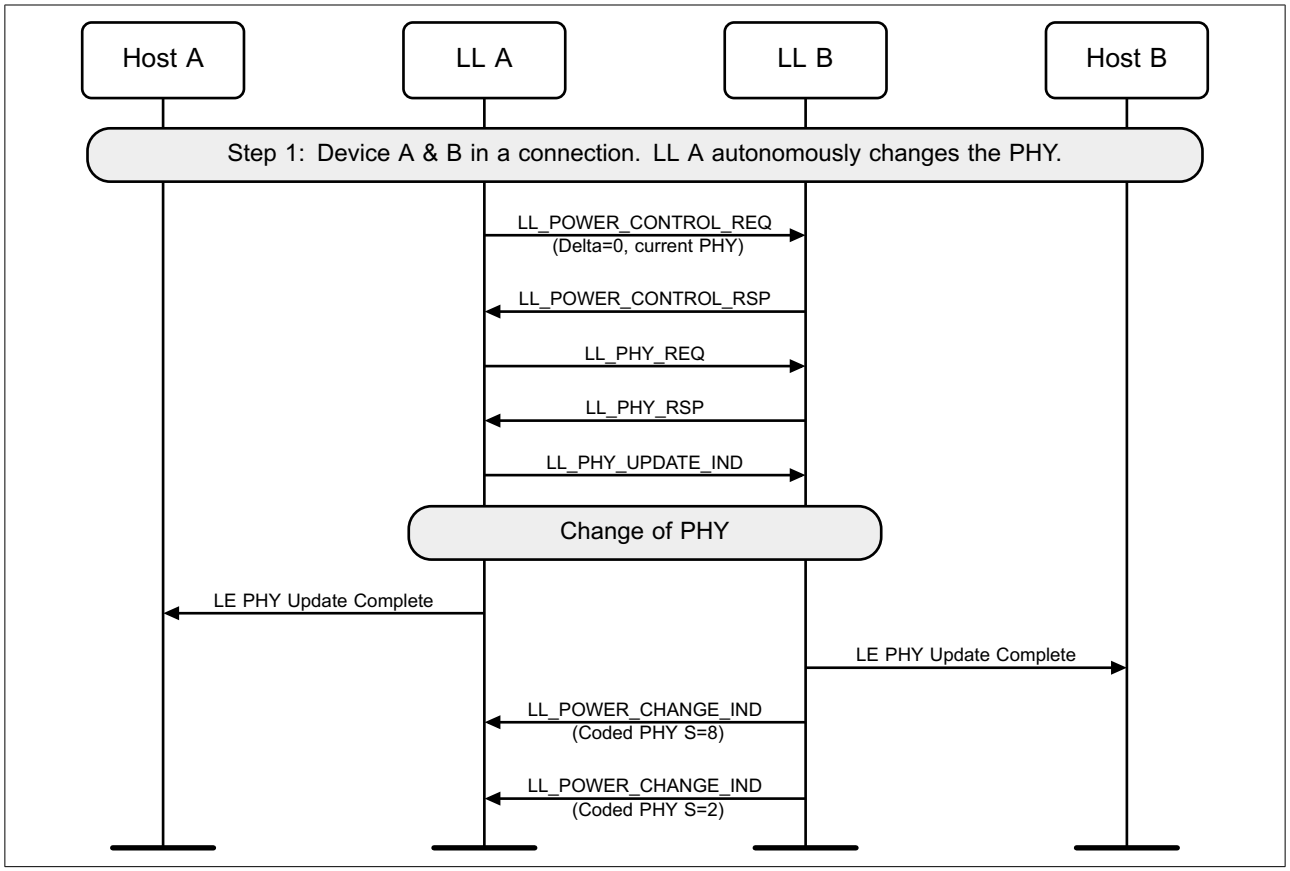

Figure 6.65: Autonomous Central-initiated PHY Update procedure to change to the LE Coded PHY (S=8 and S=2). PHY changed in both directions.

When an associated CIS is established on a PHY different from the one used by ACL, the Power Change Indication procedure may be used to indicate the transmit power level used on the new PHY. When the associated CIS is disconnected, the implementations may choose to stop managing the PHY used on the CIS (see Figure 6.66).

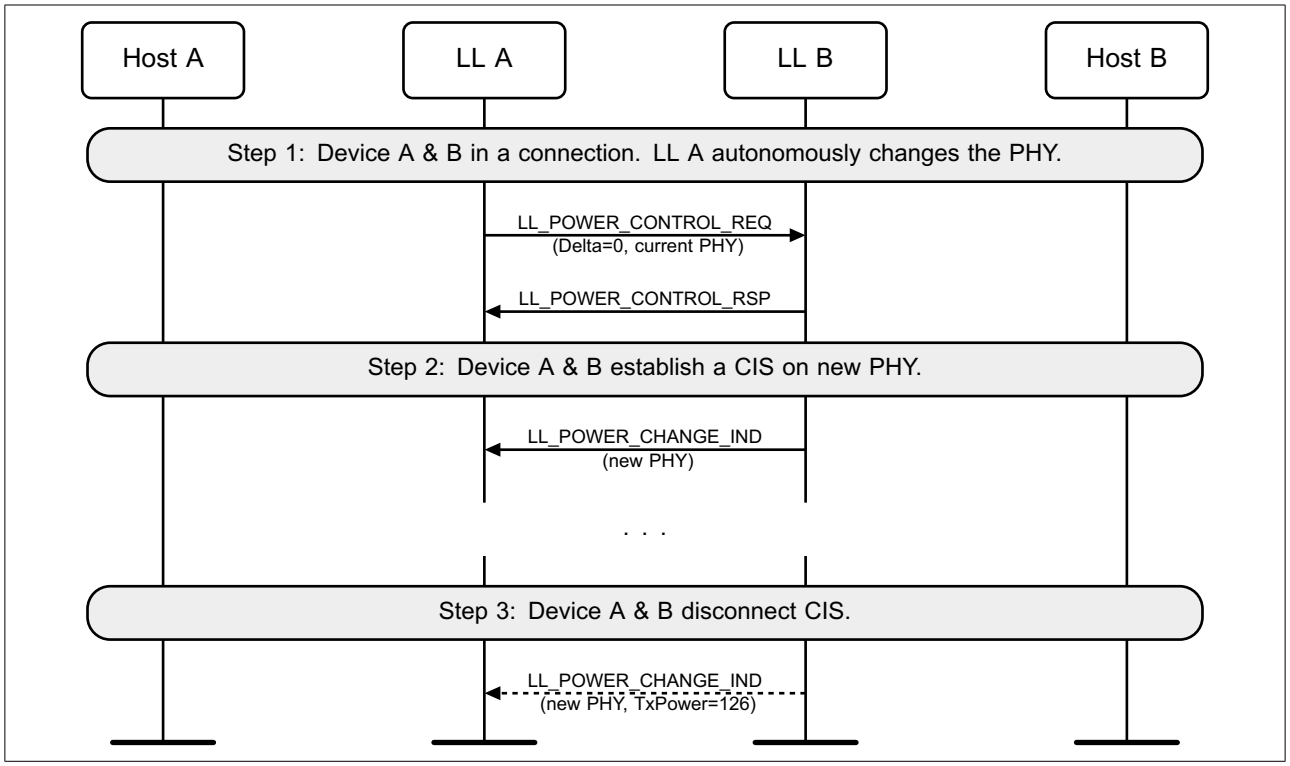

Figure 6.66: ACL with associated CIS established on a new PHY different from one on ACL

When a Host enables path loss monitoring, the Controller may initiate the Power Control Request procedure to query the remote transmit power level. As the remote device moves around, the Controller monitors the path loss on the connection and sends events to the Host as appropriate (see Figure 6.67).

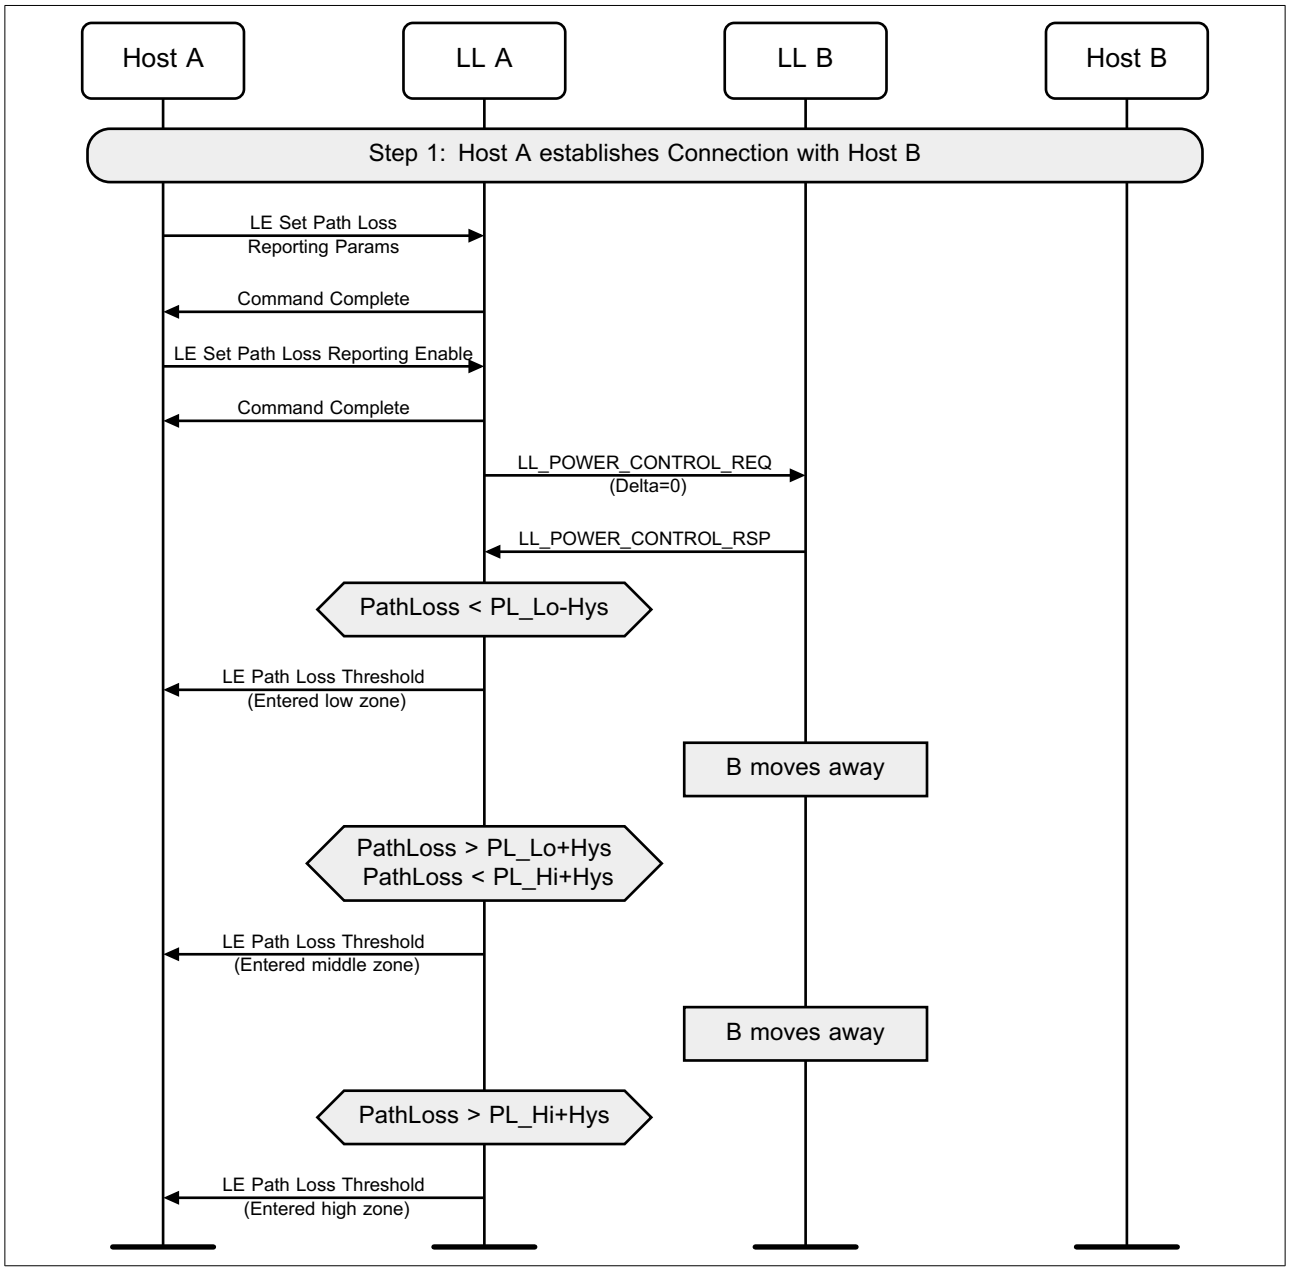

Figure 6.67: Power Control Request procedure in context of path loss monitoring

6.28 Data path setup for a music stream over a CIS

Figure 6.68 shows an example of unidirectional music streaming from Host A to Host B. Host A does LC3 codec processing in the Host and sends data over HCI to the Controller, which transmits the PDUs over the air without further processing. Host B

configures an output data path to the speaker(s) and enables LC3 codec processing in the Controller.

Note: The notifications between the Hosts are specified by the relevant profile(s).

Note: The audio data may be mono or stereo. In the latter case, how the data sent to the output data path is split into the separate audio signals is outside the scope of this specification.

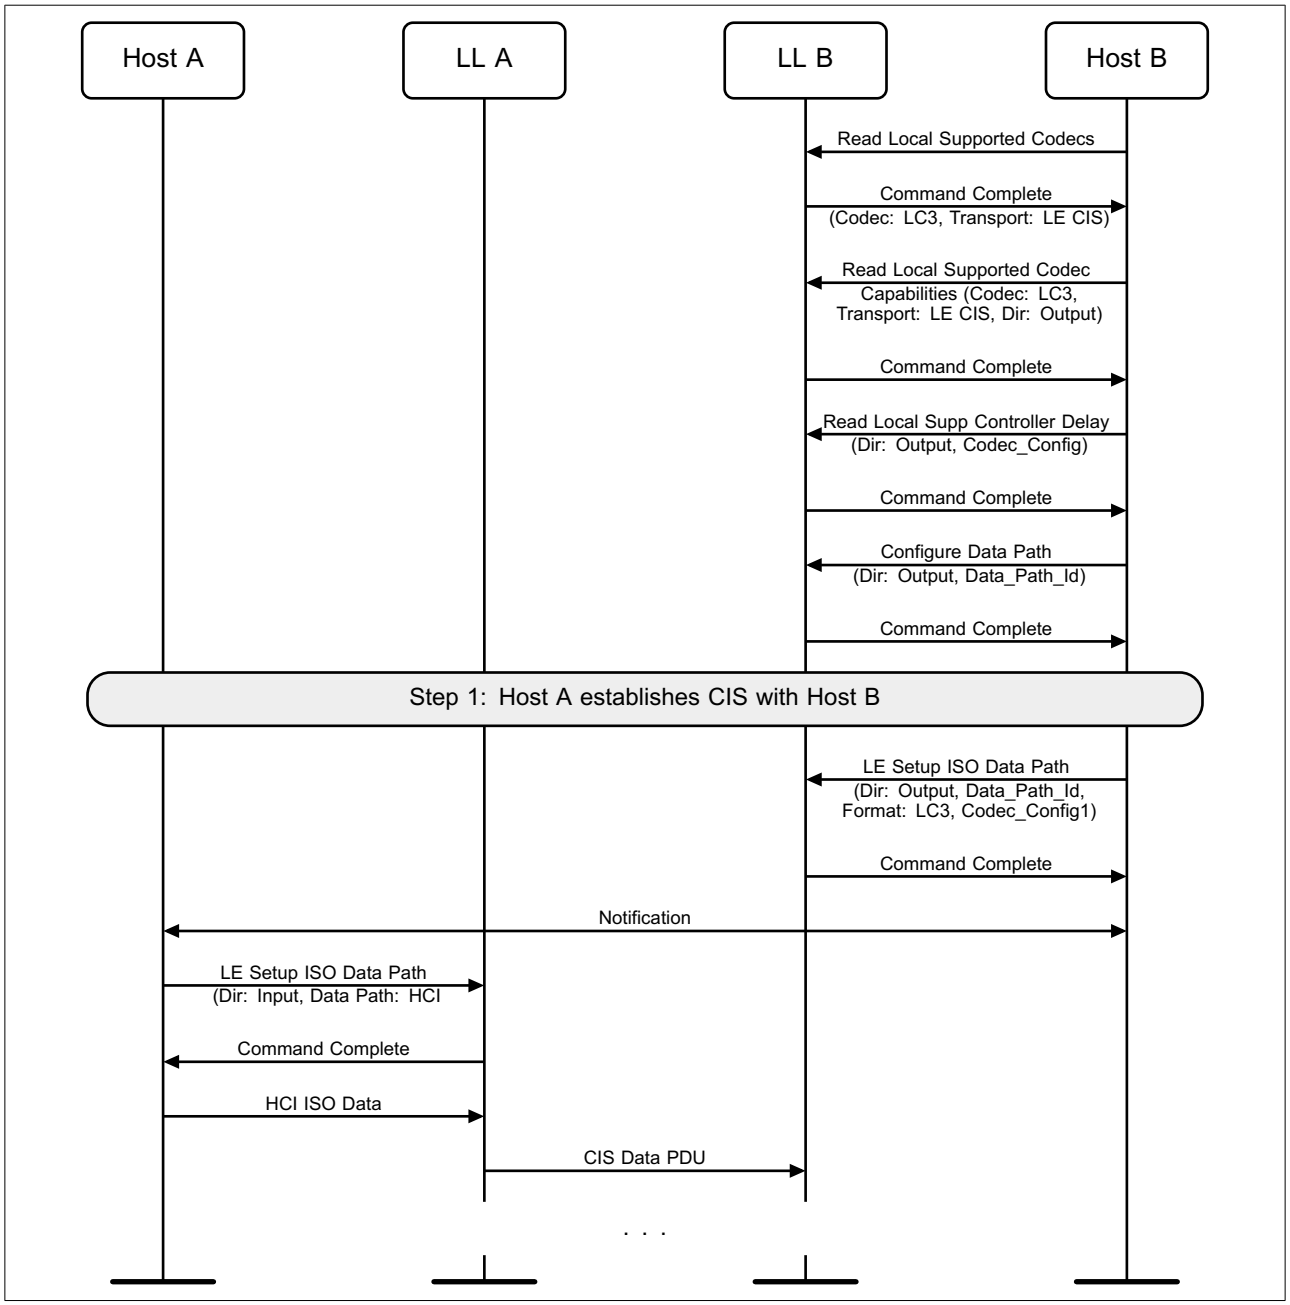

Figure 6.68: Host A with codec in the Host streams music to Host B which has a codec in the Controller

6.29 Data path setup for bi-directional voice over a CIS

Figure 6.69 shows an example of a bidirectional voice call between Host A and Host B. Device A contains proprietary audio interface hardware with an embedded LC3 codec. Hence the Host sets up the ISO data path with Coding_Format set to transparent mode. Device B supports LC3 codec processing in the Controller and hence Host B sets up the ISO data path with Coding_Format set to LC3 along with the codec configuration data defined by the relevant profile(s).

Note: The notifications between the Hosts are specified by the relevant profile(s).

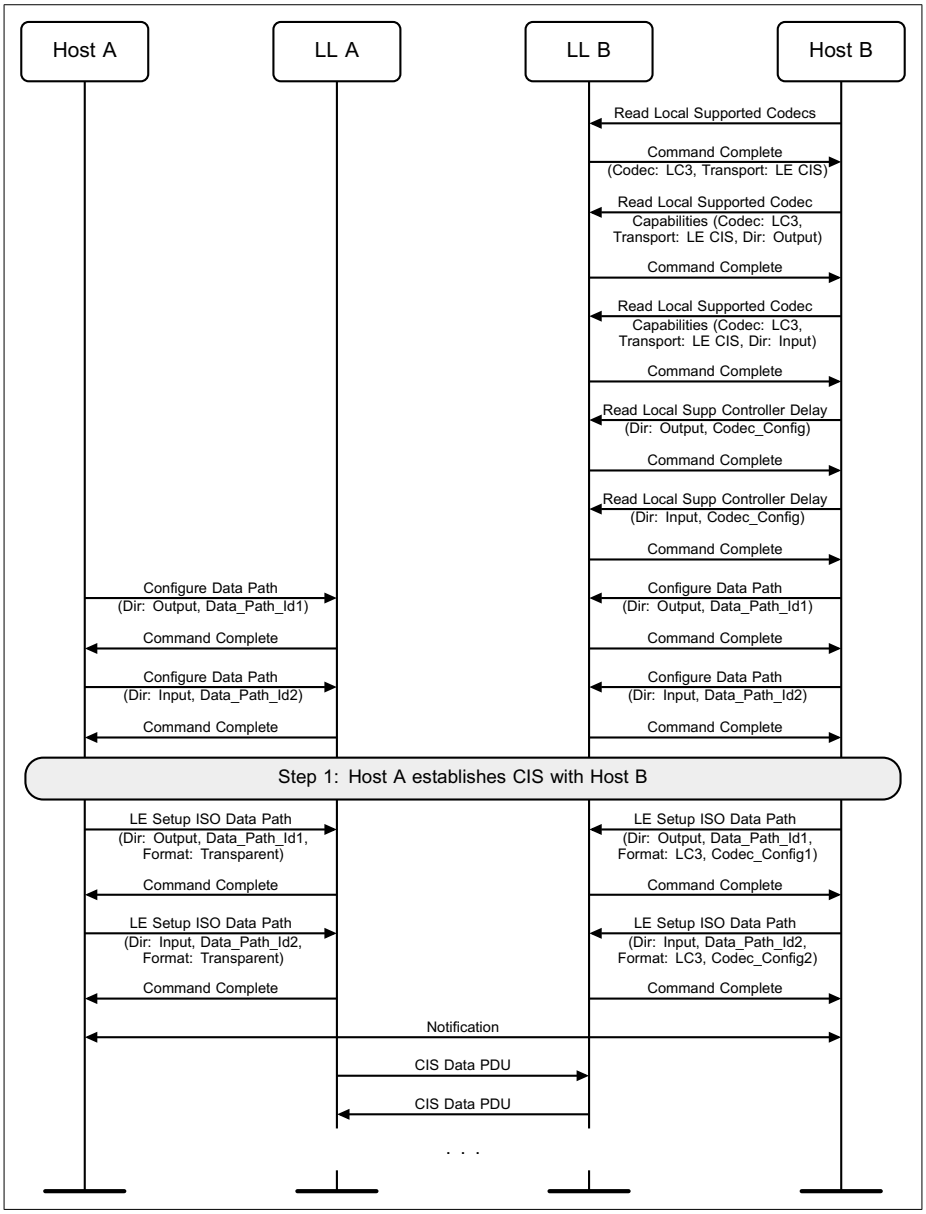

Figure 6.69: Host A with codec in the data path establishes a bi-directional voice call with Host B with codec in the Controller

6.30 [This section is no longer used]

The contents of this section are now in Section 8.5.

6.31 Modifying the subrate of a connection

A Central A in a connection with a Peripheral B modifies the subrating of the connection. The first two PDUs are not received by device B (see Figure 6.70).

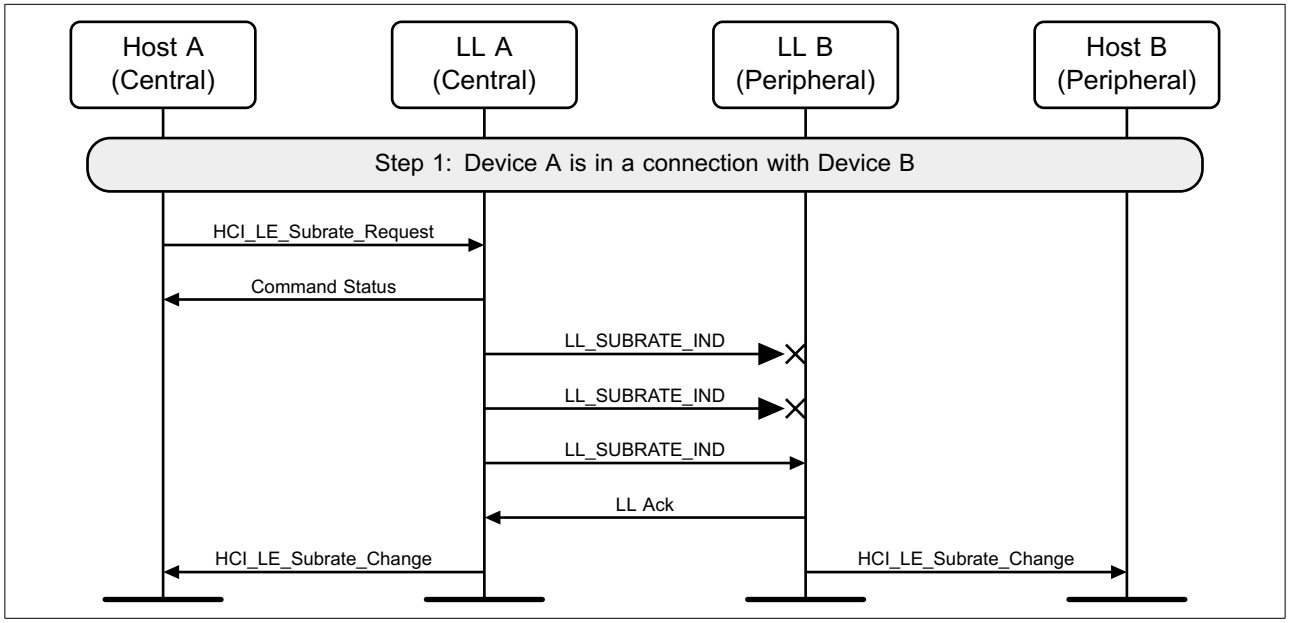

Figure 6.70: Central A modifies the connection subrating

Peripheral B requests a new subrating for its connection with device A and makes the change (see Figure 6.71).

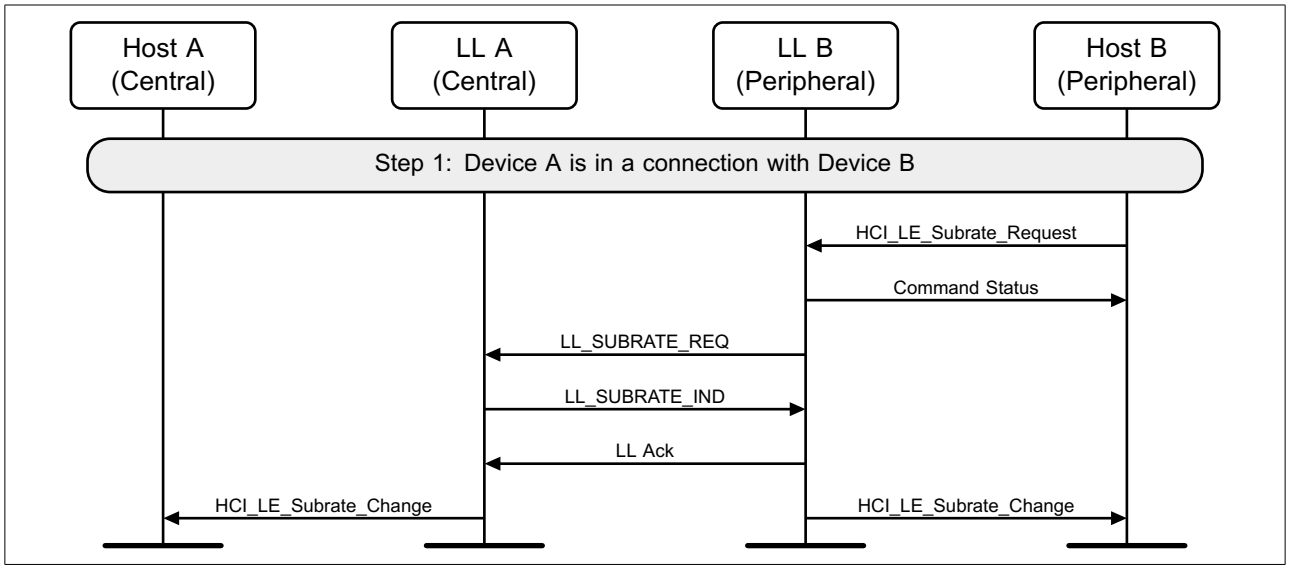

Figure 6.71: Peripheral B requests a change to the connection subrate which is accepted

Peripheral B requests a new Subrating for its connection with device A but device A rejects the change (see Figure 6.72).

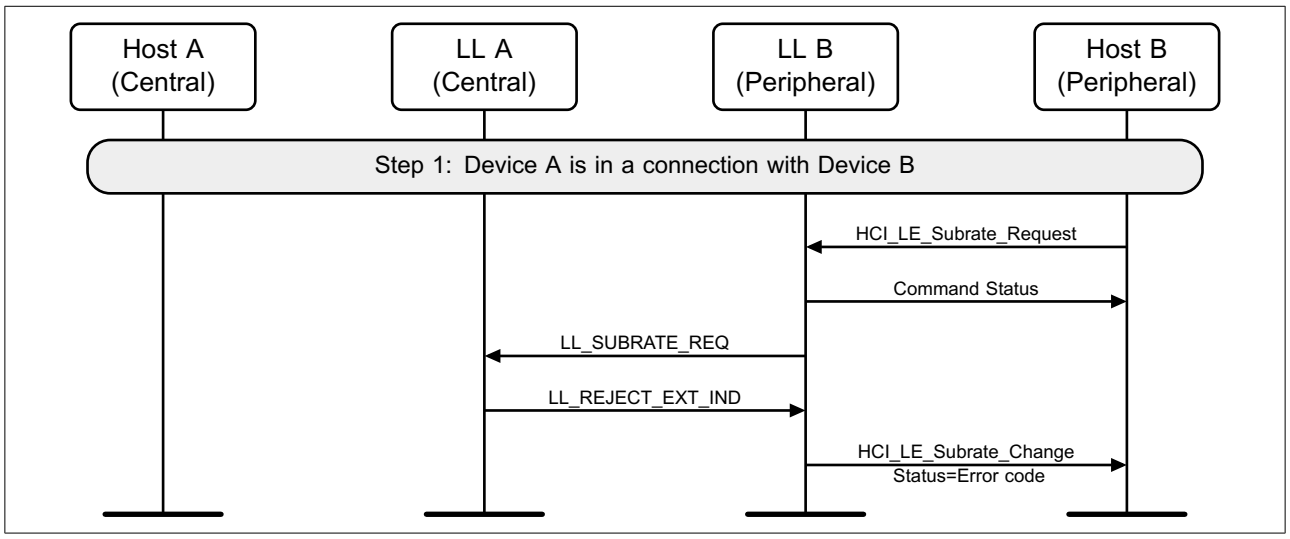

Figure 6.72: Peripheral B requests a change to the connection subrate which is rejected

6.32 Channel Classification Enable

The Central can enable reporting of channel classification information on the Peripheral.

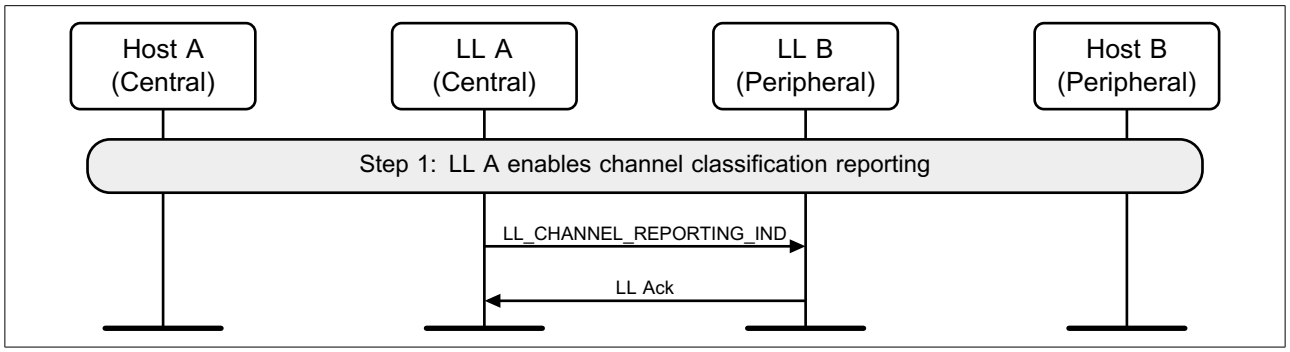

Figure 6.73: Central requests the Peripheral to enable reporting of channel classification information

6.33 Channel Classification Reporting

The reporting is enabled, the Peripheral can provide channel classification information to the Central.

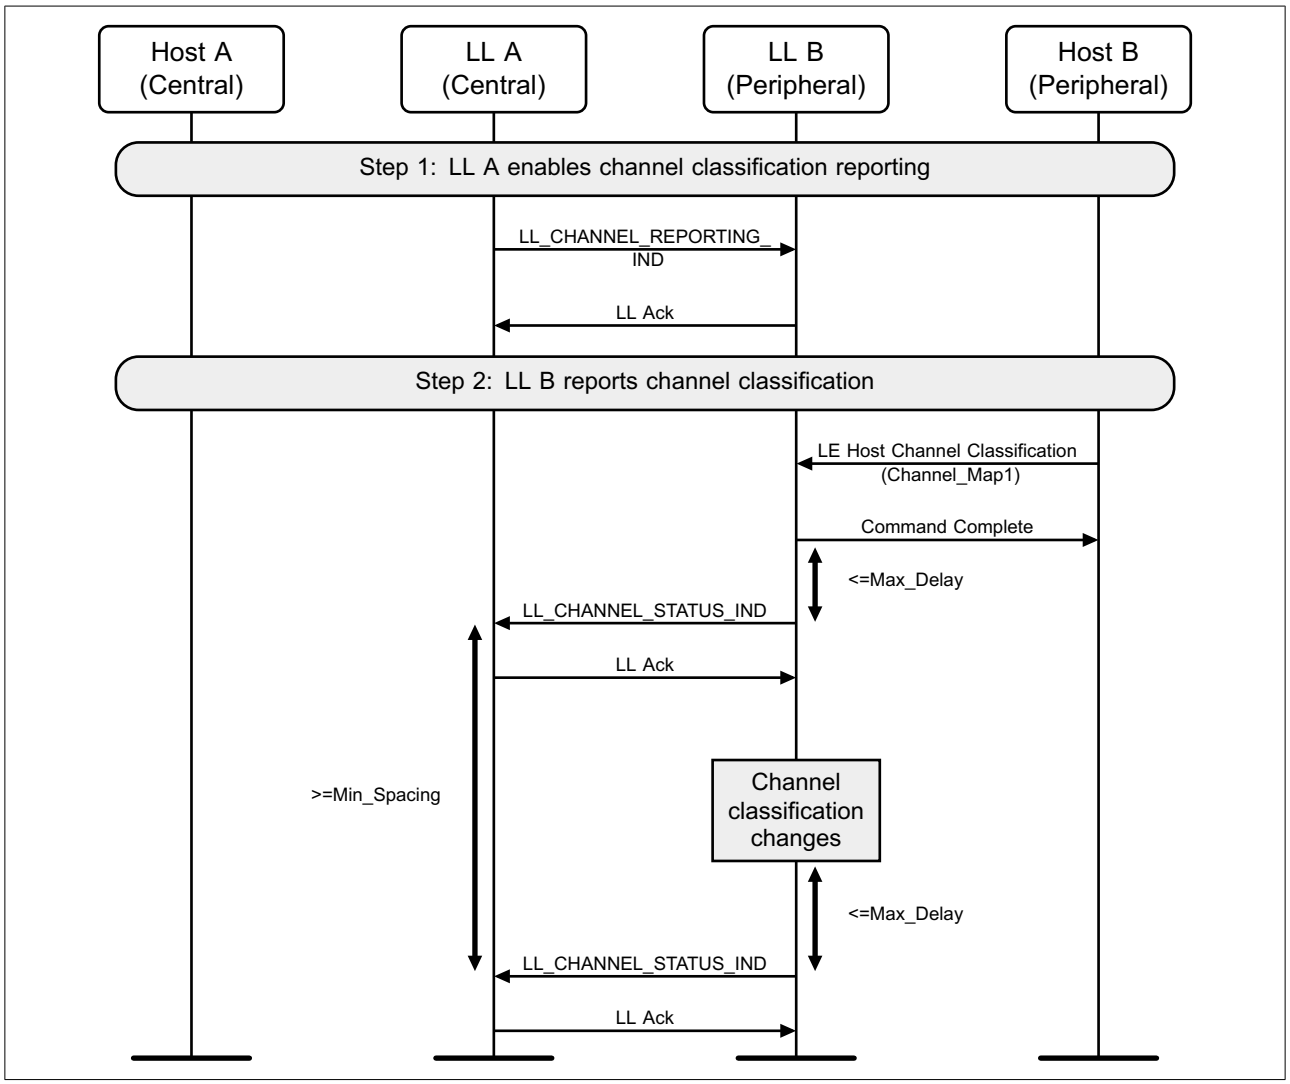

Figure 6.74: Peripheral provides channel classification information to the Central

6.34 Channel Sounding setup phase

The example flow in Figure 6.75 shows the CS setup phase, in which CS capabilities are read and roles are enabled at both ends of a connection. An encrypted ACL connection is established before exchanging CS capabilities and security parameters.

A distance measurement application in a Host can issue HCI commands to start the setup phase with the Channel Sounding Capability Exchange procedure. The local and remote Host can then set the default settings for Channel Sounding. Based on the

capability support for a non-zero Frequency Actuation Error, the application can issue appropriate commands to read or write the mode-0 Frequency Actuation Error table. The application can create CS configurations using the Channel Sounding Configuration procedure. The Controller in the Central role can then start the Channel Sounding Security Start procedure. After the Channel Sounding Security Start procedure completes, the application can consider the setup phase to be completed.

After the first time the setup phase is completed with a specific remote device, an application may cache the remote capabilities, remote FAE table, and CS configuration parameters used. During subsequent connections, the Host may avoid LL control procedure exchanges as described in Figure 6.75.

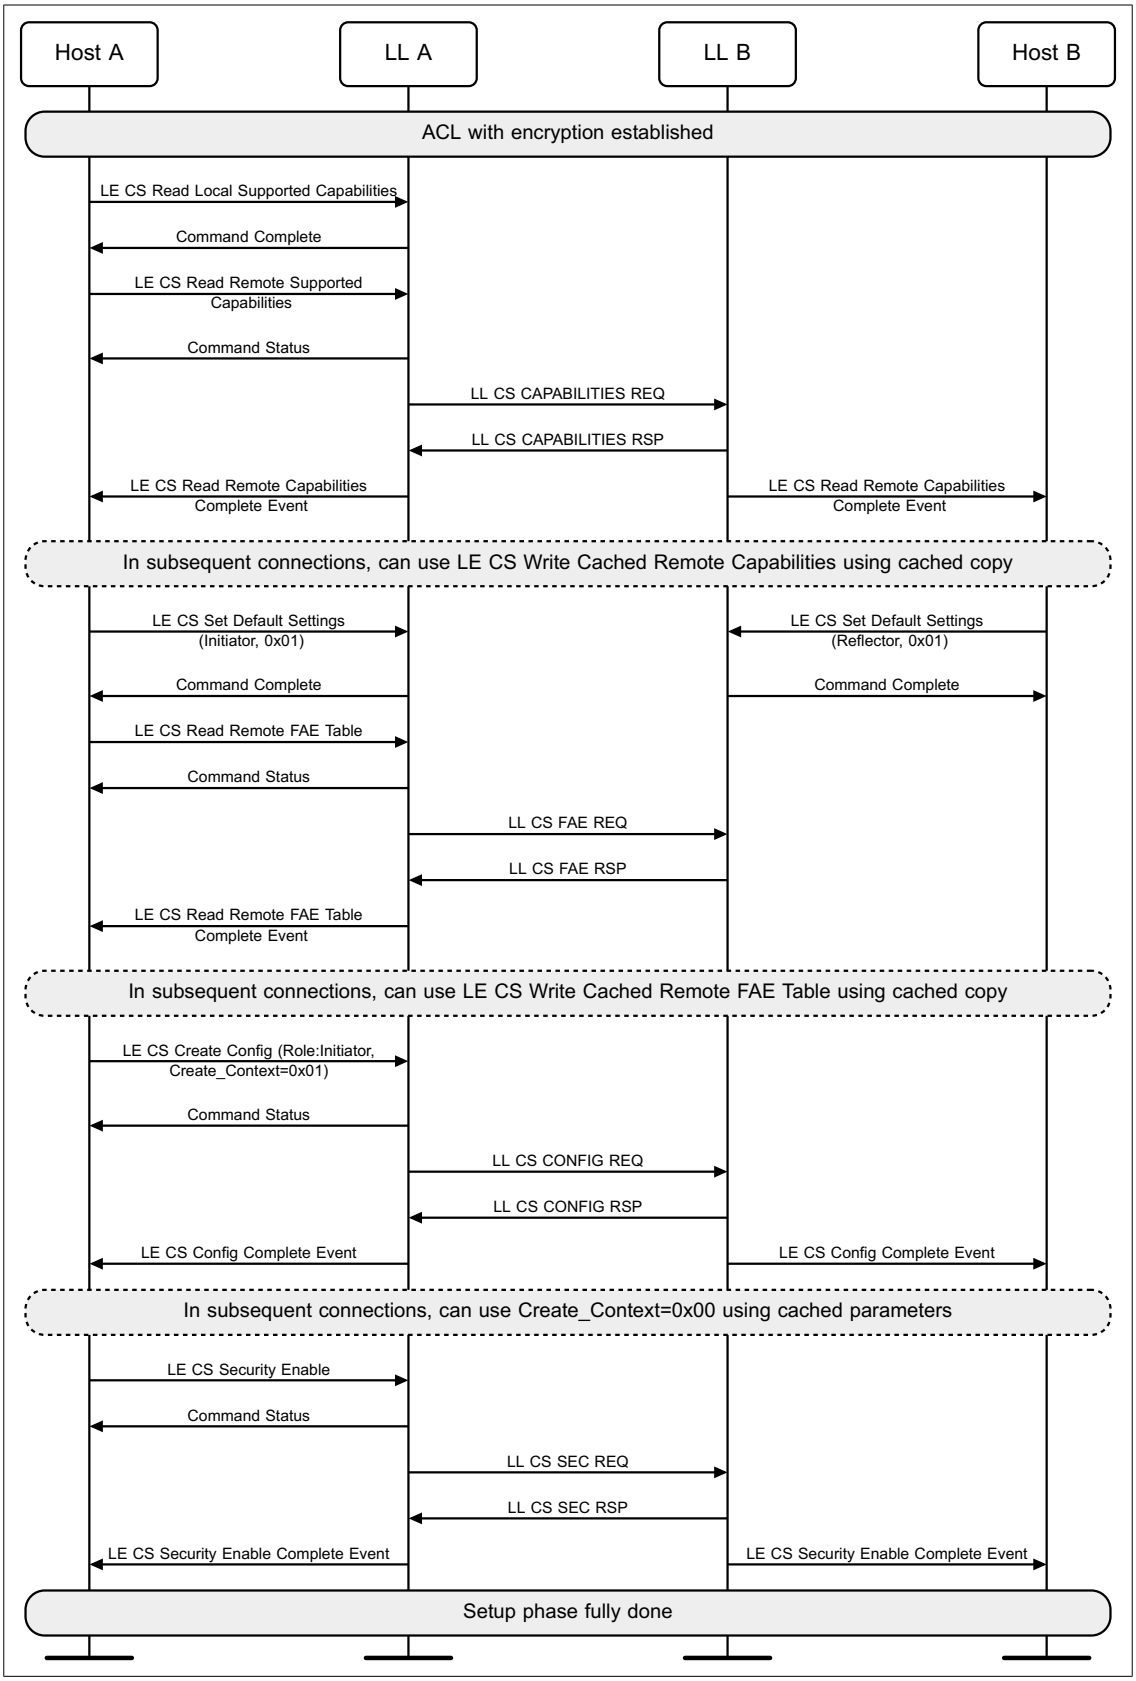

Figure 6.75: Channel Sounding example setup phase

6.35 Channel Sounding started by Central in initiator role

As mentioned in [Vol 1] Part A, Section 3.3.2.5.3, an LE device may assume either the initiator or reflector role. In the example shown in Figure 6.76, an application running on a Central device in the initiator role starts a CS measurement.

Message Sequence Charts

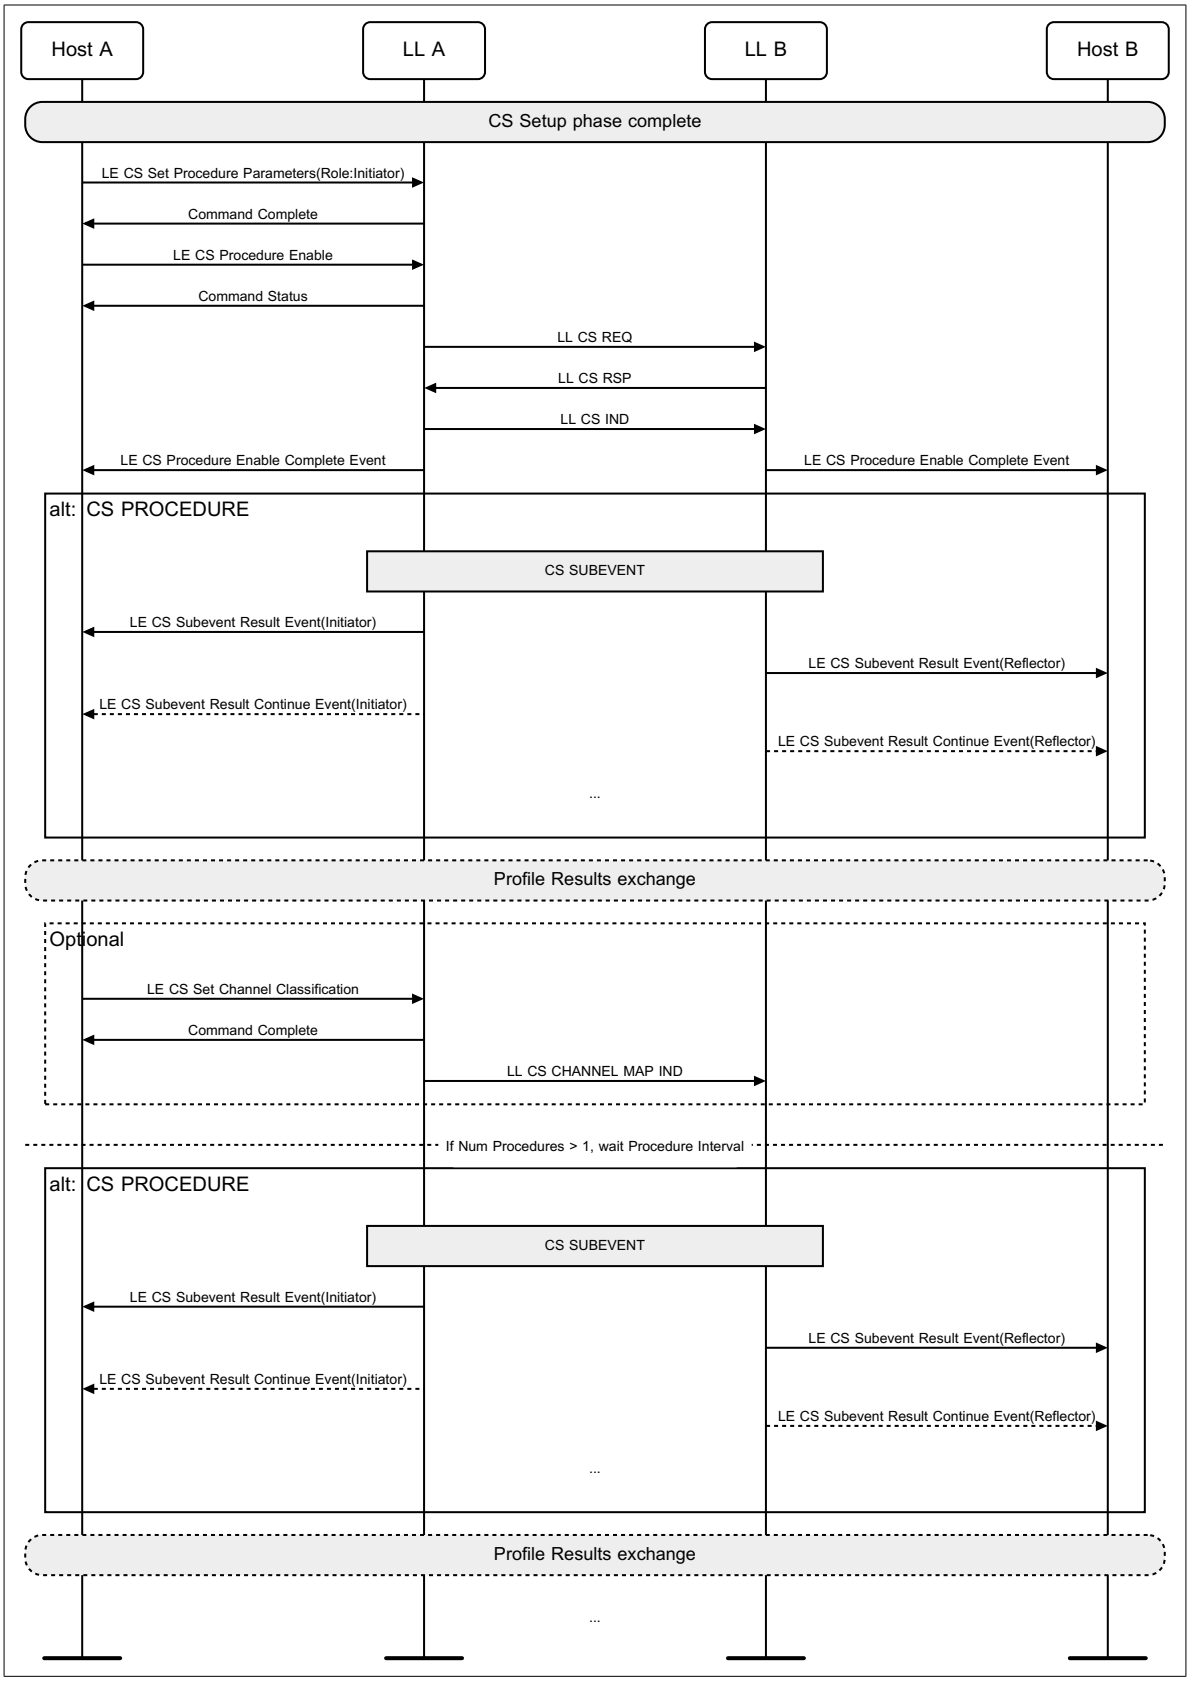

Figure 6.76: Channel Sounding started by Central in initiator role

6.36 Channel Sounding started by Peripheral in reflector role

As mentioned in [Vol 1] Part A, Section 3.3.2.5.3, an LE device may assume either the initiator or reflector role. In the example shown in Figure 6.77, an application running on a Peripheral device in the reflector role starts a CS measurement.

Message Sequence Charts

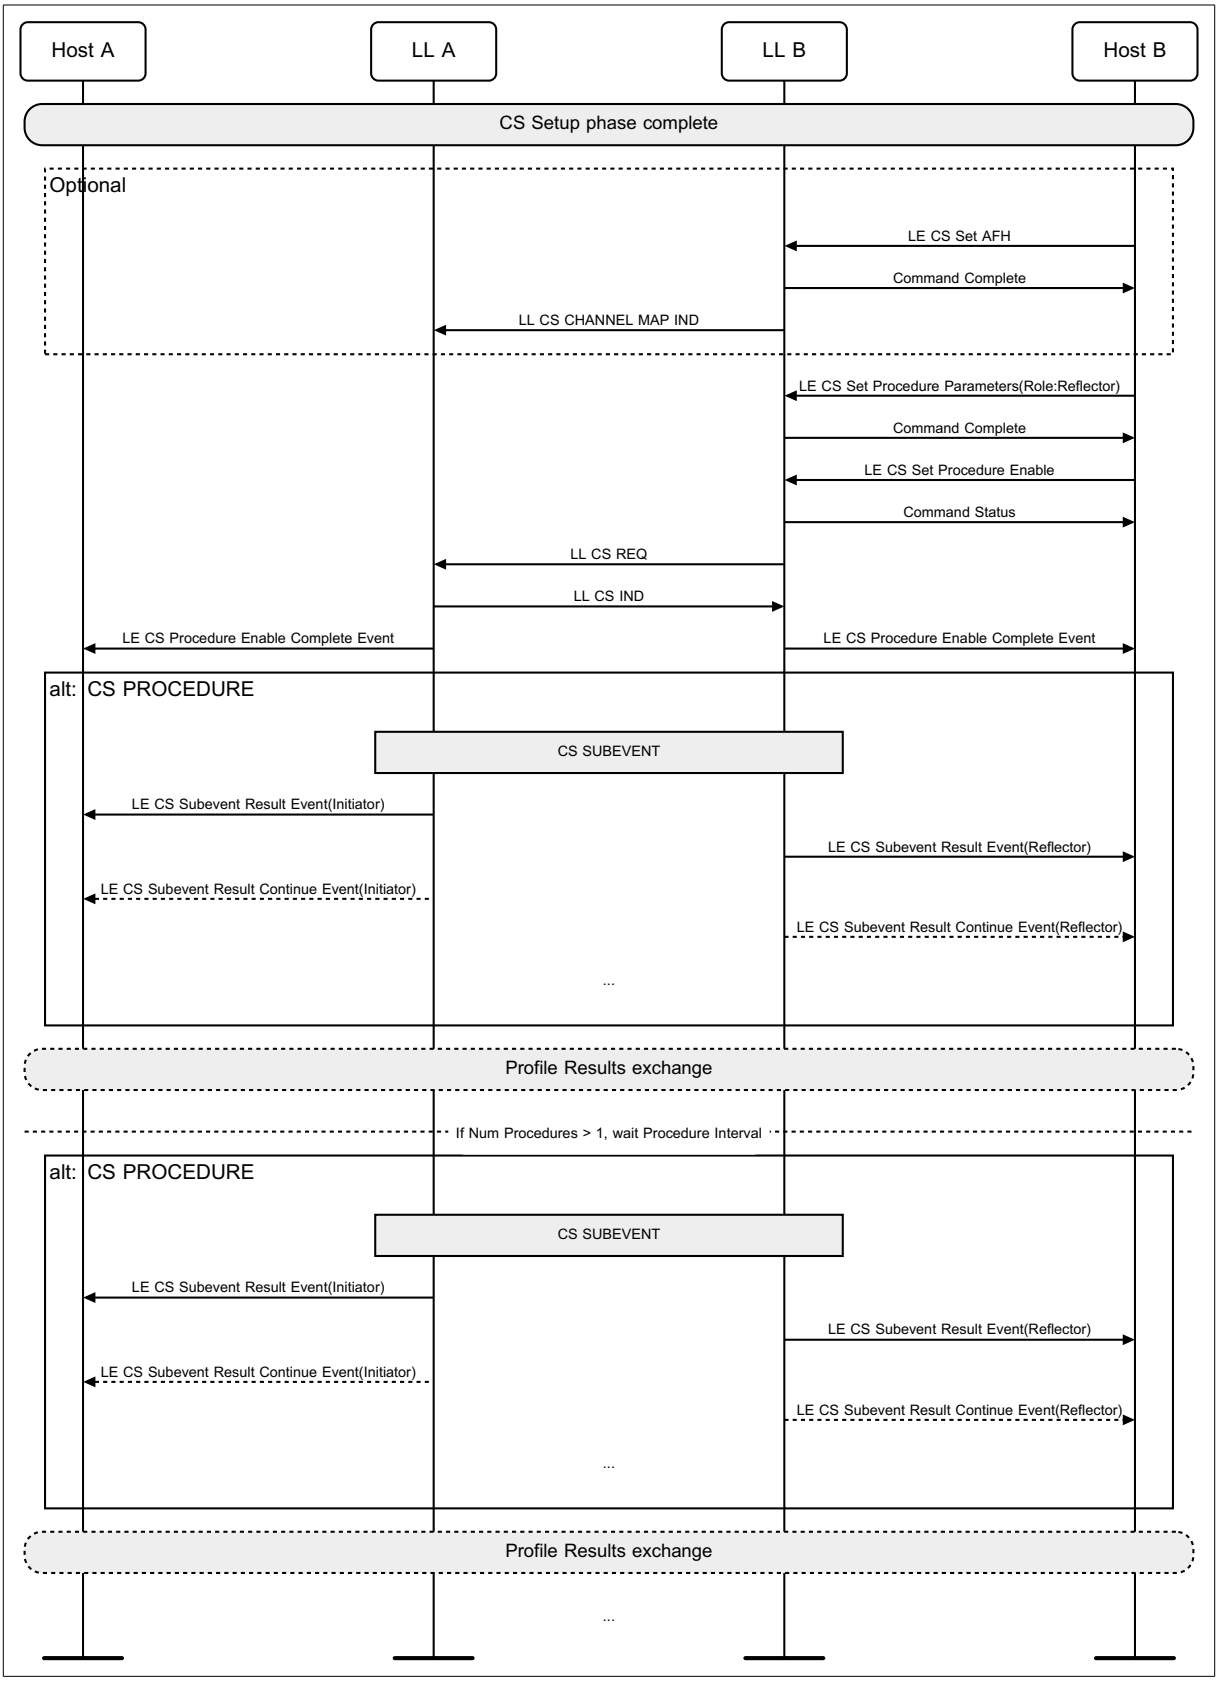

Figure 6.77: Channel Sounding started by Peripheral in reflector role

6.37 Channel Sounding started by Central, rejected by Peripheral

In the example shown in Figure 6.78, an application running on a Central device in the initiator role starts a CS measurement. The Peripheral rejects the LL_CS_REQ because the requested parameters are not acceptable.

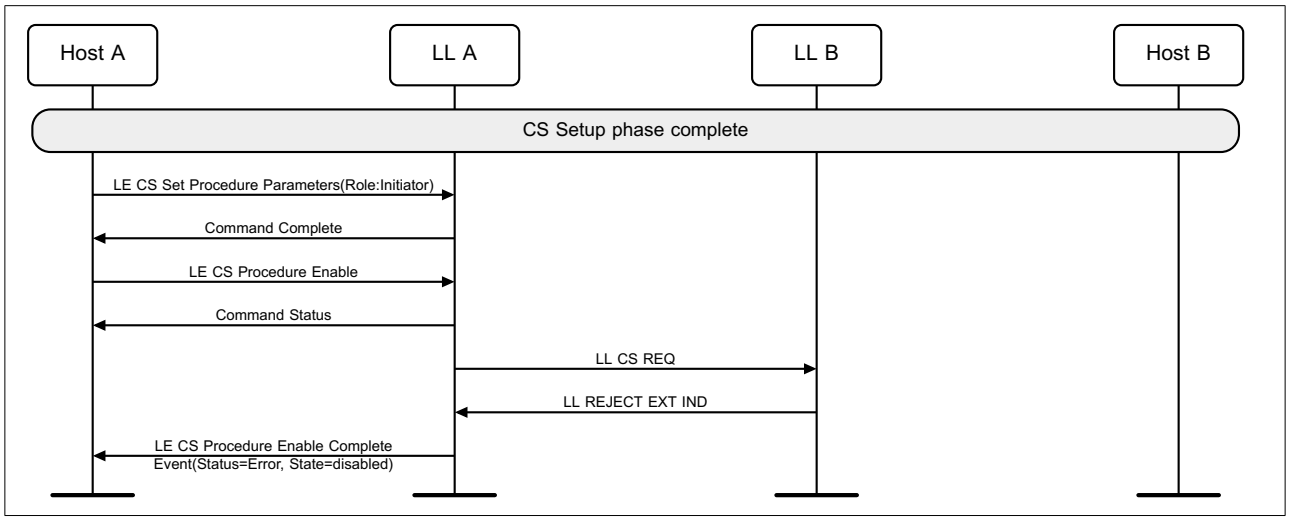

Figure 6.78: Channel Sounding started by Central, rejected by Peripheral

6.38 Channel Sounding configuration removal during an active CS measurement

In the example shown in Figure 6.79, an application running on a Central device in the initiator role starts a CS measurement. When the Host wants to remove a CS

configuration that is being used in an active CS measurement, the Host first terminates the active CS procedure and then issues a LE CS Remove Config command.

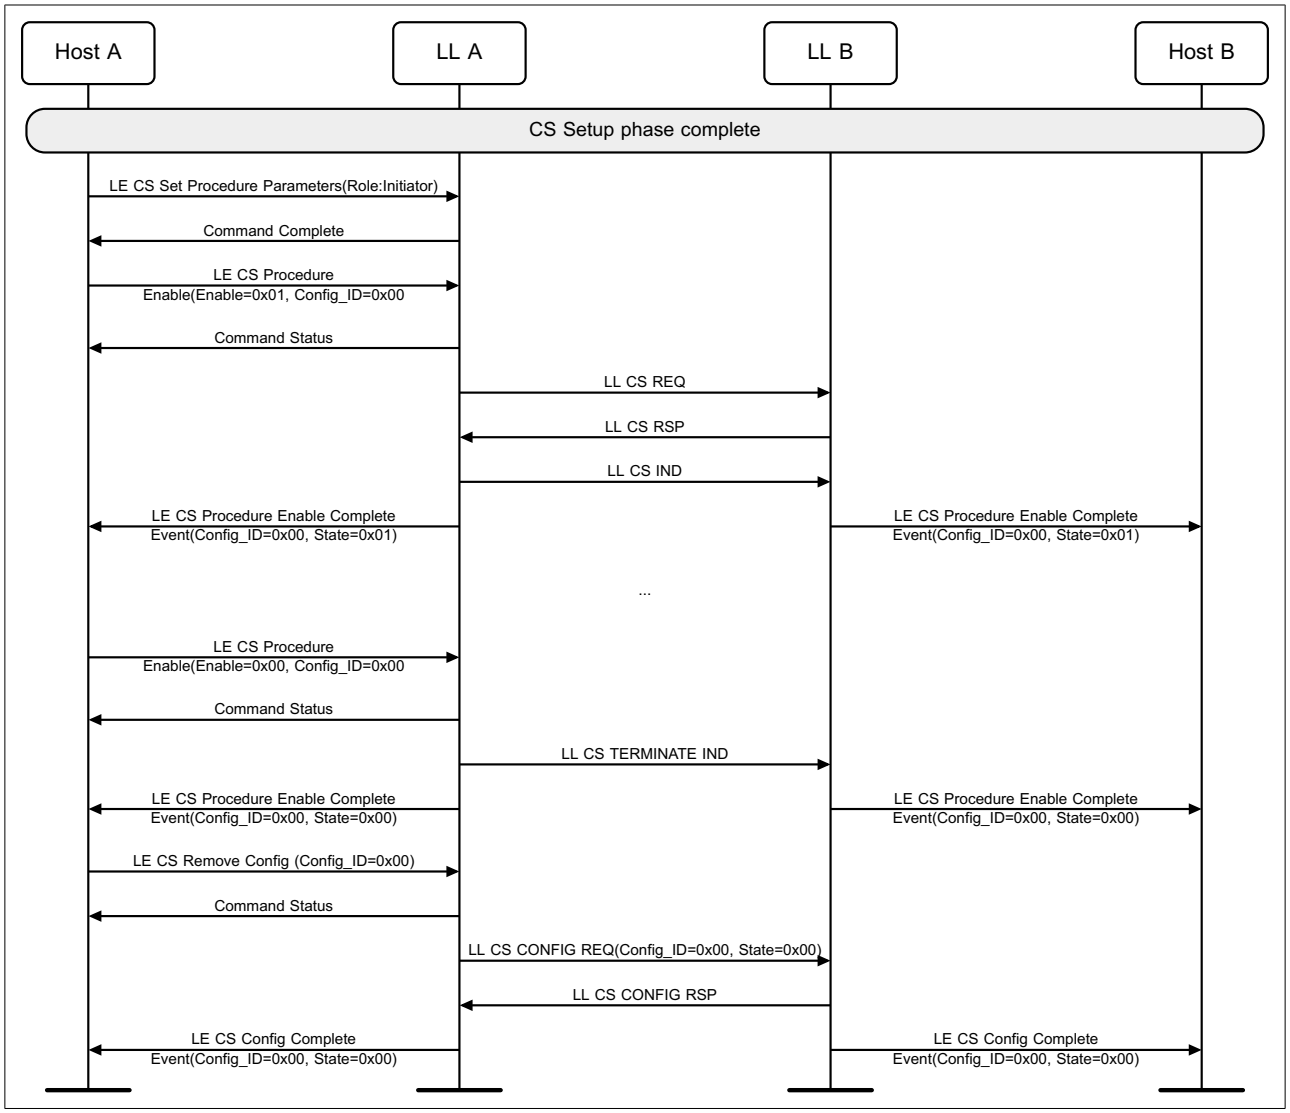

Figure 6.79: Channel Sounding configuration removal during an active CS measurement

6.39 Frame Space Update

Either the Host or the Controller of device A requests a change to the frame space values of the connection, specifying a change to T_IFS_CIS, T_MSS_CIS, or a PHY that is not the PHY used on the ACL.

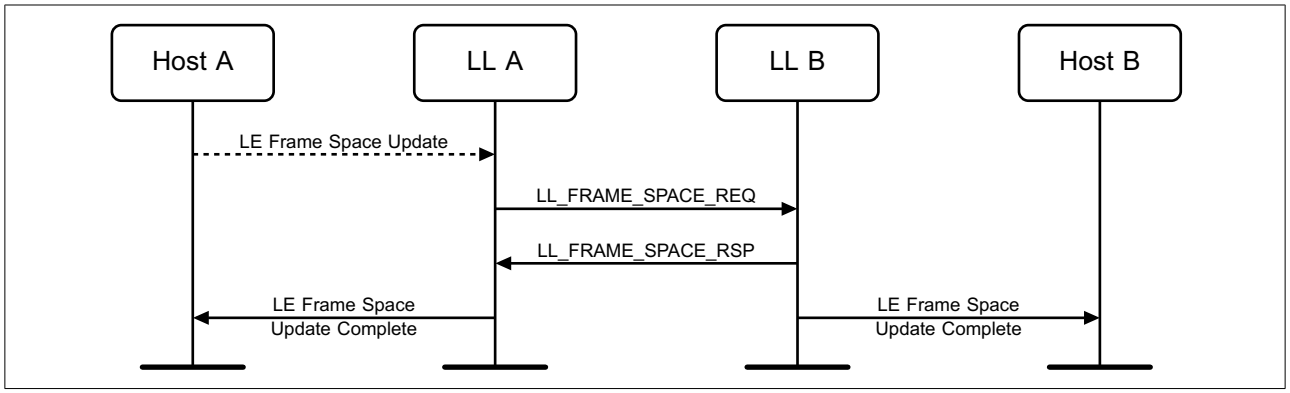

Figure 6.80: Frame Space Update affecting CIS only

Either the Host or the Controller of device A requests a change to the frame space value of the connection, specifying a change to T_IFS_CIS and a change to either T_IFS_ACL_CP, T_IFS_ACL_PC, or T_MCES. Device B responds with only a change to a PHY that is not the PHY used on the ACL.

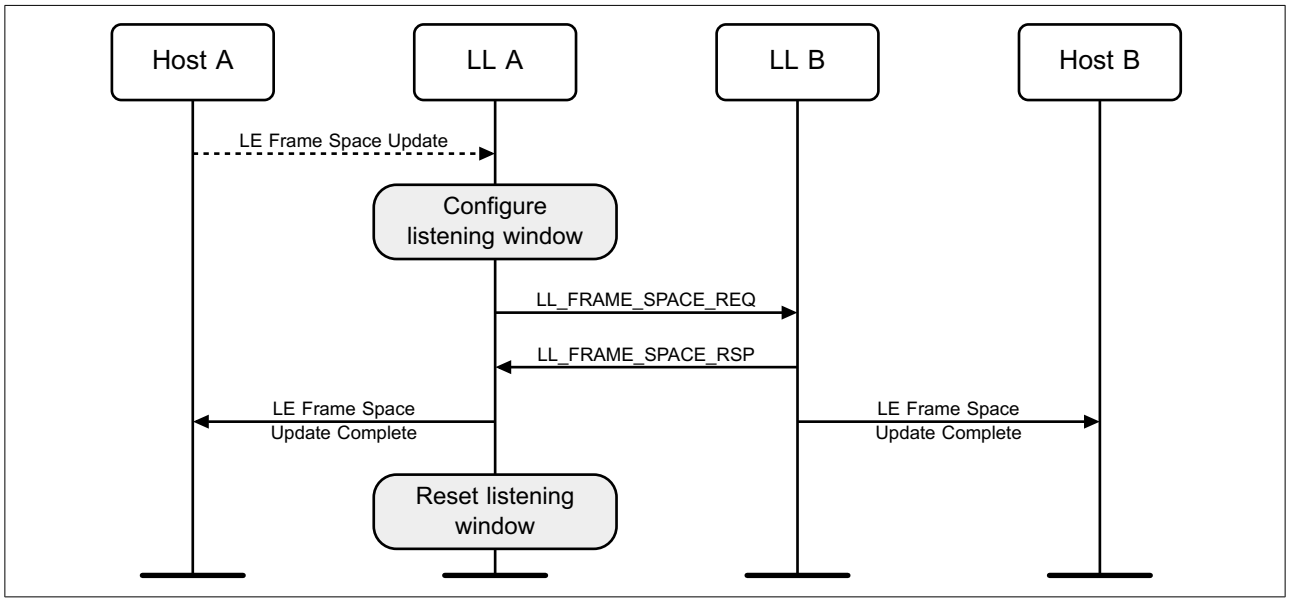

Figure 6.81: Frame Space Update procedure where the responding device does not update the frame space for the PHYs used for the connection

Either the Host or the Controller of device A requests a change to the frame space value of the connection. Device B responds that it can modify T_IFS_ACL_CP on the PHY used on the ACL.

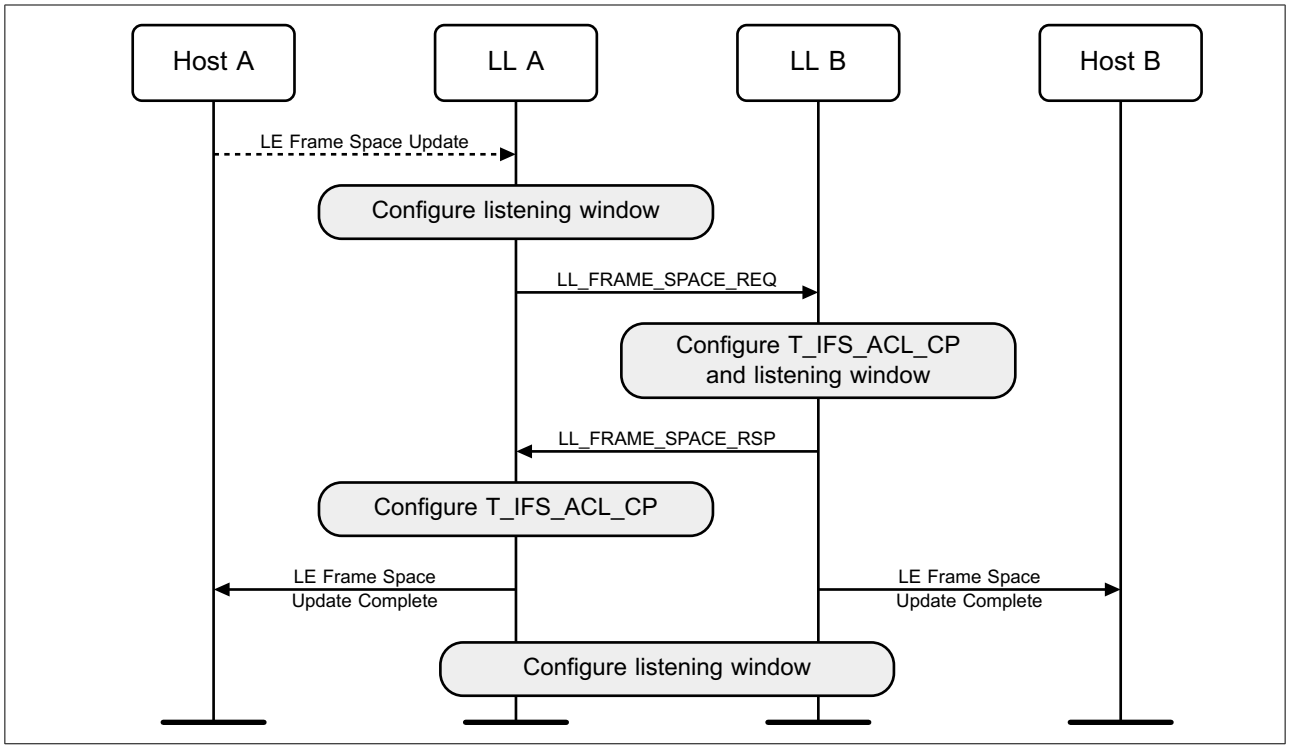

Figure 6.82: Frame Space Update where the frame space for the connection is affected

7 PERIODIC ADVERTISING SYNC TRANSFER

In the following examples, device B is carrying out periodic advertising. Either device A or device B is in a connection with device C and transfers periodic advertising synchronization information about the periodic advertising train to device C.

7.1 Transfer by scanner, reports initially disabled

The scanning device (A) transfers periodic advertising synchronization information to device C, which starts listening to the periodic advertising train but only sends reports to the Host when explicitly requested.

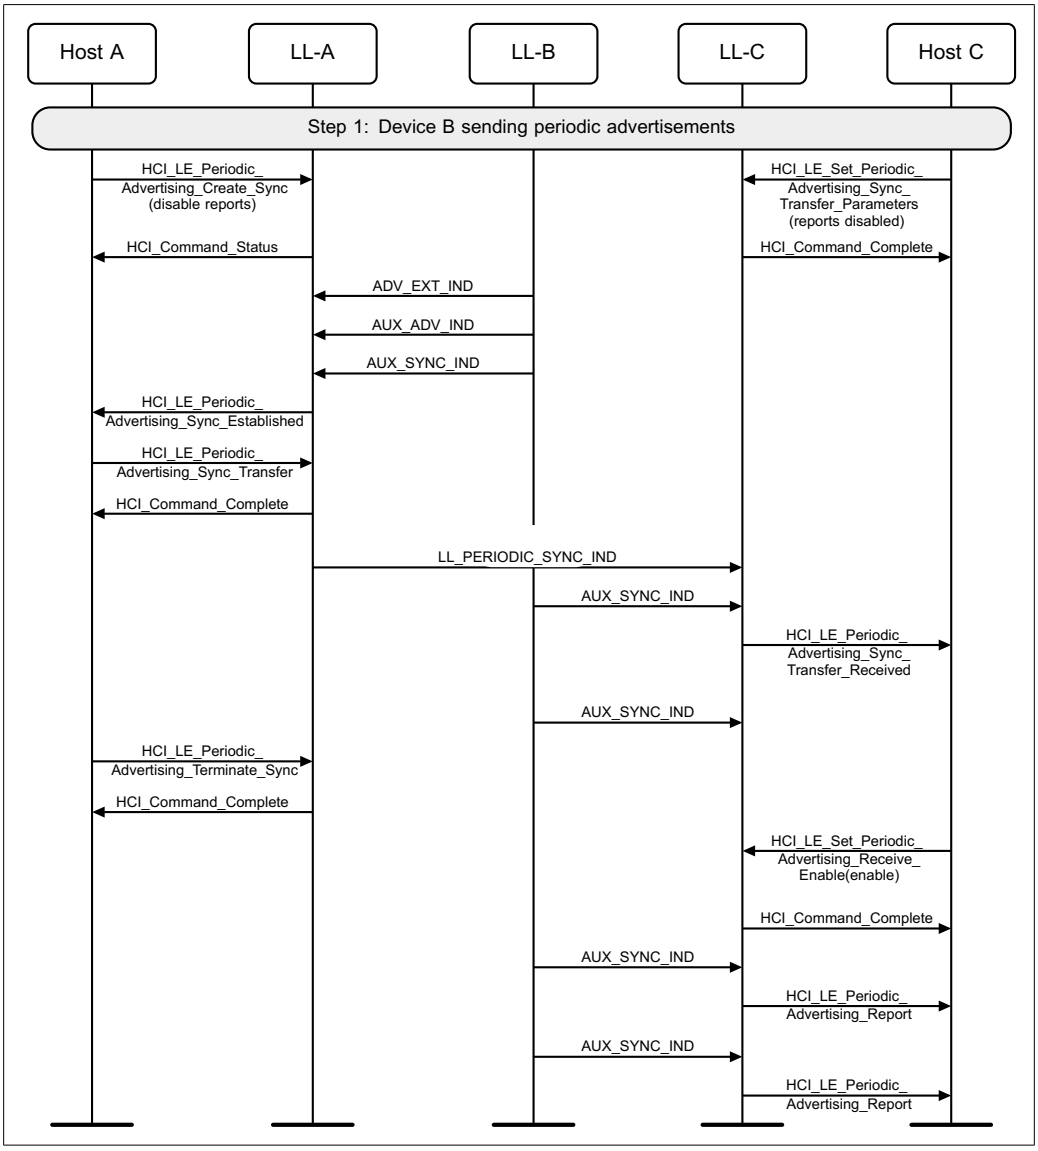

Figure 7.1: Periodic Advertising Sync Transfer by scanner, reports initially disabled

7.2 Transfer by scanner, reports initially enabled

The scanning device (A) transfers periodic advertising synchronization information to device C, which starts listening to the periodic advertising train and immediately sends reports to the Host.

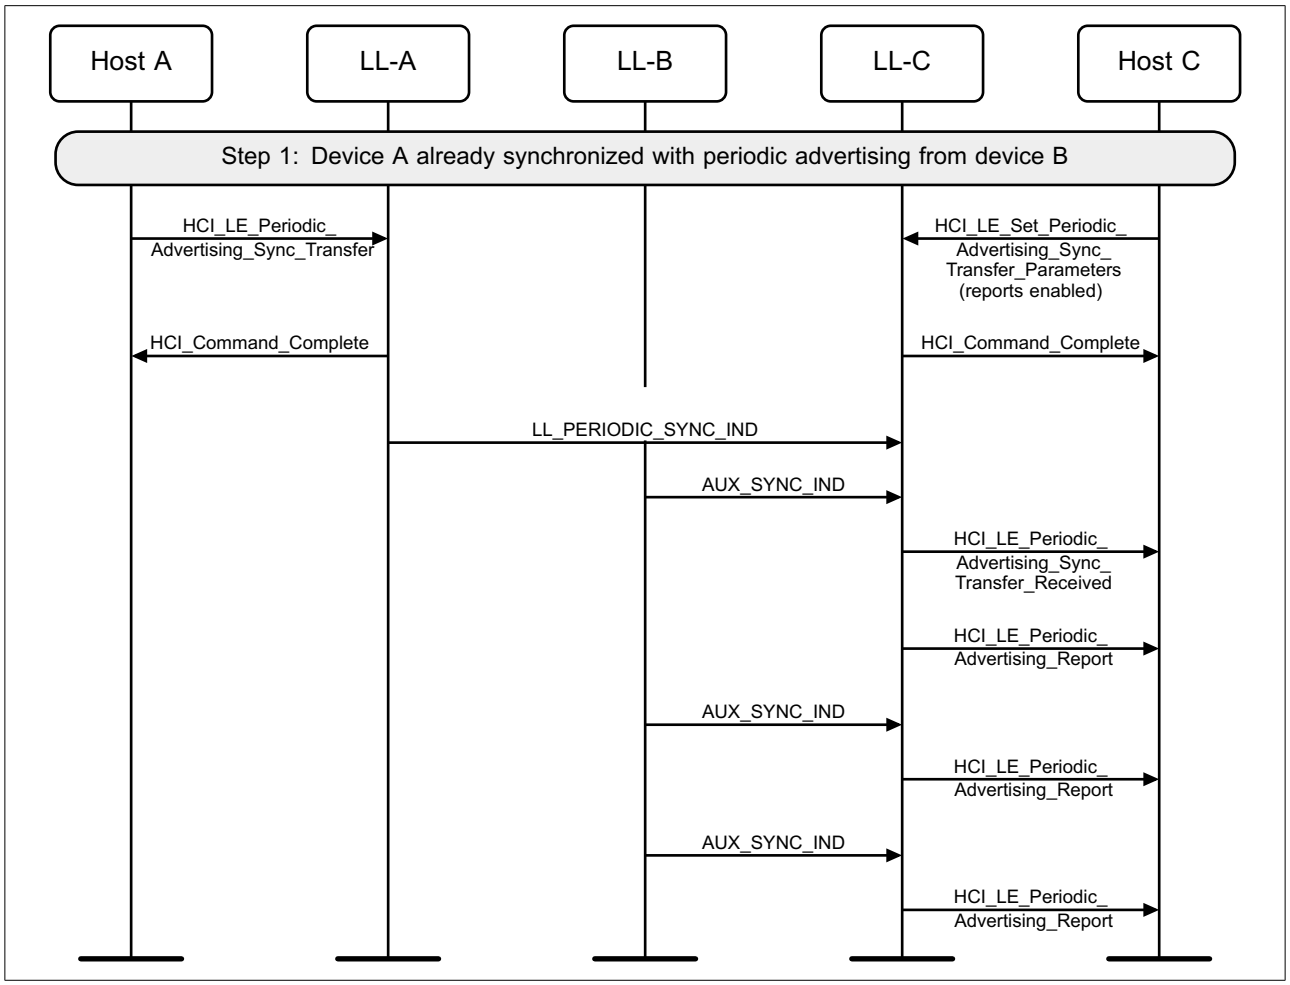

Figure 7.2: Periodic Advertising Sync Transfer by scanner, reports initially enabled

7.3 Transfer by the advertiser

The advertiser (B) directly transfers periodic advertising synchronization information about its periodic advertising to device C. In this example reports to Host C are disabled.

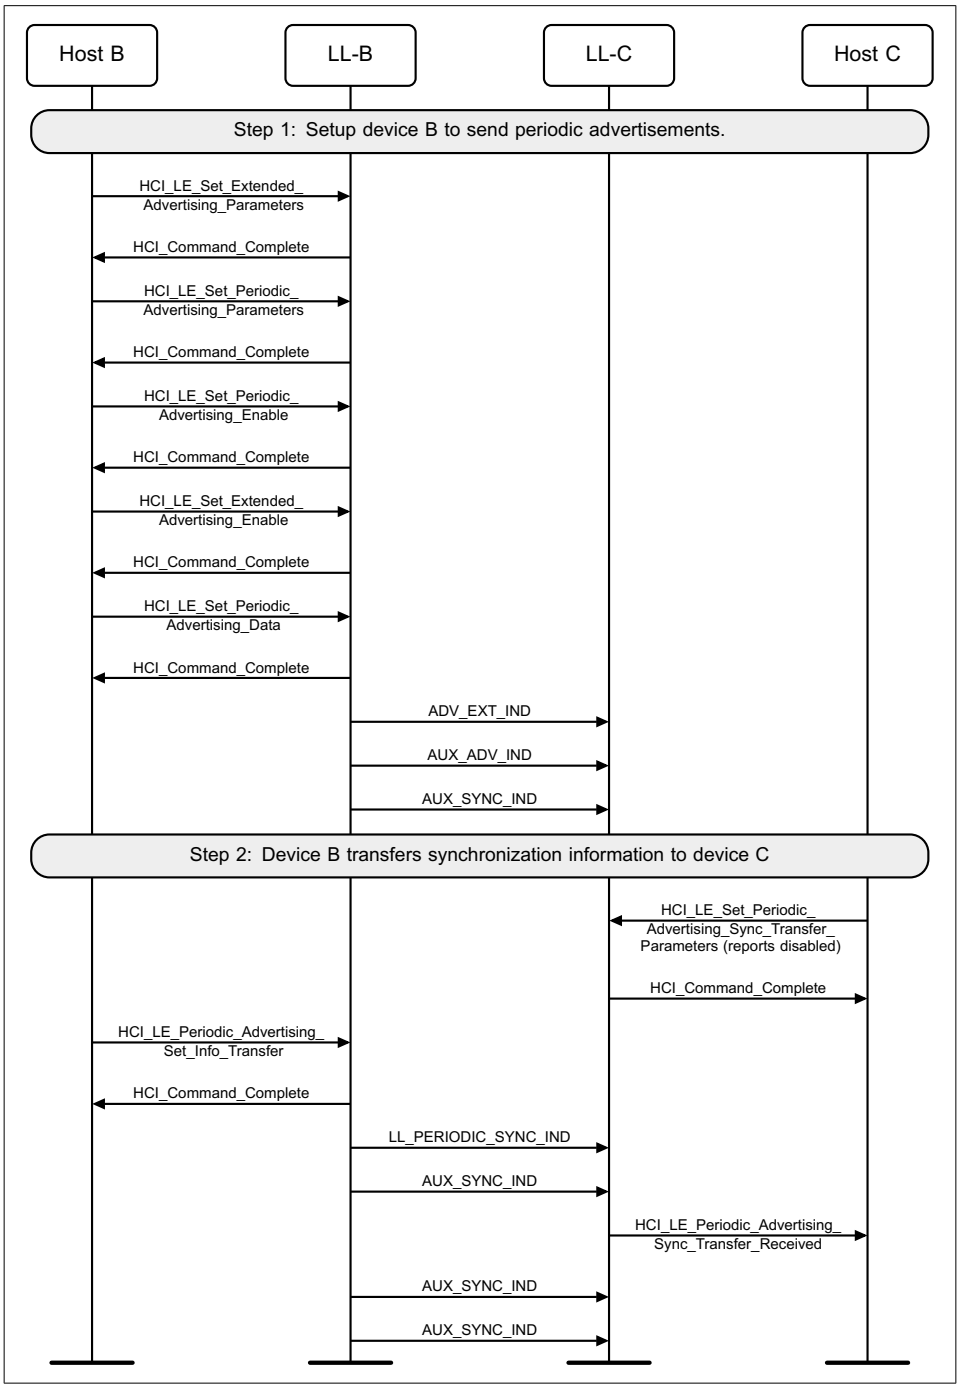

Figure 7.3: Periodic Advertising Sync Transfer by advertiser, reports initially disabled

8 SYNCHRONIZATION STATE

8.1 Synchronizing with a Broadcast Isochronous Group

A device enters the Synchronization state, receives the synchronization information from the periodic advertising train that is associated with the BIG, and synchronizes to a BIS (see Figure 8.1).

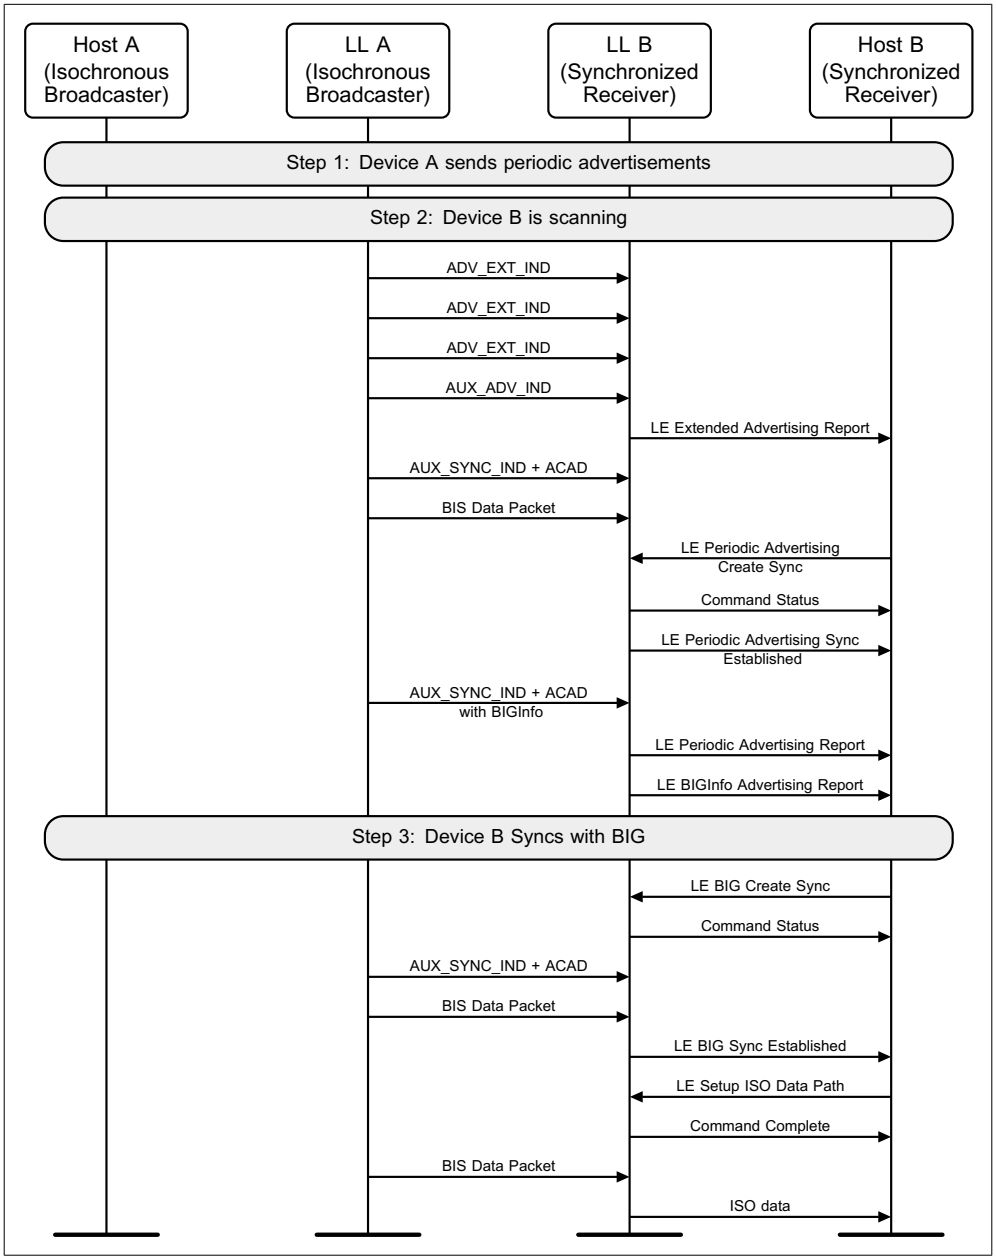

Figure 8.1: Device B synchronizes with a BIG

8.2 Terminate Synchronization with a BIG

A device terminates synchronization with a BIG (see Figure 8.2).

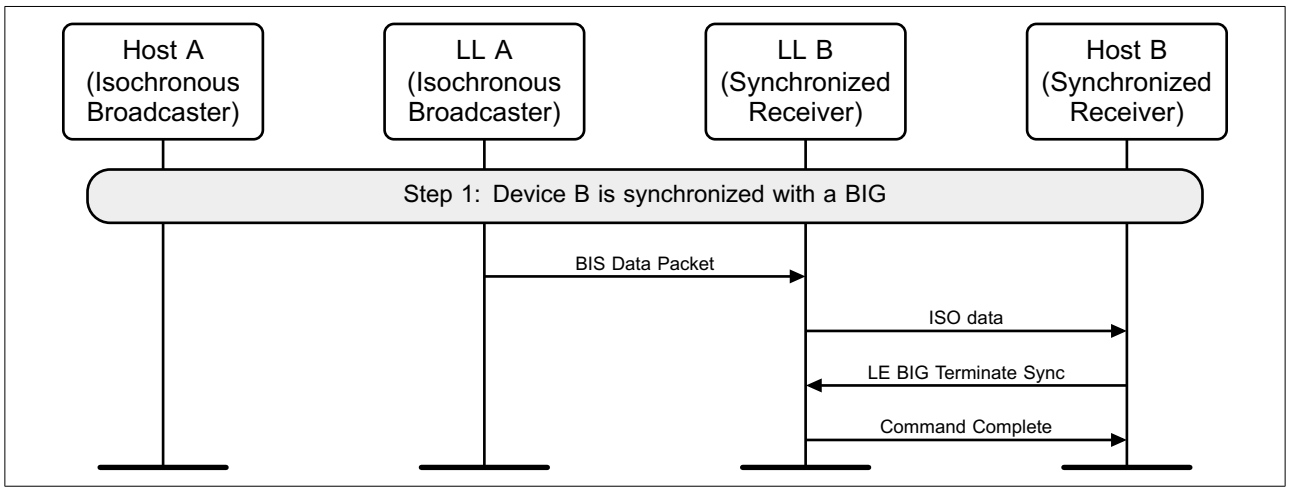

Figure 8.2: Synchronization with a BIG is terminated

8.3 New Channel Map for Broadcast Isochronous Group

A device receives a channel map update for a BIG (see Figure 8.3).

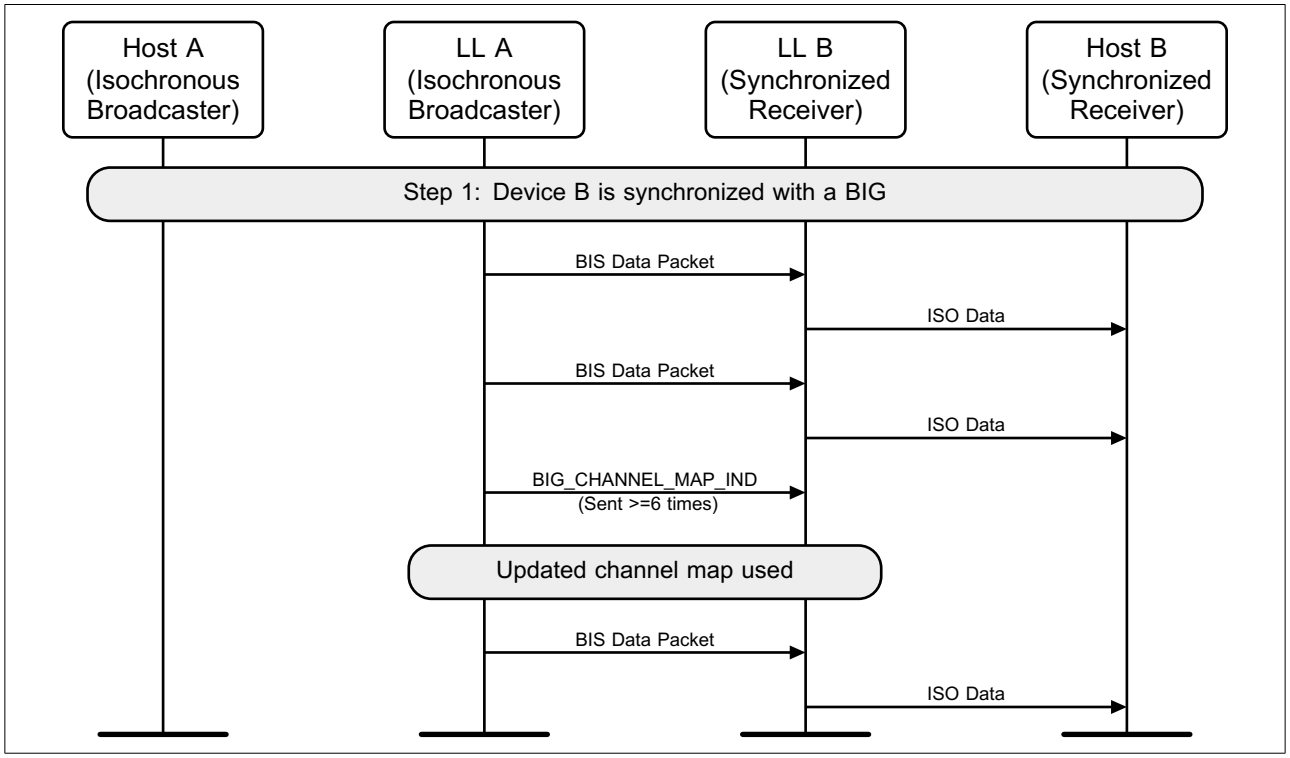

Figure 8.3: Device A sends a channel map update for a BIG

8.4 Lost Synchronization with a Broadcast Isochronous Group

A device loses synchronization with a BIG (see Figure 8.4).

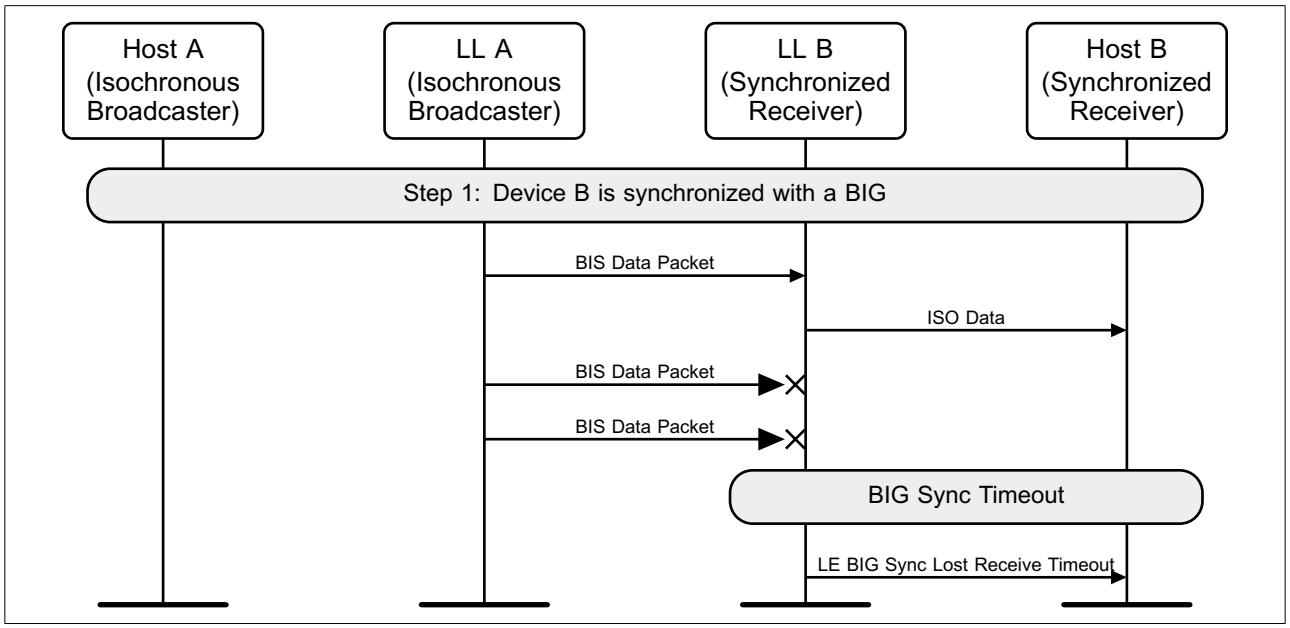

Figure 8.4: Device B loses synchronization with a BIG

8.5 Data path setup for a BIS

Figure 8.5 shows an example of an isochronous broadcast stream from the Broadcaster A. Host A sets up the ISO data path with codec processing in the Controller to create the PDUs transmitted over the BIS. Device B becomes a Synchronized Receiver for

the BIS and sets up the ISO data path to do codec processing in the Controller on the received data PDUs.

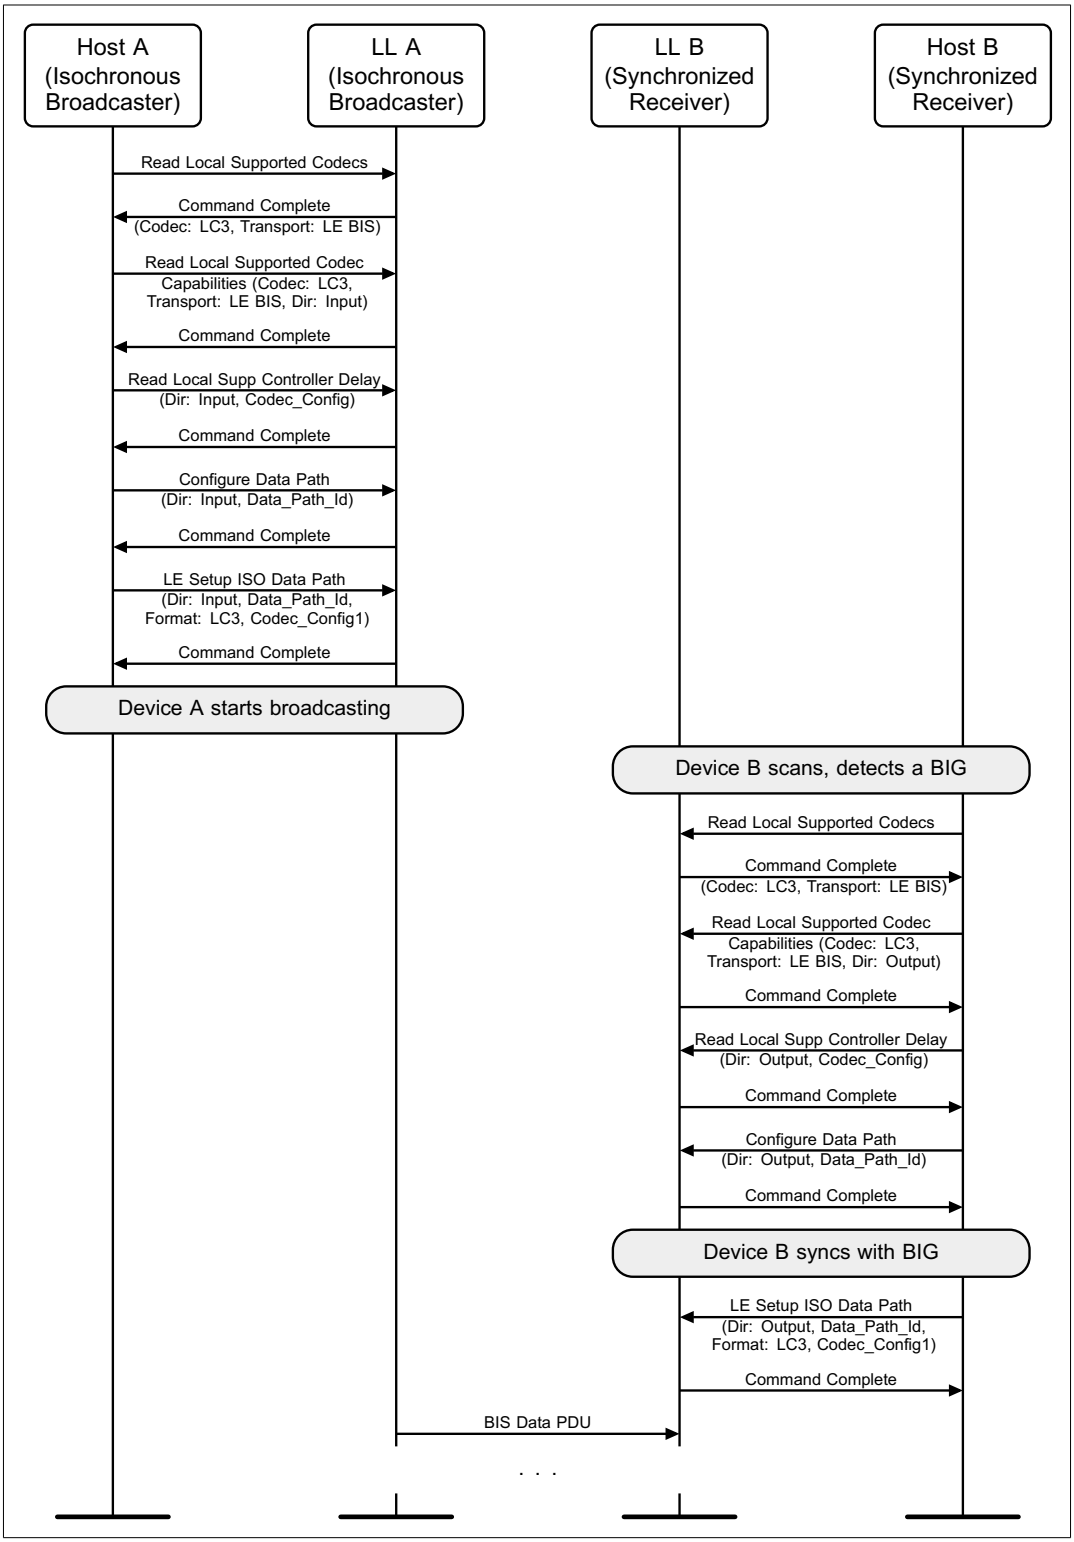

Figure 8.5: Isochronous broadcasting between devices which both have a codec in the Controller

Low Energy Controller
Part E

LOW ENERGY LINK LAYER SECURITY

This Part describes the Link Layer security for Bluetooth Low Energy.

CONTENTS

1 ENCRYPTION AND AUTHENTICATION OVERVIEW

The Link Layer provides encryption and authentication using Counter with Cipher Block Chaining-Message Authentication Code (CCM) Mode, which shall be implemented consistent with the algorithm as defined in IETF RFC 3610 (http://www.ietf.org/rfc/rfc3610.txt) in conjunction with the AES-128 block cipher as defined in NIST Publication FIPS-197 (http://csrc.nist.gov/publications/fips/fips197/fips-197.pdf). A description of the CCM algorithm can also be found in the NIST Special Publication 800-38C (http://csrc.nist.gov/publications/PubsSPs.html).

This specification uses the same notation and terminology as the IETF RFC except for the block cipher key K that in this specification is called the session key (see Section 2.4) and for the Message Authentication Code (MAC) that in this specification is called the Message Integrity Check (MIC) to avoid confusion with the term Media Access Controller.

CCM has two size parameters, M and L. The Link Layer defines these to be:

- M = 4; indicating that the MIC (authentication field) is 4 octets
- L = 2; indicating that the Length field is 2 octets

CCM requires a new session key whenever encryption is started. CCM also requires a unique nonce value for each PDU that is protected by a given session key. The CCM nonce shall be 13 octets.

An ACL connection or a BIS (if present), may be either encrypted and authenticated or unencrypted and unauthenticated. A CIS shall be encrypted and authenticated if, and only if, the associated ACL connection is.

When encryption is enabled, all Data Physical Channel and Isochronous Physical Channel PDUs with a non-zero length Payload shall be encrypted and authenticated. Authentication is performed by appending a MIC field to the Payload. The MIC shall be calculated over the PDU's Payload and the first octet of the header with certain bits (specified in Table 2.3) masked to zero. Encryption shall be applied to the PDU's Payload and MIC.

Each new encrypted PDU with a non-zero length Payload shall be decrypted and authenticated before being sent to the Host or processed by the Link Layer. Authentication is unrelated to the Link Layer acknowledgment scheme; authentication does not have to be performed before the packet is acknowledged by the Link Layer.

In the event of an authentication failure being detected in a Data Physical Channel PDU or CIS Data PDU, the connection or stream carrying the affected PDU shall be

considered lost (see [Vol 6] Part B, Section 4.5.12). The notification to the Host shall specify the error code *Connection Terminated due to MIC Failure* (0x3D). The peer Link Layer will detect this loss of connection through the supervision timeout procedure.

In the event of a MIC failure being detected in a Broadcast Isochronous PDU, synchronization shall be considered lost. The Link Layer shall not receive any further packets on the BIS and the Host shall be notified of the loss of synchronization with the error code *Connection Terminated due to MIC Failure* (0x3D).

1.1 Cryptographic Toolbox

The following cryptographic functions are defined:

- h8 is used to generate group session keys for BIGs.

The building block for the cryptographic functions h8 is the security function AES-CMAC.

When a multi-octet integer parameter is used as input to AES-CMAC inside the h8 function, the most significant octet of the integer shall be the first octet of the stream and the least significant octet of the integer shall be the last octet of the stream.

The functions h6 and h7 used in this Part are defined in [Vol 3] Part H, Section 2.2.

1.1.1 Group Session Key Derivation Function h8

The function h8 is used to generate the Group Session Key (GSK) for encrypting or decrypting payloads of an encrypted BIS. The definition of the h8 function makes use of the AES-CMAC function. The inputs to the function h8 are:

K is 128 bits
S is 128 bits
keyID is 32 bits

For the first AES-CMAC function, K is used as the data m and S is used as the key. The output of the first AES-CMAC function IK (intermediate key which is 128 bits) is used as the key for the second AES-CMAC function and keyID is used as the data m:

$IK = AES\text{-}CMAC_S(K)$
$h8(K, S, keyID) = AES\text{-}CMAC_{IK}(keyID)$

1.1.2 Derivation of Group Session Key

The Link Layer shall derive the Group Long Term Key (GLTK) and Group Session Key (GSK) as follows:

IGLTK = h7(“BIG1”, Broadcast_Code)
GLTK = h6(IGLTK, “BIG2”)
GSK = h8 (GLTK, GSKD, “BIG3”)

The string "BIG1" is mapped into a SALT using ASCII as 0x00000000_00000000_00000000_42494731.

The string "BIG2" is mapped into a keyID using ASCII as 0x42494732.

The string "BIG3" is mapped into a keyID using ASCII as 0x42494733.

2 CCM

This section provides the details for using the CCM algorithm. As specified, the CCM algorithm requires the payload and some additional parameters to be formatted into the CCM nonce, counter-mode blocks and encryption blocks. The CCM nonce provides uniqueness to each packet. The counter-mode blocks are used to calculate the MIC. The encryption blocks provide the keystream that is used to encrypt the payload and the MIC of the Data Physical Channel PDU, CIS Data PDU, BIS Data PDU, and BIG Control PDU.

Sample data of the blocks (see Section 2.2 and Section 2.3) can be found in [Vol 6] Part C, Section 1 and Section 1.2.

2.1 CCM nonce

The CCM nonce is constructed from a 39-bit *packetCounter*, 1-bit *directionBit* and an 8-octet IV (initialization vector). The format of the 13-octet nonce shall be as shown in Table 2.1.

Octet	Field	Size (octets)	Value	Description
0	Nonce0	1	variable	*packetCounter*[7:0]
1	Nonce1	1	variable	*packetCounter*[15:8]
2	Nonce2	1	variable	*packetCounter*[23:16]
3	Nonce3	1	variable	*packetCounter*[31:24]
4	Nonce4	1	variable	Bit 6 – Bit 0: *packetCounter*[38:32] Bit 7: *directionBit*
5	Nonce5	1	variable	IV[7:0]
6	Nonce6	1	variable	IV[15:8]
7	Nonce7	1	variable	IV[23:16]
8	Nonce8	1	variable	IV[31:24]
9	Nonce9	1	variable	IV[39:32]
10	Nonce10	1	variable	IV[47:40]
11	Nonce11	1	variable	IV[55:48]
12	Nonce12	1	variable	IV[63:56]

Table 2.1: CCM nonce format

The Link Layer shall maintain one *packetCounter* per Role for each ACL and CIS connection and one for each BIS that the Link Layer is transmitting or is synchronized to.

For each ACL connection, the *packetCounter* shall be set to zero for the first encrypted Data Physical Channel PDU sent during the encryption start procedure. The *packetCounter* shall then be incremented by one for each new Data Physical Channel PDU that is encrypted. The *packetCounter* shall not be incremented for retransmissions.

For each CIS, *packetCounter* shall equal *cisPayloadCounter* defined in [Vol 6] Part B, Section 4.5.13.1.

For each BIS, *packetCounter* shall equal *bisPayloadCounter* defined in [Vol 6] Part B, Section 4.4.6.3

The value of *packetCounter* used for a BIG Control PDU shall be equal to the value of *packetCounter* used in the first subevent of the BIG event that the BIG Control PDU is part of.

The *directionBit* shall be set to 1 for Data Physical Channel PDUs and CIS Data PDUs sent by the Central and set to 0 for Data Physical Channel PDUs and CIS Data PDUs sent by the Peripheral. The *directionBit* shall be set to 1 for Broadcast Isochronous PDUs sent by the Isochronous Broadcaster.

The IV is common for both Roles of an ACL and CIS. Whenever encryption is started or restarted, a new 8-octet IV shall be used for each pair of communicating devices. The IV for an ACL is determined as specified in [Vol 6] Part B, Section 5.1.3.1. The IV for a CIS or BIS is calculated from an IV_{base} and the Access Address of the CIS or BIS respectively. For a CIS, the IV_{base} shall be set to the value of IV of the associated ACL. For a BIS, the IV_{base} shall be set to the value of GIV contained in the BIGInfo. IV[31:0] shall equal IV_{base}[31:0] XORed with the Access Address of the CIS or BIS while IV [63:32] shall equal IV_{base}[63:32], as shown in Figure 2.1. The IV for a BIG control logical link shall be determined in the same way as for a BIS.

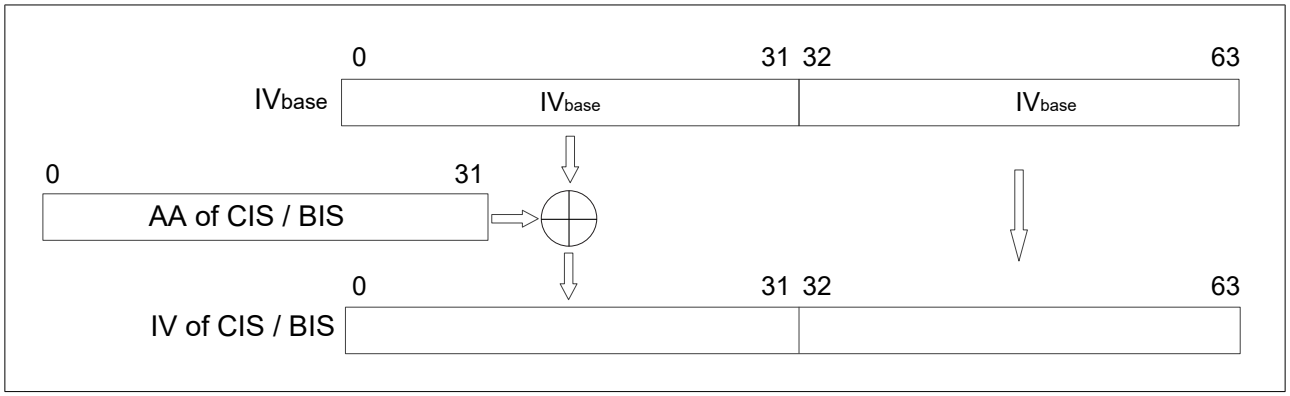

Figure 2.1: Generation of IV for a CIS or BIS

Note: If a CIS is terminated or considered lost and then a new CIS with the same CIS_ID is created in the same CIG, the new CIS must still have a new access address (see [Vol 6] Part B, Section 2.1.2).

2.2 Counter mode blocks

For calculating the MIC, the multiple counter mode blocks are generated according to the CCM specification. These are referred to as blocks B_0 – B_n. Table 2.2 defines the format of block B_0. Table 2.3 defines the format of block B_1 that is devoted to the authentication of the additional authenticated data. Additional B blocks are generated as needed for authentication of the payload.

Offset (octets)	Field	Size (octets)	Value	Description
0	Flags	1	0x49	As per the CCM specification
1	Nonce	13	variable	The nonce as described in Table 2.1. Nonce0 shall have offset 1. Nonce12 shall have offset 13.
14	Length[MSO]	1	0x00	The most significant octet of the length of the payload
15	Length[LSO]	1	variable	The least significant octet of the length of the payload

Table 2.2: Block B_0 format

Offset	Field	Size (octets)	Value	Description
0	AAD_Length[MSO]	1	0x00	The most significant octet of the length of the additional authenticated data
1	AAD_Length[LSO]	1	0x01	The least significant octet of the length of the additional authenticated data

Offset	Field	Size (octets)	Value	Description
2	AAD	1	variable	The PDU header's first octet with the following bits masked to 0. Data Physical channel PDU: NESN, SN, MD. Connected Isochronous PDU: NESN, SN, NPI, CIE. Broadcast Isochronous PDU: CSSN, CSTF.
3	Padding	13	0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00	These octets are only used to pad the block. They are not part of the packet and never transmitted.

Table 2.3: Block B_1 format

2.3 Encryption blocks

The CCM algorithm uses the A_i blocks to generate keystream that is used to encrypt the MIC and the PDU payload. Block A_0 is always used to encrypt and decrypt the MIC. Block A_1 is always used to encrypt and decrypt the first 16 octets of the Payload. Subsequent blocks are always used to encrypt and decrypt the rest of the Payload as needed.

Offset (octets)	Field	Size (octets)	Value	Description
0	Flags	1	0x01	As per the CCM specification
1	Nonce	13	variable	The nonce as described above Nonce0 shall have offset 1. Nonce12 shall have offset 13.
14	i[MSO]	1	variable	The most significant octet of the counter i
15	i[LSO]	1	variable	The least significant octet of the counter i

Table 2.4: Block A_i format

2.4 Session Keys

The session key for an ACL connection shall be generated as specified in [Vol 6] Part B, Section 5.1.3.1.

The session key for a CIS shall be the same as that for the associated ACL.

The session key for a BIS shall be the Group Session Key derived in Section 1.1.2.

3 DETERMINISTIC RANDOM BIT GENERATOR

The Link Layer provides the ability to generate random bit sequences using a Deterministic Random Bit Generator (DRBG), which is implemented consistent with the recommendations defined in NIST Special Publication 800-90Ar1 [1] with a security strength of 128 bits, in conjunction with the AES-128 block cipher. Table 3.1 shows the operational definitions for the DRBG specification.

Block Cipher	**AES-128**
Supported security strength	128 bits
Temporal key length	128 bits
Nonce vector V length	128 bits
Seed length	256 bits
Entropy input length	128 bits
Required minimum entropy for instantiation	128 bits
Personalization string length	128 bits
Maximum number of requests between reseeds	2^{48}

Table 3.1: DRBG definitions

The DRBG requires a temporal key K_{DRBG} and a nonce vector V_{DRBG}. These two values shall both be instantiated locally within each peer Controller before the first invocation of the DRBG within each LE connection on which CS is being used. The inputs to this instantiation procedure are the initialization vector, instantiation nonce, and personalization vector, which are the result of the CS Security Start procedure described in [Vol 6] Part B, Section 5.1.23. The nonce vector V_{DRBG} shall be incremented at each invocation of the DRBG, and its value shall not repeat for the life of the DRBG temporal key. This increment function is described in Section 3.2.2.

The values of K_{DRBG} and V_{DRBG} shall not be exported outside the local Controller.

Figure 3.1 provides a functional overview of the DRBG function. Entropy material (a) in the form of an initialization vector, instantiation nonce, and personalization vector used to seed the DRBG, is generated from the CS Security Start procedure described in [Vol 6] Part B, Section 5.1.23. The instantiation function h9 (b) described in Section 3.1.5 is invoked to generate the security material for the DRBG. A CS step counter, transaction ID, and transaction counter are used to increment (c) the DRBG security nonce, as described in Section 3.2.2, which in turn is used as an input to the DRBG (d) to generate the required random bits (e) as described in Section 3.1.6. Finally, backtracking resistance (f) is invoked every time a new CS procedure is started, as described in Section 3.1.7.

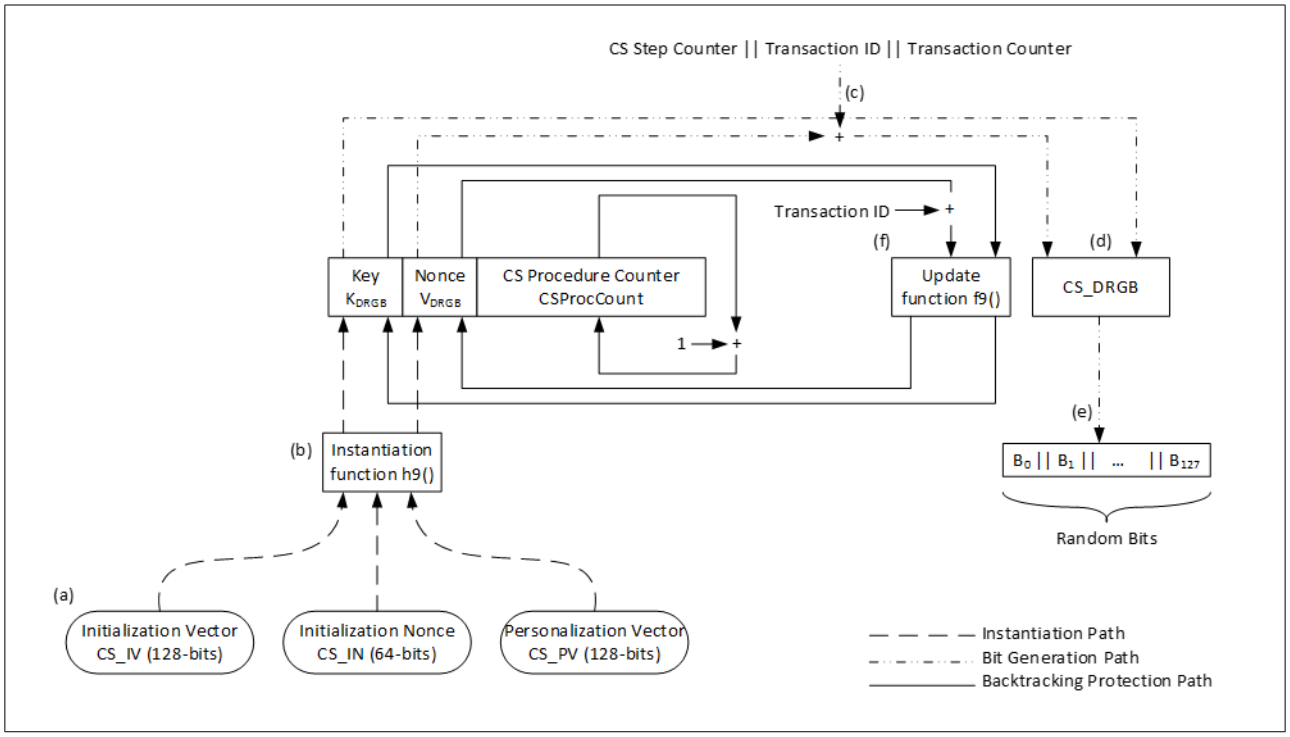

Figure 3.1: DRBG functional overview

3.1 Cryptographic toolbox

Section 3.1 defines several cryptographic functions for the DRBG. The instantiation function h9 and random bit generation function CS_DRBG are the primary cryptographic procedures, which in turn invoke subordinate functions. Figure 3.2 shows the call tree for the cryptographic toolbox described in this section.

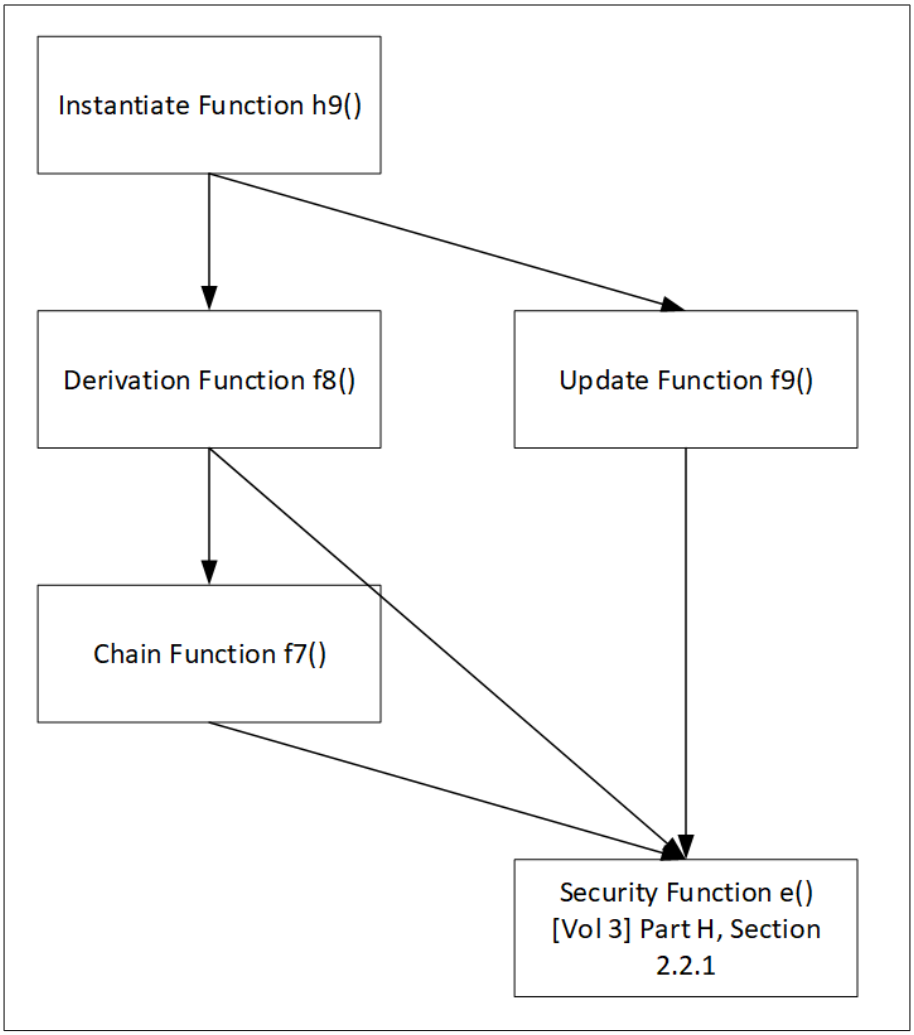

Figure 3.2: CS cryptographic call tree

Within these cryptographic procedures, the following operations are used.

Operation	Meaning
len(X)	Computes the 8-bit byte length of X in octets
leftmost(X)	Returns the leftmost 128 bits of X
rightmost(X)	Returns the rightmost 128 bits of X

Table 3.2: Operators used by the cryptographic toolbox

3.1.1 Octet and bit ordering

With the exception of the random bit generation function CS_DRBG (see Section 3.1.6), all toolbox functions operate on one or more input arguments represented by a series of octets, and all toolbox functions output results that are a series of octets. With the exception of V_{DRBG}, the leftmost to rightmost representation is indexed starting from

octet 0, which is then followed by octet 1, and so on. For V_{DRBG}, the leftmost to rightmost representation is indexed starting from octet 15 and ending with octet 0.

In several toolbox functions, the hexadecimal notation of the form 0xXXXXXX is used to represent a series of octet values necessary for the processing of that function. In these cases, the leftmost to rightmost representation is used. In the example below, 0x01 represents the leftmost octet and 0x06 represents the rightmost octet.

0x010203040506

In several toolbox functions, octet and bit strings may be converted to integers to perform a mathematical operation such as increment or modulus function. Let $\{b_0, b_1, \ldots b_n\}$ represent that string in its leftmost to rightmost format. The following summation is then used to convert that bit string into an integer where *i* represents the position of each bit from the original bit string and is indexed from [0...n].

$$\sum \left(2^{n-i} \times b_i\right) \quad \text{(EQ 1)}$$

The reverse operation is used to convert an integer into a string of bits, using the same leftmost to rightmost format.

3.1.2 DRBG chain function f7

The DRBG chain function f7 takes a 128-bit key and an input string whose length is a multiple of 128 bits and generates an output that is 128 bits long using a cipher block chaining technique. The input string is segmented into 128-bit blocks that are processed in sequence. The security function e (see [Vol 3] Part H, Section 2.2.1) is invoked on each block whose output is XORed with the next block. This process is repeated until all input blocks are processed.

The following value is returned from f7:

hout is 128 bits

The following temporary values are used:

block[i] is an array of 128-bit string quantities

The input/output format of h7 is as follows:

hout = f7(k, input_bit_string)

f7 processing is as follows:

hout = 0x00000000000000000000000000000000

Starting with the leftmost bits of input_bit_string, split into 128-bit blocks from block[1] to block[n]

for each block[i]

hout = hout xor block[i]

hout = e(k, hout);

return hout

The block diagram representing function f7() is shown in Figure 3.3.

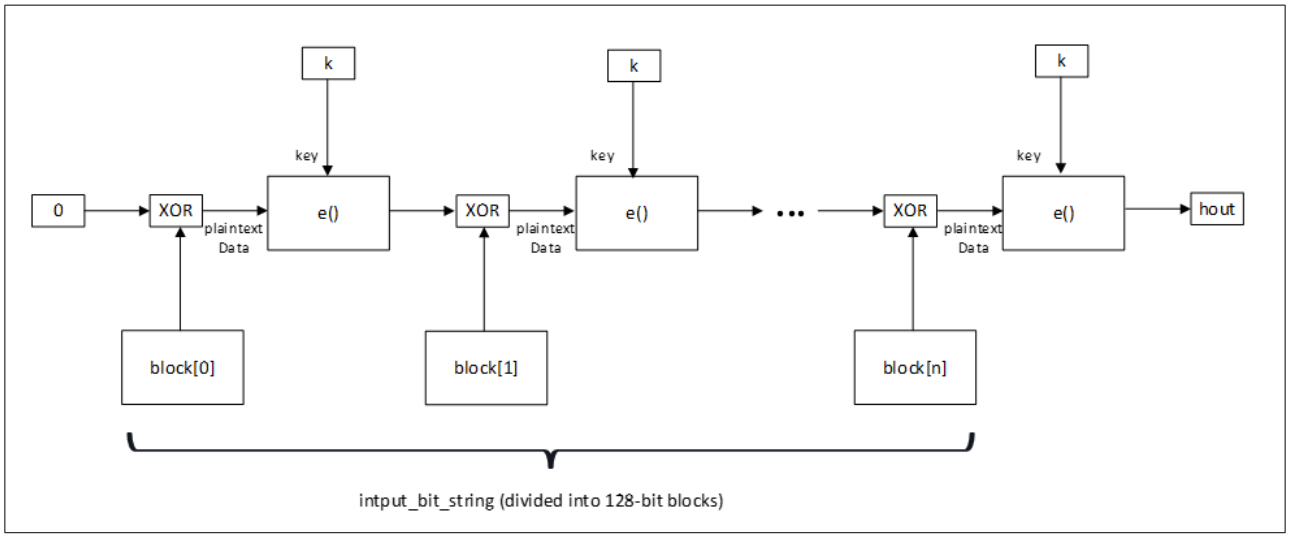

Figure 3.3: f7() block diagram

3.1.3 DRBG derivation function f8

The DRBG derivation function f8 is used to generate DRBG seed material that is 256 bits long. It takes an input bit string that is 320 bits long. Both f7 (see Section 3.1.2) and security function e (see [Vol 3] Part H, Section 2.2.1) are invoked by f8.

The following values are returned from f8:

SM is 256 bits

The following temporary values are used:

S is 512 bits

K is 128 bits

K2 is 128 bits

V is 128 bits

X is 128 bits

The input/output format of f8 is as follows:

SM = f8(input_bit_string)

The derivation function uses the input_bit_string to form a temporary bit string S constructed as shown below.

S = 0x0000002800000020 || input_bit_string || 0x80 || 0x00000000000000000000000000000000

K = 0x000102030405060708090A0B0C0D0E0F

V = 0x00000000000000000000000000000000

K2 = f7(K, V || S)

V = 0x00000001**1**00000000000000000000000

X = f7(K, V || S)

SM = e(K2, X)

SM = SM || e(K2, SM)

return SM

The block diagram representing function f8() is shown in Figure 3.4.

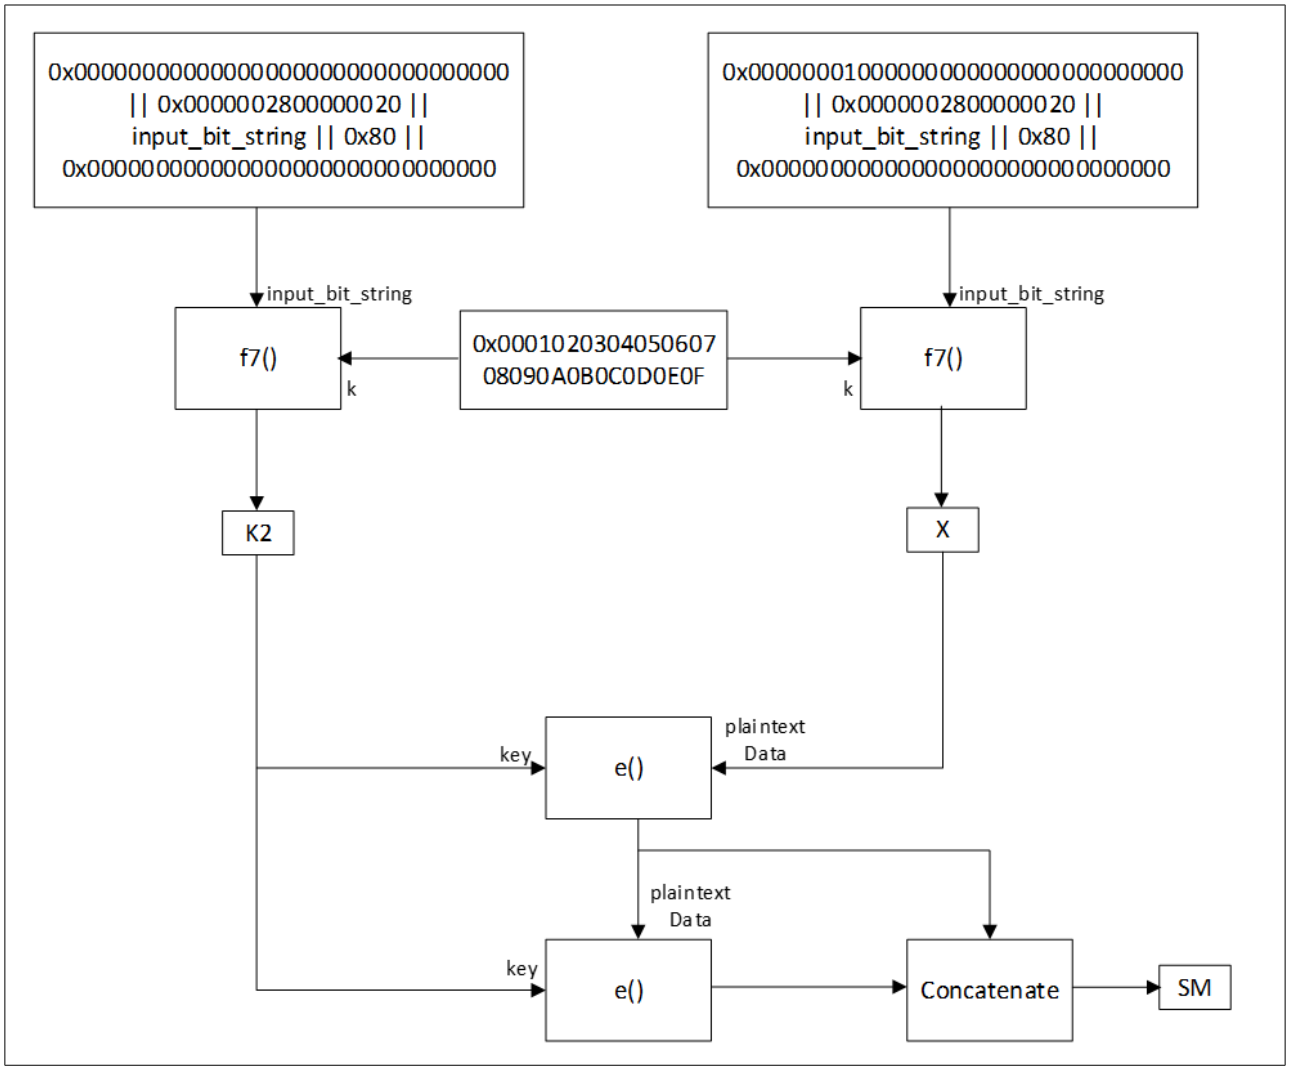

Figure 3.4: f8() block diagram

3.1.4 DRBG update function f9

The DRBG update function f9 is used to update and refresh a DRBG 128-bit temporal key K and a 128-bit nonce vector V using a 256-bit seed material (SM) that may carry fresh entropy. The SM value may also be 0 if f9 is called for backtracking purposes, as described in Section 3.1.7. The security function e (see [Vol 3] Part H, Section 2.2.1) is invoked by f9.

The following values are returned from f9:

K_{out} is 128 bits

V_{out} is 128 bits

The following temporary values are used:

X is 256 bits

The input/output format of f9 is as follows:

K_{out}, V_{out} = f9(SM, K, V)

f9 processing is as follows:

V = V[127:8] || ((V[7:0] + 1) mod 2^8)

X = e(K, V)

V = V[127:8] || ((V[7:0] + 1) mod 2^8)

X = X || e(K, V)

X = X $\oplus$ SM

K_{out} = leftmost(X)

V_{out} = rightmost(X)

return K_{out}, V_{out}

The block diagram representing function f9() is shown in Figure 3.5.

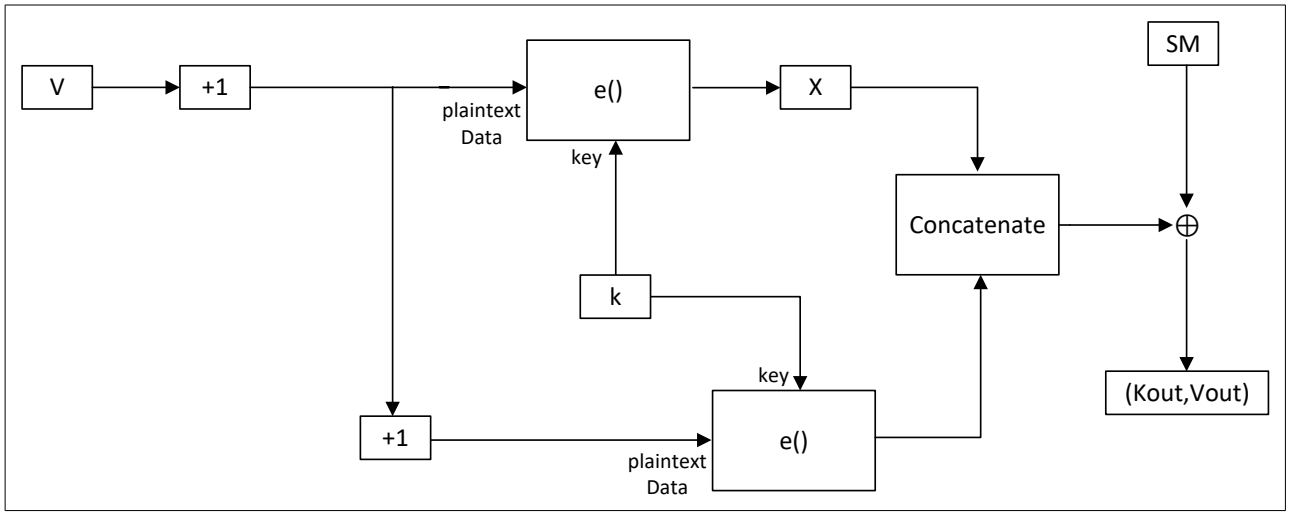

Figure 3.5: f9() block diagram

3.1.5 DRBG instantiation function h9

The DRBG instantiation function h9 is used to instantiate the DRBG temporal key K_{DRBG} and a nonce vector V_{DRBG}. The inputs to h9 are the 128-bit CS_IV, 64-bit CS_IN, and 128-bit CS_PV values that are the result of the CS Security Start procedure described in [Vol 6] Part B, Section 5.1.23. SM below represents the derived seed material for the DRBG instantiation.

The following values are returned from h9:

K_{DRBG} is 128 bits

V_{DRBG} is 128 bits

The following temporary values are used:

SM is 256 bits

K is 128 bits

V is 128 bits

The input/output format of h9 is as follows:

K_{DRBG}, V_{DRBG} = h9(CS_IV, CS_IN, CS_PV)

In the instantiation function, both a seed derivation function f8 (see Section 3.1.3) and a key and nonce vector update function f9 (see Section 3.1.4) are invoked.

SM = f8(CS_IV || CS_IN || CS_PV)

K = 0x00000000000000000000000000000000

V = 0x00000000000000000000000000000000

K_{DRBG}, V_{DRBG} = f9(SM, K, V)

return K_{DRBG}, V_{DRBG}

The block diagram representing function h9() is shown in Figure 3.6.

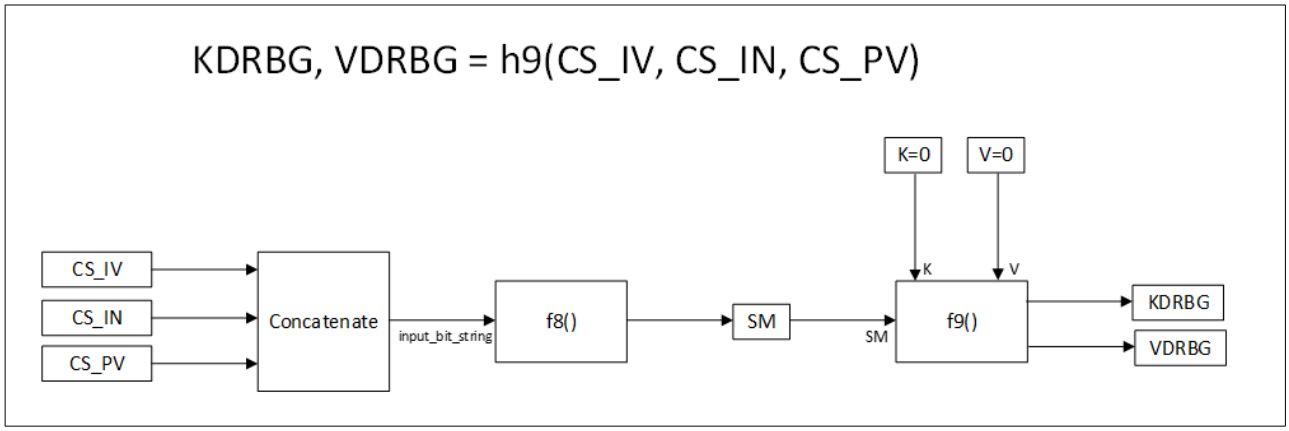

Figure 3.6: h9() block diagram

3.1.6 Random bit generation function CS_DRBG

Random bit generation function CS_DRBG makes use of the security function e (see [Vol 3] Part H, Section 2.2.1) to generate a fresh 128-bit random bit sequence. The instantiated key and nonce vector V values are described in Section 3.

randomBits[0:127] = e(K_{DRBG}, V_{DRBG} + counters)

CS_DRBG(number of required bits) ⊆ randomBits[0:127]

Refer to Section 3.2.1 for a description of the counters that contribute the nonce V value.

The maximum number of bits that may be generated in any single invocation is 128 bits. The number of required bits may vary from operation to operation. If less than 128 bits are required, then the return value of CS_DRBG shall be a subset of the bits returned from security function e The subset of bits shall be extracted starting from the most significant bit in leftmost to rightmost order. For example, on a new invocation of e, if an operation requires 8-bit values, then randomBits[0:7] would be the first set used, randomBits[8:15] would be the second set used, and so on. If at any point the number of required bits exceeds the number of fresh bits remaining to draw upon, then the remaining bits shall be discarded, the nonce vector V_{DRBG} shall be updated (see Section 3.2.2), and the security function e shall be invoked again.

Depending on the operation, the random bits may also be used as unsigned integer values. If unsigned integer values are used, the most significant bit returned shall represent the most significant bit of the unsigned integer that is formed from that set of bits.

3.1.7 DRBG backtracking resistance

Backtracking resistance as described in [1] is included in DRBG. Backtracking resistance shall be invoked every time the CSProcCount is incremented (see [Vol

6] Part B, Section 5.1.26) before the first invocation of the CS_DRBG for that CS procedure (see Section 3.1.6).

The procedure for backtracking resistance makes use of the DRBG update function f9 (see Section 3.1.4) to update the K_{DRBG} and V_{DRBG} values for any subsequent CS procedure. The inputs to f9 are the running set of values for K_{DRBG} and V_{DRBG}. From this value, the CS Transaction_Identifier field shall be set as described in [Vol 6] Part H, Section 4.8. The CS Step_Counter and CS Transaction_Counter fields shall be reset to zero relative to this V_{DRBG} value. The procedure for applying these modifications of the V_{DRBG} value is described in Section 3.2.2.

The following values are returned from f9 when used for backtracking resistance:

K_{DRBG} is 128 bits

V_{DRBG} is 128 bits

f9 is invoked as follows using the values for K_{DRBG} and V_{DRBG} as described above as inputs:

K_{DRBG}, V_{DRBG} = f9(0, K_{DRBG}, V_{DRBG})

return K_{DRBG}, V_{DRBG}

3.2 DRBG based on a block cipher

The Deterministic Random Bit Generator uses a block cipher as described in [1]. The block cipher employed is the security function e described in [Vol 3] Part H, Section 2.2.1. The inputs to e for the DRBG are key K_{DRBG} and nonce vector V_{DRBG}, both of which shall be instantiated using security function h9 as described in Section 3.1.5, and afterwards updated using security function f9 as described in Section 3.1.4, before any use of the DRBG.

3.2.1 DRBG nonce V

The instantiation content of the nonce V vector, as described in Section 3.1.5 represents the starting value from which the DRBG increment function operates. From that starting value, several nonce counter fields are defined, as shown in Table 3.3. Each counter field octet is structured in leftmost to rightmost bit format, from bit 7 to bit 0.

Octet	Field	Size (octets)	Value	Description
0	Counter0	1	variable	8-bit CS Transaction_Counter, with bit 7 being the most significant bit
1	Counter1	1	variable	8-bit CS Transaction_Identifier, with bit 7 being the most significant bit
2	Counter2	1	variable	Octet 0 (LSO) of the CS Step_Counter, with bit 7 being the most significant bit
3	Counter3	1	variable	Octet 1 (MSO) of the CS Step_Counter, with bit 7 being the most significant bit
4	Counter4	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
5	Counter5	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
6	Counter6	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
7	Counter7	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
8	Counter8	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
9	Counter9	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
10	Counter10	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
11	Counter11	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
12	Counter12	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
13	Counter13	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
14	Counter14	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key
15	Counter15	1	fixed	Bits remain set as instantiated or updated for the life of the DRBG key

Table 3.3: DRBG nonce/counter format

3.2.2 DRBG nonce increment function

The Link Layer shall maintain one DRBG nonce/counter (V) value per ACL connection as described in Section 3.2.1.

The management of the nonce V CS Step_Counter field, CS Transaction_Identifier field, and CS Transaction_Counter field are described in this section. All other fields in the nonce V counter shall be set relative to the V_{DRBG} content resulting from either the procedure described in Section 3.1.5 or the Backtracking Resistance procedure described in Section 3.1.7.

The nonce V CS Step_Counter field shall be initialized from the V_{DRBG} value resulting from either the instantiation procedure described in Section 3.1.5 or the Backtracking Resistance procedure described in Section 3.1.7. This value shall be used for invocations of the DRBG that are necessary to the start of the first step of a CS procedure. Thereafter, the nonce V CS Step_Counter initialization value shall be added to the step number, *CSStepCount* at the time that the DRBG is invoked again, as described in [Vol 6] Part H, Section 4.3, modulo 2^{16}.

$$\text{CS Step\_Counter} = (V_{DRBG}[31:16] + \textit{CSStepCount}) \textit{ mod } 2^{16}$$

The CS Step_Counter value shall not exceed a value of 2^{16} - 1 when used within the CS Step_Counterfield of the nonce V value in each CS procedure instance. The DRBG is not invoked at every CS step within a CS procedure.

The nonce V CS Transaction_Identifier field shall be set to a specific transaction identifier, *CSTransactionID* as defined in [Vol 6] Part H, Section 4.8, added to the V_{DRBG} value resulting from either the instantiation procedure (see Section 3.1.5) or the Backtracking Resistance procedure (see Section 3.1.7), modulo 2^8.

$$\text{CS Transaction\_Identifier} = (V_{DRBG}[15:8] + \textit{CSTransactionID}) \textit{ mod } 2^{8}$$

The nonce V CS Transaction_Counter field is incremented in conjunction with each CS transaction identifier type defined in [Vol 6] Part H, Section 4.8. That is, for each CS transaction identifier type, it might be necessary to invoke the DRBG one or more times. The CS Transaction_Counter field shall be incremented each time the DRBG is invoked for that specific CS transaction identifier type at a specific CS step. A separate CS Transaction_Counter field value shall be maintained for each possible CS transaction identifier type because the invocation of the DRBG might be interleaved with different CS transaction identifier types at any one CS step. In the next two paragraphs, the possible CS Transaction_Counter field values are referred to collectively as the CS Transaction_Counter field.

The CS Transaction_Counter field shall be initialized to the V_{DRBG} value resulting from either the instantiation procedure (see Section 3.1.5) or the Backtracking Resistance procedure (see Section 3.1.7), each time the nonce V CS Step_Counter field is set to a new value. The CS Transaction_Counter initialization value shall be added to the transaction counter, *CSTransactionCounter* as defined in [Vol 6] Part H, Section 4.8

before each invocation of the DRBG, for the specific CS Transaction_Identifier field setting.

$$\text{CS Transaction\_Counter} = (V_{DRBG}[7:0] + \textit{CSTransactionCounter}) \textit{ mod } 2^8$$

The CS Transaction_Counter field shall not be incremented more than $2^8 - 1$ times for any combined single setting for the CS Transaction_Identifier and the CS Step_Counter fields.

Low Energy Controller
Part F

DIRECT TEST MODE

This Part describes the Direct Test Mode for RFPHY testing of Bluetooth Low Energy devices.

CONTENTS

1 INTRODUCTION

Direct Test Mode is used to control the implementation under test (IUT) and provides a report back to the Tester.

Direct Test Mode shall be set up using one of two alternate methods:

1. over HCI (as defined in Section 2) or
2. through a 2-wire UART interface (as defined in Section 3)

Each IUT shall implement one of the two Direct Test Mode methods in order to test the Low Energy PHY layer. Figure 1.1 illustrates the alternatives for Direct Test Mode setup.

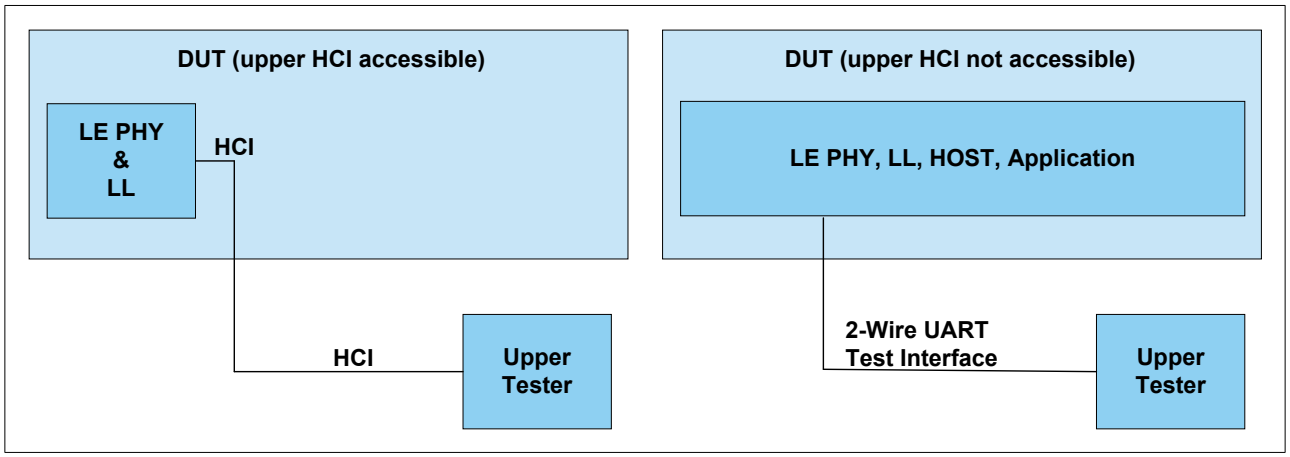

Figure 1.1: Setup alternatives for LE Direct Test Mode

Figure 1.2 illustrates the Bluetooth LE Direct Test Mode setup principle using a 2-wire UART interface.

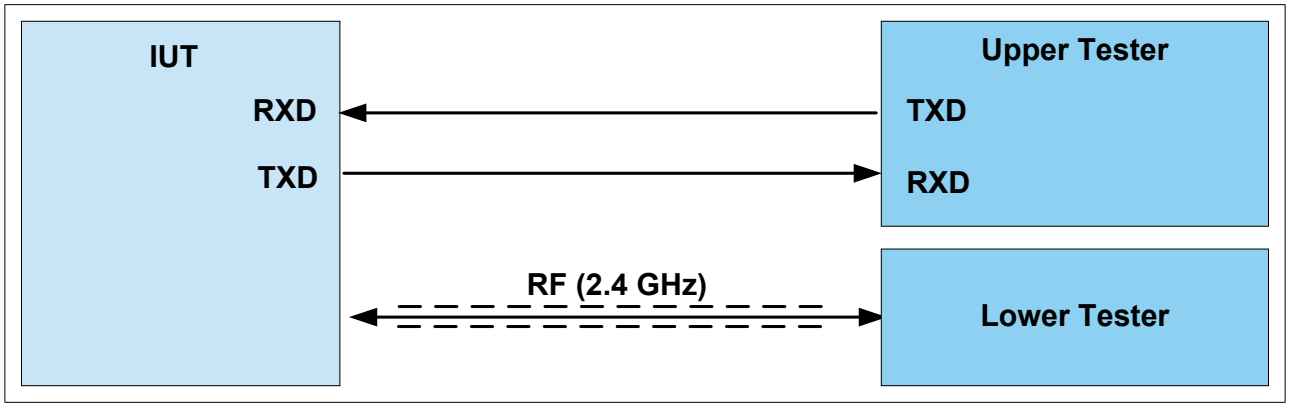

Figure 1.2: RFPHY test setup for Direct Test Mode (UART control)

For LE devices supporting the Channel Sounding feature, DTM shall only be available when an accessible Host Controller Interface is provided, as shown in Figure 1.1 (left). The applicable CS commands and event are defined in Section 2.3.

2 LOW ENERGY TEST SCENARIOS

2.1 Test sequences

These sequences are used as routines and used to control an LE IUT with an accessible HCI or a 2-wire UART interface for RF testing.

The following mapping shall be performed from the RF testing commands to HCI commands and events or 2-wire UART commands and events, depending on which method is used:

RF Test command / event	HCI command / event	2-wire UART command / event
LE_Transmitter_Test command	HCI_LE_Transmitter_Test command	LE_Transmitter_Test command
LE_Receiver_Test command	HCI_LE_Receiver_Test command	LE_Receiver_Test command
LE_Test_End command	HCI_LE_Test_End command	LE_Test_End command
LE_Status event	HCI_Command_Complete event	LE_Test_Status event
LE_Packet_Report event	HCI_Command_Complete event	LE_Packet_Report event

Table 2.1: Mapping table of HCI / 2-wire UART commands and events

The HCI commands and events used in Direct Test Mode are defined in [Vol 4] Part E, Section 7.8 and [Vol 4] Part E, Section 7.7.65 respectively.

Receiver Test

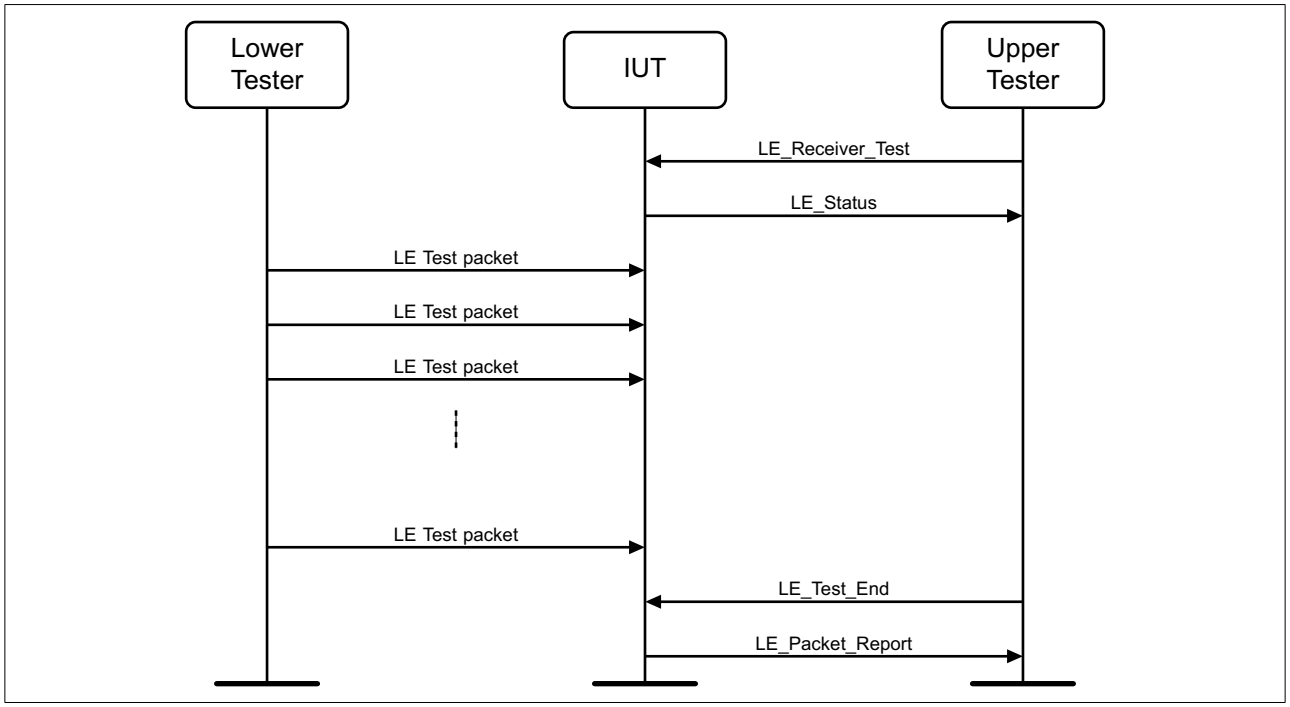

Figure 2.2: Receiver Test MSC

2.3 Channel Sounding test commands

The relevant HCI commands and events for performing RFPHY Channel Sounding testing are defined in Table 2.2.

HCI command / event	Description
HCI_LE_CS_Test command	This command is used to begin a CS test where the IUT is placed in the role of either the initiator or reflector. A single CS procedure which consists of one or more CS subevents is scheduled.
HCI_LE_CS_Subevent_-Result event	This event is generated when the local Controller has results to report for a CS subevent within the CS procedure.
HCI_LE_CS_Subevent_-Result_Continue event	This event is generated after the local Controller has comple-ted a new CS subevent measurement and has already sent an HCI_LE_CS_Subevent_Result event for the specified subevent.
HCI_LE_CS_Test_End com-mand	This command is used to terminate any CS test that is in progress.
HCI_LE_CS_Test_End_-Complete event	This event is generated when the local Controller has stopped an ongoing CS test as a result of the HCI_LE_CS_Test_End command.

Table 2.2: Channel Sounding HCI commands and events

The HCI commands and events used in Direct Test Mode are defined in [Vol 4] Part E, Section 7.8.

2.4 Channel Sounding message sequence charts

Test scenarios for Channel Sounding require the Tester and IUT having interchangeable roles, one side being in the initiator role, and the other in the reflector role. Figure 2.3 shows an MSC with the IUT in the initiator role, with Figure 2.4 the IUT in the reflector role.

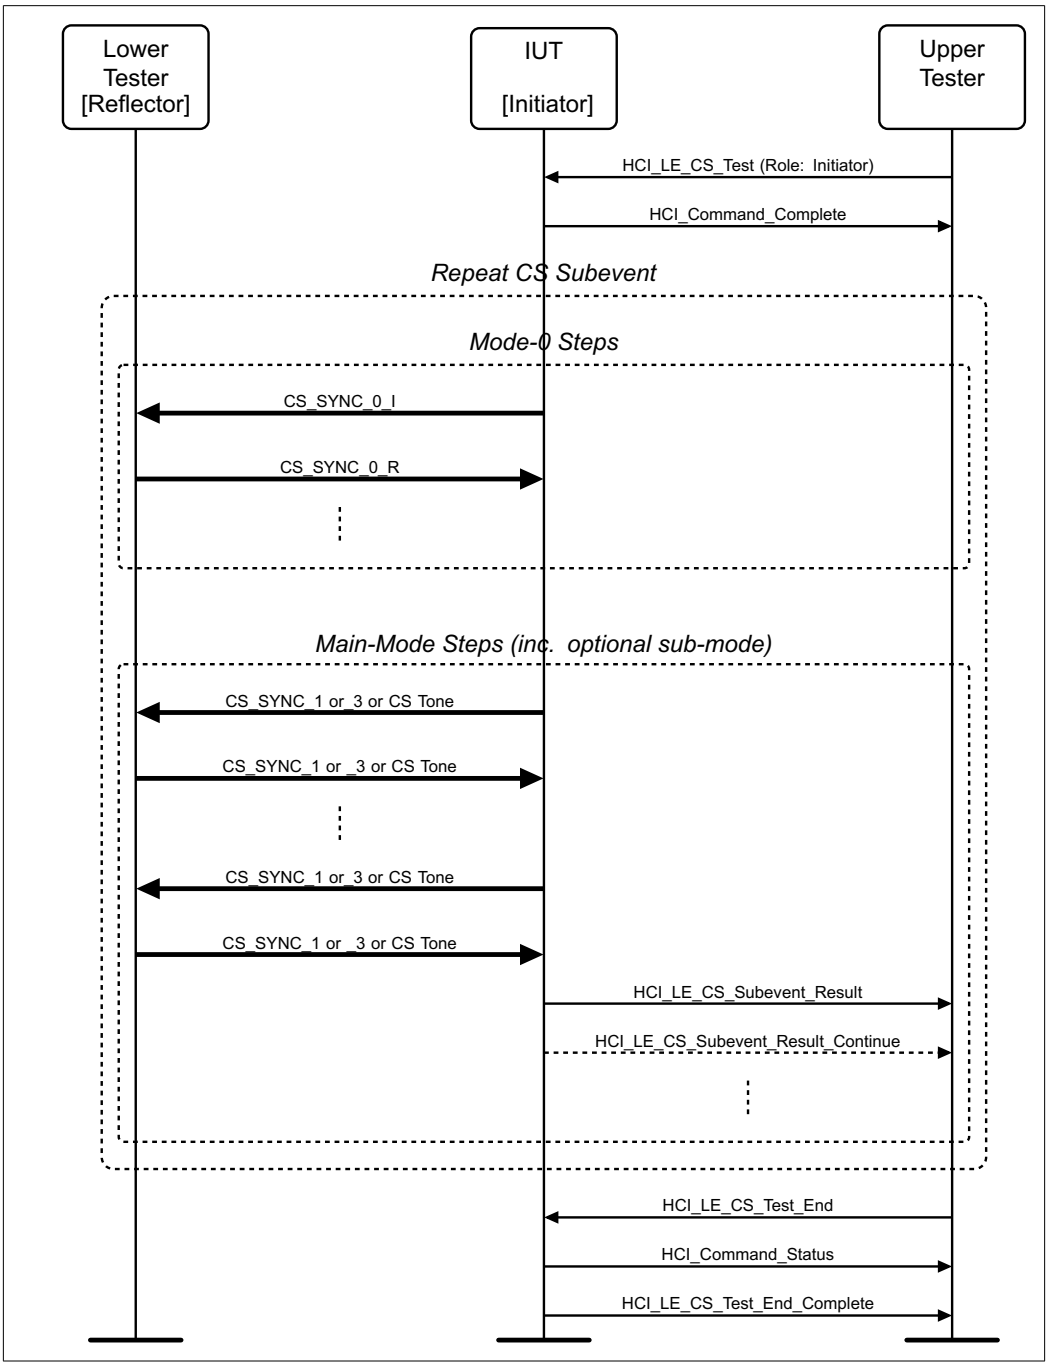

Figure 2.3: Channel Sounding Test MSC: IUT in Initiator Role

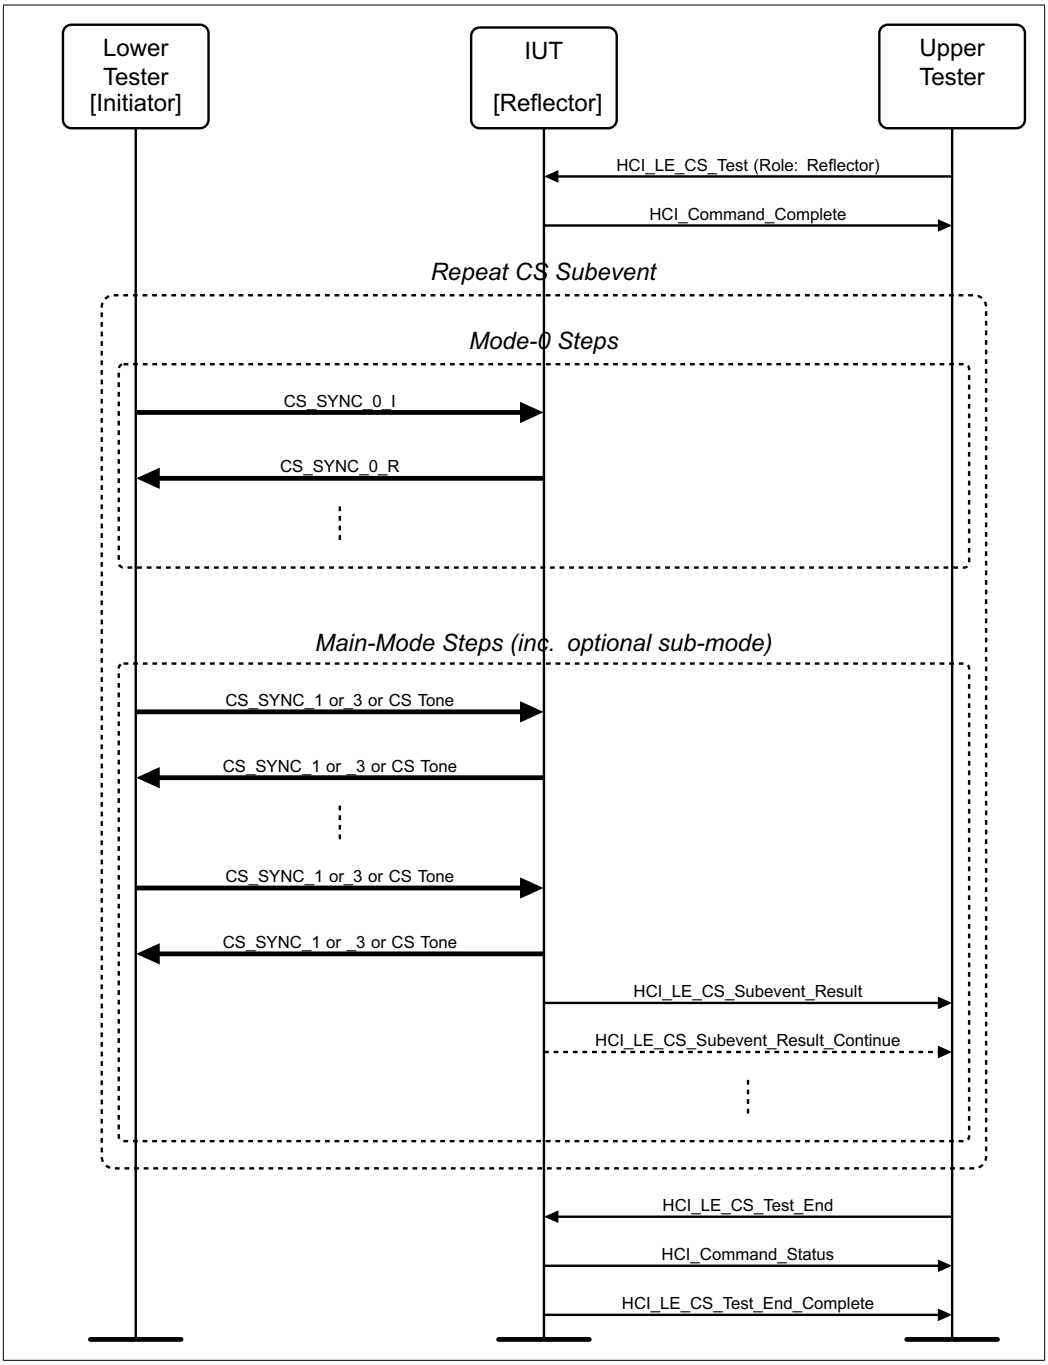

Figure 2.4: Channel Sounding Test MSC: IUT in Reflector Role

The test procedure below applies to all test scenarios, the IUT can assume either of the Initiator or Reflector roles as described in Figure 2.3, and Figure 2.4.

1. The Upper Tester sends an HCI_LE_CS_Test command to the IUT with Role configured appropriately to either 0x00 (initiator), or 0x01 (reflector) and receives a successful HCI_Command_Complete event response. All Channel Sounding parameters referred to in this test procedure are derived from the HCI_LE_CS_Test

command. The first channel in the Channel parameter list is used as the starting channel for the test. At the beginning of the test, either the IUT or Lower Tester in the reflector role shall listen on this channel until it receives the first mode-0 transmission from the initiator.

2. The initiator sends the mode-0 CS_SYNC_0_I transmission to the reflector.
3. The reflector responds with the mode-0 CS_SYNC_0_R transmission to the initiator.
4. Repeat steps 2 and 3 the number of times specified by the Mode_0_Steps parameter.
5. The initiator sends the Main-Mode step transmission to the reflector.
6. The reflector responds with a Main-Mode transmission to the initiator.
7. Optional Sub_Mode steps specified by Sub_Mode_Type may be exchanged.
8. Repeat steps 5 to 7 with the parameters configured by the HCI_LE_CS_Test command from step 1 for this Channel Sounding test procedure observing the Subevent_Len, Subevent_Interval, the computed channel map or Channel array override, and so on.
9. The IUT sends an HCI_LE_CS_Subevent_Result event to the Upper Tester for each CS subevent based on the procedure parameters from step 1. The IUT may also send one or more HCI_LE_CS_Subevent_Result_Continue events for each CS subevent to the Upper Tester.
10. The Upper Tester sends an HCI_LE_CS_Test_End command to the IUT. The IUT shall respond to the Tester with an HCI_Command_Status event. When the IUT has successfully sent all pending CS subevent results it shall generate an HCI_LE_CS_Test_End_Complete event.

The test scenario for the Stable Phase measurement differs from every other Channel Sounding RFPHY test. The Stable Phase test is enabled via the Override_Config Bit 10 in the HCI_LE_CS_Test command, defined in [Vol 4] Part E, Section 7.8.143. The Tester shall assume the role of the reflector, and IUT the role of initiator.

The Stable Phase measurement period is defined as T_PM_MEAS. T_PM_MEAS is equal to the CS step mode-2 duration with parameter configuration as defined in [Vol 6] Part A, Section 3.4.

The Stable Phase measurement is performed on CS_Tone transmissions. As CS_Tone transmissions are continuous unmodulated carrier waves the Tester cannot accurately synchronize. Instead, the Tester shall rely up on the preceding mode-0 step transmission (CS_SYNC_0_I) sent from the IUT to provide a satisfactory measurement anchor point. The Tester is not required to respond to the IUT mode-0 transmission in this test, but the IUT shall still transmit a CS_Tone as if the tester had properly

transmitted its portion of the mode-0 exchange. The IUT is not required to provide a measurement report on the mode-0 packet (CS_SYNC_0_R) if sent back from the Tester. The measurement period T_PM_MEAS shall begin following a duration T_RD + T_IP2 + T_SY + T_GD + T_FM + T_RD + T_FCS (not including the 1µs exclusion period).

Figure 2.5 shows the Stable Phase measurement MSC. Each Stable Phase measurement cycle uses a single CS procedure containing a single CS subevent. Each CS subevent contains a single mode-0 step, followed by a single CS_Tone. As such, there is a single measurement period T_PM_MEAS available for obtaining phase

measurement samples per CS procedure. The number of measurement cycles may be adjusted dependent upon the number of phase measurement samples required.

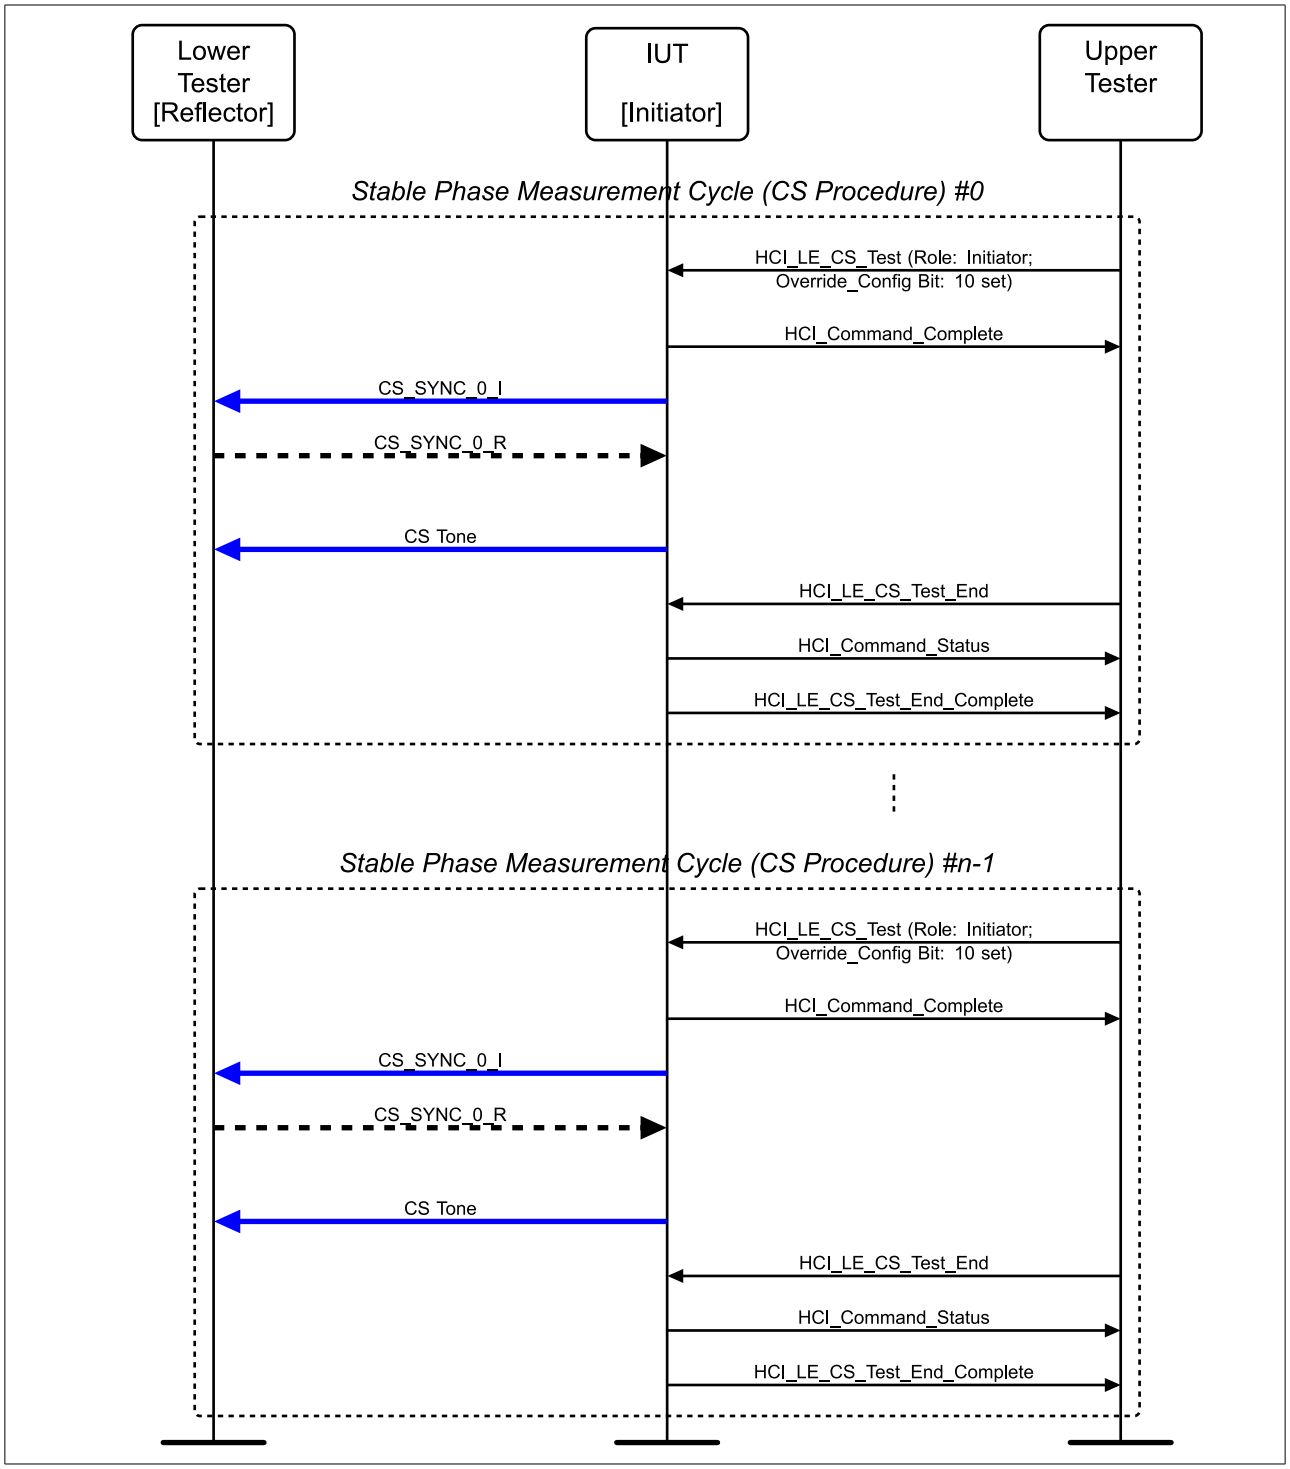

Figure 2.5: Stable Phase Channel Sounding Test MSC

3 UART TEST INTERFACE

3.1 UART Interface characteristics

The UART interface characteristics shall be set to use the following parameters:

- Baud rate: One of the following shall be supported by the IUT:

  1200, 2400, 9600, 14400, 19200, 38400, 57600, 115200
- Number of data bits: 8
- No parity
- 1 stop bit
- No flow control (RTS or CTS)

3.2 UART functional description

The Upper Tester shall always initiate any a test scenario using the UART interface. The IUT shall respond to the commands from the Upper Tester.

The Upper Tester sends test commands to the IUT. The IUT shall respond with a test status event or packet report event.

The Upper Tester shall not transmit further commands before it receives a response from the IUT. If the Upper Tester does not receive a response from the IUT within the time $t_{TIMEOUT}$, the Upper Tester shall transmit a reset command (i.e., a test setup command with the control argument set to 0x00) to the IUT and display an appropriate error message. For the reset command, $t_{RESPONSE}$ and $t_{TIMEOUT}$ do not apply.

On reception of a reset command, the IUT shall reset all parameters to their default state.

Definitions

- All commands and events consist of 16 bits (2 bytes).
- The most significant bit is bit number 15.
- The least significant bit is bit number 0.
- The most significant byte is from bit 15 to 8.
- The least significant byte is from bit 7 to 0.
- Commands and events are sent most significant byte (MSB) first, followed by the least significant byte (LSB).

3.3 Commands and events

3.3.1 Command and event behavior

Table 3.1 outlines the set of commands which can be received by the IUT and the corresponding response events that can be transmitted by the IUT.

Command (IUT RXD)	Event (IUT TXD)
LE_Test_Setup	LE_Test_Status SUCCESS LE_Test_Status FAIL
LE_Receiver_Test	LE_Test_Status SUCCESS LE_Test_Status FAIL
LE_Transmitter_Test	LE_Test_Status SUCCESS LE_Test_Status FAIL
LE_Test_End	LE_Packet_Report LE_Test_Status FAIL

Table 3.1: 2-Wire command and event behavior

3.3.2 Commands

Command packet formats are shown in Figure 3.1 and Figure 3.2.

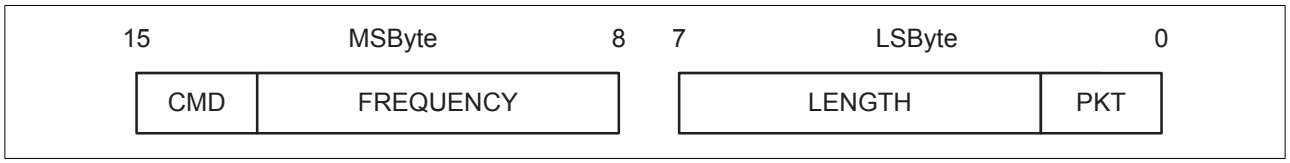

Figure 3.1: Command message format for LE_Transmitter_Test and LE_Receiver_Test commands

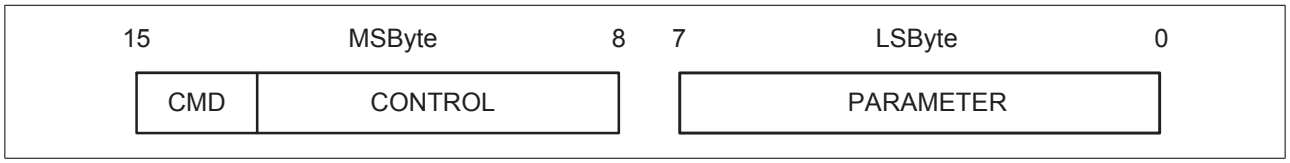

Figure 3.2: Command message format for LE_Test_Setup and LE_Test_End commands

Note: Some cases of the Test Setup and Test End commands have four parameter values, differing only in the bottom 2 bits, specified for the same action. In these cases the specific value chosen does not affect the behavior of the command.

Direct Test Mode

CMD (command): *Size: 2 bits*

Value b_1b_0	Parameter Description
00	LE_Test_Setup command
01	LE_Receiver_Test command
10	LE_Transmitter_Test command
11	LE_Test_End command

Test Setup command: *Size: 14 bits*

Control (6 bits)	Parameter (8 bits)	Description
0x00	0x00 to 0x03	RESET; the upper 2 bits of the data length for any LE_Transmitter_Test or LE_Receiver_Test commands following are set to 00, the PHY is set to LE 1M, the receiver assumes the transmitter has a standard modulation index, and no Constant Tone Extension is present.
	Any other value	Reserved for future use
0x01	0x00 to 0x0F	Set the upper 2 bits of the data length for any LE_Transmitter_Test or LE_Receiver_Test commands following to bits 2 and 3 of the parameter (to enable a length greater than 0x3F to be used)
	Any other value	Reserved for future use
0x02	0x04 to 0x07	PHY set to LE 1M
	0x08 to 0x0B	PHY set to LE 2M
	0x0C to 0x0F	PHY set to LE Coded; transmitter is to use S=8 data coding
	0x10 to 0x13	PHY set to LE Coded; transmitter is to use S=2 data coding
	Any other value	Reserved for future use
0x03	0x00 to 0x03	Receiver assumes transmitter has a standard modulation index
	0x04 to 0x07	Receiver assumes transmitter has a stable modulation index
	Any other value	Reserved for future use
0x04	0x00 to 0x03	Read the test case supported features. The LE_Test_Status event will return the state of the test case supported features as detailed in the LE_Test_Status event (Section 3.4.1).
	Any other value	Reserved for future use

Control (6 bits)	Parameter (8 bits)	Description
0x05	0x00 to 0x03	Read supportedMaxTxOctets (see [Vol 6] Part B, Section 4.5.10)
	0x04 to 0x07	Read supportedMaxTxTime (see [Vol 6] Part B, Section 4.5.10)
	0x08 to 0x0B	Read supportedMaxRxOctets (see [Vol 6] Part B, Section 4.5.10)
	0x0C to 0x0F	Read supportedMaxRxTime (see [Vol 6] Part B, Section 4.5.10)
	0x10	Read maximum length of Constant Tone Extension supported
	Any other value	Reserved for future use
0x06	0x00	No Constant Tone Extension
	Any other value	CTEInfo (see [Vol 6] Part B, Section 2.5.2)
0x07	0x01	Sample Constant Tone Extension with 1 µs slots
	0x02	Sample Constant Tone Extension with 2 µs slots
	Any other value	Reserved for future use
0x08	Bits 0 to 6: 0x01 to 0x4B	Number of antennae in the antenna array
	Any other value	Reserved for future use
	Bit 7: 0	Antenna switching pattern A: 1, 2, 3, ..., n, 1, 2, 3, ..., n, ... (where n is the number of antennae in the antenna array)
	1	Antenna switching pattern B: 1, 2, 3, ..., n, n-1, n-2, ..., 1, ... (where n is the number of antennae in the antenna array)
0x09	-127 to +20	Set transmitter to the specified or the nearest transmit power level Units: dBm
	0x7E	Set transmitter to minimum transmit power level
	0x7F	Set transmitter to maximum transmit power level
	All other values	Reserved for future use

If an AoD Constant Tone Extension is selected when transmitting, Control 0x08 shall be used before starting the test. If an AoA Constant Tone Extension is selected when receiving, Controls 0x07 and 0x08 shall be used before starting the test.

Control 0x07 does not affect receiving AoD Constant Tone Extensions or any transmissions. Control 0x08 does not affect transmitting AoA Constant Tone Extensions or receiving AoD Constant Tone Extensions.

In the receiver test, the CTEInfo field specified using Control 0x06 indicates the expected type and length of the Constant Tone Extension. If either the length or type of the Constant Tone Extension in a received LE Test packet does not match the expected value, then the IUT shall discard that packet.

LE_Test_End command: *Size: 14 bits*

Control (6 bits)	Parameter (8 bits)	Description
0x00	0x00 to 0x03	LE_Test_End command
0x00	Any other value	Reserved for future use
0x01 to 0x3F	Any value	Reserved for future use

LE_Transmitter_Test and LE_Receiver_Test commands:

Frequency: *Size: 6 bits*

Value	Parameter Description
0x00 to 0x27	The frequency to be used; a value of N represents a frequency of (2N+2402) MHz (the available range is therefore even values from 2402 MHz to 2480 MHz)
0x28 to 0x3F	Reserved for future use

Length: *Size: 6 bits*

Value	Parameter Description
0x00 to 0x3F	The lower 6 bits of the packet length in bytes of payload data in each packet (the top two bits are set by the LE_Test_Setup command)

PKT (Packet Type): *Size: 2 bits*

Value b_1b_0	Parameter Description
00	PRBS9 Packet Payload
01	11110000 Packet Payload
10	10101010 Packet Payload
11	On the LE Uncoded PHYs: Vendor Specific On the LE Coded PHY: 11111111

3.4 Events

There are two types of events sent by the IUT:

1. LE_Test_Status event
2. LE_Packet_Report event

The event packet format is shown in Figure 3.3. This packet format is used for both LE_Test_Status events and LE_Packet_Report events.

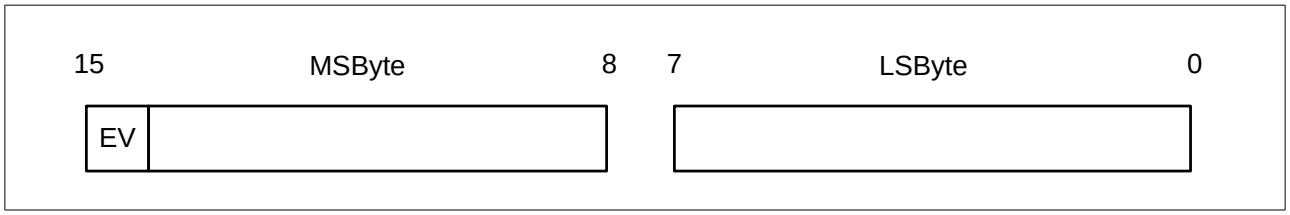

Figure 3.3: Event packet format

EV (event): *Size: 1 bit*

Value	Parameter Description
0	LE_Test_Status event
1	LE_Packet_Report event

3.4.1 LE_Test_Status event

The LE_Test_Status event packet format is as shown in Figure 3.4.

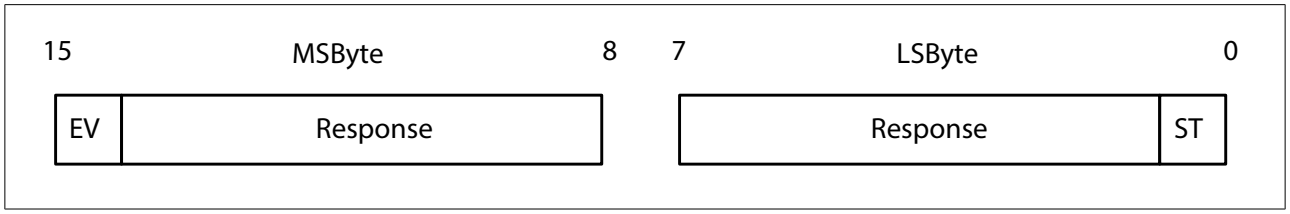

Figure 3.4: LE_Test_Status event

ST (status): *Size: 1 bit*

Value	Parameter Description
0	Success
1	Error

Response: [1] *Size: 14 bits*

[1]If the event has a status of "Error" or was generated in response to a command other than LE_Test_Setup, then this field is Reserved for future use.

LE_Test_-Setup command control parameter	**Value bits 1 to 14**[2]	**Description**
0x04	Bit 1	LE Data Packet Length Extension feature supported
	Bit 2	LE 2M PHY supported
	Bit 3	Transmitter has a Stable Modulation Index
	Bit 4	LE Coded PHY supported
	Bit 5	Constant Tone Extension supported
	Bit 6	Antenna switching supported
	Bit 7	1 µs switching supported for AoD transmission
	Bit 8	1 µs sampling supported for AoD reception
	Bit 9	1 µs switching and sampling supported for AoA reception
	Bits 10 to 14	Reserved for future use
0x05	Bits 1 to 14	One of the following values (depending on the parameter in the original query): • Maximum transmit or receive time, in microseconds, that the local Controller supports for transmission of a single Link Layer Data Physical Channel PDU, divided by 2. • Maximum number of payload octets that the local Controller supports for transmission of a single Link Layer Data Physical Channel PDU. • Maximum length of the Constant Tone Extension that the local Controller supports for transmission in a Link Layer packet, in 8 µs units. Range: • 0x00A4 to 0x2148 for times or • 0x001B to 0x00FF for number of octets. • 0x02 to 0x14 for the maximum Constant Tone Extension length All values outside the range are reserved for future use.

LE_Test_-Setup command control parameter	Value bits 1 to 14[2]	Description
0x09	Bits 1 to 8	Actual transmit power level set by the transmitter Range: -127 to +20 Units: dBm
	Bit 9	Set to 1 if the transmitter is at minimum transmit power level
	Bit 10	Set to 1 if the transmitter is at maximum transmit power level
	Bits 11 to 14	Reserved for future use
All other values		Reserved for future use

[2]This field is described as having bits 1 to 14 rather than 0 to 13 to avoid confusion.

3.4.2 LE_Packet_Report event

The LE_Packet_Report event packet format is shown in Figure 3.5. The *Packet Count* parameter indicates the number of received LE Test packets. The *Packet Count* in the LE_Packet_Report event ending a transmitter test shall be 0.

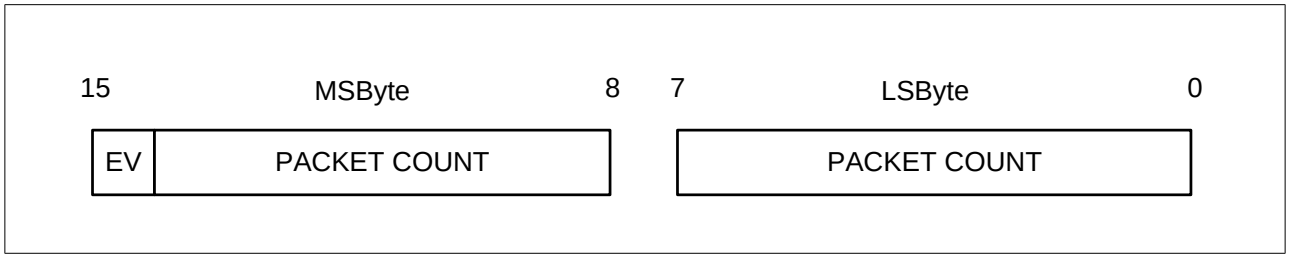

Figure 3.5: LE_Packet_Report event

PACKET COUNT: *Size: 15 bits*

Value	Parameter Description
N	N is the number of packets received Range = 0 to 32767.

Note: The IUT is not responsible for any overflow conditions of the packet count. That responsibility belongs with the RFPHY Tester or other auxiliary equipment.

3.5 Timing - command and event

The timing requirements are as shown in Table 3.2.

Symbol	Parameter	Min.	Max.	Unit
b_{ERR}	Baud rate accuracy		±5	%
t_{MIN}	The time between the first and second byte of the command or event (end of stop bit to start of start bit)	0	5	ms
$t_{RESPONSE}$	The time from a IUT receiving a command (end of stop bit) until the IUT responds (start of start bit)	0	50	ms
$t_{TURNAROUND}$	The time from when the tester receives a response (end of stop bit) until the tester sends another command (start of start bit)	5	-	ms
$t_{TIMEOUT}$	The time from when a tester sends a command (end of stop bit) until the tester times out (not having received end of the stop bit in the response)	51	100	ms

Table 3.2: Parameter requirements table for 2-wire UART interface

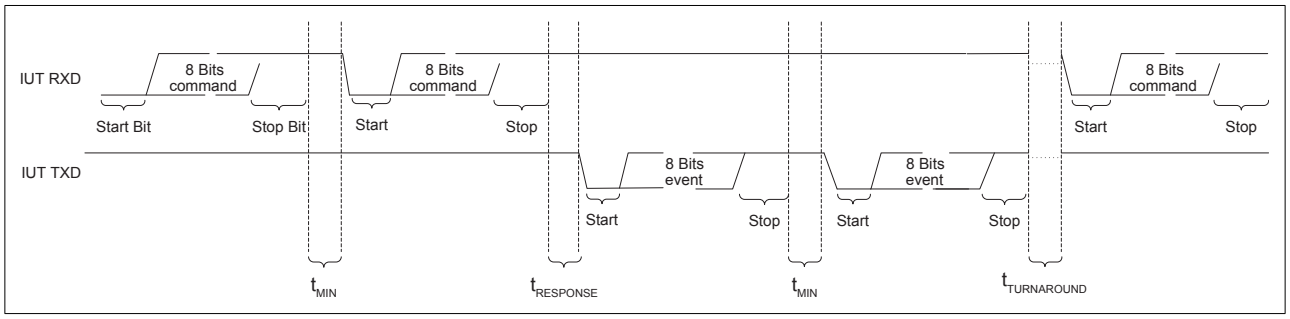

Figure 3.6: Command and event timing on 2-wire UART interface

The commands and events shall be transmitted with two 8-bit bytes with a maximum time between the 2 transmissions. A timeout is required for no response or an invalid response from the IUT.

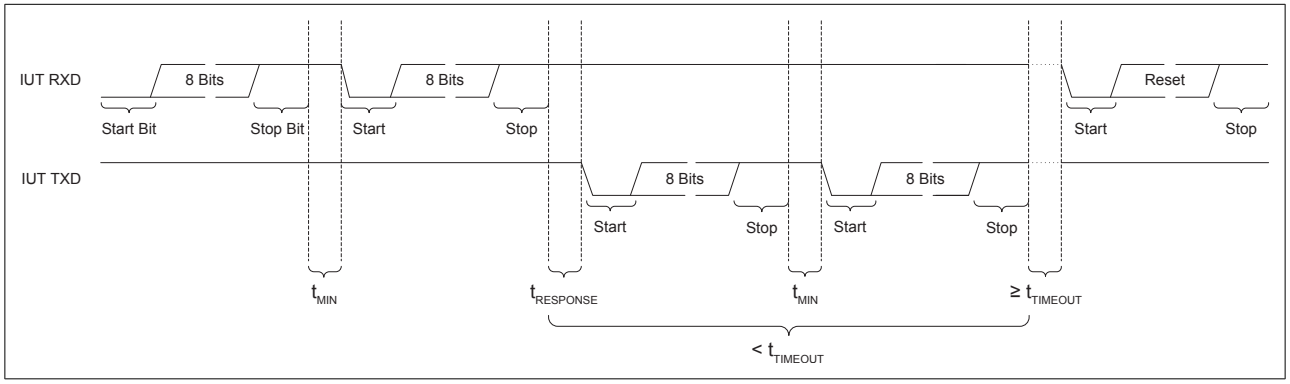

Figure 3.7: Command and event timing on 2-wire UART interface showing timeout

4 LE TEST PACKET DEFINITION

4.1 LE Test packets format

The LE Test packet format for the LE Uncoded PHYs shall be as shown in Figure 4.1. The LE Test packet format for the LE Coded PHY shall be as shown in Figure 4.2. LE test packets are required for LE RFPHY conformance testing using Direct Test Mode. Except as modified by this section, the LE Test packet formats shall be identical to the formats specified in [Vol 6] Part B, Section 2.1 and [Vol 6] Part B, Section 2.2.

Depending on the test, the packet payload content may vary

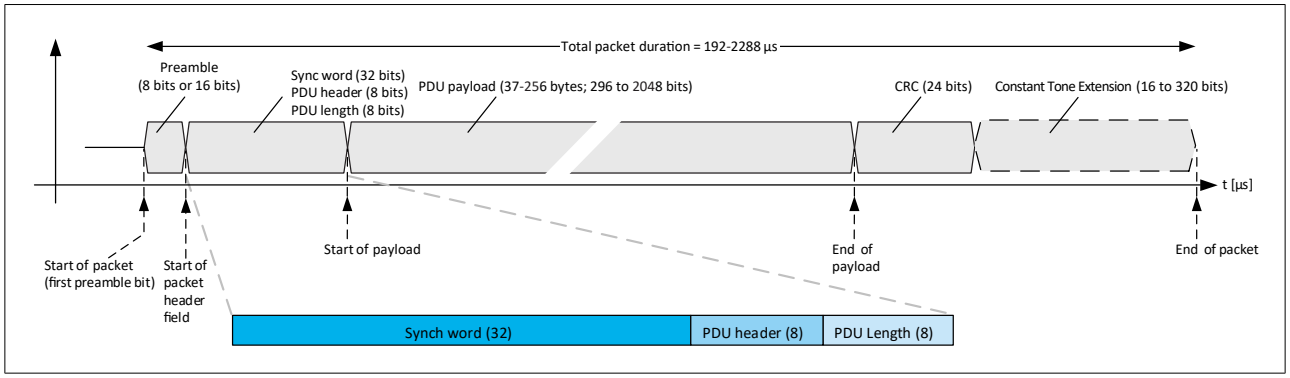

Figure 4.1: LE Test packet format for the LE Uncoded PHYs

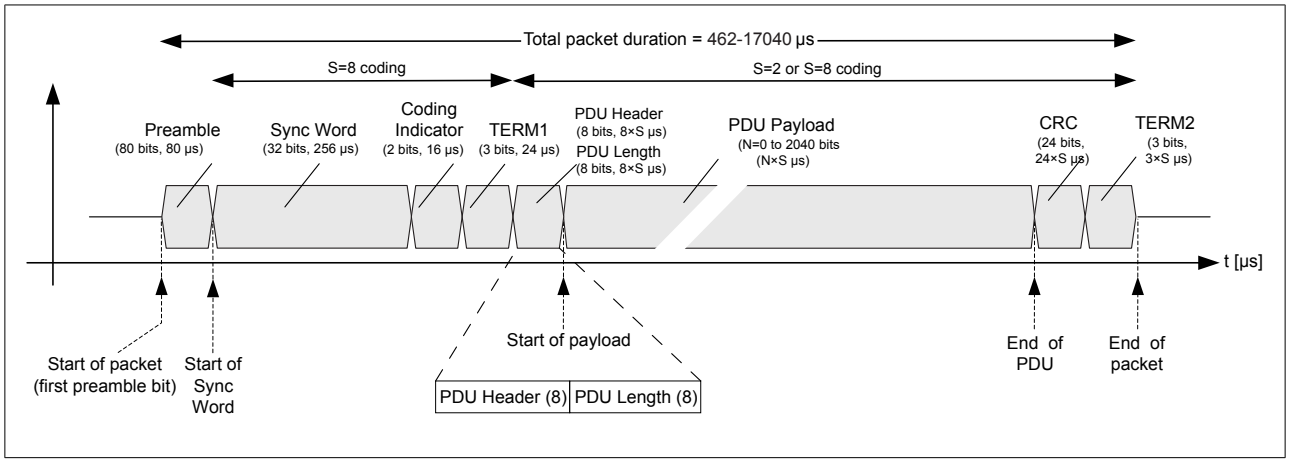

Figure 4.2: LE Test packet format for the LE Coded PHY

The LE Channel Sounding test packet (CS_SYNC) format shall be as shown in Figure 4.3. Except as modified by this section, the LE CS Test packet format shall be identical to the format specified in [Vol 6] Part H, Section 2.

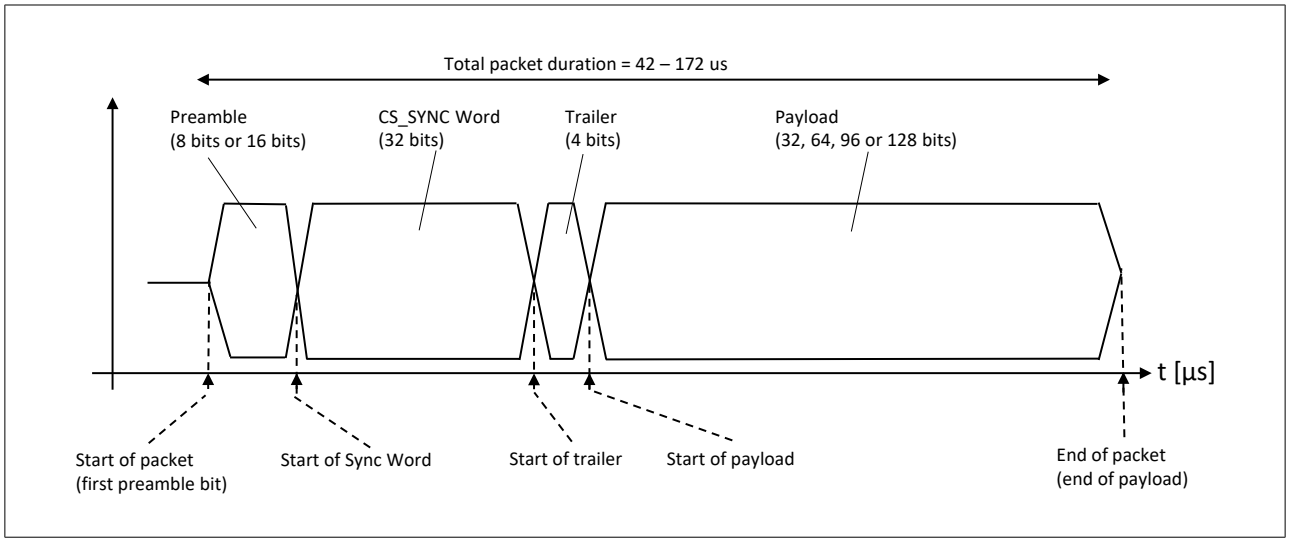

Figure 4.3: LE CS Test packet format

4.1.1 Whitening

LE test packets and LE CS test packets shall not use whitening.

4.1.2 Preamble and synchronization word

LE test packets shall have ‘10010100100000100110111010001110’ (in transmission order) as the synchronization word. The preamble for all LE test packets is thus ‘10101010’ (in transmission order) when the implementation under test is configured for the LE 1M PHY, ‘1010101010101010’ (in transmission order) if the implementation under test is configured for the LE 2M PHY, and the preamble described in [Vol 6] Part B, Section 2.2.1 if the implementation under test is configured for the LE Coded PHY.

LE CS test packets use Access Addresses (CS_SYNC Words) as defined by the HCI_LE_CS_Test command, [Vol 4] Part E, Section 7.8.

4.1.3 CRC

The CRC shift register shall be preset with 0x555555 for every LE test packet. The CRC portion is not applicable for LE CS test packets.

4.1.4 LE Test packet PDU

The LE test packet PDU consists of an 8-bit header, an 8-bit length field, an optional 8-bit CTEInfo field, and a variable size payload. Its structure is as shown in Figure 4.4 and Figure 4.5.

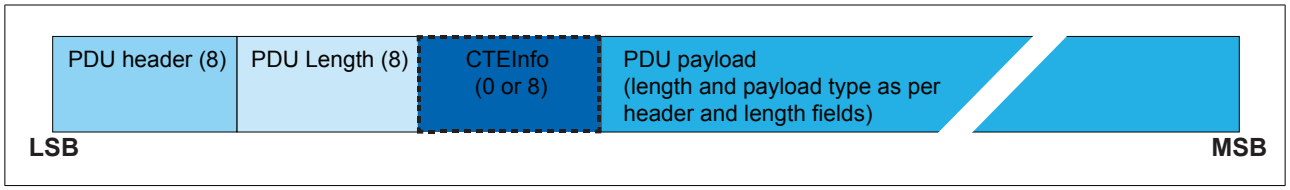

Figure 4.4: LE Test packet PDU structure

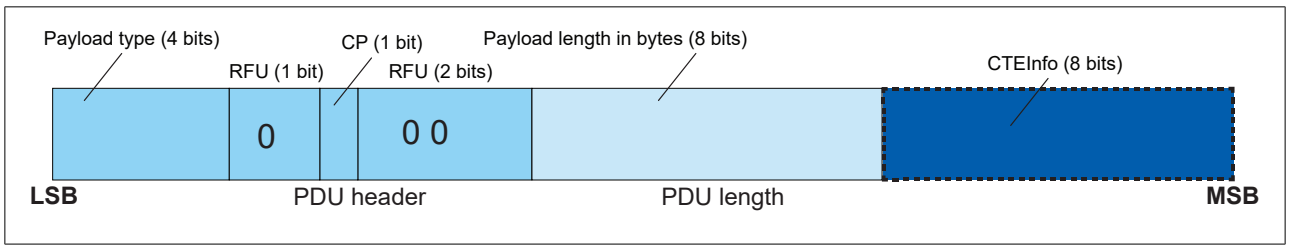

Figure 4.5: LE Test packet header and length field structure

The first four bits of the PDU header field indicate the payload content type as defined in Table 4.1. The CTEInfo Present (CP) field of the PDU header indicates whether the CTEInfo field is present and therefore whether the test packet has a Constant Tone Extension. If the CP field is 0, then no CTEInfo field is present and there is no Constant Tone Extension in the test packet. If the CP field is 1, then the CTEInfo field is present and the test packet includes a Constant Tone Extension. The CTEInfo field is defined in [Vol 6] Part B, Section 2.5.2. The length field expresses the Payload length in bytes.

Note: On the LE Coded PHY, this section defines the PDU contents before coding.

Payload type $b_3b_2b_1b_0$	**Payload description**
0b0000	PRBS9 sequence ‘11111111100000111101...’ (in transmission order) as described in Section 4.1.5
0b0001	Repeated ‘11110000’ (in transmission order) sequence as described in Section 4.1.5
0b0010	Repeated ‘10101010’ (in transmission order) sequence as described in Section 4.1.5
0b0011	PRBS15 sequence as described in Section 4.1.5
0b0100	Repeated ‘11111111’ (in transmission order) sequence
0b0101	Repeated ‘00000000’ (in transmission order) sequence
0b0110	Repeated ‘00001111’ (in transmission order) sequence
0b0111	Repeated ‘01010101’ (in transmission order) sequence

Table 4.1: LE Test packet PDU header’s Type field encoding

Example: For LE test packets with 0x0F payload contents (‘11110000’ in transmission order) and with an LE test packet payload length of 37 bytes (296 bits), the LE test packet header and length type field will be ‘1000000010100100’ in transmission order.

4.1.5 LE Test packet payload description

The LE test packet payload content alternatives required for the Bluetooth Low Energy RFPHY conformance tests are:

PRBS9:

A 9-bit pseudorandom binary sequence used for wanted signal payload content. The PRBS9 sequence repeats itself after the (2^9 -1 = 511) bit. The PRBS9 sequence may be generated in a nine stage shift register whose 5^{th} and 9^{th} stage outputs are XORed (see Figure 4.6) and the result is fed back to the input of the first stage. The sequence begins with the first ONE of 9 consecutive ONEs (i.e. the shift register is initialized with nine ONEs).

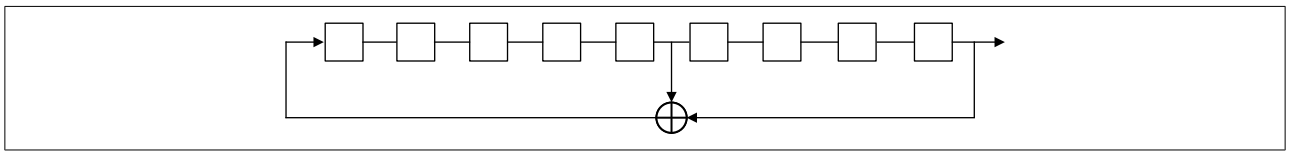

Figure 4.6: Linear feedback shift register for generation of the PRBS9 sequence

The same pseudorandom sequence of bits shall be used for each transmission (i.e. the packet is repeated).

PRBS15:

A 15-bit pseudorandom binary sequence that is used for the interfering signal and can optionally be used for wanted signal payload content. The PRBS15 sequence repeats itself after the (2^{15} -1 = 32767) bit. The PRBS15 sequence may be generated in a fifteen stage shift register whose 14th and 15th stage outputs are XORed (see Figure 4.7) and the result is fed back to the input of the first stage. The sequence begins with the first ONE of 15 consecutive ONEs (i.e., the shift register is initialized with fifteen ONEs).

This PRBS15 definition is consistent with ITU T-REC-01 150-199605-I. SERIES O: SPECIFICATIONS OF MEASURING EQUIPMENT - Equipment for the measurement of digital and analogue/digital parameters.

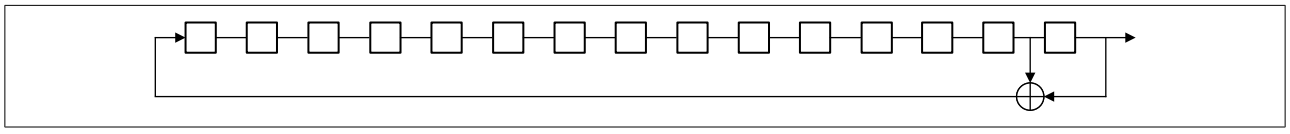

Figure 4.7: Linear feedback shift register for generation of the PRBS15 sequence

The same pseudorandom sequence of bits shall be used for each transmission (i.e. the packet is repeated).

10101010:

Repeated sequence of alternating 1's and 0's, starting at the first payload bit and ending at the start of the first bit in the CRC. This pattern is used to verify the frequency deviation and the Gaussian filtering properties of the transmitter modulator.

11110000:

Repeated sequence of alternating 0's and 1's in groups of four (i.e. 1111000011110000...), starting at the first payload bit and ending at the start of the first bit in the CRC. This pattern is used to verify the frequency deviation and the Gaussian filtering properties of the transmitter modulator.

4.1.6 LE Test packet interval

While in LE direct TX mode, LE test packets shall be transmitted from the EUT with a packet interval I(L) as defined below; see the top half of Figure 4.8 for reference.

While in LE direct RX mode, the nominal packet interval of the LE test packets transmitted from the tester is I(L), but the tester packet interval may be extended to a maximum of T(L) upon change of the dirty transmitter parameter settings and during verification of the EUT PER reporting functionality. See the bottom half of Figure 4.8 for reference.

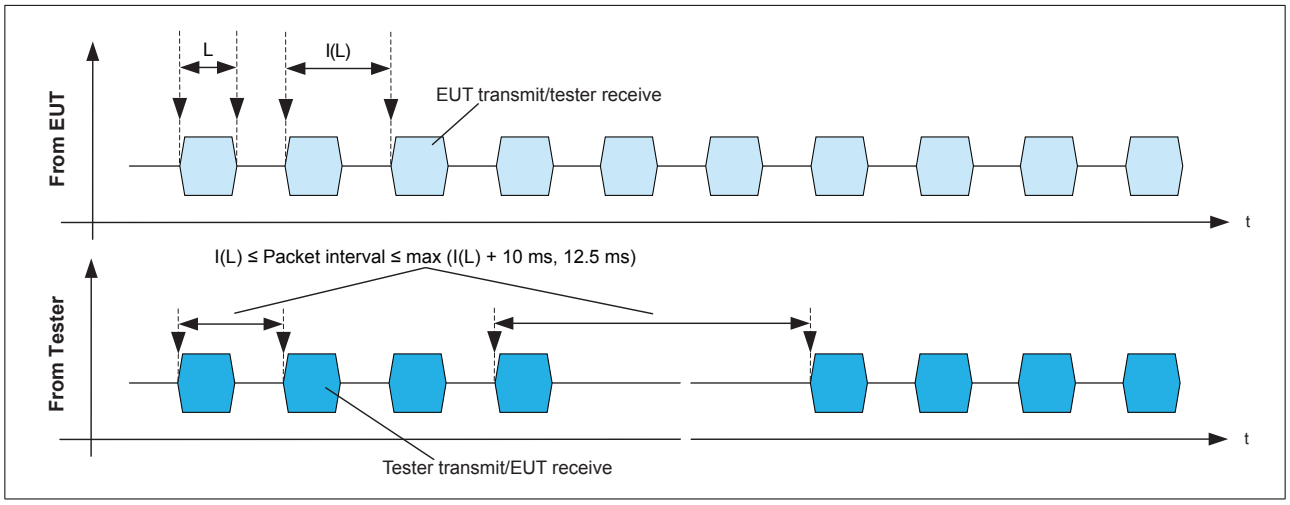

Figure 4.8: LE Test packet interval in LE Direct Test mode

For an LE Test packet length of L µs, I(L) = $\lceil (L + 249) \div 625 \rceil$ × 625 µs and T(L) = max (I(L) + 10 ms, 12.5 ms).

4.1.7 Constant Tone Extension

The Constant Tone Extension is an optional field that consists of a constantly modulated series of unwhitened 1s. It is 16 to 160 bits when operating at 1 Msym/s modulation or

32 to 320 bits when operating at 2 Msym/s modulation. The Constant Tone Extension is not included in CRC or MIC calculations. The Constant Tone Extension shall only be present on the LE Uncoded PHYs.

If Direct Test Mode is being used over HCI and a Constant Tone Extension is present in a received packet, the Controller may generate events containing IQ samples of the Constant Tone Extension (see [Vol 4] Part E, Section 7.7.65.21).

4.1.8 LE Channel Sounding Test packet trailer

The CS trailer is a sequence of 4 bits, alternating between 0 and 1 bits. The trailer is 1010 (in transmission order) when the most significant bit of the CS Access Address is a 0, and 0101 when the most significant bit of the CS Access Address is a 1.

4.1.9 LE Channel Sounding Test packet payload

The CS Test packet payload is defined by the HCI_LE_CS_Test command, [Vol 4] Part E, Section 7.8. The payload length shall be either 32, 64, 96, or 128 bits, defined in [Vol 6] Part H, Section 2.5. There are no associated PDU header or PDU length fields for LE CS Test packet.

4.1.10 LE Channel Sounding Test exchanges

In some instances Channel Sounding tests involve exchanges between initiator and reflector devices. In these cases both devices shall operate using active clock accuracy as described in [Vol 6] Part B, Section 4.2.1.

Low Energy Controller
Part G

ISOCHRONOUS ADAPTATION LAYER

This Part describes the Isochronous Adaptation Layer (ISOAL) which supports segmentation and reassembly, and fragmentation and recombination of packets to and from a higher layer.

CONTENTS

1 INTRODUCTION

The Isochronous Adaptation Layer (ISOAL) provides segmentation, fragmentation, reassembly and recombination services for conversion of SDUs from the upper layer to PDUs of the Link Layer and vice versa. The ISOAL accepts or generates SDUs, each with a length up to the maximum length (Max_SDU), at a rate that is supported by the Controller. SDUs are transferred to and from the upper layer using either HCI ISO Data packets or over an implementation-specific transport.

Note: SDUs in the ISOAL has no relation to SDUs in the L2CAP layer.

1.1 Terminology

The following terms are used in the ISOAL:

Term	Description
Upper layer	The upper layer generates and or receives isochronous data packets known as SDUs. The interface between the upper layer and ISOAL may be the HCI or a proprietary interface.
SDU (Service Data Unit)	An SDU is a packet containing isochronous data that is generated or received by the upper layer.
PDU (Protocol Data Unit)	A PDU is a data packet that is transmitted or received in a Connected or Broadcast Isochronous Stream.
Fragment	An SDU or part of an SDU, resulting from the fragmentation operation.
Segment	An SDU or part of an SDU, with a header, resulting from the segmentation operation.
Isochronous interval	The time between two consecutive BIS or CIS events (designated ISO_Interval in the Link Layer).
Unframed PDU	A PDU that contains a fragment.
Framed PDU	A PDU that contains one or more segments.
SDU interval	The nominal time between two consecutive SDUs that are sent or received by the upper layer.
Max_SDU	Maximum size of an SDU.
Synchronization Reference	A time reference of an SDU that allows synchronization of isochronous data in multiple devices.
Time_Stamp	Time stamp (32-bit value in microseconds) of a packet.
Time_Offset	Time offset (24-bit value in microseconds) of a packet.
ISO Data PDU	Either a CIS Data PDU or a BIS Data PDU.

Table 1.1: Terminology

2 ISOAL FEATURES

Figure 2.1 shows the architectural diagram of the ISOAL. The multiplexer in Figure 2.1 shows the route of SDUs to either unframed PDU or framed PDU path.

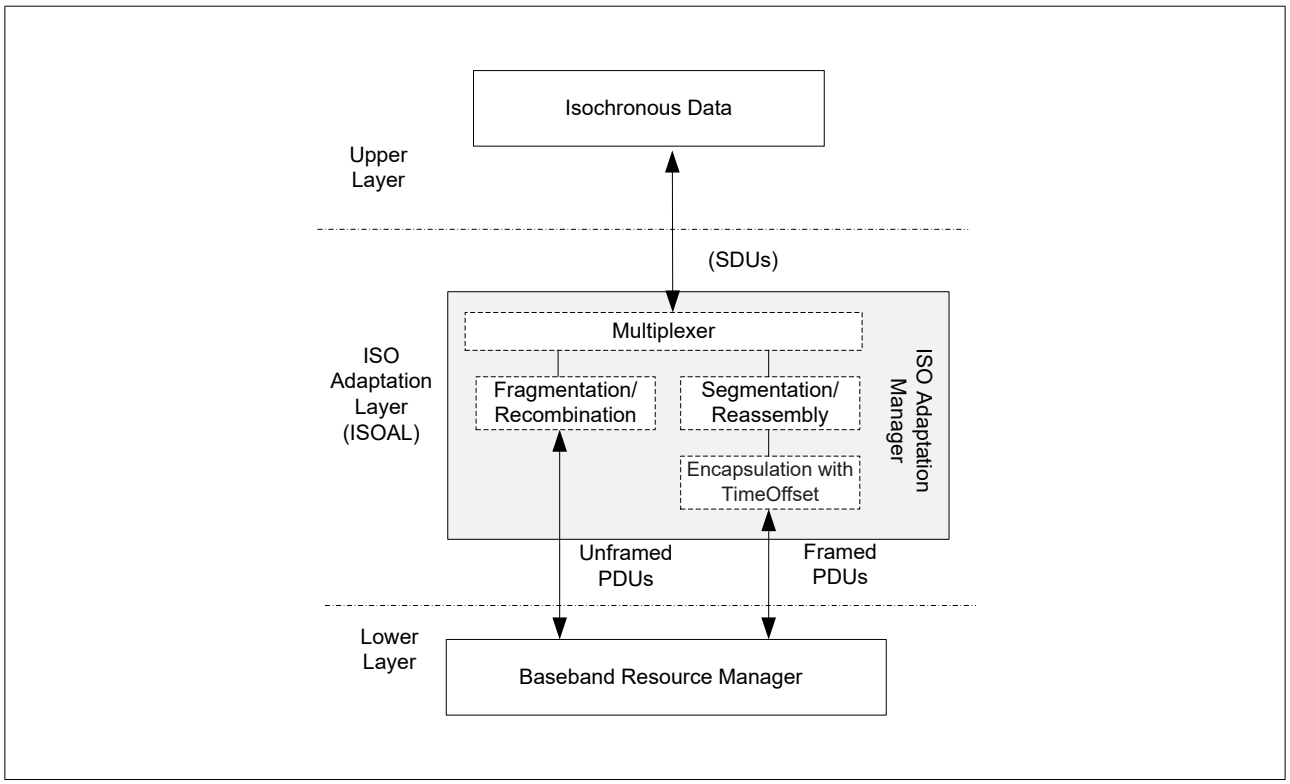

Figure 2.1: ISOAL architectural blocks

- Fragmentation and recombination

  The fragmentation process splits an SDU into one or more fragments which are carried by one or more unframed PDUs (see Section 4) in a Connected or Broadcast Isochronous Stream. A fragment shall contain only isochronous data. An SDU with a length less than or equal to the Max_PDU shall be sent in a single unframed PDU. An SDU with a length greater than the Max_PDU shall be sent in multiple fragments in multiple unframed PDUs. The fragmentation process shall use the minimum number of unframed PDUs to transmit the SDU. The recombination process generates an SDU from one or more fragments received in unframed PDUs.

- Segmentation and reassembly

  The segmentation process splits an SDU into one or more segments which are carried by one or more framed PDUs (see Figure 2.1) in a Connected or Broadcast Isochronous Stream. A segment shall contain a Segmentation Header (see Section 3) and may contain Time_Offset and isochronous data. The reassembly process

combines data from one or more segments received in framed PDUs and generates one or more SDUs.

- Encapsulation and Time_Offset

  In the encapsulation process Segmentation Headers and a Time_Offset parameter are added before the first segment of each new SDU allowing timing reconstruction at the peer device (see Section 3.)

Unframed PDUs shall only be used when the ISO_Interval is equal to or an integer multiple of the SDU_Interval and a constant time offset alignment is maintained between the SDU generation and the timing in the isochronous transport. This requires the upper layer to synchronize generation of its data to the effective transport timing. When the Host requests the use of framed PDUs, the Controller shall use framed PDUs.

Framed PDUs are not restricted by the limitations of unframed PDUs and can support any valid combinations of SDU_Interval and ISO_Interval.

SDU_Interval shall be a value, in microseconds, between 0x0000FF and 0x0FFFFF.

When the Host requests a framing packet type and mode, the Controller may use another permitted framing packet type and mode if permitted in Table 2.1.

Requested framing packet type and mode	**Permitted framing packet type and mode**		
	Unframed	Framed, Segmentable mode	Framed, Unsegmented mode
Unframed	Yes	Yes	Yes
Framed, Segmentable mode	No	Yes	Yes
Framed, Unsegmented mode	No	Yes	Yes

Table 2.1: Permitted framing modes in isochronous PDUs

SDUs sent to the upper layer by the ISOAL shall be given a sequence number which is initialized to 0 when the CIS or BIS is created. SDUs received by the ISOAL from the upper layer shall be given a sequence number which is initialized to 0 when the CIS or BIS is created. The upper layer may synchronize its sequence number with the sequence number in the ISOAL once the Datapath is configured and the link is established.

The sequence number shall be incremented by one for each SDU_Interval, whether or not an SDU was received from the upper layer or included in reports sent to the upper layer.

The sequence number shall be 16 bits and shall be included in the Packet_Sequence_Number parameter in HCI ISO Data Packets.

2.1 Unframed PDU

An unframed PDU is an ISO Data PDU; it shall contain payload from the SDU without additional headers in the payload. An unframed PDU shall only contain payload from a single SDU.

There are two types of unframed PDUs. An unframed PDU containing an end fragment or a complete SDU, and an unframed PDU containing a start or a continuation fragment. Unframed PDUs are identified by the LLID field as described below:

LLID in the header of the ISO Data PDU shall be set to 0b00 in the following conditions:

- When the payload of the ISO Data PDU contains the end fragment of an SDU.
- When the payload of the ISO Data PDU contains a complete SDU.

LLID in the header of the ISO Data PDU shall be set to 0b01 in the following conditions:

- When the payload of the ISO Data PDU contains a start or a continuation fragment of an SDU.
- When the ISO Data PDU is used as padding. This is required when the fragments do not add up to the configured number of PDUs specified by the BN parameter per BIS or CIS event.

In the receiving device the payload from a PDU with LLID = 0b00 shall append the payload from PDUs with LLID = 0b01 to derive the length of the payload of the SDU. The SDU can contain some invalid or missing data due to missing or invalid PDUs. All SDUs shall be sent to the upper layer including the indication of validity of data. A report shall be sent to the upper layer if the SDU is completely missing.

Each fragment shall be sent in a new unframed PDU. Multiple fragments shall not be sent in a single PDU.

BN, Max_PDU and ISO_Interval parameters of the Connected or Broadcast Isochronous Stream shall be set such that the bandwidth of the data transmitted by the Link Layer shall be greater than or equal to the bandwidth of data from the upper layer.

The following two additional parameters are defined for unframed PDUs. USPI is the number of SDUs scheduled per ISO_Interval and equals ISO_Interval ÷ SDU_Interval. UPPS is the maximum number of fragments that an SDU is divided into and therefore the number of PDUs allocated to transmit each SDU. Both these parameters are integers.

UPPS shall be at least $\lceil \mathrm{Max\_SDU} \div \mathrm{Max\_PDU} \rceil$. BN shall equal UPPS × USPI.

Each SDU shall generate UPPS fragments. All these fragments shall be sent to the Link Layer before any fragments of the next SDU. If an SDU generates less than UPPS fragments, empty payloads shall be used to make up the number. Empty payloads shall be PDUs with LLID 0b01 with zero length payload, e.g., when UPPS=4 and only 3 PDUs are generated from the SDU, an additional padding PDU needs to be added.

When an SDU contains zero length data, the corresponding PDU(s) shall be of zero length and the LLID field shall be set to 0b00.

2.2 Framed PDU

A framed PDU is an ISO Data PDU where the payload field is made up of segments or is empty. Each segment is encapsulated by a Segmentation Header and, for each first segment of a new SDU, a Time_Offset field is included to allow for reconstruction of the original SDU timing.

Framed PDUs shall be used when the requirements for using unframed PDUs are not met. Framed PDUs support the aggregation of data from multiple SDUs into a single PDU. The maximum allowed drift (MaxDrift) on the average timing of SDU delivery shall not exceed 100 ppm from the configured value of SDU_Interval.

There are two modes for use with framed[1] PDUs: Segmentable mode and Unsegmented mode. Segmentable mode shall be supported; Unsegmented mode may be supported.

In the Segmentable mode, the Controller may segment an SDU over multiple PDUs and a PDU may contain segments from more than one SDU. In the Unsegmented mode, each SDU shall be contained in a single segment in a single PDU; a PDU may contain more than one SDU.

Both modes use the same Segmentation Header format.

In Segmentable mode, the BN, Max_PDU and ISO_Interval parameters of the Connected or Broadcast Isochronous Stream shall be set such that the bandwidth of the data transmitted by the Link Layer shall be greater than or equal to the bandwidth of data from the upper layer plus the amount of space needed for the headers (including an allowance for MaxDrift). This requirement is met if:

$$BN \times (Max\_PDU - 2) \geq \lceil F \rceil \times 5 + \lceil F \times Max\_SDU \rceil$$

where F = (1 + MaxDrift) × ISO_Interval ÷ SDU_Interval

The requirement can be met without the inequality being satisfied.

[1] Before the introduction of Unsegmented mode, “Framed” only referred to Segmentable mode.

In Unsegmented Mode, the Max_PDU parameter shall be set to $\lceil (\text{ISO\_Interval} \div \text{SDU\_Interval} \times (1 + \text{MaxDrift}) \div \text{BN}) \rceil \times (5 + \text{Max\_SDU})$. For example, 40-octet SDUs generated at 10 ms intervals (with the worst-case drift of 100 ppm) will require a Max_PDU of 45 octets when sent at 7.5 ms ISO_Interval (since there is at most one SDU per PDU, BN will equal 1).

Figure 2.2 shows how multiple segments from multiple SDUs may fit in multiple ISO Data PDUs. Each row in the figure shows the payload field of one PDU. The number and length of segments in the payload shall be limited such that the length of the ISO Data PDU does not exceed the Max_PDU set for the Connected or Broadcast Isochronous Stream.

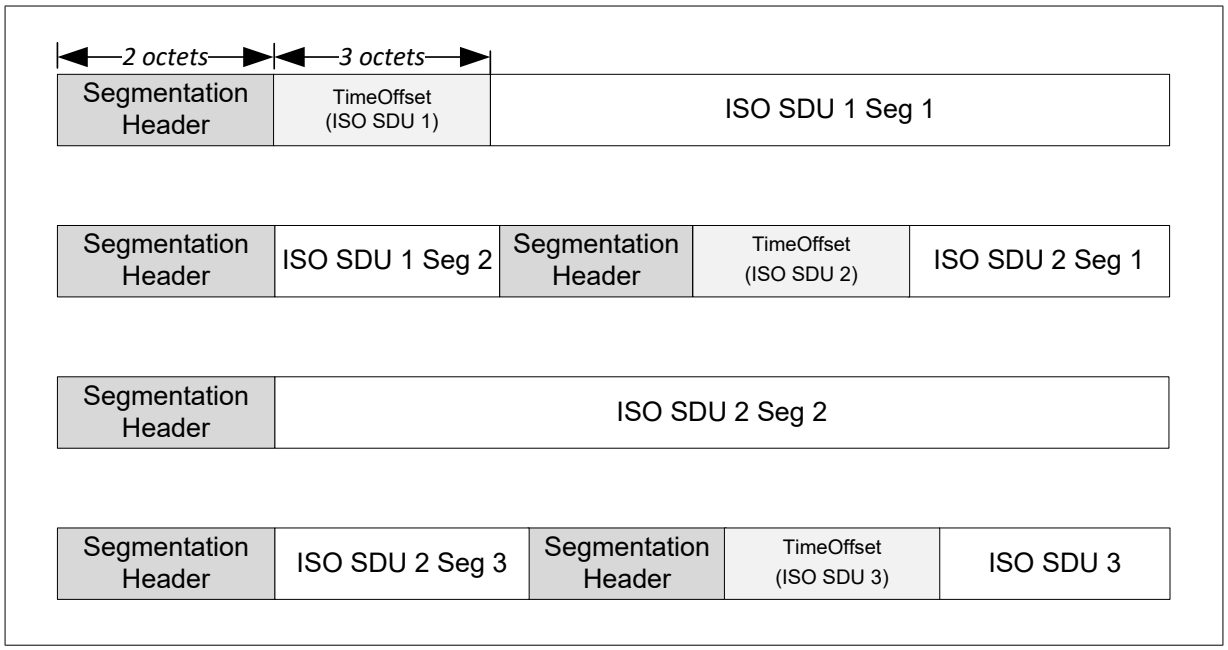

Figure 2.2: Examples of ISO data PDU payload fields with one or more segments

The format of a Segmentation Header is shown in Figure 2.3.

Segmentation Header			
LSB			**MSB**
SC (1 bit)	CMPLT (1 bit)	RFU (6 bits)	Length (8 bits)

Figure 2.3: Segmentation header format

The fields in the Header is shown in Table 2.2.

Field Name	Description
SC	The Start or Continuation (SC) field indicates that the data following the Segmentation Header is the start of a new SDU or the continuation of a previous SDU.
CMPLT	The Completion (CMPLT) field indicates that the segment following the Segmentation Header in the PDU is the end segment of an SDU.
Length	The length field indicates the size, in octets, of the segment that follows the Segmentation Header in this PDU and, when present, includes the Time_Offset parameter.

Table 2.2: Segmentation Header fields

Each framed PDU starts with a Segmentation Header that contains a SC, CMPLT and a Length field. Depending on the SC field, an additional Time_Offset parameter is included between the Segmentation Header and the start of SDU data to indicate the relative timing difference between the SDU and CIG reference point or BIG anchor point timing.

A framed PDU with non-zero length shall contain one or more segments. A framed PDU with zero length can be used as a padding PDU; such a PDU does not have a Segmentation Header. Padding is required when the data does not add up to the configured number of PDUs that are specified by the BN parameter per BIS or CIS event.

The Segmentation Header includes the SC and the CMPLT fields with the following requirements:

- When SC is set to 0, it indicates the start of a new SDU and that the data that follows the header is part of a new SDU. If SC is set to 1, it indicates a continuation of an SDU that was partially transmitted in a previous isochronous PDU.
- When SC is set to 0, the Segmentation Header shall be followed by a Time_Offset field, otherwise the Time_Offset is omitted and the header is directly followed by a segment of an SDU.
- When CMPLT is set to 0, not all data of the SDU has been included in the current PDU. One or more additional framed PDUs are required to complete the SDU transfer. When CMPLT is set to 1, all remaining data of the SDU is included in the segment and the SDU may be transferred to the higher layer.
- CMPLT is independent of the value of SC.

The Segmentation Header shall contain a Length field. The Length field indicates the number of octets of the SDU data segment following the Segmentation Header including the length of Time_Offset when present (see Section 3).

Data from a single SDU shall not be split over multiple segments in a single PDU. Additional Segmentation Headers and data from other SDUs may be added depending

on available remaining octets in that PDU. When an SDU has zero length, the SDU shall be included with a Segmentation Header with SC set to 0, CMPLT set to 1, and the length field set to the length of the Time_Offset. Such an empty SDU shall contain a correct Time_Offset, to allow the higher layer of the device that receives the empty SDU to maintain synchronization.

Because an isochronous transport is not a reliable transport, Segmentation Headers shall integrally be contained in a single PDU. When insufficient octets remain in a framed isochronous PDU to contain the Segmentation Header and the Time_Offset field, no new Segmentation Header can be added, as shown in Table 2.3. When only 5 octets remain, a new Segmentation Header, including the start of the next SDU, may be included but is not recommended.

SC Start/ continuation	COMPLT Completion	Time_Offset Added	Description
0	0	Yes	The start of a new SDU, where not all SDU data is included in the current PDU, and additional PDUs are required to complete the SDU.
0	1	Yes	The start of a new SDU that contains the full SDU data in the current PDU.
1	0	No	The continuation of a previous SDU. The SDU payload is appended to the previous data and additional PDUs are required to complete the SDU.
1	1	No	The continuation of a previous SDU. Frame data is appended to previously received SDU data and completes in the current PDU.

Table 2.3: Description of Segmentation Header types in framed isochronous PDUs

A start of a new SDU with SC = 0 shall only be used when the previous frame has completed. A continuation of an SDU with SC = 1 shall only be used if the previous transmitted Segmentation Header had the completion flag set to 0.

When one or more ISO Data PDUs are not received, the receiving device may discard all SDUs affected by the missing PDUs. Any partially received SDU may also be discarded. A report shall be sent to the upper layer for each discarded SDU.

3 TIME_STAMP AND TIME_OFFSET

Framed PDUs include a Time_Offset field to allow the reconstruction of the original SDU timing. When using HCI ISO Data packets, a Time_Stamp field may be included. This section defines the usage of these parameters. Every Time_Stamp and Time_Offset shall be derived from a free running reference clock that is not affected by adjustments to synchronize with other devices, such as a Peripheral synchronizing to a received packet from the Central (see [Vol 6] Part B, Section 4.5.7) or an adjustment done as part of the PCA feature (see [Vol 2] Part B, Section 8.6.10).

3.1 Time_Offset in framed PDUs

At the transmitter, the Time_Offset is measured from the reference time of the SDU at the source to the CIG Reference point or BIG anchor point of the corresponding CIG or BIG event of the isochronous payload containing the first Segmentation Header of that SDU. This computation excludes any potential retransmissions or missed subevents, resulting in the time of transmission under perfect link conditions. The Time_Offset shall be a positive value.

The reference time of the SDU is determined based on the local timing in the Controller based on either a time stamp of that SDU (e.g., provided via the Time_Stamp parameter in the HCI ISO Data packet) or another mechanism used by the implementation tracking the SDU timing to the transport timing.

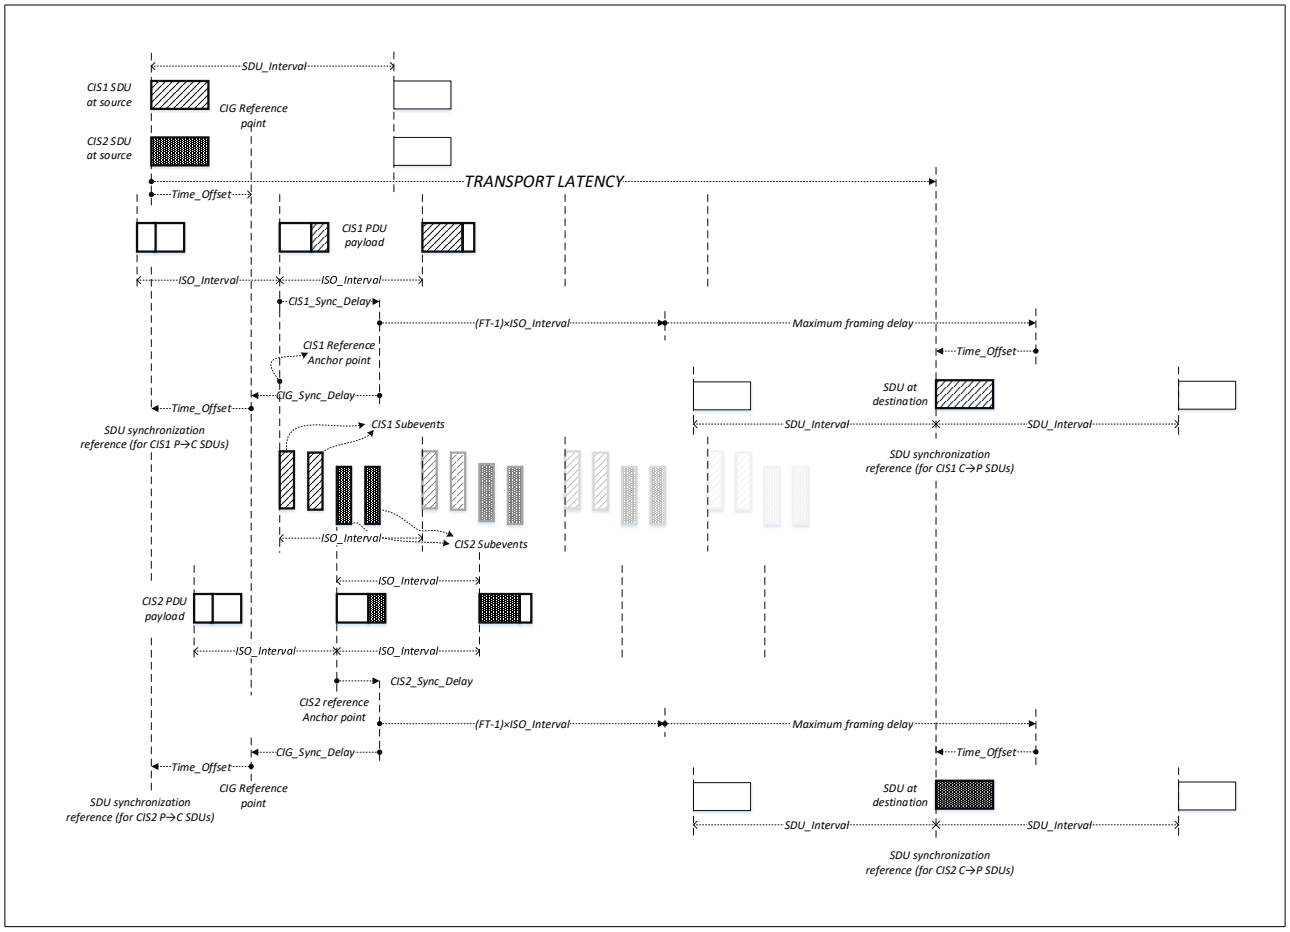

Figure 3.1: SDU synchronization reference using the Time_Offset parameter

For details on the computation of the SDU synchronization reference and transport latency for all options of framed and unframed PDU in CIS and BIS, see Section 3.2.

At the receiver, the CIS reference anchor point is computed excluding any retransmissions or missed subevents, resulting in the time of transmission under perfect link conditions. Similar calculations can be performed for BIG.

Any potential delays in effective transmission shall be excluded in the calculation of Time_Offset.

When BN is greater than 1, all PDUs belonging to the same CIS or BIG event use the same reference anchor point.

For example, in a CIS with BN=2 and FT = 10, payload number 720 can have its first transmission potentially in CIS event 360 and its last potential transmission in CIS event 369. Even when the transfer effectively takes place in CIS event 365, the CIS reference anchor point for this payload is the anchor point of CIS event 360.

The Controller transmitting an SDU may use any of the following methods to determine the value of the SDU reference time, indicated in Figure 3.1, to define the Time_Offset for that SDU:

- A captured timestamp of the SDU
- A timestamp provided by the higher layer
- A computed timestamp based on a sequence counter provided by the higher layer
- Any other method of determining Time_Offset

3.2 SDU synchronization reference

This section describes the method of managing the SDU synchronization reference in framed and unframed PDUs.

3.2.1 SDU synchronization reference using framed PDUs

Using framed PDUs introduces additional delay in transferring SDUs. This additional delay shall be included when computing the SDU synchronization reference.

When using framed PDUs, the additional delay caused by the segmentation in a system where SDU creation is not synchronized to the transport timing equals one SDU interval plus one Isochronous interval.

The transport latency is the duration between the CIG reference point (or BIG anchor point for BIG) of the first possible CIG event (or BIG event) containing the payload to the CIG synchronization point (or BIG synchronization point) of the last possible CIG event (or BIG event) containing the payload, plus the maximum framing delay[1] (shown in Figure 3.1 for CIG). Transport latency is measured from the reference time of the SDU to its SDU_Synchronization_Reference and does not include any implementation specific processing times or internal transport delays (e.g., delays over the HCI transport or PDU processing times).

The maximum framing delay is one isochronous interval plus one SDU interval in Segmentable mode and is one isochronous interval in Unsegmented mode. In the following formulae, Framing_Delay_C, Framing_Delay_P, and Framing_Delay_B equal SDU_Interval_C_To_P, SDU_Interval_P_To_C, and SDU_Interval respectively in Segmentable mode and all equal zero in Unsegmented mode.

The transport latency for a CIG is the actual latency of transmitting payloads of all CISes in the CIG, and is calculated as:

$$\text{Transport\_Latency\_C\_To\_P} = \text{CIG\_Sync\_Delay} + (\text{FT\_C\_To\_P}) \times \text{ISO\_Interval} + \text{Framing\_Delay\_C}$$

[1]This parameter was named “segmentation delay” in earlier specification versions.

Transport_Latency_P_To_C = CIG_Sync_Delay + (FT_P_To_C) × ISO_Interval + Framing_Delay_P

The transport latency for a BIG is the actual latency of transmitting payloads of all BISes in the BIG, and is calculated as:

Transport_Latency_BIG = BIG_Sync_Delay + PTO × (NSE ÷ BN – IRC) × ISO_Interval + ISO_Interval + Framing_Delay_B

The calculated transport latencies shall be less than or equal to those set by the Host.

Each SDU is given a synchronization reference based on the Reference Anchor point.

The CIS reference anchor point is computed excluding any retransmissions or missed subevents and shall be set to the anchor point of the CIS event in which the first PDU containing the SDU could have been transferred.

The BIG reference anchor point is the anchor point of the BIG event that the PDU is associated with (see [Vol 6] Part B, Section 4.4.6.6).

For the Central to Peripheral direction or from the Isochronous Broadcaster to Synchronized Receiver direction, the SDU synchronization point represents the absolute time where the data from a CIG or BIG should be available, and can be used to synchronize between multiple devices.

For SDUs sent from the Central to the Peripheral in a CIS using framed PDUs the SDU_Synchronization_Reference shall be calculated as follows:

SDU_Synchronization_Reference = CIS Reference Anchor point + CIS_Sync_Delay + Framing_Delay_C + FT_C_To_P × ISO_Interval – Time_Offset

For the Peripheral to Central direction, the SDU synchronization point represents the absolute reference time of the origin of an SDU and can be used to synchronize data coming from multiple sources. This point is at the start of the CIG reference point. It could be earlier for framed PDUs.

For SDUs sent from the Peripheral to the Central in CIS using framed PDUs, the SDU_Synchronization_Reference shall be calculated as follows:

SDU_Synchronization_Reference = CIS reference anchor point + CIS_Sync_Delay – CIG_Sync_Delay – Time_Offset

For SDUs received in a BIS using framed PDUs, the SDU_Synchronization_Reference shall be calculated as follows:

SDU_Synchronization_Reference = BIG reference anchor point + BIG_Sync_Delay + ISO_Interval + Framing_Delay_B – Time_Offset

For example, when Segmentable mode is in use, the SDU interval is 10.6 ms, and the isochronous interval is 10 ms, an additional 20.6 ms is added due to segmentation, while if Unsegmented mode is in use, only 10 ms is added.

This example clarifies the usage of Time_Offset in the Central to Peripheral direction of CIS: at the source an SDU has a reference time X at the Controller clock. The start of the CIS event of the first potential transmission of the PDU that can contain the first part of that SDU is 6.123 ms later in time. The Time_Offset for the initial segment for that SDU will contain the value 6123 decimal or 0x0017EB. During the exchange over the isochronous transport, the PDU was not transmitted at the first possible opportunity, rather the PDU was received by the peer in the p^{th} subevent n events later due to actual conditions of physical transport and potential Controller behavior such as scheduling conflicts at a subevent with starting time Y. Time Y is captured at the clock of the receiving device.

The receiving device computes the CIS reference anchor point time Y1 as follows:

$$Y1 = Y – (p–1) \times Sub\_Interval – n \times ISO\_Interval$$

The SDU synchronization reference for the SDU known as Y2 in µs is computed as:

$$Y2 = Y1 + CIS\_Sync\_Delay + SDU\_Interval\_C\_To\_P + (FT\_C\_To\_P \times ISO\_Interval) – 6123$$

The SDU may be exchanged over multiple PDUs, but the synchronization reference point shall only be computed based on the PDU timing of the PDU containing the first Segmentation Header of the applicable SDU.

3.2.2 SDU synchronization reference using unframed PDUs

Using unframed PDUs does not introduce additional delay when the SDU interval equals the isochronous interval. When the Isochronous interval is larger than the SDU interval, multiple SDUs are received per BIS or CIS event which increases the delay. This additional delay shall be included when computing the SDU_Synchronization_Reference.

The transport latency is the duration between the CIG reference point (or BIG anchor point for BIG) of the first possible CIG event (or BIG event) containing the payload to the CIG synchronization point (or BIG synchronization point) of the last possible CIG event (or BIG event) containing the payload, plus the additional delay when grouping multiple SDUs in a single ISO_Interval (as shown in Figure 3.2 for CIG). Transport latency is measured from the reference time of the SDU to its SDU_Synchronization_Reference and does not include any implementation specific processing times or internal transport delays (e.g., delays over the HCI transport or PDU processing times).

The Transport_Latency for a CIG is the actual latency of transmitting payloads of all CISes in the CIG, and is calculated as:

> Transport_Latency_C_To_P = CIG_Sync_Delay + (FT_C_To_P – 1) × ISO_Interval + (USPI_C_To_P – 1) × SDU_Interval_C_To_P
>
> Transport_Latency_P_To_C = CIG_Sync_Delay + (FT_P_To_C – 1) × ISO_Interval + (USPI_P_To_C – 1) × SDU_Interval_P_To_C

where USPI_C_To_P and USPI_P_To_C are the values of USPI for the two directions.

These calculations can be simplified as follows:

> Transport_Latency_C_To_P = CIG_Sync_Delay + FT_C_To_P × ISO_Interval – SDU_Interval_C_To_P
>
> Transport_Latency_P_To_C = CIG_Sync_Delay + FT_P_To_C × ISO_Interval – SDU_Interval_P_To_C

The Transport_Latency for a BIG is the actual latency of transmitting payloads of all BISes in the BIG, and is calculated as:

> Transport_Latency = BIG_Sync_Delay + PTO × (NSE ÷ BN – IRC) × ISO_Interval + (USPI – 1) × SDU_Interval

This calculation can be simplified as follows:

> Transport_Latency = BIG_Sync_Delay + (PTO × (NSE ÷ BN – IRC) + 1) × ISO_Interval – SDU_Interval

For example, when the SDU interval is 10 ms and the Isochronous interval is 20 ms an additional 10 ms is added due to combination of 2 SDUs in one BIS or CIS event.

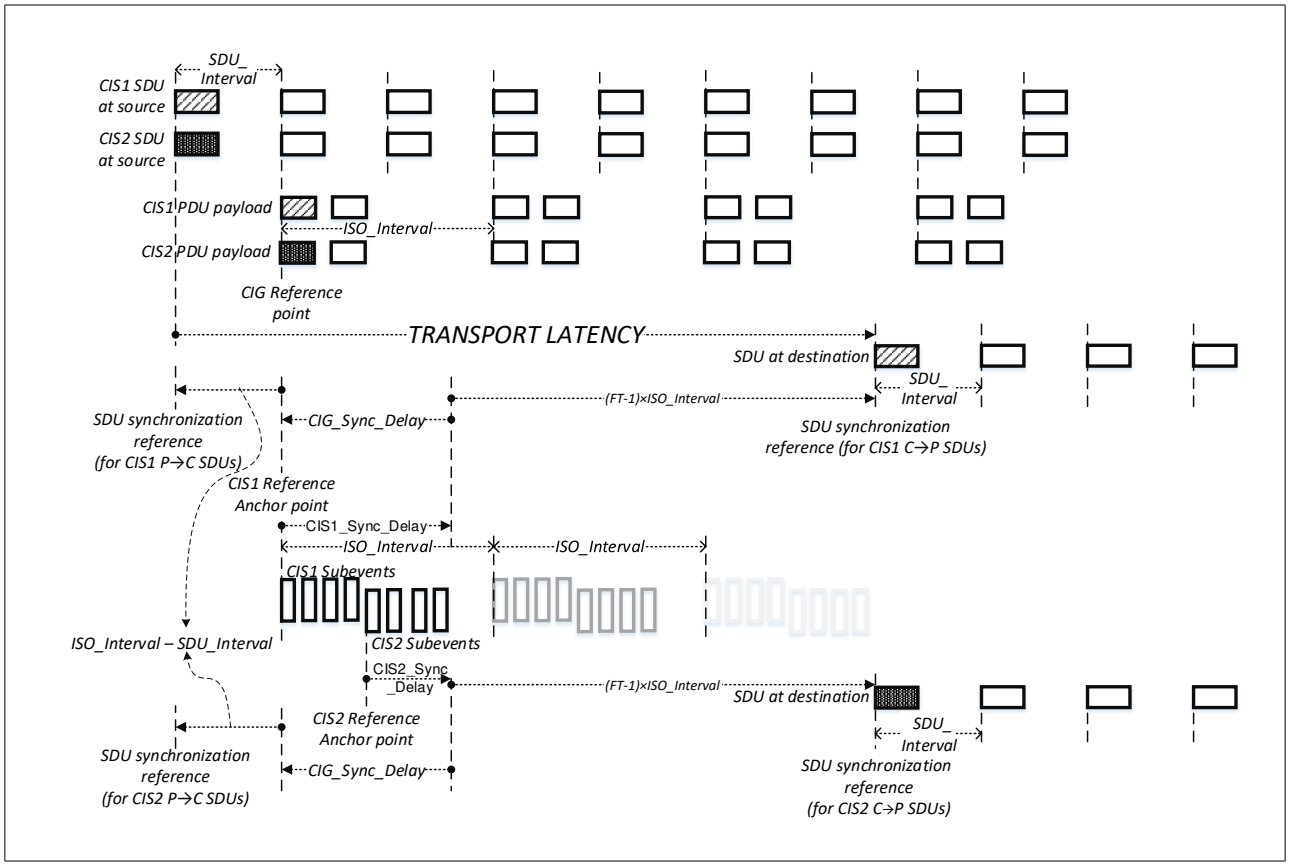

Figure 3.2: SDU synchronization reference using the unframed PDUs

Each SDU is given a synchronization reference point based on the reference anchor point.

The CIS reference anchor point is computed excluding any retransmissions or missed subevents and shall be set to the start of the CIS event in which the first PDU containing the SDU could have been transferred.

The BIG reference anchor point is the anchor point of the BIG event that the PDU is associated with (see [Vol 6] Part B, Section 4.4.6.6).

For the Central to Peripheral direction or from the Isochronous Broadcaster to Synchronized Receiver direction, the SDU synchronization point represents the absolute time where the data from a CIG or BIG should be available, and can be used to synchronize between multiple devices.

For SDUs sent from the Central to the Peripheral in CIS using unframed PDUs the SDU_Synchronization_Reference for the first SDU received in a burst of PDUs shall be calculated as follows:

SDU_Synchronization_Reference = CIS reference anchor point + CIS_Sync_Delay + (FT_C_To_P – 1) × ISO_Interval

For the Peripheral to Central direction, the SDU synchronization point represents the absolute reference time of the origin of an SDU and can be used to synchronize data coming from multiple sources. This point is at the start of the CIG reference point.

For SDUs sent from the Peripheral to the Central in CIS using unframed PDUs, the SDU_Synchronization_Reference for the first SDU received in a burst of PDUs shall be calculated as follows:

> SDU_Synchronization_Reference = CIS reference anchor point + CIS_Sync_Delay – CIG_Sync_Delay + SDU_Interval – ISO_Interval

For SDUs received in BIS using unframed PDUs, the SDU_Synchronization_Reference shall be calculated as follows:

> SDU_Synchronization_Reference = BIG reference anchor point + BIG_Sync_Delay

All PDUs belonging to a burst as defined by the configuration of BN have the same reference anchor point. When multiple SDUs have the same reference anchor point, the first SDU uses the reference anchor point timing. Each subsequent SDU increases the SDU_Synchronization_Reference timing by one SDU interval.

3.3 Time Stamp for SDU

When the Time_Stamp field is included in an HCI ISO Data packet from the Controller to the Host, the value of Time_Stamp is set to the synchronization reference for the SDU, as defined in Section 3.2, and is based on the CIS or BIG reference anchor point of the Controller's clock. The Controller should include a Time_Stamp.

The Host may determine the CIG reference point or BIG anchor point for the last transmitted SDU from the TX_Time_Stamp and Time_Offset return parameters of the HCI_LE_Read_ISO_TX_Sync command, as shown in Figure 3.1. It may then use this information when providing the Time_Stamp in future HCI ISO Data packets. For each HCI ISO Data packet where the Host can provide a valid Time_Stamp value, it should include a Time_Stamp in those HCI ISO Data packets that it sends.

When an HCI ISO Data packet sent by the Host does not contain a Time_Stamp or the Time_Stamp value is not based on the Controller's clock, the Controller should determine the CIS or BIS event to be used to transmit the SDU contained in that packet based on the time of arrival of that packet.

In each direction, in a given packet, the Time_Stamp provided (if any) shall be one that applies to the SDU corresponding to the Packet_Sequence_Number.

When using the Time_Stamp or another suitable method for synchronization, both the higher layer and Controller should implement a mechanism to compensate potential

clock drift and jitter. These mechanisms should include long term drift compensation and tolerances on the synchronization method used.

The Controller or the higher layer sending or receiving an SDU may use any of the following methods to transfer the synchronization reference of the SDU to the higher layer:

- Timestamps at the Controller’s clock
- Any other signaling method suitable to the higher layer

4 SDU RECOMBINATION AND REASSEMBLY

The ISOAL shall reconstruct SDUs from the received framed PDUs and pass all correct SDUs to the upper layer.

As an isochronous transport is not a reliable transport, errors can occur in the transfer of PDUs. Upon packet loss or erroneous reception, multiple SDUs can be affected. The number of affected SDUs will be (new synchronization reference – last valid SDU synchronization reference) ÷ SDU_Interval, rounded to the nearest integer, unless clock drift in this period is greater than SDU_Interval.

Each SDU shall be reported to the upper layer. SDUs that are completely missing shall be reported as "lost data". The following SDUs shall either be discarded and reported as “lost data” or be reported as “data with possible errors”:

- SDUs with violations in the Segmentation Headers of framed PDUs.
- SDUs with a length exceeding Max_SDU. In this case, the length of the SDU reported to the upper layer shall not exceed the Max_SDU length. The SDU shall be truncated to Max_SDU octets.
- SDUs with missing isochronous data due to loss of PDUs or only containing empty data PDUs with LLID=0b01.
- SDUs with unreliable isochronous data due to CRC errors in PDUs.
- Unframed SDUs without exactly one fragment with LLID=0b00.
- Unframed SDUs where the fragment with LLID=0b00 is followed by a fragment with LLID=0b01 and containing at least one octet of data.
- PDUs on unframed links with LLID=0b10.
- PDUs on framed links with LLID=0b00 or LLID=0b01.

Low Energy Controller
Part H

CHANNEL SOUNDING

CONTENTS

1 CHANNEL SOUNDING PHYSICAL CHANNELS

Channel Sounding (CS) defines 79 RF channels in the 2.4 GHz ISM band and defines a new channel index for each of these channels. Table 1.1 shows the relationship between CS channel indices and RF center frequency. Table 1.1 also shows some of the CS channel indices are not allowed for CS communication.

CS Channel Index	RF Center Frequency	Allowed
0	2402 MHz	No
1	2403 MHz	No
2	2404 MHz	Yes
…	…	…
22	2424 MHz	Yes
23	2425 MHz	No
24	2426 MHz	No
25	2427 MHz	No
26	2428 MHz	Yes
…	…	…
76	2478 MHz	Yes
77	2479 MHz	No
78	2480 MHz	No

Table 1.1: Mapping of CS channel indices to RF physical channels

2 PACKET FORMATS FOR CHANNEL SOUNDING

CS uses a specific modulated bit sequence known as CS_SYNC. The CS_SYNC packet format is similar to a packet format for LE Uncoded PHY, except that the CS_SYNC packet has no PDU, CRC, or CTE fields. The format of the CS_SYNC packet is shown in Figure 2.1.

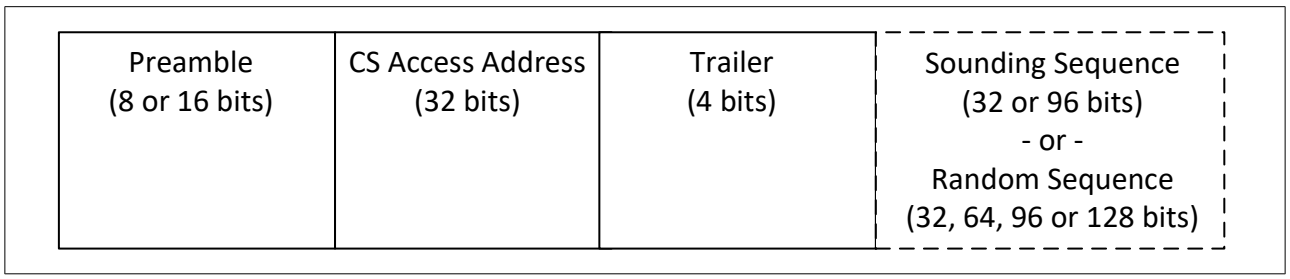

Figure 2.1: CS_SYNC packet format

The preamble is 8 bits when transmitting or receiving on the LE 1M PHY and 16 bits when transmitting or receiving on the LE 2M and the LE 2M 2BT PHYs. The CS Access Address is 32 bits. The trailer is 4 bits. The Sounding Sequence and Random Sequence fields are optional. If present, the Sounding Sequence field shall be of length 32 or 96 bits. If the Random Sequence field is present, it shall be of length 32, 64, 96, or 128 bits.

The variable length of the optional Sounding Sequence and Random Sequence fields allows an implementation to optimize the total packet length versus the correlation accuracy of the field. CS packets with no Sounding Sequence or Random Sequence fields take 44 µs to transmit when sent using the LE 1M PHY and 26 µs to transmit when using the LE 2M and the LE 2M 2BT PHYs. CS packets that include a Sounding Sequence or Random Sequence field take longer to transmit based on the length of the field and the PHY selection.

2.1 Preamble

The same rules defined for the preamble of the LE Uncoded PHY packet format as described in [Vol 6] Part B, Section 2.1.1 shall apply to the preamble of the CS packet format. The preamble for CS_SYNC is shown in Figure 2.2.

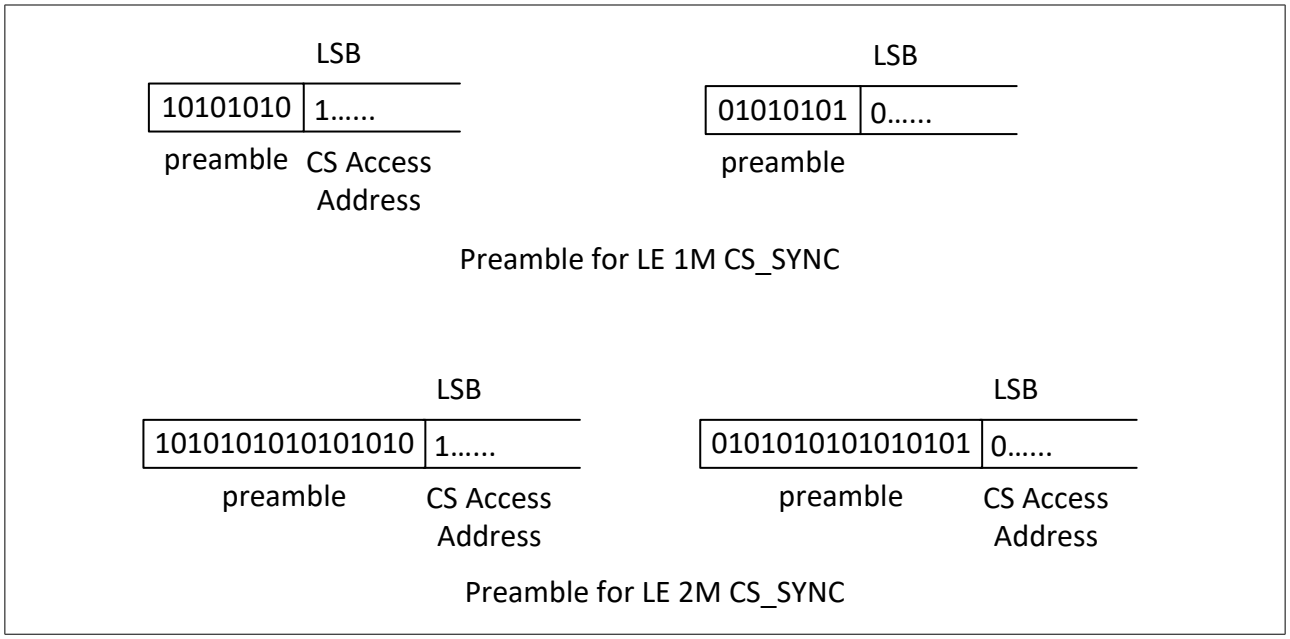

Figure 2.2: CS_SYNC preamble

2.2 Channel Sounding Access Address

Each CS Access Address is a sequence of bits that shall be cryptographically generated using the CS DRBG described in [Vol 6] Part E, Section 3.1.6. Devices that communicate with CS shall generate a common set of CS Access Addresses using the CS Access Address selection rules described below. The CS Access Addresses are used for synchronization, security, and round-trip time purposes.

Each CS step that transmits a CS_SYNC packet requires two CS Access Addresses that are derived from four DRGB output vectors of 32 bits each. The four vectors form four bit sequences s_0, s_1, s_2, and s_3 in the order the vectors were generated. Each bit sequence is constructed directly from the ordered bit output from the DRGB, with the first bit from the DRGB forming bit 32 (the most significant bit) of the sequence, the second bit forming bit 30, and so on, with the final bit forming bit 0 (the least significant bit) of the sequence. This ordered bit assignment is shown in Figure 2.3.

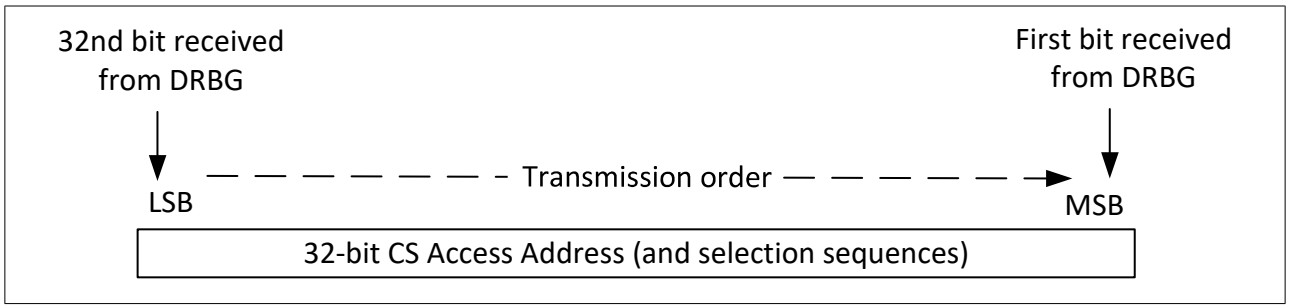

Figure 2.3: CS Access Address and selection sequence bit ordering

Sequences s_0 and s_1 are fed into the CS Access Address selection rules to produce a 32-bit sequence that becomes the CS Access Address of the first part of the CS step. Similarly, sequences s_2 and s_3 are fed into the CS Access Address selection rules to produce a 32-bit sequence that becomes the CS Access Address of the second part of the CS step.

The CS Access Address is transmitted least significant bit first (i.e., from bit 0 to bit 31).

2.2.1 Channel Sounding Access Address selection rules

The CS Access Address selection rules determine which of the two 32-bit candidates is selected to become the CS Access Address. These two 32-bit values shall be generated using the CS DRBG described in Section 4.8 at the step that requires the RTT exchange. The two random 32 bits for the CS Access Address candidates used in the CS_SYNC from the initiator to reflector shall be generated first. These two 32-bit values are referred to as s_0 and s_1 per the notation in Section 2.2. The two random 32 bits for the CS Access Address candidates used in the CS_SYNC from the reflector to the initiator shall be generated second. These two 32-bit values are referred to as s_2 and s_3 per the notation in Section 2.2. Filtering rules assign one autocorrelation score to each pair of 32-bit candidates. The sequence with the lower autocorrelation score is selected as the CS Access Address. If both sequences achieve the same autocorrelation score, then the second of the sequence pair (i.e., s_1 and s_3) shall be selected.

The CS autocorrelation score is a function that applies to a 32-bit sequence that is composed of 32 individual bits s_i (i in the 1 to 32 range) and is defined as:

$$score = abs(2 \times C_1 - 31) + abs(2 \times C_2 - 30) + abs(2 \times C_3 - 29)$$

Where each of the C_k elements is defined as:

$$C_k = \sum_{i=1}^{32-k} (s_i \oplus s_{i+k})$$

2.2.2 Channel Sounding Access Address checking

A device shall return a CS Access Address quality indication value, as shown in Table 2.1, for a CS_SYNC packet received or intended to be received in a CS step. Although the generation of an Access Address quality indication value is implementation specific, the meaning noted in Table 2.1 should be followed. Only packets with an Access Address quality indication value of 0 shall be used for testing RTT accuracy measurements.

Value	Meaning
0	CS Access Address check is successful and all bits match the expected sequence. For non-Mode-0 packets, the device has obtained a ToA-ToD (or ToD-ToA) measurement from the packet.
1	CS Access Address check contains 1 or more bit errors. For non-Mode-0 packets, the device has obtained a ToA-ToD (or ToD-ToA) measurement from the packet.
2	CS Access Address not found
3	RFU

Table 2.1: CS Access Address integrity check result values

2.3 Trailer

The CS trailer is a sequence of 4 bits, alternating between 0 and 1 bits. As shown in Figure 2.4, the trailer is 1010 (in transmission order) when the most significant bit of the CS Access Address is a 0, and 0101 when the most significant bit of the CS Access Address is a 1.

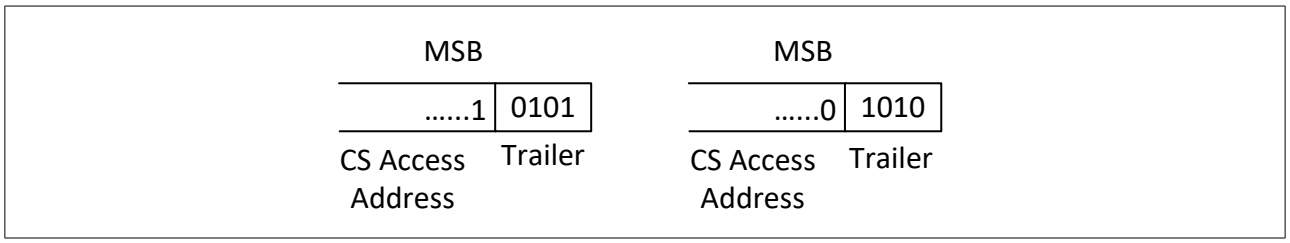

Figure 2.4: CS_SYNC trailer

2.4 Sounding sequence

The optional sounding sequence is a sequence of bits alternating between 0 and 1, starting with a 0 as the first bit (LSB) in transmission order, which is then partially overwritten by one or two marker signals for resilience against spoofing attacks. Both the marker signal position and bit pattern are selected separately for each CS_SYNC transmitted.

The marker signal is 4 bits long. There are two possible signals that are selected randomly, seeded by the CS DRBG as described in Section 4.8. CS DRBG shall be invoked to generate a single random bit (see Section 4.8). If this bit is a 0, then the marker signal consists of the bits ‘1100’ in transmission order. If the bit is a 1, then the marker signal consists of the bits ‘0011’ in transmission order. This marker signal selection process shall be repeated if a sounding sequence of 96 bits is used and only if the second marker is not omitted.

Each marker signal shall overwrite four consecutive bits of the sounding sequence starting at a position determined by invoking the random number generation function

hr1 (see Section 4.8.1). For the 32-bit sounding sequence, a single marker shall be used starting at bit number hr1(29) of the sequence (where the first bit is bit number 0). For the 96-bit sounding sequence, one or two markers shall be used. The first marker shall start at bit number hr1(64) and the second marker shall start at bit number hr1(75) + 67; if the starting bit position for the second marker exceeds 92, then the second marker shall be omitted.

See Section 4.8 for CS DRBG invocation ordering rules.

Figure 2.5 shows the construction of the sounding sequence with a single marker inserted. The sounding sequence is transmitted with the least significant bit first, and the most significant bit transmitted last.

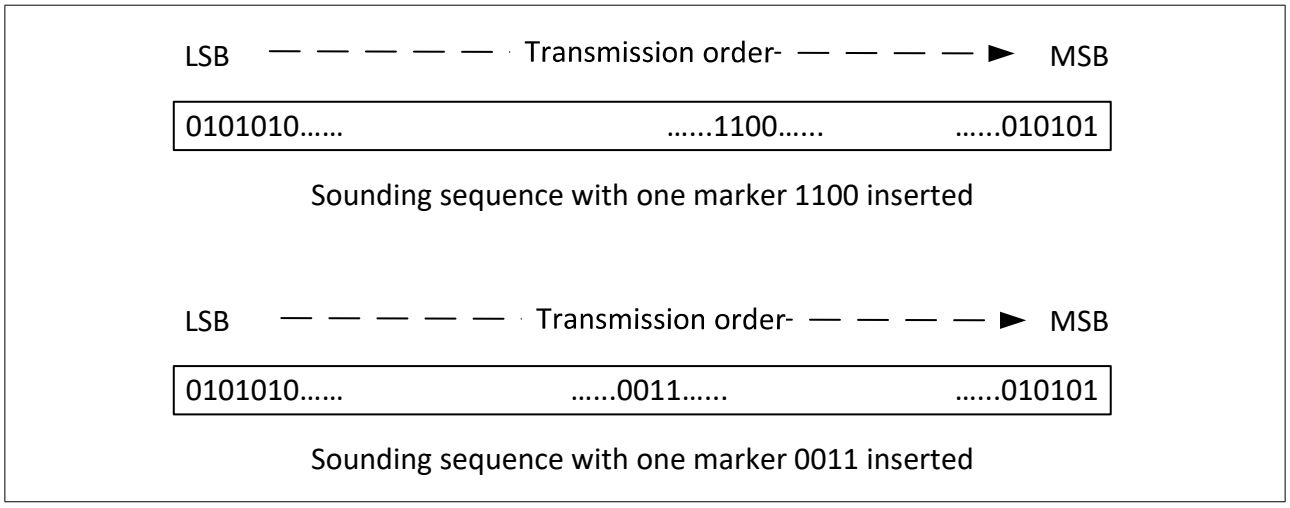

Figure 2.5: CS_SYNC sounding sequence

2.5 Random sequence

The optional random sequence payload is a sequence of randomized bits. This random sequence is generated separately for each CS_SYNC transmitted. This bit sequence shall be generated using the output of the CS DRBG described in Section 4.8. The length of this bit sequence is identified by the RTT_Types selected during the CS configuration procedure described in [Vol 6] Part B, Section 5.1.25.

See Section 4.8 for CS DRBG invocation ordering rules.

The random sequence is constructed directly from the ordered bit output from the DRBG, with the first bit from the DRBG occupying the most significant bit of this field, which is the bit position equal to the length of the random sequence minus 1. The final bit from the DRBG occupies the least significant bit at position 0, as shown in Figure 2.6.

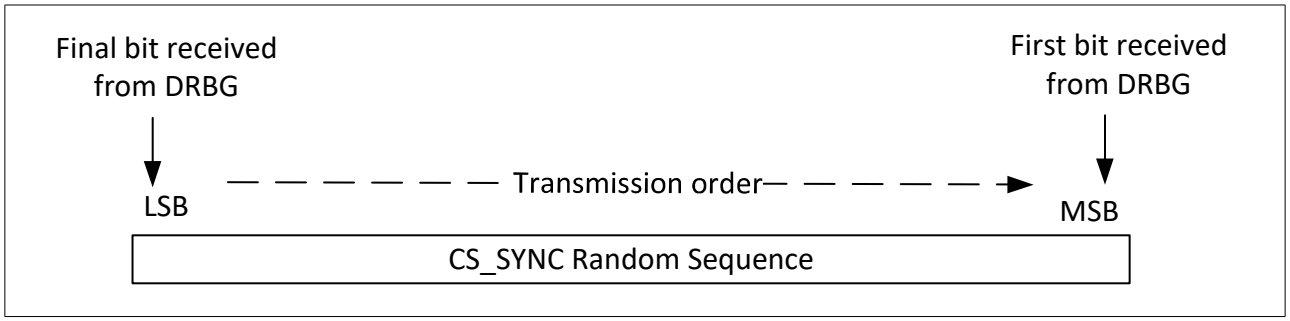

Figure 2.6: CS_SYNC random sequence

The random sequence is transmitted with the least significant bit first and the most significant bit transmitted last.

2.6 Channel Sounding extended packet formats

CS defines two additional packet formats.

A CS_SYNC followed by a CS tone is shown in Figure 2.7. The CS_SYNC has two mode-specific variations: a CS_SYNC_0_R, as described in Section 4.3.1, and a CS_SYNC_3_I, as described in Section 4.3.4.

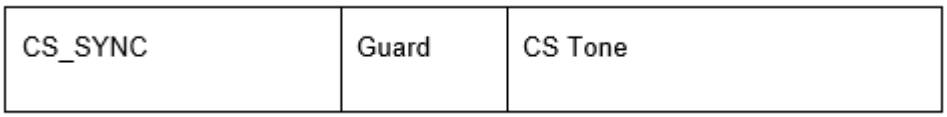

Figure 2.7: CS_SYNC followed by a CS tone

A CS tone followed by a CS_SYNC is shown in Figure 2.8. In this case, the CS_SYNC occurrence is the CS_SYNC_3_R as described in Section 4.3.4.

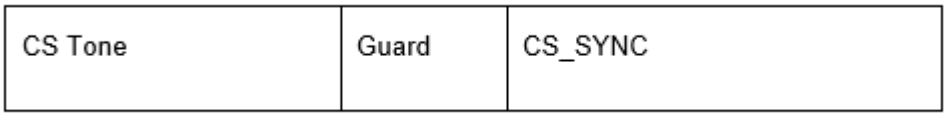

Figure 2.8: CS tone followed by a CS_SYNC

In both cases, the guard time (T_GD) is 10 µs in duration, independent of the LE PHY being used. The transmitted signal during the guard time should be ignored by the receiver.

In both cases, the CS tone and CS_SYNC are transmitted on the same RF frequency and are subject to the rules of frequency and phase stability established in [Vol 6]

Part A, Section 3.5. The duration of the two additional packet formats is variable and depends on various configuration factors, as described in Section 4.3.1 and Section 4.3.4.

3 CHANNEL SOUNDING BIT STREAM PROCESSING

3.1 Measuring RTT

Devices may use CS_SYNC exchanges to measure the propagation channel's round-trip time (RTT).

Device A is the device that begins the RTT procedure with the transmission of the first packet in the RTT exchange. Device B is the device that receives the transmission from device A and then sends a response transmission back to device A.

Let ToD_A represent the time of departure, measured at the antenna port, of the first packet transmitted in this exchange from device A. Also, let ToA_A represent the time of arrival of the received packet, measured at the antenna port.

Similarly, let ToA_B represent the time of arrival of the received packet from device A. Also, let ToD_B represent the time of departure.

Consolidated, let ToX_Y represent the time of departure from device Y if X is replaced with D, or the time of arrival of arrival if X is replaced with A measured from device Y at its antenna port.

The value of ToX_Y is determined by optimizing the solution to the equation

$$ToX_Y\left[k\right] = \underset{\tau}{\operatorname{argmax}}\left|\int_{\tau+t_A}^{\tau+t_B} \hat{x}_Y(k,t)\hat{x}_Y^*(k,t-T_{sym})s^*\left(k,t-\tau\right)s\left(k,t-\tau-T_{sym}\right)\ dt\right| \qquad \text{(EQ 1)}$$

where $\hat{x}_Y(k,t)$ is the signal at the antenna port of Device Y during step k, after applying the reference down-conversion for a CS packet as defined in Section 3.1.1, and $s(k,t)$ is the reference transmitted signal of the CS packet for step k as defined in Section 3.5.2. The value T_{sym} represents the symbol period. The value t_A represents the start of the CS access address of the reference transmitted signal, where the preamble starts at $t = 0$. The value t_B represents the end of the CS access address of the reference transmitted signal in the case of no random payload; alternatively, it represents the end of the random payload.

The RTT measurement obtained by Device A is obtained by using the difference of the values of $ToA_A - ToD_A$ and $ToD_B - ToA_B$ as expressed in the equation:

$$RTT = 2ToF = \left[\frac{1}{1 + FFO_{RX^*}10^{-6}}(ToA_A - ToD_A)\right] - (ToD_B - ToA_B)$$

FFO_{RX^*} is defined in [Vol 6] Part A, Section 3.5.1.

A single step for this exchange is shown in Figure 3.1.

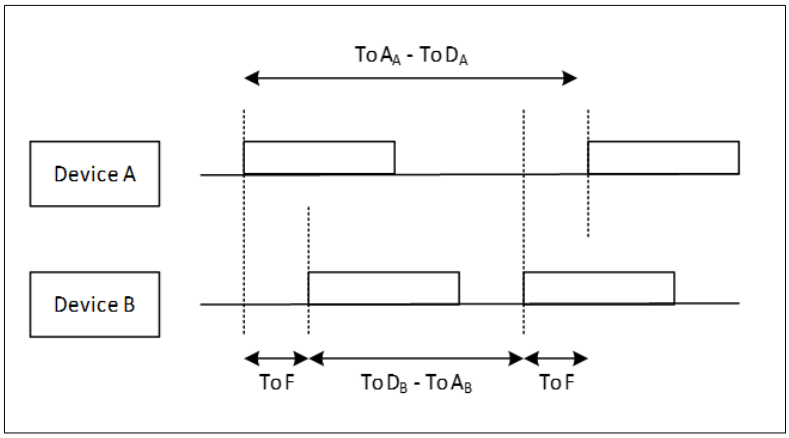

Figure 3.1: Round-trip time

Devices should measure the ToD and ToA values as accurately and precisely as possible. Devices shall compensate for any known internal delays from the antenna to the actual measurement point for these values. Device A shall compensate for the effects of clock drift based on the FFO estimate of device B, relative to its own clock as described in [Vol 6] Part A, Section 3.5.1. Device A shall implement frequency-based timing compensation based on the equation above and using the value of FFO_{RX^*}. Device B shall not attempt any related compensation for timing drift. Devices may choose to delay the start of their transmissions by up to one symbol period of the expected transmit point to increase the overall security of the RTT measurements.

Three variations of RTT timing estimates are defined in this section for the purpose of coordination between devices. A method for simultaneous extraction of a phase-based estimate along with an RTT timing estimate is also defined. Both device A and device B shall select the same method when performing both RTT timing and CS_SYNC phase-based estimates.

3.1.1 Reference receiver for round-trip time measurements

The reference down-conversion for the CS packet for step $k = M + 1, \ldots, M + K$, is defined at the antenna of the device as

$$\hat{x}\left(k,t\right) = LPF\left[x(t)e^{-j2\pi f_E[k]t}\right]$$

where $x(t)$ is the signal at the antenna of device as defined in [Vol 6] Part A, Appendix B and LPF is a low-pass filter that removes the high frequency components. $f_E[k]$ represents the expected center frequency of the CS_SYNC packet as defined in [Vol 6] Part A, Section 3.5.2. $\hat{x}(t)$ is defined for all time t within step k.

3.1.2 ToD and ToA reporting accuracy

Let *2ToF* represent the expected known two-way round-trip time of flight between device A and device B. In this section, the initiator is represented by device A and the reflector is represented by device B.

Denote $(ToD - ToA)_B[k]$ as the measurement value reported by Device B for step k.

Define the value of $(ToD - ToA)'_B[k]$

$$(ToD - ToA)'_B[k] = \frac{((ToD - ToA)_B[k] + T\_SY\_CENTER\_DELTA[k])}{\left(1 + FFO_E \cdot 10^{-6}\right)}$$

where $T\_SY\_CENTER\_DELTA[k]$ is the value of T_SY_CENTER_DELTA for the mode used at step k as defined in Section 4.3.2 and Section 4.3.4. FFO_E is the fractional frequency offset of the CS subevent as defined in [Vol 6] Part A, Section 3.5.2.

The error in Device B's reported time measurement for step k, is defined as

$$\Delta T_{RESP}[k] = (ToD_B[k] - ToA_B[k]) - (ToD - ToA)'_B[k]$$

where $ToD_B[k]$, $ToA_B[k]$ are the values measured as described in Section 3.1.

Similarly, denote $(ToA - ToD)_A[k]$ as the measurement value reported by Device A for step k that must include the correction for clock drift as described in Section 3.1.

Define the value of $(ToA - ToD)'_A[k]$ as

$$(ToA - ToD)'_A[k] = (ToA - ToD)_A[k] + T\_SY\_CENTER\_DELTA[k]$$

Let *2ToF* represent the expected known two-way round-trip time of flight between device A and device B.

Device A's RTT measurement error for step k, is defined as

$$\Delta T_{RTT}[k] = \left(ToA_A[k] - ToD_A[k]\right) \cdot \left(1 + FFO_E \cdot 10^{-6}\right) - (ToA - ToD)'_A[k] - 2ToF\,.$$

where $ToD_A[k]$, $ToA_A[k]$ are the values measured by the tester as described in Section 3.1.

Let MeasurementValid[k] be equal to 1 if the CS Access Address quality indication value for the CS_SYNC received at step k is reported as 0, as described in Section 2.2.2. MeasuremetValid[k] is equal to 0 if the CS Access Address quality indication value is reported otherwise.

Within a single procedure i, with N steps of single packet exchanges, Device B's procedure wise response time error is defined as

$$\Delta T_{RESP,PROC} = \frac{\sum_{k=1}^{N} \Delta T_{RESP}[k] \cdot MeasurementValid[k]}{\sum_{k=1}^{N} MeasurementValid[k]}$$

Similarly, Device A's procedure wise RTT measurement error is given by

$$\Delta T_{RTT,PROC} = \frac{\sum_{k=1}^{N} \Delta T_{RTT}[k] \cdot MeasurementValid[k]}{\sum_{k=1}^{N} MeasurementValid[k]}$$

For Device B, the absolute bias B is the absolute value of the mean of $\Delta T_{RESP,PROC}$ for Device B across procedures. The standard deviation of $\Delta T_{RESP,PROC}$ for Device B across procedures is denoted as σ. For Device A, the absolute bias B is the absolute value of the mean of $\Delta T_{RTT,PROC}$ for Device A across procedures. The standard deviation of $\Delta T_{RTT,PROC}$ for Device A across procedures is denoted as σ.

Each device shall be characterized and the values of B and σ shall meet one of two possible criteria at a receiver input level of -70 dBm:

$$2\sigma + B < 10 \text{ ns} \quad \text{(EQ 2)}$$

for a minimum number of mode-1 and mode-3 CS_SYNC packet exchanges *N* per procedure, where *N* ≤ 255, or alternatively

$$2\sigma + B < 150 \text{ ns} \quad \text{(EQ 3)}$$

for a minimum number of mode-1 and mode-3 CS_SYNC packet exchanges *N* per procedure, where *N* ≤ 255.

3.2 Timing estimate based on an Access Address

This section describes two methods for deriving ToA timing estimates based on the CS Access Address.

3.2.1 Timestamps using a native clock

Timestamping of the ToA may be done using the receiver's native clock. The resolution provided by this method for a single sample is therefore proportional to the accuracy and clock rate of that receiver.

To improve the overall resolution of the measurement, measurements over several packets may be taken and averaged. Because the sampling clocks of a pair of devices are unrelated in phase, the distribution derived from several measurements is used to normalize the ToA value to a more precise average.

To improve the distribution of results, a transmitter may choose to transmit a CS_SYNC with an added fractional timing delay of up to one symbol period, which itself is pseudo-random with respect to the expected transmit point. The selection of the pseudo-random offset is left to the implementation.

3.2.2 Timing estimate based on a pseudo-noise bit sequence

RTT timing measurements may use a pseudo-noise sequence in a CS Access Address or payload, of sufficient length to obtain an indication of the timing error of the received signal with regard to the receiver's local sampling clock. This timing error is the difference between the optimum sampling point and the actual sampling point, also known as the fractional timing component.

Several methods exist for extraction of this fractional timing component. One such method searches for the symbol correlation peak across all the symbols in the pseudo-noise sequence. Fractional timing extraction is not dependent on pseudo-random clock phase distribution between packet exchanges.

3.3 Fractional timing estimate based on a sounding sequence

Timing estimates may be derived from a modulated repeating [0 1] bit sequence. The modulation is either at the LE 1M PHY, the LE 2M PHY, or the LE 2M 2BT PHY. The periodicity of this sequence creates two distinct tones in the output spectrum, of which the periodic components are associated with the basic repetition of the two symbols. At the 1 Msym/s rate, this periodicity is at 2 µs. At the 2 Msym/s rate, it is at 1 µs.

Let

f represent the frequency of the complex sinusoid, and

α represent a common complex gain on these two signals.

The two complex sinusoid baseband signals are then denoted as

$$S_{+f}(t) = ae^{+j2\pi ft}$$

$$S_{-f}(t) = ae^{-j2\pi ft}$$

Now let

T_s represent the sampling period at the receiver,

n represent the number of samples of the respective complex sinusoids from a time *t*, and

M represent the integration period in units of full cycles of the complex sinusoids.

Then *L*, which represents the number of samples taken within that integration period, is denoted as

$$L = \frac{M}{fT_s} - 1$$

Denote the signal containing the modulated repeating [0 1] bit sequence as

$$S(n,t) = s(t + nT_s)$$

Then the phase of the two complex sinusoids is measured through the following two correlations:

$$\varphi\left(t, +f\right) = \angle\left(\sum_{n=0}^{L} S\left(n,t\right) \times e^{-j2\pi fnT_s}\right) \quad \text{(EQ 4)}$$

$$\varphi\left(t, -f\right) = \angle\left(\sum_{n=0}^{L} S\left(n,t\right) \times e^{+j2\pi fnT_s}\right)$$

Because of the time quantization error and random sampling clock offset at the receiver, the estimated ToA timing measured at the receiver's sampling clock rate is not the same as the actual ToA. Denote the coarse estimate of the start of the sounding sequence measured at the receiver's antenna port as t_{sync}. Using the two equations above, the fractional delay is calculated as:

$$\Delta t = \frac{\varphi(t_{sync}, +f) - \varphi(t_{sync}, -f)}{4\pi f}$$

The final estimate of the actual ToA is $t_{\text{sync}} + \Delta t$, which is used for the ToA value in Section 3.1.

3.3.1 Phase-based PCT estimate based on a sounding sequence

The properties of the modulated repeating [0 1] bit sequence also allow for the extraction of distance estimates using phase-based calculations. Similar to RTT exchanges, the phase measurements consist of two exchanges and measurements, first in the direction from a device A to a receiving device B, then in the reverse direction. Exchanges over at least two channels are required to resolve the 2π ambiguity in the distance estimate.

Let

φ_0^a represent the RF initial phase of device *A* transmitting the signal,

φ_0^b represent the RF receive phase of the signal as seen at the receiving device *B*,

ω_{lo} represent the carrier frequency of that signal, and

ω_m represent the frequency of the modulated tones.

The complex representation of the modulated [0 1] signal at the transmitting device *A* is

$$S_{rf\_a}\left(t\right) = e^{j(\omega_{lo}t + \varphi_0^a)} \cdot \left(e^{+j\omega_m t} + e^{-j\omega_m t}\right)$$

Let

D represent the propagation distance, and

C represent the speed of light.

At the receiving device *B*, the representation of the receive signal is

$$S_{rf\_b}\left(t\right) = e^{j\left(\omega_{lo}t + \varphi_0^a - \frac{\omega_{lo}D}{C}\right)} \cdot \left(e^{+j\omega_m t} + e^{-j\omega_m t}\right)$$

After processing at the receiver, the equation above can be represented as

$$S_{rf\_b}\left(t\right) = e^{j\left(\varphi_0^a - \varphi_0^b - \frac{\omega_{lo}D}{C}\right)} \cdot \left(e^{+j\omega_m t} + e^{-j\omega_m t}\right)$$

Applying the same correlations represented in Section 3.3, EQ X yields the following phase results for each of the two complex sinusoids:

$$SS\_PCT_1 = \varphi\left(t, +f\right) = \left(\sum_{n=0}^{L} S_{rf\_b}\left(n,t\right) \times e^{-j2\pi fnT_s}\right)$$

$$SS\_PCT_2 = \varphi\left(t, -f\right) = \left(\sum_{n=0}^{L} S_{rf\_b}\left(n,t\right) \times e^{+j2\pi fnT_s}\right)$$

At device *B*, to correct for phase change of the local oscillator while transmitting, the phase correction should be performed by complex multiplying both correlations by exp(j×phase_correction), where the phase correction is expressed in radians. The reference point for this definition is the local device's antenna. The reference point for this definition is the local device's antenna. SS_PCT results shall be consistent with the format for PCT results as described in Section 4.6. If a subevent contains PCT results, the same reference power level (RPL) should be used for the SS_PCT. Otherwise, the RPL shall be encoded as an 8-bit signed number. The RPL expressed in dBm shall

correspond to the power of the sounding sequence sidelobe that produces a SS_PCT whose amplitude is 2048, obtained by integrating the received signal over the payload of the CS_SYNC packet at the expected sidelobe frequency. In all cases, a single RPL is used for all the SS_PCT values in a CS subevent.

The conversion between SS_PCT IQ values as unitless values to power in dBm can be expressed as denoted by EQ 4 in Section 4.6. In all cases the magnitude should be adjusted to give the power in the sounding sequence tone plus 6 dB.

These two equations can be further simplified, where t_i is the same arbitrary time at which the correlations start, to

$$\varphi\left(t, +f\right) = e^{j\left(\varphi_0^a - \varphi_0^b - \frac{\omega_{lo} D}{C}\right)} \cdot \left(e^{+j\omega_m t_i}\right)$$

$$\varphi\left(t, -f\right) = e^{j\left(\varphi_0^a - \varphi_0^b - \frac{\omega_{lo} D}{C}\right)} \cdot \left(e^{-j\omega_m t_i}\right)$$

Then the phase-based rotation result from device A to device B is

$$\varphi_{ab} = \left(\angle\varphi(t, +f) + \angle\varphi(t, -f)\right) \div 2 = \left(\varphi_0^a - \varphi_0^b - \frac{\omega_{lo} D}{C}\right)$$

Device *B* then reciprocates with a transmission of its own, and a similar result is obtained with device *B* as the transmitter and device *A* as the receiver. If both devices retain (or correct for) phase continuity in their local oscillators, then the phase-based rotation result from device *B* to device *A* is

$$\varphi_{ba} = \left(\angle\varphi(t, +f) + \angle\varphi(t, -f)\right) \div 2 = \left(\varphi_0^b - \varphi_0^a - \frac{\omega_{lo} D}{C}\right)$$

When combined, these two results provide an estimated distance *D* between the two devices.

$$\Phi_{2w}\left(\omega_{lo}, D\right) = \varphi_{ab} + \varphi_{ba} = \frac{2\omega_{lo} D}{C}$$

This estimate is compromised by the 2π ambiguity. To obtain an unambiguous range, the results from measurements over several frequencies, as defined in [Vol 2] Part A, Section 2, may be combined:

$$\Delta_\Phi = \Phi_{2w}\left(\omega_{lo}{}^1, D\right) - \Phi_{2w}\left(\omega_{lo}{}^0, D\right) = \frac{2\Delta\omega_{lo} D}{C}$$

$$D = \frac{C}{2\Delta\omega_{lo}} \Delta_\Phi \ mod \ \frac{C}{2\Delta\omega_{lo}}$$

3.3.1.1 Reference receiver for phase-based ranging from a sounding sequence

Let the CS step at which a sounding sequence is exchanged occur at step index k as defined for CS tones in [Vol 6] Part A, Section 6.1. The reference down-conversion for the sounding sequence is then defined at the antenna of the device as

$$\hat{x}(t) = LPF\left[x(t)e^{-j2\pi f_E[k]t}\right]$$

where $x(t)$ is the signal at the antenna of a device used as defined in [Vol 6] Part A, Appendix B, and LPF is a low-pass filter that removes the high frequency components. $f_E[k]$ represents the center frequency of the CS_SYNC packet carrying the sounding sequence, as defined in [Vol 6] Part A, Section 3.5.2. $\hat{x}(t)$ is defined for all time t within step k.

Define the start time of the transmission of the sounding sequence from the vector signal generator as $t_{SS}^{TX}[k]$.

Denote the time of arrival of the CS Access Address of the transmission from the implementation under test as $t_{SS}^{RX}[k]$.

In the reference receiver, the following are also defined:

T_s represents the sampling period at the receiver.

L_{ss} represents the length of the sounding sequence in terms of the number of symbols (see Section 2.4).

symbol_time is 1 µs for LE 1M and 0.5 µs for LE 2M and LE 2M 2BT.

$f = \frac{1}{2 \times \text{symbol\_time}}$ represents the frequency of the complex exponential function used for correlations.

Then L, which represents one less than the number of samples taken within the integration period, is denoted as

$$L = \frac{L_{SS} \times \text{symbol\_time}}{T_S} - 1$$

3.3.1.2 Accuracy requirements

The observed average transmitted phase $\varphi_{tx}(k,+f)$ and $\varphi_{tx}(k,-f)$ for step k is measured through the following two correlations:

$$\varphi_{tx}(k, +f) = \angle\left(\sum_{n=0}^{L} \hat{x}\left(t_{SS}^{TX}[k] + nT_s\right) \times e^{-j2\pi f n T_s}\right)$$

$$\varphi_{tx}(k, -f) = \angle\left(\sum_{n=0}^{L} \hat{x}\left(t_{SS}^{TX}[k] + nT_s\right) \times e^{+j2\pi f n T_s}\right)$$

These results are then combined to give the observed average transmitted phase for step *k*, $\Phi_{TX}[k]$:

$$\Phi_{TX}[k] = (\varphi_{tx}(k, +f) + \varphi_{tx}(k, -f))$$

The observed average received phase $\varphi_{rx}(k, +f)$ and $\varphi_{rx}(k, -f)$ for step *k* is measured through the following two correlations:

$$\varphi_{rx}(k, +f) = \angle\left(\sum_{n=0}^{L} \hat{x}\left(t_{SS}^{RX}[k] + nT_s\right) \times e^{-j2\pi f n T_s}\right)$$

$$\varphi_{tx}(k, -f) = \angle\left(\sum_{n=0}^{L} \hat{x}\left(t_{SS}^{RX}[k] + nT_s\right) \times e^{+j2\pi f n T_s}\right)$$

These results are then combined for step *k*, according to the following equation:

$$\Phi_{RX}[k] = (\varphi_{rx}(k, +f) + \varphi_{rx}(k, -f))$$

The internal phase offset for step *k* is defined as

$$\theta_C[k] = principal(\Phi_{TX}[k] - \Phi_{RX}[k] + 2 \times \angle(SS\_PCT_1[k] + SS\_PCT_2[k]))$$

where *principal*( ) is defined in [Vol 6] Part A, Section 5.2.1, and $SS\_PCT_1[k]$ and $SS\_PCT_2[k]$ are the correlations defined in Section 3.3.1 for step *k*, provided by the IUT.

Denote $\theta_{C,UW}[k]$ as the phase-unwrapped version of $\theta_C[k]$.

Denote $\alpha f_{E,\text{ord}}[k] + \beta$ as the solution to the linear regression of the set of points defined by $(f_{E,\text{ord}}[k], \theta_{C,UW}[k])$.

For any subevent where

- An RTT Sounding Sequence of at least 32 bits is exchanged at least once for all CS channels,
- the transmit signal received signal satisfies the conditions for frequency offset described in [Vol 6] Part A, Section 3.5.2, and
- the receiver input level is -55dBm,

the solution to the linear regression shall satisfy

$$|\alpha| < 2\pi \times 10.2 \text{ ns},$$

for 95% of subevents.

3.4 Fractional timing estimate based on a random sequence

Fractional RTT timing measurements based on a random sequence may use the same properties for the extraction of fractional timing components based on a pseudo-noise bit sequence as those described in Section 3.2.2. The symbol correlation peak derived from the individual symbols of an added random sequence bit field may be used to further refine the fractional timing extracted from the CS Access Address.

3.5 Attack detection requirements

This section describes a metric for reflecting the level of symbol attack detection, describes a reference signal construction, and provides reference attack signal definition. Reference attack signal definitions are used as a basis for detecting the presence of attack signals.

3.5.1 Normalized attack detector metric

The normalized attack detector metric (NADM) provides a measure of how much a received GFSK modulated packet signal differs from the expected packet signal as described in Section 3.5.2. A NADM value range indicates a progressively increased chance that an attacker is present. Refer to Table 3.1 for a description of these ranges.

Figure 3.2 shows the components of the overall attack detector system. The attack detector system uses a Controller-based NADM algorithm to determine a NADM value from each received packet in each CS device on both sides of the link. The NADM values are aggregated while an attack detector algorithm determines the threat level using the NADM values collected from one or more packet exchanges within a CS procedure. A user application can use the attack detector algorithm to determine its future actions.

The specifics of the user application and attack detector algorithm are beyond the scope of this specification.

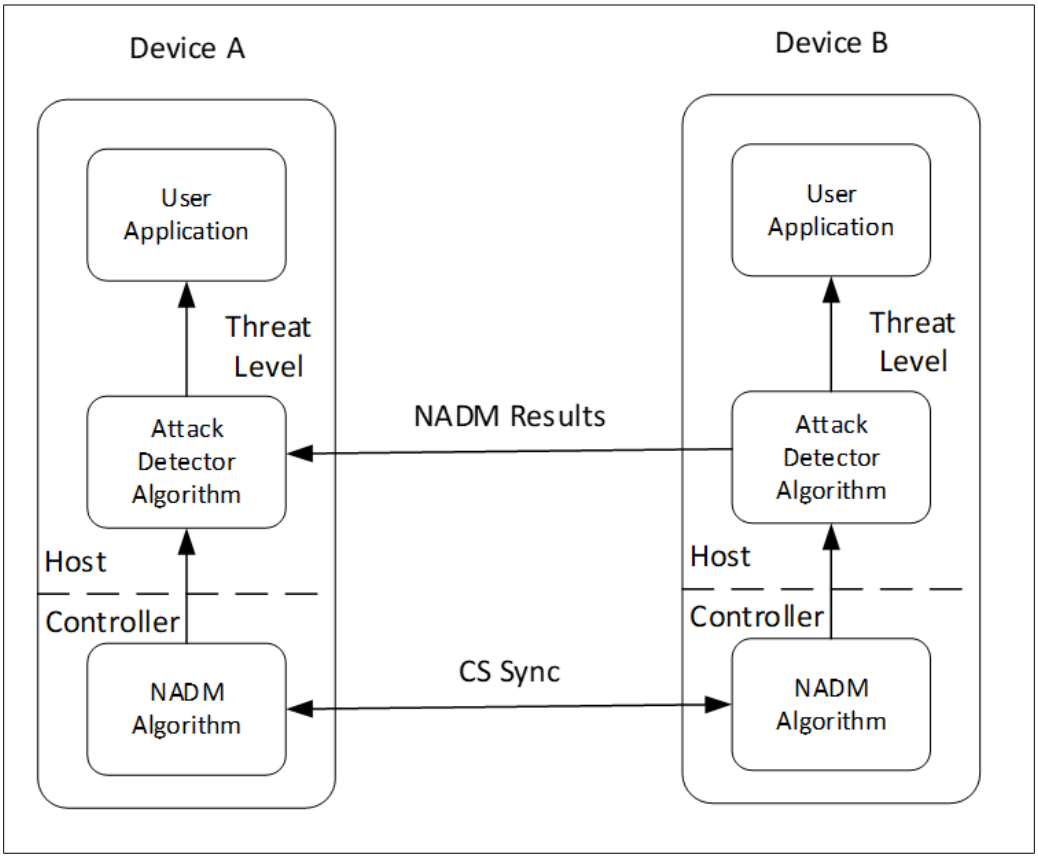

Figure 3.2: Components of a NADM attack detector system

Figure 3.3 shows an example NADM system. In this example, a packet is received and its signal phase is extracted. This signal phase contains the relative phase information associated with the encoded data symbols from GFSK modulation. Because the data symbols for the received packet are known in advance, they can be modulated to construct a reference phase signal. A reference phase signal is described in Section 3.5.2. The received and reference signals should be similar. Differences in the phases of the two signals may be used to produce a raw attack detector metric. This raw metric may be combined with other information, such as the number of bit errors in the received signal, to produce the NADM.

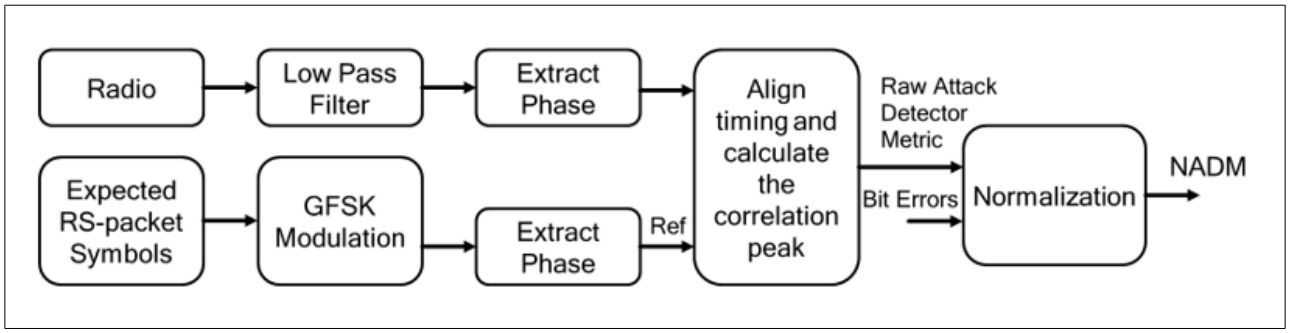

Figure 3.3: NADM processing

A raw detector metric for a CS_SYNC with sounding sequence or random sequence is described in Section 3.5.3.4.

The list of NADM values is shown in Table 3.1.

NADM	Attack Type
0x00	Attack extremely unlikely
0x01	Attack very unlikely
0x02	Attack unlikely
0x03	Attack is possible
0x04	Attack is likely
0x05	Attack very likely
0x06	Attack extremely likely
0xFF	Unknown
All other values	Reserved for future use

Table 3.1: NADM values

Values starting from “Attack unlikely” through to “Attack extremely unlikely” indicate with increasing confidence the absence of an attacker. Values starting from “Attack is possible” through to “Attack extremely likely” indicate with increasing confidence the presence of an attacker. The implementation shall determine whether an attack is present or not present, and the selection of the level of confidence of that event. If a device is unable to determine a NADM value or does not support NADM processing, then it shall report a NADM value of *Unknown* (0xFF).

3.5.2 Reference signal modulated with BT=0.5, h=0.5 GFSK

Let B = [b_0.. b_{N-1}] be a binary sequence of N elements in the [0,1] space.

Let A = [a_0.. a_{N-1}] the symbol sequence of N elements corresponding to the binary sequence, following the mapping defined in [Vol 6] Part A, Section 3.1. Also, $a_i = 2b_i - 1$.

Let p(t) be a Gaussian-shaped pulse function of BT=0.5, for a normalized symbol period of 1, as defined by:

$$p(t) = \frac{1}{\sigma\sqrt{2\pi}} e^{-2\left(\frac{t}{\sigma}\right)^2}$$

Where

$$\sigma = \frac{\sqrt{\ln 2}}{\pi}$$

And g(t) is the convolution of p(t) with a rectangle pulse of normalized duration 1, rect(t) = 1 when 0 < t < 1 and 0 otherwise.

$$g(t) = p(t) * rect(t)$$

Where the * operator represents the time convolution of the two signals.

Based on these definitions, the normalized reference phase is given by:

$$\varphi_r\left(t\right) = \frac{\pi}{2}\sum_{i=0}^{N-1} a_i \int_{-\infty}^{t} g\left(\tau - i\right) d\tau$$

For a reference signal with symbol period T_{Sym} then the reference signal phase is defined as

$$\varphi_r(t) = \varphi_{r,1}\left(\frac{t}{T_{sym}}\right)$$

and the reference signal is then

$$x_r(t) = \exp(j\varphi_r(t))$$

3.5.3 Early commit attacks with phase based detection

3.5.3.1 Sounding sequence attack signal definition

The format of the sounding sequence with marker insertion is described in Section 2.4. An early commit, late detect (ECLD) attack is a relevant MITM attack strategy due to the regular, repeating pattern of the sounding sequence. During an ECLD attack, the attacker receives the first device's transmitted signal, and may regenerate the sounding sequence with a timing advance while searching for the randomized marker. The MITM attacker detects the marker while observing an unexpected bit transition (i.e., 0b1 to a 0b1, or 0b0 to a 0b0, instead of 0b1 to a 0b0, or 0b0 to a 0b1). The MITM may then change the phase trajectory to correct the rest of the symbol so the second device does not receive an incorrect symbol and the attack is not detected.

Table 3.2 shows the positions of the symbol(s) where an attacker-induced glitch might be detected given the symbol position of the marker start.

Symbol position of marker start	**Symbol(s) with Glitch**	
	Marker Sequence 0b0011	**Marker Sequence 0b1100**
k odd, original bit is 1	k+1 and possibly k+2	k and possibly k+1
k even, original bit is 0	k and possibly k+1	k+1 and possibly k+2

Table 3.2: Sounding sequence detectable symbol glitch positions

The following definitions are used to generate the attack signal:

- Initialize the reference attack packet P_A as the CS_SYNC packet without any markers in its sounding sequence. Define the oversampled discrete-time phase of the attack signal, $\Phi_A[n]$, as the phase of the GFSK modulated version of P_A. This is defined in terms of the reference signal defined in Section 3.5.2. where binary input sequence is P_A. Then $\Phi_A[n] = \varphi_r\left(\frac{nT_{sym}}{R}\right)$, where T_{sym} is the symbol period, and R is the oversampling rate within one symbol period.
- The MITM attack signal is defined based on a detection delay of M samples of the original transmitted signal. The attacker determines a bit flip at the end of the detection delay and then applies a correction to follow its estimate of the original transmitted signal. The duration of this correction is denoted as the transition period. Table 3.3 shows this detection latency as well as other parameters (as explained below) that define this reference attack signal set.

Parameter	Value	Definition
R	≥ 16	Symbol oversampling rate
M	0.25R	Detection latency period
W	0.25R	Transition period

Table 3.3: Sounding Signal attacker signal configuration

- The correction is a function of a Hanning window, that here is parameterized by its half window size width W:

$$Han(l) = \frac{1}{2} \times \left(1 - \cos\left(\frac{2\pi \times l}{2W+1}\right)\right), l = [0, 2W].$$

The reference attack signal is further defined as follows:

1. Denote position p, as the first bit in the packet that differs with the initial reference attack packet. If this bit is a 1, then the marker is 0b0011, otherwise it is 0b1100. For some bit positions there will be only one possible start position of marker. For example, if there is a bit flip in position 0 or 30 in the case of a single marker. If there is more than one possible start of the marker, then the attacker then makes a guess whether bit p is the first or second bit of the marker. This guess is independently distributed with equal probability. Denote the attacker's first guess of the marker start position as k_1. If there is a valid second guess of the marker start position, denote this as k_2.
2. Define P_1 as the reference attack packet with the marker starting in position k_1, and $\Phi_1(n)$ as the signal obtained by GFSK modulating P_1. Similarly, define P_2 as the reference attack packet with the marker starting in position k_2, and $\Phi_2(n)$ as the signal obtained by GFSK modulating P_2.
3. Modify the phase trajectory of the reference attack signal $\Phi_A(n)$ at samples from symbol starting at $n = R \times p + 1$.

4. Segment 1: during the first M samples (detection latency period), the current reference attack signal is sent:

$$\Phi_A(n) \leftarrow \Phi_A(n),\ n \in [R \times p + 1,\ R \times p + M]$$

   - Segment 2: during the next W samples (transition period), a (half) Hanning windowed phase transition is applied from $\Phi_A(R \times p + M + 1)$ to the first guess $\Phi_1(R \times p + (M + W))$:

$$\Phi_A(n) \leftarrow \Phi_A(R \times p + M) + \Delta\Phi \times Han(n - R \times p + M),$$
$$n \in [R \times p + M + 1,\ R \times p + M + W]$$

$$\Delta\Phi = \Phi_1(R \times p + (W + M)) - \Phi_A(R \times p + M)$$

   - Segment 3: in this segment, the phase trajectory follows the first guess:

$$\Phi_A(n) \leftarrow \Phi(n), \quad n \geq R \times p + M + W + 1$$

   - The reference attack packet becomes P_1 i.e. $P_A \leftarrow P_1$.

5. In the case that the attacker's first guess is wrong, then the attacker observes a bit flip at $p' = p + 1$. The attacker then modifies the phase trajectory of the attack signal $\Phi_A(n)$ to produce a second glitch. Define the phase trajectory as follows:

   - Segment 1: during the first M samples (detection latency period), the current reference attack signal is sent:

$$\Phi_A(n) \leftarrow \Phi_A(n),\ n \in [R \times p' + 1,\ R \times p' + M]$$

   - Segment 2: during the next W samples (transition period), a (half) Hanning windowed phase transition is applied from $\Phi_A(R \times p' + M + 1)$ to the correct phase $\Phi_2(R \times p' + (M + W))$:

$$\Phi_A(n) \leftarrow \Phi_A(R \times p' + M) + \Delta\Phi \times Han(n - R \times p' + M),$$
$$n \in [R \times p' + M + 1,\ R \times p' + M + W]$$

$$\Delta\Phi = \Phi_2(R \times p' + (W + M)) - \Phi_A(R \times p' + M)$$

   - Segment 3: in this segment, the phase trajectory follows the second guess:

$$\Phi_A(n) \leftarrow \Phi_2(n),\ n \geq R \times p' + M + W + 1$$

   - The reference attack packet becomes P_2 i.e. $P_A \leftarrow P_2$.

6. If the marker is the first marker in the packet, and there exists a second marker in the packet, then return to step 1. Otherwise, the reference attack signal is $\Phi_A(n)$.

3.5.3.2 Random sequence attack signal definition

The phase of an attacker signal $\Phi_a(t)$ is the sum of the ideal reference signal $\phi_r(t)$ with symbol period T_{sym} as defined in Section 3.5.2 and an adjustment term $\psi(t)$:

$$\Phi_a(t) = \phi_r(t) + \psi(t)$$

The adjustment term approximates the behavior of an MITM attack to make the sequence appear earlier than the original signal. This adjustment is achieved by applying a phase transition using a Gaussian mono-pulse early within the symbol period. The sign of the pulse acting over symbol *n* is determined by the symbol value a_n.

For each encoded symbol $n = 0, \ldots, N-1$, a pulse is added to $\psi(t)$ centered at $t = (n + p + 1)T_{sym}$, where *p* is a time adjustment that significantly defines the attacker's desired distance offset.

In this context, a Gaussian mono-pulse is defined as minus the derivative of a Gaussian pulse. The width of the pulse is roughly $T_{sym} \div K$, where *K* is the pulse sharpness factor. The magnitude *M*, time adjustment *p*, and sharpness factor *K* are used to manipulate the timing of $\Phi_a(t)$ compared to $\phi_r(t)$.

$\psi(t)$ is defined as

$$\psi\left(t\right) = M \sum_{n=0}^{N-1} a_n \left(\frac{t}{T_{\text{sym}}} - p - n - 1\right) e^{-K\left(\frac{t}{T_{\text{sym}}} - p - n - 1\right)^2} \quad \text{(EQ 5)}$$

where $a_n \in \{-1, 1\}$ is the symbol sequence as defined in Section 3.5.2.

Table 3.4 shows the parameters from EQ 5 that define a Reference attack signal set for LE 1M and LE 2M.

Parameter	Definition	Value LE1M	Value LE 2M	Value LE 2M 2BT
K	Pulse sharpness factor	12	12	12
M	Pulse sharpness factor	3	3	3
p	Pulse time adjustment factor These values of p equate to approximately 3 meters of distance decrease.	-0.56	-0.61	-0.62
T_{sym}	Symbol period in microseconds	1.0	0.5	0.5

Table 3.4: Attacker signal configuration

3.5.3.3 Raw attack detector metric based on a sounding sequence or a random sequence

A raw attack detector estimate may be derived from a modulated random sequence if this sequence is known between a transmitting and receiving set of devices. A preconstructed reference model based on this sequence is used as a basis of comparison for detecting symbol manipulation.

The modulation of the signal for which an attack detection estimate is generated is either at the 1 Msym/s rate or at the 2 Msym/s rate.

Let

f represent the frequency of the modulated bits.

T_S represent the sampling period at the receiver.

M represent the integration period in units of symbol full cycles.

The integration period for an RTT with sounding sequence is the span of symbols with the possibility of detectable glitches when manipulation is present, as defined in Section 2.4. The integration period for RTT with random sequence is the span of the entire random sequence, as defined in Section 2.5.

Let l, which represents the number of samples within each full symbol, be denoted as

$$l = \frac{1}{fT_S}$$

And *L*, which represents the number of samples within the full integration period, is denoted as

$$L = Ml$$

Denote the measured signal containing the random sequence as

$$S(n,t) = s(t + nT_s)$$

Similarly, denote the reference signal of that same random sequence as

$$S_r(n,t) = s(t + nT_s)$$

Then the instantaneous phase of the measured signal and the reference signal, respectively, are

$$\varphi(n,t) = \angle S(n,t)$$
$$\varphi_r(n,t) = \angle S_r(n,t)$$

The phase of the measured signal is then compared to the reference signal to calculate the quality factor. Ambiguity exists between the start instants of the two signals, because the data points of the two signals are collected separately and because of quantization error at the receiver.

Two reference methods for deriving a raw attack detector metric are described.

3.5.3.3.1 Raw attack detector metric based on normalized cross correlation

Normalized cross-correlation may be used to compare a measured signal to a reference signal. In the following description, the mean phase of the reference signal is shifted

over a full symbol worth of sample offsets. Then each reference mean phase value is compared with the mean phase of the measured signal.

Let *L'*, which represents the maximum number of samples to process within an integration period that is one full sample less than the full integration period, be denoted as

$$L' = L - l$$

Denote the mean of the phase of the measured signal as

$$\varphi_{Mean} = \frac{1}{L'}\left(\sum_{n=1}^{L'} \varphi\left(n, 0\right)\right)$$

Similarly, denote the mean of the phase of the reference signal over a full symbol worth of sample offsets as

$$\varphi_{rMean}\left(z \middle| 1 \leq z \leq l\right) = \frac{1}{L'}\left(\sum_{n=z}^{L'+z} \varphi r\left(n, 0\right)\right)$$

Cross-correlation is then calculated over the relative phase of the two signals, with a lag span of a full symbol cycle to compensate for receiver quantization error.

$$Corr\left(z \middle| 0 \leq z \leq l\right) = \frac{\frac{1}{L'}\sum_{n=1}^{L'}(\varphi(n,0) - \varphi_{Mean})(\varphi r(n+z,0) - \varphi_{rMean}(z))}{\sqrt{\sum_{n=1}^{L'}(\varphi(n,0) - \varphi_{Mean})^2}\sqrt{\sum_{n=1}^{L'}(\varphi r(n+z,0) - \varphi_{rMean})^2}}$$

The autocorrelation result of the two signals is then

$$MaxCorr = \max\left(Corr(z)\right)$$

From this result, a raw attack detector metric can be derived.

3.5.3.3.2 Raw attack detector metric based on phase minimum square error

Phase minimum square error is an alternate method for comparing a measured signal to a reference signal. In contrast to the description in Section 3.5.3.3.1, the mean phase of the collected signal is shifted over a full symbol worth of sample offsets starting ½ symbol before the nominal start point. Then each measured mean phase value is compared with the mean phase of the reference signal.

Let *l'* represent the number of samples within ½ of a full symbol, and be denoted as

$$l' = \frac{l}{2}$$

Denote the mean of the phase of the measured signal over sample offsets z in the range $-l' + 1$ *to* l', relative to the nominal start and end of the target symbol(s) used in the comparison, as

$$\varphi Mean\left(z \middle| \left(-l' + 1\right) \leq z \leq l'\right) = \frac{1}{L}\left(\sum_{n=1}^{L} \varphi(n + z, 0)\right)$$

Similarly, denote the mean of the phase of the reference signal as

$$\varphi rMean = \frac{1}{L}\left(\sum_{n=1}^{L} \varphi r(n, 0)\right)$$

The phase square error is then calculated as

$$PhaseSE\left(z\right) = \sum_{n=1}^{L} \left(\left(\varphi(n + z, 0) - \varphi Mean(z)\right) - \left(\varphi r(n, 0) - \varphi rMean\right)\right)^2$$

The minimum phase mean square error is then

$$\text{PhaseMse} = \min(\text{PhaseSE}(z)) .$$

From this result, a raw attack detector metric can be derived.

3.5.3.4 Phase-based attack detection requirements for RTT with sounding sequence and random sequence packets

This section describes how the RTT with sounding sequence or RTT with random sequence and the normalized attack detector metric (NADM) shall be tested. CS mode-1 and CS mode-3 steps, described in Section 4.3, carry the packet contents.

This test requires a tester CS device that can transmit either a normal signal or an attacker signal during mode-1 and mode-3 CS steps. The normal signal is the transmitted signal after either the sounding sequence or random sequence portion has been modulated using normal GFSK. The attacker signal is the normal signal, but with its phase adjusted to approximate a signal from an MITM attack. The attacker signal for RTT with sounding sequence is defined in Section 3.5.3.1. The attacker signal for RTT with random sequence is defined in Section 3.5.3.2.

The tester device shall generate a reference signal of -67 dBm power together with a Gaussian Noise Floor of -152 dBm/Hz for the LE1M PHY. The tester device shall generate a reference signal of -67 dBm power together with a Gaussian Noise Floor of -155 dBm/Hz for the LE2M PHY.

The tester device acts as an initiator to start a CS procedure with the IUT. Each test comprises one or more CS procedures executing the total CS subevent count specified in Table 3.5 and Table 3.6. Each CS subevent comprises a normal mode-0 CS step,

followed by a single mode-1 CS step or a mode-3 CS step with specified sounding and random sequence lengths.

For each CS step, the tester device makes a random decision to transmit either a normal signal or an attacker signal. The tester CS device records these random decisions over the whole CS procedure. These random decision sequences are later compared with the resulting NADM values from the IUT.

Table 3.5 and Table 3.6 define multiple mandatory tests that depend on the supported capabilities of the IUT. The tests are designed to verify the minimum performance for a NADM value. CS_SYNC packets used in mode-1 and mode-3 are both tested. LE 1M, LE 2M, and LE 2M 2BT are also tested. For RTT with sounding sequence, the attacker signal is designed to exhibit abnormal phase glitch behavior around the associated marker bits. For RTT with random sequence, the attacker signal is designed to appear D meters (see Table 3.6) earlier than the normal signal.

Test	LE PHY	RTT Step Type	Sounding Sequence Length (bits)	Number of Subevents	Expected min SNR in Reflec-tor-Under-Test / dB	Detection Latency	Transition Period
1	LE 1M	Mode-1	32	100	25	¼ symbol	¼ symbol
2	LE 1M	Mode-3	32	100	25	¼ symbol	¼ symbol
3	LE 2M	Mode-1	32	100	25	¼ symbol	¼ symbol
4	LE 2M	Mode-3	32	100	25	¼ symbol	¼ symbol
5	LE 2M 2BT	Mode-1	32	100	25	¼ symbol	¼ symbol
6	LE 2M 2BT	Mode-3	32	100	25	¼ symbol	¼ symbol

Table 3.5: Definitions of sounding sequence tests

Test	LE PHY	RTT Step Type	Random Sequence Length (bits)	Number of Subevents	Expected min SNR in Reflector-Under-Test / dB	Manipulated Distance D for Attacker (meters)
1	LE 1M	Mode-1	32	100	25	-3
2	LE 1M	Mode-3	32	100	25	-3
3	LE 2M	Mode-1	32	100	25	-3
4	LE 2M	Mode-3	32	100	25	-3
5	LE 2M 2BT	Mode-1	32	100	25	-3
6	LE 2M 2BT	Mode-3	32	100	25	-3

Table 3.6: Definitions of random sequence tests

After each test is complete, the tester device shall compare the NADM values from each CS_SYNC packet against the random attack decision sequence it recorded earlier. For each test, 90% of the NADM values shall correctly identify the presence or absence of an attacker as defined in Section 3.5.1.

4 CHANNEL SOUNDING INTERFACE PROTOCOL

4.1 Channel selection Algorithm #3

The algorithms described in this section support Channel Selection for each CS step within a CS procedure. A CS step involves the execution of one of four CS modes, described in Section 4.3. The algorithms described here generate a set of channel indices on which the mode exchanges take place.

Two sets of channel indices are generated. The first sequence defines the hopping pattern used by mode-0 CS steps. The second sequence defines the hop pattern used by non-mode-0 CS steps. Two separate algorithms are defined for the latter sequence.

Each sequence is further filtered by the channel index filter bit map CSFilteredChM, which is described in [Vol 6] Part B, Section 5.1.28. In that bit map, a bit set to 1 indicates that the channel represented by that bit shall be included in the resulting hop set. A bit set to 0 indicates that the channel represented by that bit shall not be included in the resulting hop set. Prohibited channel indices shall be immediately excluded from the resulting hop set (see [Vol 6] Part A, Section 2).

Each resulting channel index array shall be used starting from index 0 in ascending order whenever a CS step (either mode-0 or non-mode-0) is executed. Each entry in the resulting channel index array shall only be used once unless otherwise specified in this specification. After it is exhausted, this array shall be regenerated at the CS step where a new channel index is needed.

4.1.1 Conventions

The following procedural conventions are used in this description of Channel Selection Algorithm #3.

Function	Meaning
length_of()	Returns the populated length of an unsigned integer array

Table 4.1: Procedural conventions

4.1.2 Channel index shuffling function cr1

When deriving the channel index selection within a CS procedure, the CS DRBG is invoked to shuffle the list of available channels. The channel index shuffling function cr1 is defined for this purpose. The inputs to cr1 are a one-dimensional unsigned integer array, ChannelArray, that lists all available channel indices, and the length of that array, nChannels.

The following are values returned from cr1:

ShuffledChannelArray, a one-dimensional unsigned integer array of length nChannels

The following temporary values are used:

i, j are unsigned integers

The input/output format of cr1 is as follows:

ShuffledChannelArray = cr1(nChannels, ChannelArray)

cr1 processing is as follows:

```
for i = 0 to nChannels – 1 do

    j = random integer such that 0 <= j <= i

    if i != j

        ShuffledChannelArray[ i ] = ShuffledChannelArray[ j ]

    ShuffledChannelArray[ j ] = ChannelArray[ i ]
```

The random integer j noted above shall be seeded using the random number generation function hr1 (see Section 4.8.1). The random integer j shall be computed using the increasing index i from above as follows:

hr(i + 1)

4.1.3 Channel selection Algorithm #3a for mode-0 steps

Channel Selection Algorithm #3a is used to generate a randomized channel map with uniform distribution for mode-0 CS steps.

The number of times that the mode-0 channel list is regenerated in a CS procedure depends on several factors, including:

- The size of the list of included filtered channels as indicated by the filter channel bit map CSFilteredChM
- The number of mode-0 steps included in a CS subevent
- The number of CS subevents within a CS procedure
- The run-time construction of CS subevents, whose content may vary from subevent to subevent as described in Section 4.4

The randomized channel map is created by first converting the filtered channel bit map to a one-dimensional unsigned integer array of channel indices that shall include only the indices of the CSFilteredChM marked as included, as described in Section 4.1. This intermediate array is called the filteredChannelArray. The filteredChannelArray is used to create a shuffled channel list in an array of the same size, the Mode0ShuffledChannelArray. The Mode0ShuffledChannelArray is generated using the channel index shuffling function cr1 (see Section 4.1.2) as follows:

> Mode0ShuffledChannelArray = cr1(length_of(filteredChannelArray), filteredChannelArray)

4.1.4 Channel index selection for non-mode-0 steps

Channel Selection Algorithms #3b and #3c support channel selection for each non-mode-0 CS step within a CS procedure. Only one of the two algorithms shall be used within a single CS procedure.

The number of times the non-mode-0 channel list shall be regenerated in a CS procedure depends on several factors, including:

- The size of the list of included filtered channels as indicated by the filter channel bit map CSFilteredChM
- The number of times the filtered channel map is repeated in a procedure for non-mode-0 steps, as defined by CSNumRepetitions (see [Vol 6] Part B, Section 5.1.26)
- The run-time construction of CS subevents whose content may vary from subevent to subevent, as described in Section 4.4

4.1.4.1 Channel Selection Algorithm #3b

Channel Selection Algorithm #3b is used to generate a randomized channel map with uniform distribution for non-mode-0 CS steps.

The filtered channel bit map is first converted to a one-dimensional unsigned integer array of channel indices that shall include only the indices of the CSFilteredChM marked as included, as described in Section 4.1. This intermediate array is called the filteredChannelArray. The resulting shuffled channel list is held in an array of the same size and is known as NonMode0ShuffledChannelArray. To generate this array, the channel index shuffling function cr1 (see Section 4.1.2) shall be invoked as follows:

> NonMode0ShuffledChannelArray = cr1(length_of(filteredChannelArray), filteredChannelArray)

4.1.4.2 Channel Selection Algorithm #3c

Channel Selection Algorithm #3c integrates rising and falling ramps into the resulting channel map for non-mode-0 CS steps. These ramps are useful for estimating timing

drift and object motion correction. The ramps have the shape of either a hat or an X pattern. In a hat shape, a rising ramp is directly followed by a falling ramp. In an X pattern, rising and falling ramps are interleaved. These shapes are incorporated into a shuffled channel map so that they appear random, preserving equal channel distribution qualities.

A block diagram of the overall algorithm is shown in Figure 4.1. Each process block, as well as inputs and outputs, are described in subsequent sections.

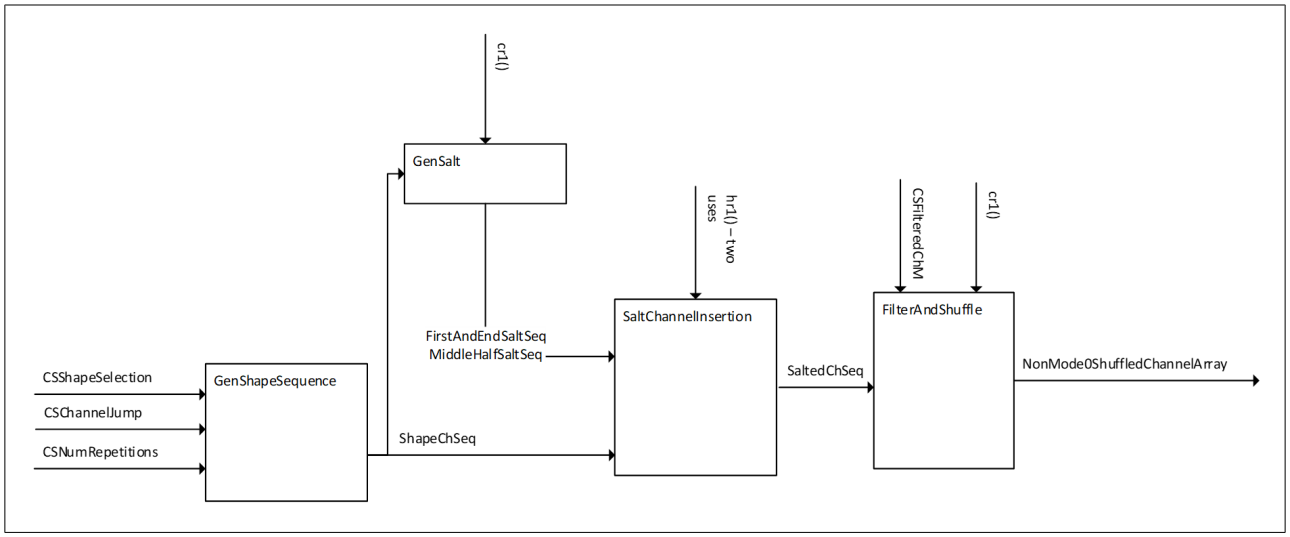

Figure 4.1: Channel Selection Algorithm #3c functional block diagram

4.1.4.2.1 Inputs and basic components

Channel Selection Algorithm #3c has the following inputs:

- CSShapeSelection – indicates the selection of either the hat shape or the X pattern.
- CSChannelJump – indicates the number of channels skipped over when rendering the selected shape, based on the CS channel index values described in Section 1.
- CSNumRepetitions – indicates the number of times Channel Selection Algorithm #3c is invoked. This number is the same as the number of times the filtered channel bit map is repeated within that CS procedure.

Table 4.2 shows additional algorithm-related parameters. The value selected for CSChannelJump determines which row in Table 4.2 shall be used in Channel Selection Algorithm #3c.

CSChannelJump	seq1StartCh	seq2StartCh	maxRepsAllowed	saltRate
2	1	76	1	2
3	77	0	1	2
4	78	0	2	2
5	78	0	2	2
6	76	1	3	2
7	74	1	3	2
8	76	0	3	2

Table 4.2: Channel Selection Algorithm #3c parameter blocks based on CSChannelJump parameter selection

The values of seq1StartCh and seq2StartCh denote the starting channel index used to construct the two ramps of the selected shape indicated by CSShapeSelection. These parameters refer to the CS channel index values described in Section 1.

maxRepsAllowed is the upper limit of the CSNumRepetitions parameter. The value of CSNumRepetitions shall be greater than or equal to 1 and less than or equal to maxRepsAllowed.

saltRate is the rate at which alternate hop channels are inserted into the constructed hopping pattern. These alternate hop channels shall not include the channels used in the shape construction selected by the CSChannelShape parameter. These alternate channels are mixed into the hopping pattern for uniform channel distribution containing the valid set of CS physical channels. This alternate set of channels is referred to as salt channels.

Multiple instances of the non-mode-0 channel map, and therefore multiple iterations of the Channel Selection Algorithm #3c procedure, are required if CSNumRepetitions is greater than 1. The integer value nShapeIteration shall be maintained for each active CS procedure. nShapeIteration shall be initialized to 0 for the first iteration of this algorithm within that CS procedure and shall be incremented by one before the next iteration of the Channel Selection Algorithm #3c procedure.

4.1.4.2.2 Shape generation

Each invocation of Channel Selection Algorithm #3c begins with the identification of the channels used to hold the shape selected by the CSShapeSelection parameter. The function of the process block GenShapeSequence shown in Figure 4.1 is described in this section.

The shape generation function returns the following:

- ShapeChSeq – a one-dimensional unsigned integer array that holds the channel set constructed to form the selected shape

For the purpose of long-term uniform channel distribution, the starting position of the channel sequence that constructs the selected shape is shifted by a value from 0 to CSChannelJump -1 channel indices. The random number generation function hr1 (see Section 4.8.1) is invoked to produce the random startJitter value. If this is the first instance of the non-mode-0 channel map generation procedure with a CS procedure, which shall be the case when nShapeIteration is equal to 0, then the startJitter value is produced as follows:

startJitter = hr1(CSChannelJump)

Otherwise, the value of startJitter shall be held constant for the remaining duration of the CS procedure.

The ShapeChSeq content is then generated as follows:

- The shape ramp offset values, s1Ch and s2Ch, are calculated as follows:

$$offset = (nShapeIteration + startJitter) \bmod CSChannelJump$$
$$s1Ch = seq1StartCh + offset$$
$$s2Ch = seq2StartCh + offset$$

- Each shape ramp is computed starting from the channels identified by s1Ch and s2Ch. Channels are appended through the valid channel map range defined by the CS channel index values described in Section 1. Each computed channel value is appended to the ShapeChSeq array in turn.
- If CSShapeSelection is the X pattern, the channels offset from s1Ch and s2Ch are interleaved when appended to ShapeChSeq starting with s1Ch. If seq1StartCh is less than seq2StartCh, an increment value inc is set to CSChannelJump. If seq1StartCh is greater than or equal to seq2StartCh, inc is set to -1xCSChannelJump. Starting with s1Ch, s1Ch and s2Ch are alternately recomputed as follows and appended to the ShapeChSeq array. For each of the two individual computations, the first few sequential values may fall outside of the channel map range (see Section 1) and if so, those individual values shall not be appended to the ShapeChSeq array. Thereafter, while each newly computed value still remains within the valid channel map range, the values are appended similarly. If one of the two values then falls out of the valid channel map range, then the other value continues to be processed and appended to the ShapeChSeq array until it also falls out of the valid channel map range.

$$s1Ch = s1Ch + inc$$
$$s2Ch = s2Ch - inc$$

- If CSShapeSelection is the hat pattern, the entire rising ramp is appended to ShapeChSeq before the falling ramp by determining which ramp s1Ch and s2Ch represent, using the following procedure. In the procedure, risingCh is the set of channel indices for the rising ramp and fallingCh is the set of channel indices for the falling ramp.
  - If s1Ch is less than s2Ch, then risingCh = s1Ch and fallingCh = s2Ch. If s1Ch is greater than or equal to s2Ch, risingCh = s2Ch and fallingCh = s1Ch.
  - The increment value of CSChannelJump is used.
  - The values based on risingCh are computed first. The first few sequential values may fall outside of the valid channel map range (see Section 1) and if so, shall not be appended to the ShapeChSeq array. Thereafter, the next computed values are appended to the ShapeChSeq array while they remain within the valid channel map range.

$$risingCh = risingCh + CSChannelJump$$

  - Thereafter, the values based on fallingCh are computed. The first few sequential values may fall outside of the valid channel map range (see Section 1) and if so, shall not be appended to the ShapeChSeq array. Thereafter, the next computed values are appended to the ShapeChSeq array while they remain within the valid channel map range.

$$fallingCh = fallingCh - CSChannelJump$$

4.1.4.2.3 Salt generation

Salt channels are used to generate a uniform channel distribution in the valid set of CS physical channels, as defined in Section 1. The function of the process block GenSalt, shown in Figure 4.1, is described in this section.

The salt channel generation function returns the following:

- FirstAndEndSaltChSeq – a one-dimensional unsigned integer array holding an intermediate salt channel list
- MiddleSaltChSeq – another one-dimensional unsigned integer array holding a second intermediate salt channel list

Salt channels are channels that are not part of the shape generation list ShapeChSeq described in Section 4.1.4.2.2 but are still valid CS channel index values as described in Section 1. The list of available salt channels for a specific hop channel generation procedure is derived by direct comparison against the shape generation channel list ShapeChSeq.

The list of candidate salt channels is populated in a one-dimensional unsigned integer array called unusedChSeq, which is first initialized as an empty list. Starting from

channel index 0 in ascending order, each valid CS channel index as described in Section 1 is compared to the ShapeChSeq array. If a channel index is not present, then that channel index is appended to the unusedChSeq list.

The valid CS physical channel range is then divided into four quadrants which approximately surround the channel shape held in the ShapeChSeq. This grouping is shown in Figure 4.2. In the figure, the vertical lines show stepwise sequence boundaries, and the horizontal lines show channel segmentation boundaries for the entire valid CS physical channel range. The boxes denote a delineation of the salt channel set. The boxes labeled First and End contain the same set of channels, corresponding to the first and end quadrants of the shape. Approximately 50% of the valid CS physical channel range is divided between the First and the End, and the remaining physical channel range is contained within the Middle boxes.

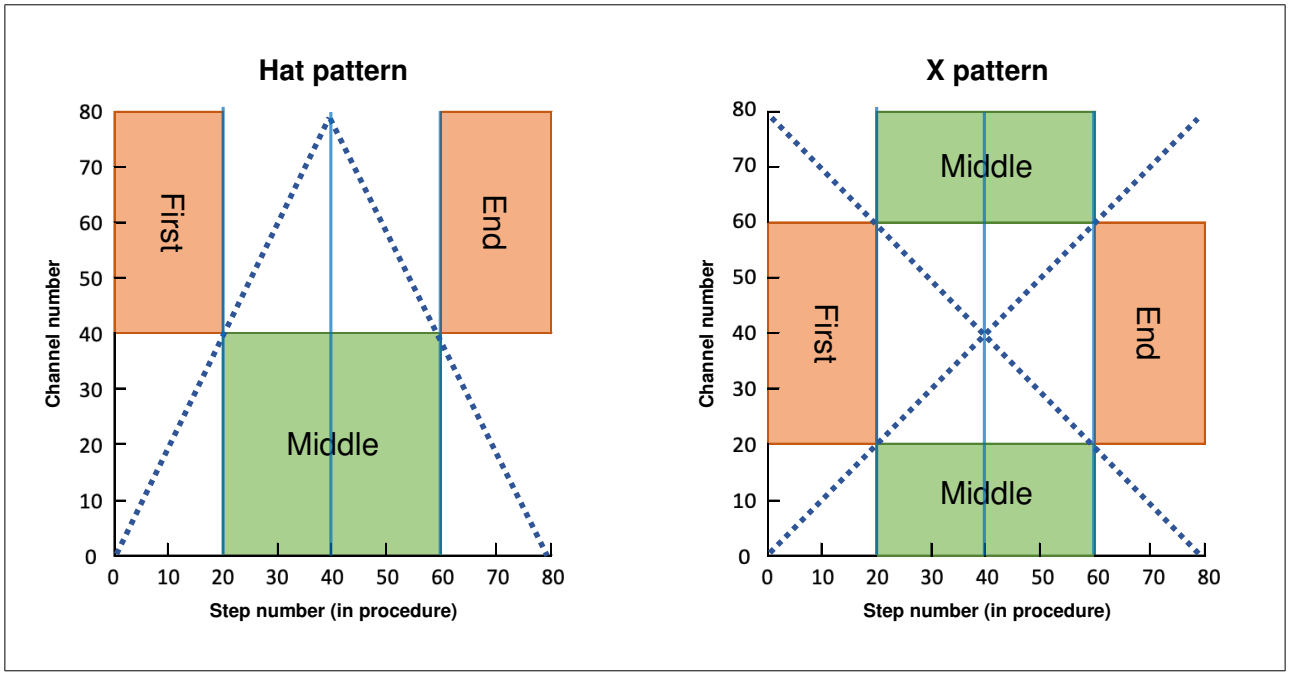

Figure 4.2: Salt channel groupings for both the hat and the X pattern (represented by the blue dots)

Four unsigned integer arrays holding intermediate sequences divide the valid CS physical channel range into four approximately equal sized regions:

chQ1All = [0, 19]

chQ2All = [20, 39]

chQ3All = [40, 59]

chQ4All = [60, 78]

From the arrays above, a second set of intermediate sequences are constructed and held in another set of four unsigned integer arrays initialized as empty lists: chQ1Unused, chQ2Unused, chQ3Unused, and chQ4Unused. The content of each of these four channel sets is compared to the previous unusedChSeq in search of common channels. Each channel in chQ1All is compared with the content of unusedChSeq. If a channel in chQ1All appears in unusedChSeq, it is appended to the chQ1Unused array. This process is repeated to construct the content of chQ2Unused, chQ3Unused, and chQ4Unused.

From the content generated for chQ1Unused, chQ2Unused, chQ3Unused, and chQ4Unused, a third set of intermediate sequences is constructed and held in another set of four unsigned integer arrays: firstAndEndUnusedChSeq, firstAndEndAllChSeq, middleUnusedChSeq, and middleAllChSeq. The construction of these sequences depends on the shape selected with CSShapeSelection.

- If CSShapeSelection is the X pattern, then
  - firstAndEndAllChSeq is constructed by concatenating chQ3All to the end of chQ2All.
  - middleAllChSeq is constructed by concatenating chQ4All to the end of chQ1All.
  - firstAndEndUnusedChSeq is constructed by concatenating chQ3Unused to the end of chQ2Unused.
  - middleUnusedChSeq is constructed by concatenating chQ4Unused to the end of chQ1Unused.
- If CSShapeSelection is the hat pattern, then
  - firstAndEndAllChSeq is constructed by concatenating chQ4All to the end of chQ3All.
  - middleAllChSeq is constructed by concatenating chQ2All to the end of chQ1All.
  - firstAndEndUnusedChSeq is constructed by concatenating chQ4Unused to the end of chQ3Unused.
  - middleUnusedChSeq is constructed by concatenating chQ2Unused to the end of chQ1Unused.

The channel index shuffle function cr1 (see Section 4.1.2) shall then be invoked on each of the above four intermediate channel sequences as follows:

firstAndEndAllChSeq = cr1(firstAndEndAllChSeq, length_of(firstAndEndAllChSeq))

middleAllChSeq = cr1(middleAllChSeq, length_of(middleAllChSeq))

firstAndEndUnusedChSeq = cr1(firstAndEndUsusedChSeq, length_of(firstAndEndUsusedChSeq))

middleUnusedChSeq = cr1(middleUnusedChSeq, length_of(middleUnusedChSeq))

FirstAndEndSaltChSeq is then constructed by concatenating firstAndEndAllChSeq to the end of firstAndEndUnusedChSeq. MiddleSaltChSeq is constructed by concatenating middleAllChSeq to the end of middleUnusedChSeq.

4.1.4.2.4 Shape and salt channel mixing

After salt channels are generated, shape channels are mixed with salt channels. The function process block SaltChannelInsertion shown in Figure 4.1 is described in this section.

The following is returned from the salt channel insertion function:

- SaltedChSeq – a one-dimensional unsigned integer array containing the salted shape channel sequence

SaltedChSeq is first initialized as an empty list.

If this is the first instance of non-mode-0 channel map generation procedure within a CS procedure, which shall be the case when nShapeIteration is equal to 0, then a random set of between 0 and CS3C_N_INITIAL_SALT salt channels shall be appended to SaltedChSeq as follows:

- CS3C_N_INITIAL_SALT shall be equal to 9.
- The random number generation function hr1 (see Section 4.8.1) is invoked to generate the random nInitialSalt value as follows:
  - nInitialSalt = hr1(CS3C_N_INITIAL_SALT + 1)
- Beginning from element 0, nInitialSalt channels are appended to SaltedChSeq, starting with the FirstAndEndSaltChSeq array and alternating between the FirstAndEndSaltChSeq array and the MiddleSaltChSeq array.

Shape channels and salt channels are then appended in a mixing fashion. Channels from arrays ShapeChSeq (starting from element 0), FirstAndEndSaltChSeq, and

MiddleSaltChSeq are selected and appended to the SaltedChSeq array. Channels from the originating arrays shall be consumed in ascending order and never reused. Previously consumed channels from the FirstAndEndSaltChSeq and MiddleSaltChSeq arrays are also not reused. Channels from these arrays are consumed starting with the next available entry. In the procedure below, i and j are temporary variables.

```
For i = 0 to length_of( ShapeChSeq ) - 1 do

    if ( i mod saltRate ) == 0

        Append a salt step to SaltedChSeq as described below.

    Append the next entry from ShapeChSeq to SaltedChSeq.
```

In the procedure above, when a salt step is appended to the SaltedChSeq, the following procedure shall be used.

```
j = ⌊( ShapeChSeq[i] ÷ 20 )⌋ + 1

if CSShapeSelection is the X pattern

    if ( j == 1 ) or ( j == 4 )

        Append the next entry from FirstAndEndSaltChSeq to SaltedChSeq

    else

        Append the next entry from MiddleSaltChSeq to SaltedChSeq

else if CSShapeSelection is the hat pattern

    if ( j == 1 ) or ( j == 2 )

        Append the next entry from FirstAndEndSaltChSeq to SaltedChSeq

    else

        Append the next entry from MiddleSaltChSeq to SaltedChSeq
```

If this procedure is the last instance of the non-mode-0 channel map generation procedure within the CS procedure, which shall be the case when

nShapeIteration is equal to CSNumRepetitions-1, then a random set of between 0 to CS3C_N_FINAL_SALT salt channels is appended to SaltedChSeq as follows:

- CS3C_N_FINAL_SALT shall be equal to 4.
- The random number generation function hr1 (see Section 4.8.1) is invoked to generate a random nFinalSalt value as follows:
  - nFinalSalt = hr1(CS3C_N_FINAL_SALT + 1)
- nFinalSalt channels are appended to SaltedChSeq, starting first from the next available FirstAndEndSaltChSeq array and alternating between the next available FirstAndEndSaltChSeq array and the next available MiddleSaltChSeq array.

If more channels from FirstAndEndSaltChSeq than from MiddleSaltChSeq were appended to the SaltedChSeq, then the deficit amount of the next available entries from MiddleSaltChSeq are appended to the end of SaltedChSeq. Alternatively, if more channels from MiddleSaltChSeq than from FirstAndEndSaltChSeq were appended to the SaltedChSeq, then the deficit amount of the next available entries from FirstAndEndSaltChSeq are appended to the end of SaltedChSeq.

Any remaining entries from the FirstAndEndSaltChSeq and MiddleSaltChSeq shall be discarded.

4.1.4.2.5 Filtering and shuffling

After the SaltedChSeq array is generated, it is then filtered through the filter channel bit map CSFilteredChM described in [Vol 6] Part B, Section 5.1.28. The resulting filtered channel set is then shuffled in a block-based fashion. The function process block FilterAndShuffle shown in Figure 4.1 is described in this section.

The following is returned from the filtering and shuffling function. It is also the final output of Channel Selection Algorithm #3c:

- NonMode0ShuffledChannelArray – a one dimensional unsigned integer array containing the non-mode-0 channel index array

If this is the first instance of the non-mode-0 channel map generation procedure with a CS procedure, which shall be the case when nShapeIteration is equal to 0, then NonMode0ShuffledChannelArray is initialized as an empty list. Otherwise, the prior content of NonMode0ShuffledChannelArray is appended to by the procedure described in this section.

filteredSaltedChSeq is an intermediate unsigned integer array that holds the filtered channel content of the SaltedChSeq array. filteredSaltedChSeq is initialized as an empty list.

The content of the SaltedChSeq is filtered using the content of the CSFilteredChM bit map. Each bit position of the CSFilteredChM starting from bit 0, represents a valid CS channel index as described in Section 1. If a bit is set to 0, then that channel index is filtered out. Otherwise, if a bit is set to 1, then that channel index is allowed for use within a CS procedure. Starting from the first element, the content of the SaltedChSeq array is compared with the content of the CSFilteredChM bit map. Channels that are not filtered out are then appended to the filtered sequence filteredSaltedChSeq in order. Channels that are filtered out are discarded.

The content remaining in filteredSaltedChSeq is then shuffled in smaller block quantities. The size of each block is computed as follows.

$$nStepsInBlock = \max\left(10, floor\left(\frac{length\_of(\text{ filteredSaltedChSeq })}{4}\right)\right)$$

Therefore, the number of blocks contained in the filteredSaltedChSeq array can be derived as follows.

$$nBlocksToShuffle = \max\left(1, floor\left(\frac{length\_of(\text{ filteredSaltedChSeq })}{nStepsInBlock}\right)\right)$$

NonMode0ShuffledChannelArray is then constructed by shuffling filteredSaltedChSeq in blocks of nStepsInBlock channels. This starts from the beginning of the filteredSaltedChSeq and progresses through the entire array content. The channel index shuffling function cr1 (see Section 4.1.2) shall be invoked as follows. Here i is a temporary unsigned integer and tempBlockSeq is a temporary unsigned integer array. filteredSaltedChSeq is referenced starting from the first element at array position 0.

```
For i = 0 to nBlocksToShuffle-1

    delete all content from tempBlockSeq

    if i < nBlocksToShuffle-1 // not the last block in filteredsaltedChSeq

        Copy elements ( i x nStepsInBlock ) to ((( i + 1 ) x nStepsInBlock ) – 1 ) of
        filteredChSeq to tempBlockSeq

    else

        Copy remaining elements filteredChSeq to tempBlockSeq

    tempBlockSeq = cr1( tempBlockSeq, length_of( tempBlockSeq ))

    Append tempBlockSeq to NonMode0ShuffledChannelArray
```

4.2 Channel Sounding channel indices

Channel Selection Algorithm #3 shall be used to define the frequency hop pattern for all CS steps within a CS procedure. This hop pattern is seeded by the CSChM and the CSNumRepetitions parameters of the CS configuration selected for that procedure (see [Vol 6] Part B, Section 5.1.26) as well as the running channel map update (see [Vol 6] Part B, Section 5.1.28). The maximum number of non-mode-0 steps included in a CS procedure shall be bounded by the number of used channels in the CSFilteredChM channel map (see [Vol 6] Part B, Section 5.1.28) multiplied by the CSNumRepetitions parameter, plus any salted channel insertions as described in Section 4.1.4.2 and any steps that reuse channels as described in this section and in Section 4.4.

A CS procedure is considered complete and closed when at least one of the following conditions occurs.

- The execution of the next CS step in its entirety would cause the extent of the CS procedure to exceed T_MAX_PROCEDURE_LEN.
- The combined number of mode-0 steps and non-mode-0 steps executed is equal to N_STEPS_MAX as described in [Vol 6] Part B, Section 4.5.18.1.
- The number of CS subevents executed is equal to N_MAX_SUBEVENTS_PER_PROCEDURE.
- If Channel Selection Algorithm #3b is used for non-mode-0 steps, and the channel map generated from CSFilteredChM has been used for CSNumRepetitions cycles for non-mode-0 steps including the use for both Main_Mode and Sub_Mode steps.
- If Channel Selection Algorithm #3c is used for non-mode-0 steps, and CSNumRepetitions invocations of Channel Selection Algorithm #3c have been completed for non-mode-0 steps including the use for both Main_Mode and Sub_Mode steps.

For CS steps besides those in mode-0, a new channel shall be selected from the Channel Selection Algorithm #3 non-mode-0 shuffled channel list each time a Main_Mode step is transmitted. The channel selected shall be re-used (i.e., not refreshed from the shuffled channel list content) when a subsequent mode-1 Sub_Mode step is scheduled. If no subsequent mode-1 Sub_Mode step is scheduled, a new channel shall be selected from the shuffled channel list for the Sub_Mode transmission. The channel selected shall also be re-used when repeating CS steps at the beginning of a CS subevent relative to the steps at the end of the previous CS subevent, as described in Section 4.4.

For mode-0 CS steps, a new channel shall be selected from the Channel Selection Algorithm #3 mode-0 shuffled channel list each time a mode-0 step is scheduled.

4.3 Channel Sounding steps

CS defines a set of interlocking transfers between two devices. The device initiating the CS procedures is known as the initiator, and the device responding to those procedures is known as the reflector. Within a CS procedure, *CSStepCount* shall be set to the CS step number, which starts at zero and is incremented by one at each subsequent step within that procedure, even if that step is not executed. CS steps are composed of a combination of modulated packets and modulated CS tones.

There are four different modes for the CS steps. Each of these modes has different usage goals: measuring frequency offset between devices (mode-0), measuring round-trip times (mode-1), measuring phase rotations due to distance (mode-2), and measuring both round-trip times and phase rotations (mode-3).

CS steps require a precise timing synchronization between the devices involved in the transactions (i.e., the initiator and the reflector). This timing synchronization is described in Section 4.5.

CS steps are separated by time periods that allow for performing a frequency hop. The structure is shown in Figure 4.3.

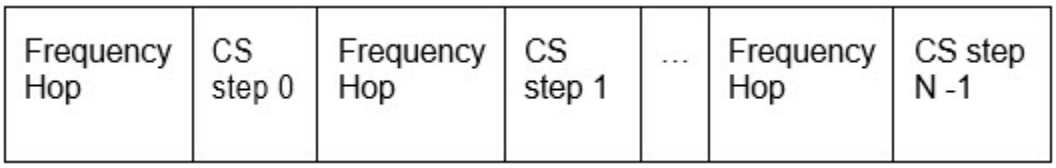

Figure 4.3: A frequency hop period separates each CS step from the next

The time allowed for the frequency hop is known as T_FCS. The permitted values for T_FCS are shown in Table 4.3.

T_FCS Index	T_FCS	Mandatory/Optional/Conditional
0	15 µs	O
1	20 µs	O
2	30 µs	O
3	40 µs	C.1
4	50 µs	O
5	60 µs	O
6	80 µs	C.1
7	100 µs	O
8	120 µs	O

T_FCS Index	T_FCS	Mandatory/Optional/Conditional
9	150 µs	M
C.1: Mandatory if any shorter T_FCS value is supported, otherwise optional.		

Table 4.3: Permitted T_FCS values

Within a CS procedure, the same T_FCS value shall be used for each of the frequency hops. Devices may use the T_FCS period to perform internal calibrations, in addition to performing the frequency change. Devices may also use this time period to allow settling of the next transmitted RF signal so that it has reached a stable state when the subsequent CS step begins.

During T_FCS, the output power of the reflector in the RF channel that is being switched to shall be at least 40 dB less than the output power to be used for transmissions by the reflector during the next CS step, as measured at the reflector's antenna connector.

4.3.1 Channel Sounding step mode-0

CS step mode-0 is used to measure the frequency offset between the initiator and the reflector at a given frequency. Devices supporting the CS feature shall implement CS step mode-0. Table 4.4 shows the structure for CS step mode-0.

The CS initiator performs a measurement of the frequency offset of the transmitted RF signal from the CS reflector during CS step mode-0. The CS initiator shall use this information to compensate for the frequency and timing error contributions in all further transmissions within subsequent CS steps in a CS subevent. For each CS subevent, the CS initiator shall report to the Host the frequency value used for this compensation. Requirements for this compensation are described in [Vol 6] Part A, Section 3.5.

Role/Duration	T_SY	T_RD	T_IP1	T_SY + T_GD + T_FM	T_RD
Initiator	CS_SYNC (CS_SYNC_0_I)	ramp down			
Reflector				CS_SYNC followed by a CS tone (CS_SYNC_0_R)	ramp down

Table 4.4: CS step mode-0

The initiator shall first transmit a CS_SYNC (CS_SYNC_0_I). The duration of the CS_SYNC (T_SY) corresponds to the definitions described in Section 2 and also depends on the CS_SYNC_PHY being used. The CS_SYNCs for mode-0 shall not carry a sounding sequence or random sequence as part of the CS_SYNC.

After the transmission from the initiator is completed, a defined ramp-down window of 5 µs (T_RD) is allowed for the initiator to remove the transmitted energy from the RF

channel. After T_RD, the output power from the initiator in the RF channel shall be at least 40 dB less than the output power used during the transmission of the CS_SYNC, as measured at the initiator's antenna connector.

T_IP1 represents the idle time between the end of the transmission from the initiator and the start of the transmission from the reflector. Devices may use this time for internal calibrations if needed. The reflector may use this time to ramp up its transmitted signal, if necessary, in advance of the transmission of the CS_SYNC followed by a CS tone (CS_SYNC_0_R), which is described in Section 2.6. The permitted values for T_IP1 are shown in Table 4.5.

T_IP1 Index	T_IP1	Mandatory/Optional/Conditional
0	10 µs	O
1	20 µs	O
2	30 µs	O
3	40 µs	C.1
4	50 µs	O
5	60 µs	O
6	80 µs	C.1
7	145 µs	M
C.1: Mandatory if any shorter T_IP1 value is supported, otherwise optional.		

Table 4.5: Permitted values for T_IP1

After T_IP1, the reflector shall transmit its CS_SYNC_0_R starting with the transmission of a CS_SYNC. The duration of the CS_SYNC (T_SY) depends on the CS_SYNC_PHY being used.

A guard time of T_GD length, as described in Section 2.6, then follows.

A frequency measurement period of T_FM follows next. The duration of T_FM for CS step mode-0 shall be 80 µs.

After the transmission from the reflector is complete, a ramp-down window of T_RD shall be present using the same requirements as defined for the initiator.

The reflector may transmit its CS_SYNC_0_R even if it does not receive a CS_SYNC from the initiator or if the CS_SYNC was received with bit errors. The time duration of a CS step mode-0 can be expressed as:

$$2 \times T_{SY} + 2 \times T_{RD} + T_{GD} + T_{FM} + T_{IP1}$$

The set of values of the time of departure of the mode-0 packets sent by an initiator in a subevent is denoted here as $ToD_I[m]$, where m = 1, .., M and M is the number of mode-0

steps in a subevent, and therefore $ToD_I[1] = 0$. Within any subevent, the range of the set of values described by the set

$$\{ToD_I[m] - (m-1) \times (2 \times T_{SY} + 2 \times T_{RD} + T_{GD} + T_{FM} + T_{IP1} + T_{FCS}) | m = 1, . . , M\}$$

shall be less than or equal to 0.25 µs.

4.3.2 Channel Sounding step mode-1

CS step mode-1 is used to measure the round-trip time between the initiator and the reflector. Devices supporting the CS feature shall implement CS step mode-1. Table 4.6 shows the structure defined for CS step mode-1.

Role/Duration	T_SY	T_RD	T_IP1	T_SY	T_RD
Initiator	CS_SYNC (CS_SYNC_1)	ramp down			
Reflector				CS_SYNC (CS_SYNC_1)	ramp down

Table 4.6: CS step mode-1

The initiator starts by transmitting a CS_SYNC (CS_SYNC_1). The duration of the CS packet (T_SY) corresponds to the definitions described in Section 2 and also depends on the CS_SYNC_PHY being used. The CS_SYNCs for mode-1 may include a sounding sequence or random sequence as part of the CS_SYNC.

The transmission SNR output level may be adjusted during the CS_SYNC transmission. The permitted SNR output levels are described in [Vol 6] Part A, Section 3.1.3.

After the transmission from the initiator is completed, a defined ramp-down window of 5 µs (T_RD) is allowed for the initiator to remove the transmitted energy from the RF channel. After T_RD, the output power in the RF channel shall be at least 40 dB less than the output power used during the transmission of the CS_SYNC, measured at the initiator's antenna connector.

T_IP1 represents the idle time between the transmission from the initiator and the transmission from the reflector. Devices may use this time for internal calibrations if needed. The reflector may use this time to ramp up its transmitted signal, if necessary, in advance of the transmission of the CS_SYNC. The duration of T_IP1 is defined in Section 4.3.1.

After T_IP1, the reflector transmits its CS_SYNC_1. Within this CS_SYNC, the presence or absence of a sounding sequence or random sequence, and the length of the sequence if present, shall match that of the intended initiator's transmission.

The transmission SNR output level may be adjusted during the CS_SYNC transmission. The permitted SNR output levels are described in [Vol 6] Part A, Section 3.1.3.

After the transmission from the reflector is complete, a ramp-down window of T_RD shall be present using the same requirements as defined for the initiator.

The reflector may transmit its CS_SYNC_1 even if it does not receive a CS_SYNC from the initiator or if the CS_SYNC was received with bit errors. The time duration of a CS step mode-1 can be expressed as:

$$2 \times T_{SY} + 2 \times T_{RD} + T_{IP1}$$

Section 3.1 describes how round-trip time is computed using CS_SYNC exchanges. When reporting round-trip time to the Host, each device excludes nominal known time offsets from the reported time. This time is equivalent to the time period between the reception and transmission of the center of the CS_SYNC fields, *T_SY_CENTER_DELTA*. For CS step mode-1, *T_SY_CENTER_DELTA* is equal to the following:

$$T\_SY\_CENTER\_DELTA = T_{SY} + T_{RD} + T_{IP1}$$

4.3.3 Channel Sounding step mode-2

CS step mode-2 is used to measure the phase rotations of the RF signal between the initiator and the reflector. Devices supporting the CS feature shall implement CS step mode-2. Table 4.7 shows the structure defined for CS step mode-2.

Role/Duration	(T_SW+T_PM)× (N_AP+1)	T_RD	T_IP2	(T_SW+T_PM)× (N_AP+1)	T_RD
Initiator	CS tone	ramp down			
Reflector				CS tone	ramp down

Table 4.7: CS step mode-2

The initiator transmits a CS tone. The duration of the CS tone shall be (T_SW+T_PM)× (N_AP+1), where T_PM is the Phase Measurement period, T_SW is the antenna switch duration, and N_AP is the number of antenna paths. The permitted values for T_PM are shown in Table 4.8.

T_PM Index	T_PM	Mandatory/Optional/Conditional
0	10 µs	O
1	20 µs	C.1

T_PM Index	T_PM	Mandatory/Optional/Conditional
2	40 µs	M
C.1: Mandatory if any shorter T_PM value is supported, otherwise optional.		

Table 4.8: Permitted values for T_PM

ASK modulation is employed during the CS tone extension slot (see Section 4.4). Here each N_AP set of T_PM length transmissions shall be followed by a single CS tone extension slot of the same T_PM length. This CS tone extension slot can carry a transmission. If a transmission is present, it shall be identical to that of the last T_PM slot and shall use the same antenna element used in that prior slot. If a transmission is not present in the CS tone extension slot, then that T_PM period shall still be present but shall not carry a transmission. The presence of a physical transmission in the extension transmission slot shall be seeded by the CS DRBG described in Section 4.8. The process of determining if a transmission is present is described in Section 4.4.

After the transmission from the initiator is completed, a defined ramp-down window of 5 µs (T_RD) is allowed for the initiator to remove the transmitted energy from the RF channel. After T_RD, the output power in the RF channel shall be at least 40 dB less than the output power used during the transmission of the CS tone, measured at the initiator's antenna connector. This ramp-down window shall also apply directly after the initiator's transmission is completed in the case where the CS tone extension slot does not carry an actual transmission. In this case, the period of T_RD shall still also be present after the CS tone extension slot and shall also not carry any added transmission from the initiator.

T_IP2 represents the idle time between the transmissions, including the CS tone extension slot from the initiator and the transmission from the reflector. Devices may use this time for internal calibrations, if needed. The reflector may use this time to ramp up its transmitted signal, if necessary, in advance of the transmission of the CS tone. Table 4.9 shows the permitted values for T_IP2. The T_IP2 value may be different from the T_IP1 value.

T_IP2 Index	T_IP2	Mandatory/Optional/Conditional
0	10 µs	O
1	20 µs	O
2	30 µs	O
3	40 µs	C.1
4	50 µs	O
5	60 µs	O
6	80 µs	C.1

T_IP2 Index	T_IP2	Mandatory/Optional/Conditional
7	145 µs	M
C.1: Mandatory if any shorter T_IP2 value is supported, otherwise optional.		

Table 4.9: Permitted values for T_IP2

After T_IP2, the reflector transmits its CS tone. The duration of the CS tone shall be (T_SW+T_PM)×(N_AP+1), where T_PM is the Phase Measurement period, T_SW is the antenna switch duration, and N_AP is the number of antenna paths. The N_AP parameter is common to the entire CS procedure and is described in [Vol 6] Part A, Section 5.3. An extension transmission slot like the one that was present in the initiator to reflector direction shall immediately follow the last valid N_AP transmission. If a transmission is present, it shall be identical to the transmission of the last T_PM slot and shall use the same antenna element used in that prior slot. If a transmission is not present in the CS tone extension slot, then that T_PM period shall still be present but shall not carry a transmission. The presence of a physical transmission in the extension transmission slot shall be seeded by the CS DRBG described in Section 4.8. The process of determining if a transmission is present is described in Section 4.4.

After the transmission from the reflector is complete, a ramp-down window of T_RD shall be present using the same requirements defined for the initiator described above in this section. In the case where a transmission was not present in the CS tone extension slot, a period of T_RD shall still also be appended after the CS tone extension slot and shall also not carry any added transmission from the reflector.

The time duration of a CS step mode-2 can be expressed as:

$$2 \times (T_{PM} + T_{SW}) \times (N_{AP} + 1) + 2 \times T_{RD} + T_{IP2}$$

For CS step mode-2, the time period between reception and transmission of the center of the CS tone at the antenna port is nominally expressed as:

$$T\_PM\_CENTER\_DELTA = (T_{PM} + T_{SW}) \times (N_{AP} + 1) + T_{RD} + T_{IP2}$$

4.3.4 Channel Sounding step mode-3

CS step mode-3 is used to measure the phase rotations of the RF signal and the round-trip time between the initiator and the reflector. Devices supporting the CS feature may optionally implement CS step mode-3. Table 4.10 shows the structure defined for CS step mode-3.

Role/ Duration	T_SY+T_GD+ (T_SW+T_PM)× (N_AP+1)	T_RD	T_IP2	(T_SW+T_PM)× (N_AP+1) +T_GD+T_SY	T_RD
Initiator	CS_SYNC followed by a CS tone (CS_SYNC_3_I)	ramp down			
Reflector				CS tone followed by a CS_SYNC (CS_SYNC_3_R)	ramp down

Table 4.10: CS step mode-3

The initiator transmits a CS_SYNC followed by a CS tone (CS_SYNC_3_I) as described in Section 2.6. The duration of the CS_SYNC (T_SY) corresponds to the definitions described in Section 2 and also depends on the CS_SYNC_PHY being used. The CS_SYNCs for mode-3 may include a sounding sequence or random sequence as part of the CS_SYNC.

The transmission SNR output level may be adjusted during the CS_SYNC transmission. The permitted SNR output levels are described in [Vol 6] Part A, Section 3.1.3.

A guard time of T_GD length, as described in Section 2.6, then follows.

The duration of the CS tone shall be (T_SW+T_PM)×(N_AP + 1), where T_PM is the phase measurement period and N_AP is the number of antenna paths. The valid values for the T_PM parameter are described in Section 4.3.3.

ASK modulation is employed during the CS tone extension slot (see Section 4.4). Here each N_AP set of T_PM length transmissions shall be followed by a single CS tone extension slot of the same T_PM length. This CS tone extension slot can carry a transmission. If a transmission is present, it shall be identical to that of the last T_PM slot and shall use the same antenna element used in that prior slot. If a transmission is not present in the CS tone extension slot, then that T_PM period shall still be present but shall not carry a transmission. The presence of a physical transmission in the extension transmission slot shall be seeded by the CS DRBG described in Section 4.8. The process of determining if a transmission is present is described in Section 4.4.

After the transmission from the initiator has completed, a defined ramp-down window of 5 µs (T_RD) is allowed for the initiator to remove the transmitted energy from the RF channel. After T_RD the output power in the RF channel shall be at least 40 dB less than the output power used during the transmission of the CS_SYNC measured at the initiator's antenna connector. This ramp-down window shall also apply directly after the initiator's transmission is completed in the case where the CS tone extension slot does not carry an actual transmission. In this case, the period of T_RD shall still be present after the CS tone extension slot and shall also not carry any added transmission from the initiator.

T_IP2 represents the idle time between the transmission from the initiator and the transmission from the reflector. Devices may use this time for internal calibrations if needed. The reflector may use this time to ramp up its transmitted signal, if necessary, in advance of the transmission. The duration of T_IP2 is defined in Section 4.3.3.

After T_IP2, the reflector transmits a CS tone followed by a CS_SYNC (CS_SYNC_3_R) as described in Section 2.6. This sequence begins with the transmission of the CS tone. The duration of the CS tone shall be either (T_SW+T_PM) ×N_AP or (T_SW+T_PM)×(N_AP + 1) depending on whether a transmission is selected for the CS tone extension slot. If a transmission is present, it shall be identical to that of the last T_PM slot and shall use the same antenna element used in that prior slot. If a transmission is not present in the CS tone extension slot, then that T_SW+T_PM period shall not be present but shall be compensated for as described below. The presence of a physical transmission in the extension transmission slot shall be seeded by the CS DRBG described in Section 4.8. The process of determining if a transmission is present is described in Section 4.4.

A guard time of T_GD length as described in Section 2.6 then follows.

The reflector may then transmit its CS_SYNC. Within this CS_SYNC, the presence or absence of a sounding sequence or random sequence, and the length of the sequence if present, shall match that of the initiator's transmission.

The transmission SNR output level may be adjusted during the CS_SYNC transmission. The permitted SNR output levels are described in [Vol 6] Part A, Section 3.1.3.

A T_PM period without a physical transmission shall be inserted directly after the reflector's CS_SYNC transmission if the CS tone extension slot was not present during the prior CS tone transmission. This T_PM period shall be accompanied by a T_SW period as if it had occurred before the CS_SYNC transmission.

After the transmission from the reflector is complete, a ramp-down window of T_RD shall be present using the same requirements defined for the initiator described above in this section. In the case where a transmission was not present in the CS tone extension slot, a period of T_RD shall also be appended after the CS tone extension slot and shall also not carry any added transmission from the reflector.

The time duration of a CS step mode-3 can be expressed as:

$$2 \times (T_{SY} + T_{GD}) + 2 \times (T_{PM} + T_{SW}) \times (N_{AP} + 1) + 2 \times T_{RD} + T_{IP2}$$

Section 3.1 describes how round-trip time is computed using CS_SYNC exchanges. When reporting round-trip time to the Host, each device excludes nominal known time offsets from the reported time. This time is equivalent to the time period between the reception and transmission of the center of the CS_SYNC fields,

T_SY_CENTER_DELTA. For CS step mode-3, *T_SY_CENTER_DELTA* is equal to the following:

- $T\_SY\_CENTER\_DELTA = T_{SY} + T_{RD} + 2 \times T_{GD} + 2 \times (T_{SW} + T_{PM}) \times N_{AP} + 2 \times (T_{SW} + T_{PM}) + T_{IP2}$, if a physical transmission is present in the reflector to initiator transmission extension slot.
- Otherwise, $T\_SY\_CENTER\_DELTA = T_{SY} + T_{RD} + 2 \times T_{GD} + 2 \times (T_{SW} + T_{PM}) \times N_{AP} + (T_{SW} + T_{PM}) + T_{IP2}$.

For CS step mode-3, the time period between reception and transmission of the center of the CS tone at the antenna port is nominally expressed as:

- $T\_PM\_CENTER\_DELTA = (T_{PM} + T_{SW}) \times (N_{AP} + 1) + T_{SY} + T_{GD} + T_{RD} + T_{IP2}$

4.4 Channel Sounding subevent and mode sequencing

CS subevents have a maximum duration of T_SUBEVENT_LEN, as described in [Vol 6] Part B, Section 4.5.18.1. Each subevent contains a varying number of CS steps. The number of steps included in a subevent depends on the varying step combinations used in that subevent.

4.4.1 Tone extension slots

For CS tones, each N_AP set of T_PM length transmissions shall be followed by a CS tone extension slot as described in Section 4.3.3 and Section 4.3.4. The presence of an actual transmission in this CS tone extension slot shall be selected at random, seeded by the CS DRBG described in Section 4.8.

CS DRBG shall be invoked to generate a single random bit (see Section 4.8). If this bit is set to 1, then a physical transmission shall be present in the CS tone extension slot. If this bit is set to 0, then no transmission shall be present in the CS tone extension slot. Even without a transmission, the CS tone extension slot shall still be present. Refer to Section 4.3.3 and Section 4.3.4 for information about the CS tone extension slot and its positioning within each step.

Figure 4.4 shows a sequence of four CS steps, each of type mode-2, with the CS tone extension slot transmission determined by the output of the CS DRBG.

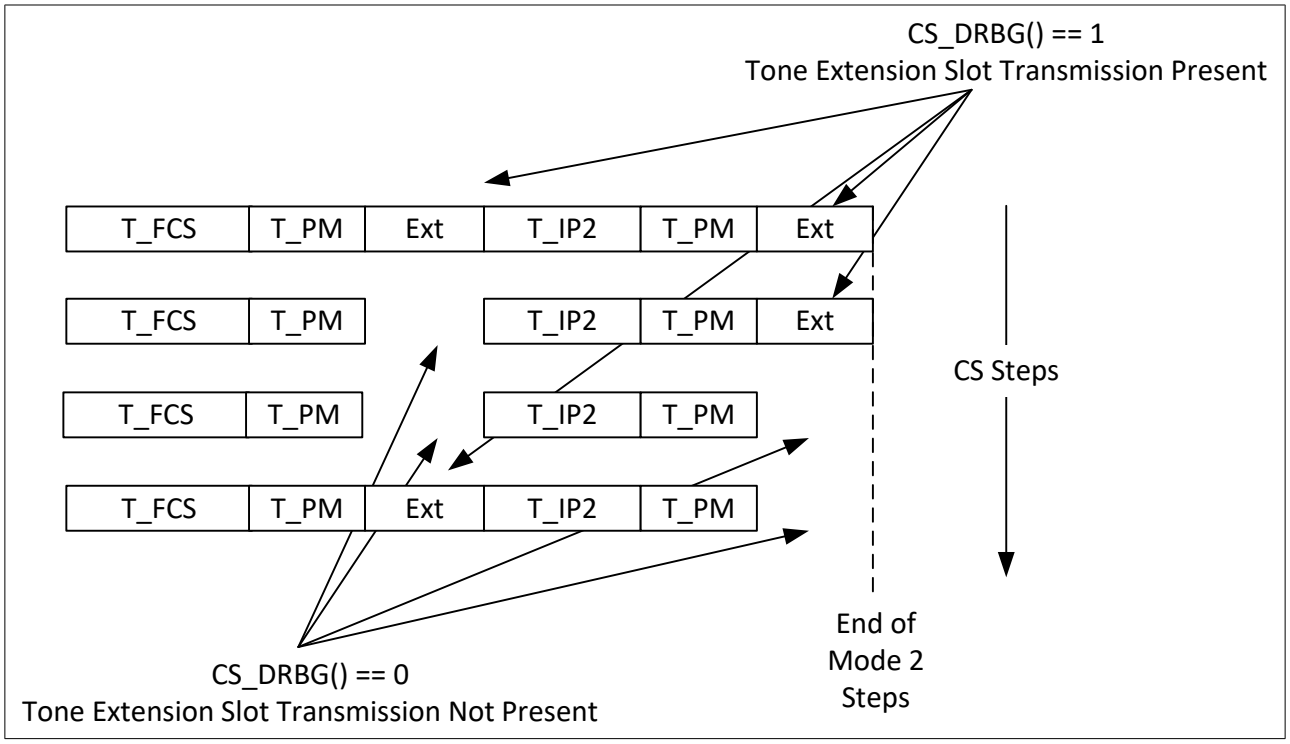

Figure 4.4: Mode-2 CS steps with CS tone extension slot transmission determined by the CS DRBG

Likewise, Figure 4.5 shows a sequence of four CS steps, each of type mode-3, with the CS tone extension slot transmission determined by the output of the CS DRBG. The position of the CS tone extension slot for mode-3 steps is described in Section 4.3.4.

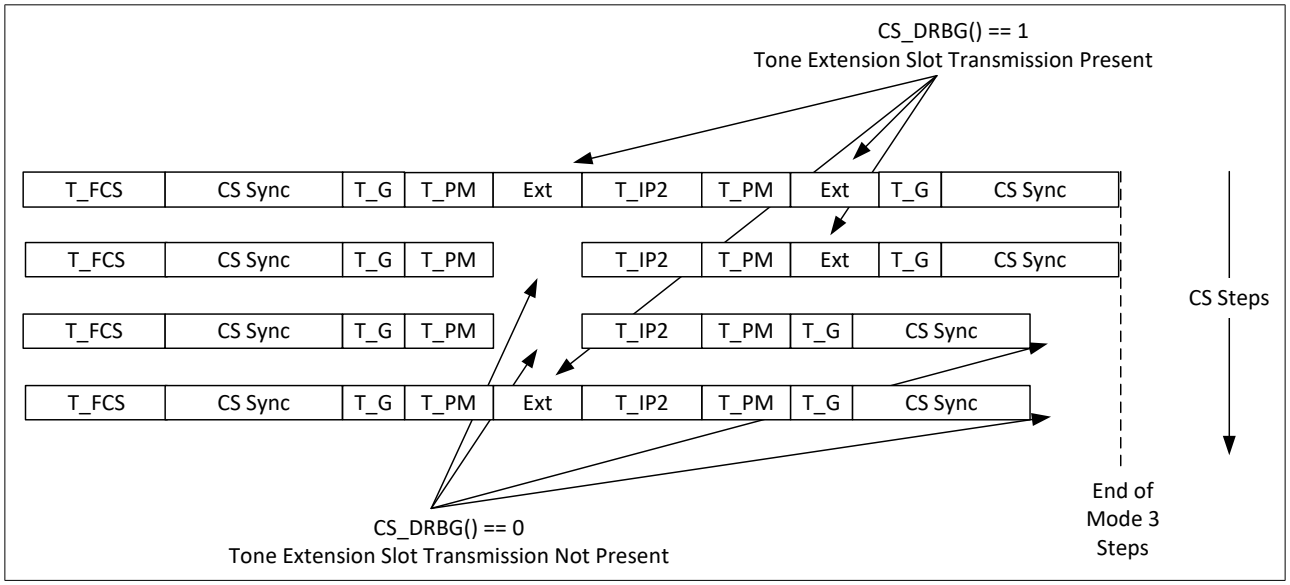

Figure 4.5: Mode-3 CS steps with CS tone extension slot transmission determined by the CS DRBG

Refer to Section 4.8 for CS DRBG invocation ordering rules.

4.4.2 CS subevent structure

Within a CS subevent, if the cumulative duration of a CS step exceeds T_SUBEVENT_LEN as described in [Vol 6] Part B, Section 4.5.18.1, then the CS subevent shall be closed, and that CS step shall occur in the next scheduled CS subevent directly after the initial mode-0 steps and after any Main_Mode Repetitions (see Section 4.2).

A CS subevent starts with one or more mode-0 steps defined by CSMode0Steps. A series of subsequent non-mode-0 steps shall follow in the same subevent. Any CS procedure shall include the use of no more than two non-mode-0 modes, the Main_Mode and the Sub_Mode. An example of this sequencing is shown in Figure 4.6.

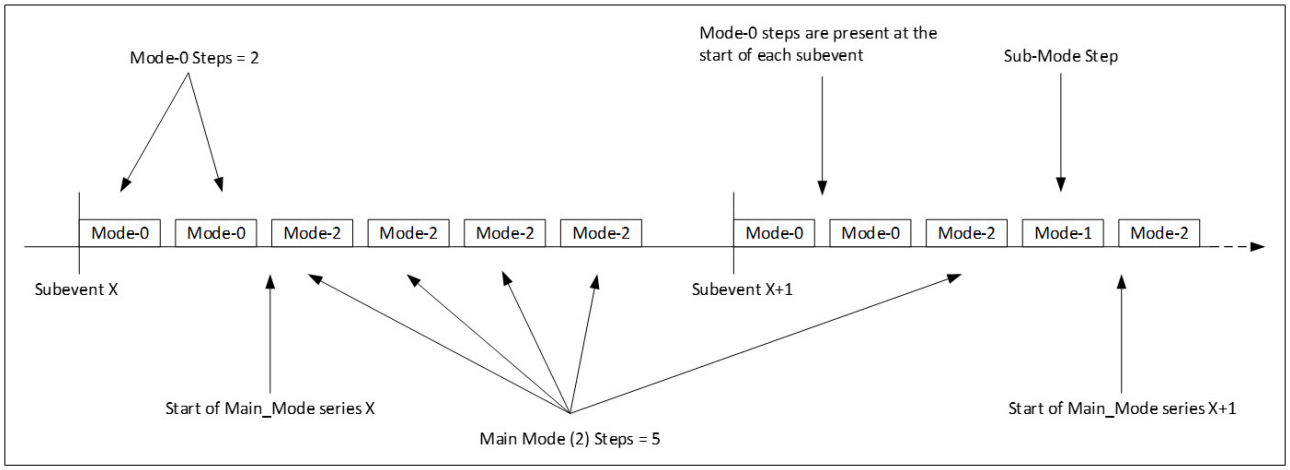

Figure 4.6: CS mode sequencing example with two mode-0 steps, five Main_Mode steps (of type mode-2), and one Sub_Mode step (of type mode-1)

For non-mode-0 steps, Main_Mode and Sub_Mode combinations shall be selected from the valid combinations defined in Table 4.11.

Main_Mode	Sub_Mode
Mode-1	None
Mode-2	None
Mode-3	None
Mode-2	Mode-1
Mode-2	Mode-3
Mode-3	Mode-2

Table 4.11: Valid combinations of Main_Mode and Sub_Mode selections for a CS procedure

4.4.3 Sub_Mode insertion

The following rules shall apply for Sub_Mode insertion only when a Sub_Mode has been selected for a CS procedure. These rules shall repeat for the entire CS procedure.

- Sub_Mode insertion is the process of sequencing the occurrence of the Main_Mode steps and the Sub_Mode steps. This sequencing is performed irrespective of the occurrence of CS subevent boundaries and shall use the following parameters:
  - Main_Mode_Min_Steps – the minimum number of Main_Mode steps that shall occur before the occurrence of a single Sub_Mode step.
  - Main_Mode_Max_Steps – the maximum number of Main_Mode steps that shall occur before the occurrence of a single a Sub_Mode step.
- The exact number of Main_Mode steps that occur before a Sub_Mode step insertion shall be randomized for each sequence. The random number generation function hr1 (see Section 4.8.1) is invoked to determine the randomized number of Main_Mode steps that occur in the sequence.
  - The number of Main_Mode steps to execute shall be calculated as follows.
    - hr1(Main_Mode_Max_Steps – Main_Mode_Min_Steps + 1) + Main_Mode_Min_Steps
  - The number of Main_Mode steps to execute before a Sub_Mode insertion shall be generated at the CS step where the first Main_Mode step within that sequence occurs. Refer to Section 4.8 for CS DRBG invocation ordering rules.

4.4.4 Main_mode repetition

After a CS subevent, a variable number of Main_Mode steps and their respective transmission channels may be optionally repeated in the next CS subevent directly after the mode-0 transmissions. The Main_Mode_Repetition value from the CS configuration selected (see [Vol 6] Part B, Section 2.4.2.45) for a CS procedure shall denote the number of Main_Mode steps that are repeated from the end of one CS subevent to the beginning of the next.

When CS steps are repeated based on the Main_Mode_Repetition value, only the channel index and Main_Mode type shall be repeated in the next CS subevent. All other aspects that involve seeding from the CS DRBG shall be newly generated in the steps that are repeated. If the value of Main_Mode_Repetition is greater than 1, then the repeated steps in the next CS subevent shall be in the same order as in the previous CS subevent.

Only CS steps from the current subevent that were not repeated from the last subevent shall be repeated in the next subevent. If the number of CS steps that are candidates to be repeated from the current subevent into the next subevent is less than the

Main_Mode_Repetition value, then only those CS steps shall be repeated in the next subevent.

Sub_Mode insertion, if present, shall be calculated as if the Main_Mode_Repetition value were specified as zero. This is equivalent to not counting the occurrences resulting from Main_Mode_Repetition when determining where the Sub_Mode insertion occurs. The step placement due to Main_Mode_Repetition shall occur first within a CS subevent in the case of pending step placement due to Sub_Mode insertion.

4.4.5 Channel Sounding procedure and procedure repeat desynchronization

A CS subevent will always start with the exchange of one or more mode-0 steps, as described in Section 4.4.2. Within each of these mode-0 steps is a CS_SYNC exchange as described in Section 4.3.1. A mode-0 exchange is considered successful in the case where both Link Layers properly receive a CS_SYNC PDU with an access address quality indication result of 0 or 1, as described in Section 2.2.2. Alternatively, a mode-0 step exchange is considered lost when either link layer fails to receive a CS_SYNC PDU or the resulting access address quality indication result is greater than 1, within that mode-0 step. In the case that all mode-0 steps within a CS subevent are lost, then that CS subevent is also considered lost.

[Vol 6] Part B, Section 4.2.4 describes the window widening recommendations for synchronization of the first CS subevent within a CS event. If the first consecutive CS subevents within a CS event are lost, then these window widening recommendations apply to the next sequential CS subevent within that CS event as if that CS subevent was the first in occurrence within that CS event.

If the first CS subevent(s) within any CS event is lost, then it is implementation dependent if an attempt is made to synchronize with the next CS subevent within that CS event. In this case, if synchronization with a CS event is abandoned, then that CS event is similarly considered lost. In the case that an entire CS procedure is abandoned due to the first consecutive CS events within that procedure being lost, then that CS procedure is also considered lost.

In the case that CS procedure instances are actively running and N_PROCEDURE_LOST=2 consecutive CS procedure repeat instances are lost, then a Link Layer should initiate the Channel Sounding Procedure Repeat Termination procedure, as described in [Vol 6] Part B, Section 5.1.27.

4.5 Timing of steps

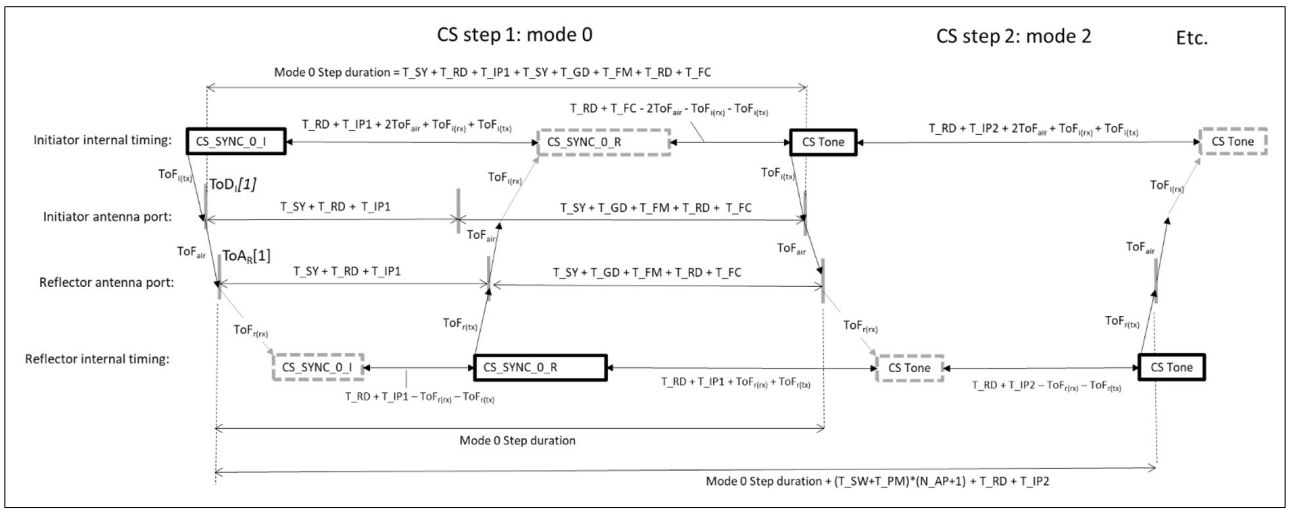

Figure 4.7: Example timing of CS steps for single antenna mode based on the reflector's timing reference

Figure 4.7 shows an example of the timing of CS steps when a single antenna is in use. All timings in Figure 4.7 are based on the reflector's timing reference. $ToD_I[k]$ represents the time of departure of the packet at the initiator's antenna port sent in the k^{th} step within a subevent, if such a packet exists within that step. $ToA_R[k]$ represents the time of arrival at the reflector's antenna port of the packet sent in the k^{th} step within a subevent, if such a packet exists within that step. ToF_{air} represents the time of flight between antenna ports. ToF_i and ToF_r represent the initiator and reflector circuit delay, respectively. In Figure 4.7, solid boxes denote transmission times and dashed grey boxes denote reception windows.

The initiator shall align its transmission timings relative to the start of its first mode-0 transmission at its antenna port, $TOD_i[1]$ (see Figure 4.7), based on the reflector's clock reference as follows:

$$\hat{t}_1^{STEP}[k] = \frac{t_1^{STEP}[k]}{1 + FFO[1] \cdot 10^{-6}} + ToD_{I[1]}, k = M + 1, \ldots, K;$$

where $t_1^{STEP}[k]$ is the nominal start time of each transmission according to its local clock reference and FFO[1] is the FFO estimated from the first mode-0 CS tone (see [Vol 6] Part A, Section 3.5.1). The initiator should adjust its CS tone reception window to compensate for the round-trip time of flight between devices and to compensate for any relevant known synchronization errors or internal circuit delays so that its phase center of measurement falls in the center of the received CS tone (see [Vol 6] Part A, Section 6.4).

The reflector shall calculate all transmission timings relative to the time of arrival of a mode-0 packet at its antenna port, using its own timing reference $ToA_r[m]$ (see

Figure 4.7), where m is assumed to be the first successfully received mode-0 packet. The reflector's timing reference, defined by the frequency of the first transmitted mode-0 packet CS tone, shall be constant throughout a subevent, and the reflector shall not perform any timing adjustment of its transmissions to compensate for the clock frequency offset between devices. The reflector should adjust its CS tone reception window to compensate for known synchronization errors or internal circuit delay so that its phase center of measurement falls in the center of the received CS tone (see [Vol 6] Part A, Section 6.4).

Both initiator and reflector shall maintain an accuracy of ±1 µs in the timing of their transmissions as described in this section.

4.6 Phase measurements during T_PM

Devices perform phase measurements during T_PM. Devices shall perform N_AP + 1 phase measurements for each of the phase measurement periods during a mode-2 or mode-3 step, one for each of the antenna paths as well as for the CS tone extension slot. The rules for T_PM measurements taken over tone extension slots are described below.

Each T_PM period shall start and end with at least a 1 µs exclusion period, as shown in Figure 4.8, to allow for peer device timing error (see Section 4.5). A longer exclusion period should be introduced as necessary to compensate for local device timing accuracy. These exclusion periods shall not be considered as valid regions for PCT extraction. PCT sampling is described in [Vol 6] Part A, Section 6.4 and Section 4.5.

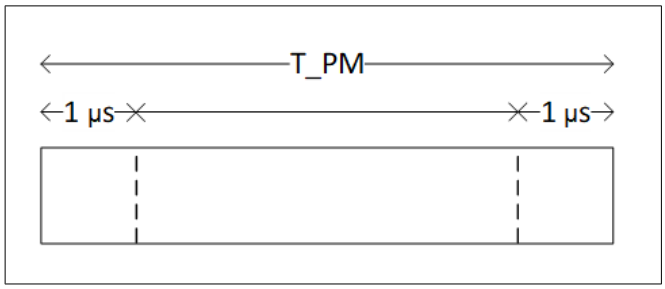

Figure 4.8: PCT sample window

Each measurement within T_PM results in a single PCT value expressed as complex number I+jQ. When a CS subevent contains multiple CS steps, devices should maintain receiver characteristics (e.g., receiver's gain and latency across T_PM periods should remain constant across the CS steps). If this is not possible, receivers should be able to make adjustments to the resulting measurements to emulate this constant behavior.

The IQ terms shall each use 12 bits to encode their value.

In addition to the IQ values, devices shall provide a reference power level (RPL) in dBm. The RPL shall be encoded as an 8-bit signed number. The RPL expressed in dBm shall

correspond to the power of a hypothetical PCT value whose amplitude is a constant value of 2048. A single RPL is used for all the PCT values in a CS subevent.

The conversion between IQ values as unitless values to power in dBm can be expressed as:

$$IQ\left[dBm\right] = 20\log_{10}\left(abs\left(\frac{IQ[linear]}{2048}\right)\right) + RPL\left[dBm\right]$$

Devices may assign a tone quality indication to each of the PCT measurements. The tone quality indication shall be a 2-bit number with definitions as shown in Table 4.12. Devices that are not able to compute a quality indication shall report a value of 3.

The following definitions pertain to devices that are capable of computing tone quality indications.

Value	Tone Quality
0	High quality
1	Medium quality
2	Low quality
3	Quality indication not available / unknown quality

Table 4.12: CS tone quality values

The following shall be tested with a T_PM value of 40 µs.

Devices shall report high quality when the signal at the antenna port is a CS tone of -67 dBm, with a Gaussian noise floor of -151 dBm/Hz or less. This reported value shall be the outcome of the measurement for 90% of the CS tones and under all valid frequency offsets of the input signal, as described in [Vol 6] Part A, Section 3.5.2.

Devices shall report low quality when the signal at the antenna port is a CS tone of -67 dBm with a Gaussian noise floor of -133 dBm/Hz or greater. This reported value shall be the outcome of the measurement for 90% of the CS tones and under all valid frequency offsets of the input signal, as described in [Vol 6] Part A, Section 3.5.2.

Devices may optionally report medium quality when the received signal is between the good quality and low quality thresholds.

The use of Gaussian noise signals to represent channel impairments is intended to represent external sources of wideband interference.

In tone extension slots, no T_PM measurement shall occur in a mode-3 step in the reflector to initiator direction when a CS tone extension slot transmission is not present. Instead, an empty T_PM measurement result shall take the place of the T_PM

measurement. In any other case of a CS tone extension, the T_PM measurement over that tone extension slot shall be reported.

An empty T_PM measurement shall be defined with IQ values each set to zero and with a tone quality indication set to “quality indication not available”.

4.7 Phase measurements with antenna switching

During CS tone exchanges, the initiator switches to the intended antenna element and transmits its CS tone first and the reflector performs phase measurements. Then, after a T_RD + T_IP2 period, the reflector switches to the intended antenna element and transmits its CS tone, and the initiator performs phase measurements. The configuration options listed in [Vol 6] Part A, Section 5.3 affect how the switching happens, which antenna is selected during the execution within a CS step, and whether the switch applies to the outgoing signal (i.e., switch on transmitted RF signal), or the incoming signal (i.e., switch on received RF signal), or both.

Antenna switching occurs just before the start of every T_PM period for each configuration with multiple antenna paths. T_SW is the switch period time and is reserved for antenna switching, irrespective of whether the antenna to be switched is a local antenna or a remote antenna. During the period when an antenna is switched, the signal might not be stable and shall not be used for measurements. The T_SW duration is local device specific and each peer shall indicate its own preferred setting, as described in [Vol 6] Part B, Section 5.1.24. When antenna switching is performed, the duration of T_SW shall be 1, 2, 4, or 10 µs. When no antenna switching is performed (e.g., in the 1:1 configuration), the value of T_SW shall be set to 0. Devices switching transmitting antennae must control switching transients according to the requirements specified in Part A.

The value of T_SW used in a CS procedure depends on the antenna switch configuration selected for that procedure, as described in the following subsections.

4.7.1 Antenna switching in the 1:1 configuration

There shall not be antenna switching activity in the 1:1 configuration.

4.7.2 Antenna switching in the N_AP:1 configuration

In the N_AP:1 configuration, only the initiator performs antenna switching. Figure 4.9 shows the procedure. In the figure, * represents the extension slot that can occur as shown, or can occur after T_SY, specifically for a mode-3 step.

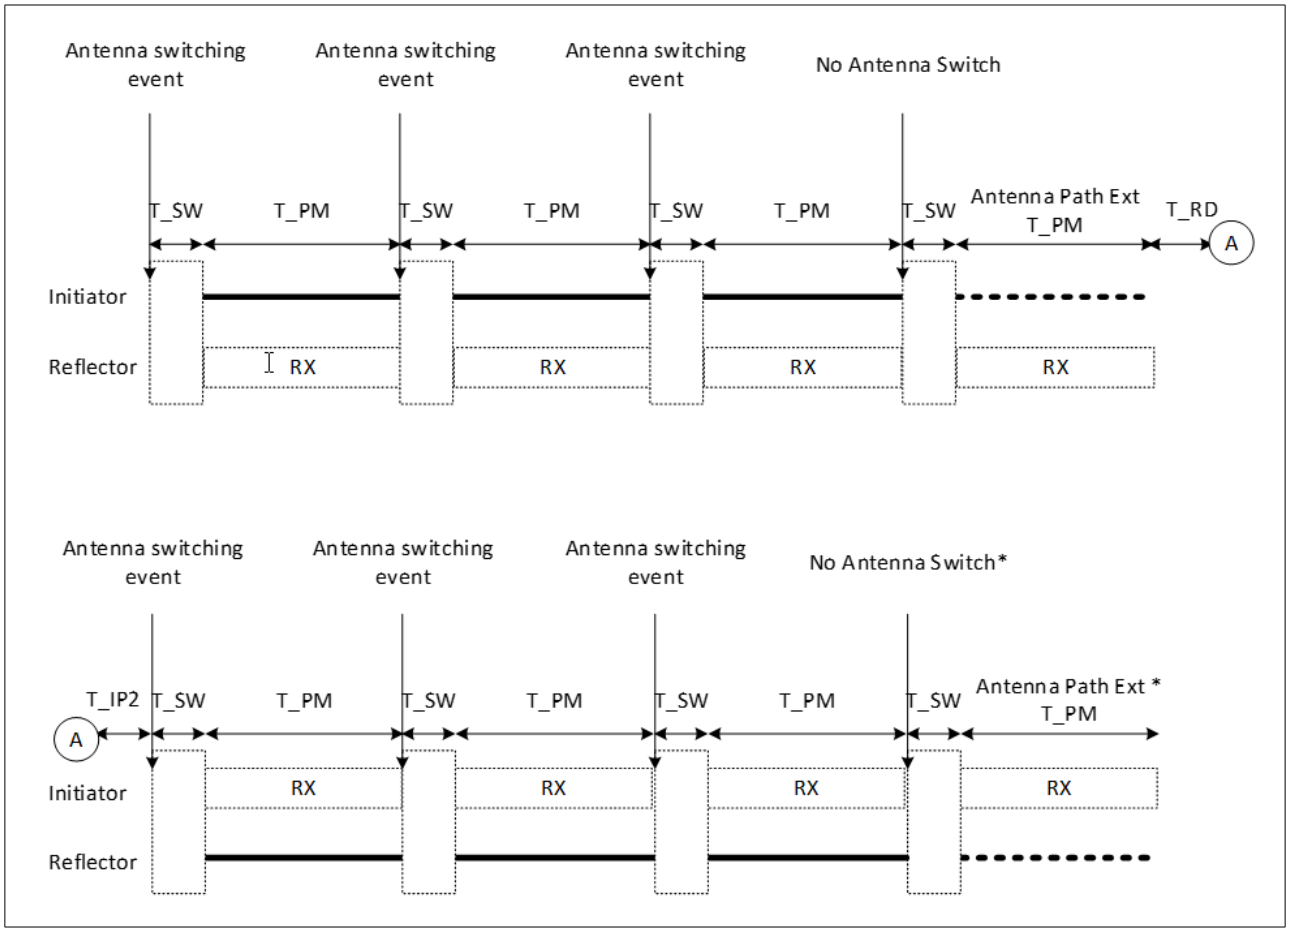

Figure 4.9: N_AP:1 antenna switch procedure in a 3:1 configuration with the antenna path permutation slot.

In this configuration, with N_AP antennae in the initiator, the initiator shall be the only device performing antenna switching. The antenna switch duration selected shall be the T_SW value of the initiator.

During its transmission phase, the initiator shall perform N_AP antenna switches. Each switch shall be performed before the start of the T_PM period.

During its reception phase, the initiator shall perform N_AP antenna switches. Each switch shall be performed before the start of the T_PM period.

The reflector shall not perform antenna switching in this configuration. The reflector shall not perform any measurements during the switch duration of the initiator.

The antenna switching sequence that the initiator selects for each T_PM period during its transmission phase shall be identical to the antenna switching sequence used during its reception phase.

Figure 4.9 shows the antenna switch procedure for a 3:1 antenna switch configuration, including the tone extension slot described in Section 4.4. For a mode-3 step in the reflector-to-initiator direction, the last T_SW period and associated tone extension slot (indicated by * in Figure 4.9) may occur as shown in the figure or may occur after T_SY as described in Section 4.3.4.

4.7.3 Antenna switching in the 1:N_AP configuration

In the 1:N_AP configuration, only the reflector performs antenna switching. Figure 4.10 shows the procedure. In this figure, * represents the extension slot that can occur as shown or can occur after T_SY.

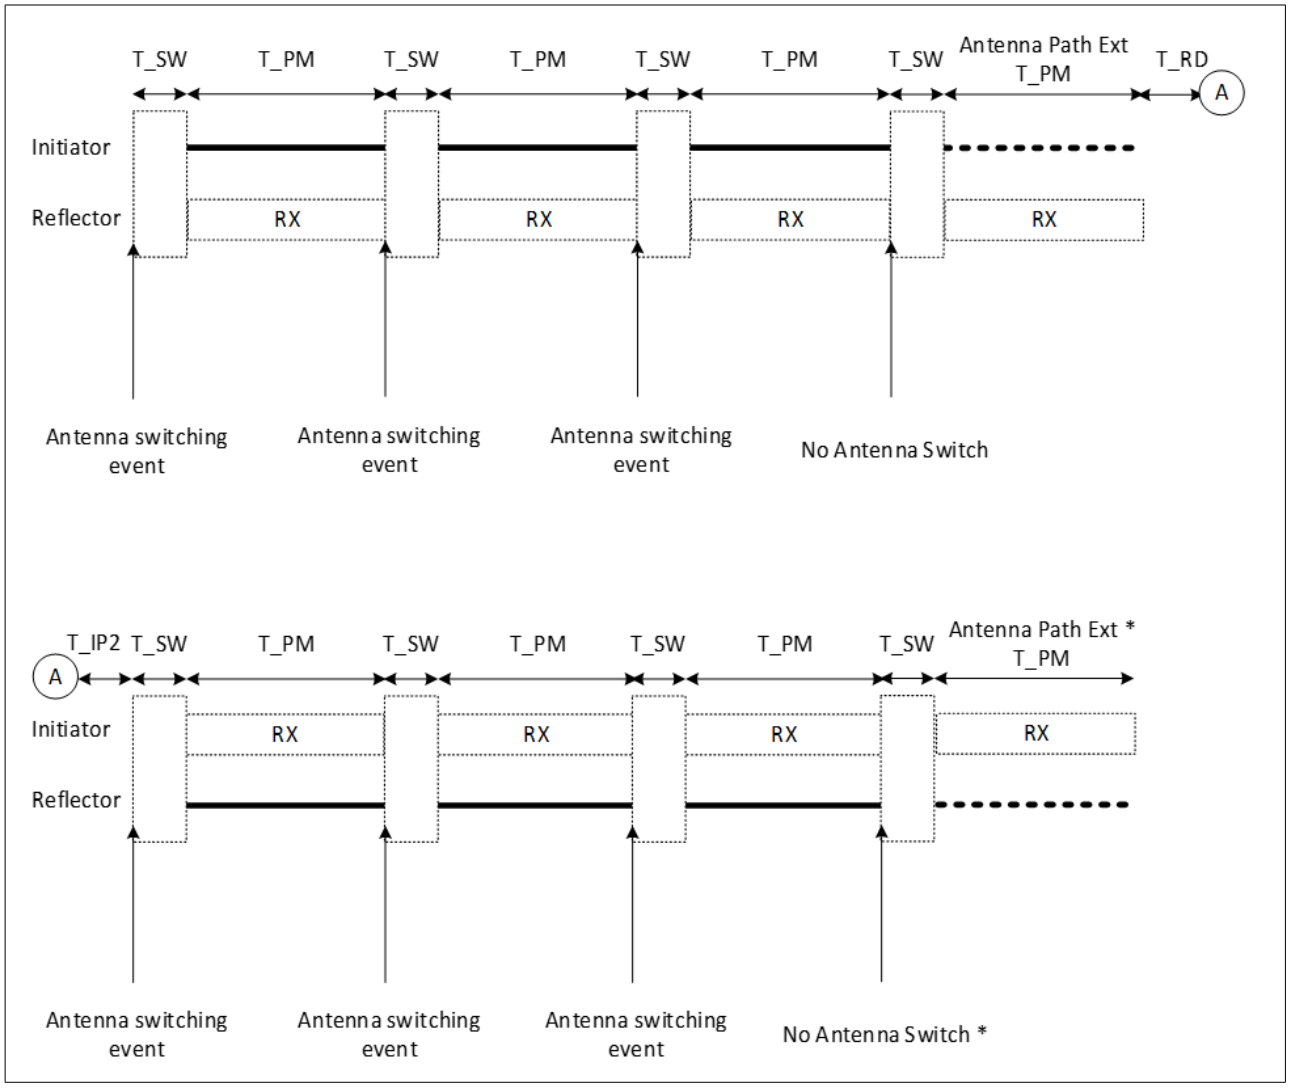

Figure 4.10: 1:N_AP antenna switch procedure in a 1:3 configuration with the antenna path permutation slot

In this configuration, with N_AP antennae in the reflector, the reflector shall be the only device performing antenna switching. The antenna switch duration selected shall be the T_SW value of the reflector.

During its reception phase, the reflector shall perform N_AP antenna switches. Each switch shall be performed before the start of the T_PM period.

During its transmission phase, the reflector shall perform N_AP antenna switches. Each switch shall be performed before the start of the T_PM period.

The initiator shall not perform antenna switching in this configuration. The initiator shall not perform any measurements during the switch duration of the reflector.

The antenna switching sequence that the reflector selects for each T_PM period during its transmission phase shall be identical to the antenna switching sequence used during its reception phase.

Figure 4.10 shows the antenna switch procedure for a 1:3 antenna switch configuration, including the tone extension slot as described in Section 4.4. For a mode-3 step in the reflector-to-initiator direction, the last T_SW period and associated tone extension slot (indicated by * in Figure 4.10) may occur as shown in the figure or may occur after T_SY as described in Section 4.3.4.

4.7.4 Antenna switching in the 2:2 (N_AP = 4) configuration

In the 2:2 (N_AP = 4) configuration, both devices perform antenna switching. At each antenna switch point, one device or both devices simultaneously may perform antenna switching. Figure 4.11 shows the procedure. In this figure, * represents the extension slot that can occur as shown or can occur after T_SY.

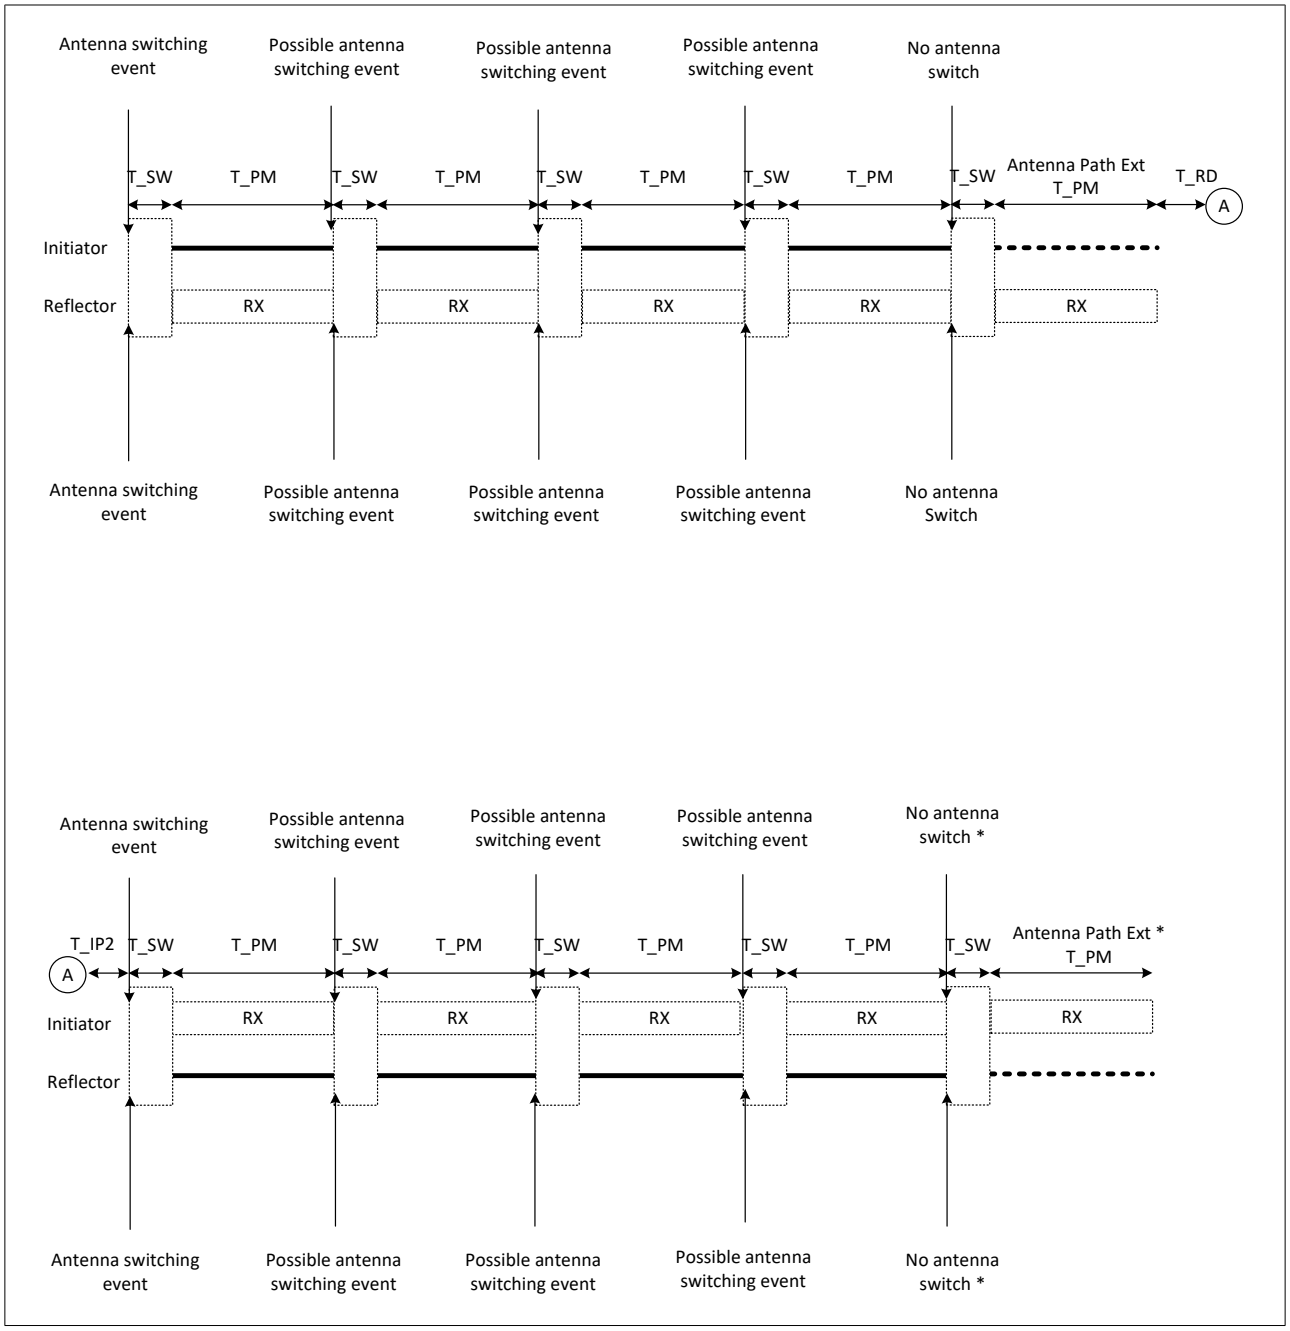

Figure 4.11: 2:2 antenna switch procedure with the antenna path permutation slot

For the 2:2 antenna switch procedure, each antenna path consists of a combination of antennae selected by both the initiator and reflector, as described in [Vol 6] Part A, Section 5.3.

During its transmission phase, the initiator shall perform an antenna switch for before the first T_PM interval and then may perform an antenna switch at each subsequent T_PM interval, depending on the antenna path selected for that interval. Each switch shall be performed immediately before the start of the T_PM period.

Similarly, during its reception phase, the reflector shall perform an antenna switch for the first T_PM interval and then may perform an antenna switch at each subsequent T_PM interval, depending on the antenna path selected for that interval. Each switch shall be performed immediately before the start of the T_PM period.

During its reception phase, the initiator shall perform an antenna switch for the first T_PM interval and then may perform an antenna switch at each subsequent T_PM interval, depending on the antenna path selected for that interval. Each switch shall be performed immediately before the start of the T_PM period.

Similarly, during its transmission phase, the reflector shall perform an antenna switch for the first T_PM interval and then may perform an antenna switch at each subsequent T_PM interval, depending on the antenna path selected for that interval. Each switch shall be performed immediately before the start of the T_PM period.

The antenna switch duration selected for all required antenna element switching shall be the larger of the T_SW values of the initiator and the reflector. The device acting as the receiver shall not perform any measurements during the switch duration of the device acting as the transmitter.

The antenna switching sequence that the initiator and reflector select for each T_PM period during the first part of the CS step (initiator to reflector) shall be identical to the antenna switching sequence used during the second part of the CS step (reflector to initiator).

Figure 4.11 shows the antenna switch procedure for a 2:2 antenna switch configuration, including the tone extension slot described in Section 4.4. For a mode-3 step in the reflector-to initiator-direction, the last T_SW period and associated tone extension slot (indicated by * in Figure 4.11) may occur as shown in the figure or may occur after T_SY, as described in Section 4.3.4.

4.7.5 Antenna path permutations

During antenna switching, the antenna path position ordering in a CS tone exchange shall be randomized. Each antenna path is described in [Vol 6] Part A, Section 5.3, where the initiator is device A and the reflector is device B.

Each device may switch between up to four antenna paths within a CS step. The randomized antenna path permutation in a CS step shall be selected using the random number generation function hr1 (see Section 4.8.1). The number of antenna paths used within the permutation is the maximum number of N_AP antenna paths, as described in [Vol 6] Part A, Section 5.3.

When N_AP is greater than 1, the antenna path permutation index shall be calculated as follows:

hr1(N_AP!)

See Section 4.8 for CS DRBG invocation ordering rules.

An antenna path permutation index is used to look up the specific antenna path position order used at each step that contains a CS tone exchange within a CS step. These lookup tables are defined based on the number of antenna paths being used.

If N_AP = 2, then Table 4.13 shall be used to select the antenna path permutation.

Antenna Path Permutation Index	Antenna Path Positions After Permutation
0	AP1 AP2
1	AP2 AP1

Table 4.13: Antenna path positions after path permutation with N_AP=2

If N_AP = 3, then Table 4.14 shall be used to select the antenna path permutation.

Antenna Path Permutation Index	Antenna Path Positions After Permutation
0	AP1 AP2 AP3
1	AP2 AP1 AP3
2	AP1 AP3 AP2
3	AP3 AP1 AP2
4	AP3 AP2 AP1
5	AP2 AP3 AP1

Table 4.14: Antenna path positions after path permutation with N_AP=3

If N_AP = 4, then Table 4.15 shall be used to select the antenna path permutation.

Antenna Path Permutation Index	Antenna Path Positions After Permutation
0	AP1 AP2 AP3 AP4
1	AP2 AP1 AP3 AP4
2	AP1 AP3 AP2 AP4
3	AP3 AP1 AP2 AP4
4	AP3 AP2 AP1 AP4

Table 4.15: Antenna path positions after path permutation with N_AP=4

Figure 4.12 shows four successive mode-2 CS steps that use a different antenna path permutation index at each step. In this figure, extension slot transmissions are present in the first and third steps.

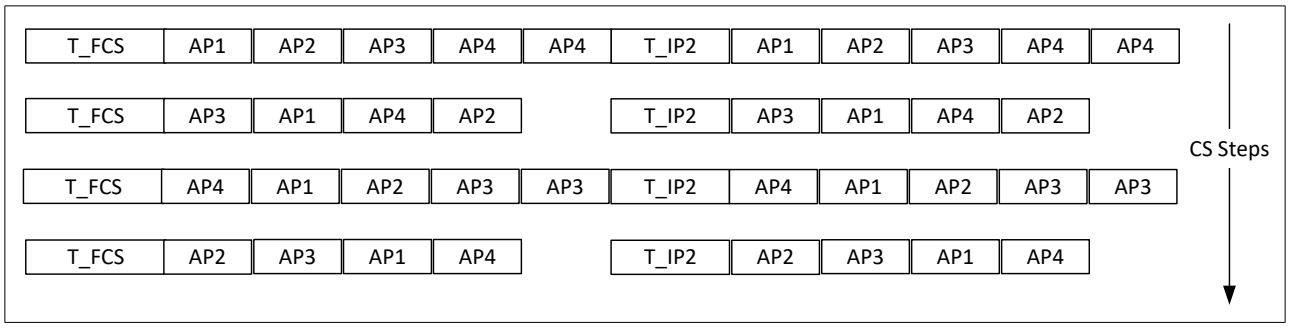

Figure 4.12: Four mode-2 steps with four antenna paths using antenna path permutation indices 0, 15, 9, and 5

4.8 Channel Sounding random bit generation

A dedicated Channel Sounding Deterministic Random Bit Generator (CS DRBG) is used to coordinate the randomization of several transaction types during a CS

procedure. These transaction types are identified by the value of the transaction identifier type, as shown in Table 4.16. *CSTransactionID* represents the transaction identifier being processed by the CS DRBG. The toolbox function CS_DRBG, which is invoked for random bit generation, is described in [Vol 6] Part E, Section 3.1.6.

Transaction Identifier (*CSTransactionID*)	**Transaction Description**
0x00	Randomization of hop channel set for non-mode-0 steps. Described in Section 4.1.
0x01	Randomization of hop channel set for mode-0 steps. Described in Section 4.1.
0x02	Randomization of subevent Sub_Mode (into Main_Mode cycle). Described in Section 4.4.
0x03	T_PM CS tone extension slot transmission presence. Described in Section 4.4.
0x04	Antenna path permutation index selection. Described in Section 4.7.5.
0x05	CS Access Address generation. Described in Section 2.2.1.
0x06	Sounding sequence marker position randomization. Described in Section 2.4.
0x07	Sounding sequence marker signal selection. Described in Section 2.4.
0x08	Random sequence generation. Described in Section 2.5.
0x09	Backtracking resistance. Described in [Vol 6] Part E, Section 3.1.7.

Table 4.16: CS DRBG transaction identifiers (CSTransactionID)

Each of the transactions listed in Table 4.16 uses a fresh set of random bits at different points within a CS procedure. Each transaction might use a different number of random bits, which might be less than the 128-bit generation output of the CS DRBG. If all bits are not used during a transaction, the remaining bits shall be preserved and used in subsequent transactions until there are not enough remaining bits to complete the transaction. At this point, the remaining bits shall be discarded and a new set of 128 random bits shall be generated.

A newly generated set of random bits might not be needed at each CS step, either because there are still an adequate number of remaining unused bits from a previous DRBG invocation for that specific transaction identifier, or because there is no need for random bit usage for the specific CS mode for that CS step.

For example, if a transaction identifier uses random bits in 8-bit quantities at each step, then at step 0 the DRBG would be invoked to provide 128 bits of random bit output. The first eight bits would be used at step 0, and the remaining 120 bits would be used in 8-bit quantities at each subsequent step through step 15. At step 16, because

not enough bits are available to complete the step, a fresh set of 128 random bits is generated and the distribution process of those bits is repeated.

When a new set of 128 random bits is generated, the CS Step_Counter described in [Vol 6] Part E, Section 3.2.2 shall be set to the value of the CS step that is being processed, with the following exceptions:

- When used for Channel Selection Algorithm #3c as described in Section 4.1.4.2, the CS Step_Counter as described in [Vol 6] Part E, Section 3.2.2 shall be set to 0.

A transaction counter represented by *CSTransactionCounter* and used in the CS Transaction_Counter described in [Vol 6] Part E, Section 3.2.2 shall be incremented if a specific transaction ID uses multiple quantities of 128 random bits at any one step. *CSTransactionCounter* shall always begin with a value of 0 the first time a new set of 128 random bits is generated at any CS step for a specific transaction ID.

The order in which the CS DRBG is invoked is critical to maintain synchronization with the peer CS device. The CS DRBG, when used for the purposes of generating random bits for each transaction identifier listed in Table 4.16, shall be invoked with the following ordered rules:

1. By CS steps – In sequential order of CS steps in a CS procedure and subevents, from first to last.
2. By device role – Values used by the initiator shall be generated first, followed by those used by the reflector.
3. By transaction type – In the transmission order of a function using a specific transaction type, if random bits for that transaction type are used more than once within any single CS step.

4.8.1 Channel Sounding random number generation function hr1

Within a CS procedure, there are several instances where the CS DRBG is used to seed random number generation with different range sets for the specific transaction types described in Section 4.8. Seeding of random number generation in a uniform distribution within a range is directly supported by the CS DRBG when the range is a power of 2. For other arbitrary ranges, the following description in this section shall be used.

Distribution bias in the random number generation procedure is mitigated with a two-step approach. First, the initial seeding input from the CS DRBG is checked for bias potential. Next, if a bias potential is detected, a supplemental bit draw from the CS DRBG is performed to extend the granularity of the random number generation process.

N_CS_RANGE_GEN_RANDOMIZED_BITS is the number of randomly generated bits used to perform the randomization seeding process. This value is fixed at 8 bits.

The CS random number generation function hr1 is used to generate random numbers within an arbitrary range. The input to hr1 is an 8-bit unsigned integer R, representing the arbitrary range 0 to R-1 from which a random number is to be generated. This value shall be greater than 0 and less than or equal to 255.

The following value is returned from hr1:

Rout is an 8-bit unsigned integer.

The following temporary value is used:

Trand is a 16-bit unsigned integer.

The input/output format of hr1 is as follows:

Rout = hr1(R)

hr1 processing is as follows:

If (R == 1)

then return 0

Trand = R x CS_DRBG(N_CS_RANGE_GEN_RANDOMIZED_BITS)

if (Trand AND 0xFF) < (256 % R)

$$\text{Rout} = \lfloor ((256 \times \text{CS\_DRBG}(\text{N\_CS\_RANGE\_GEN\_RANDOMIZED\_BITS}) \times R) + \text{Trand}) \div 65536 \rfloor$$

else

$$\text{Rout} = \lfloor \text{Trand} \div 256 \rfloor$$

return Rout

Wireless Coexistence Signaling
And Interfaces
Part A

MWS COEXISTENCE LOGICAL SIGNALING SPECIFICATION

This Part specifies the Mobile Wireless Standards (MWS) coexistence logical interface between the Controller and an MWS device.

CONTENTS

1 INTRODUCTION

This Part of the specification describes the MWS Coexistence Logical Signaling. A Bluetooth Controller may incorporate a real-time transport interface to transport the logical signals defined in this section between the Bluetooth Controller and an MWS device.

Figure 1.1 depicts the signaling and messaging architecture.

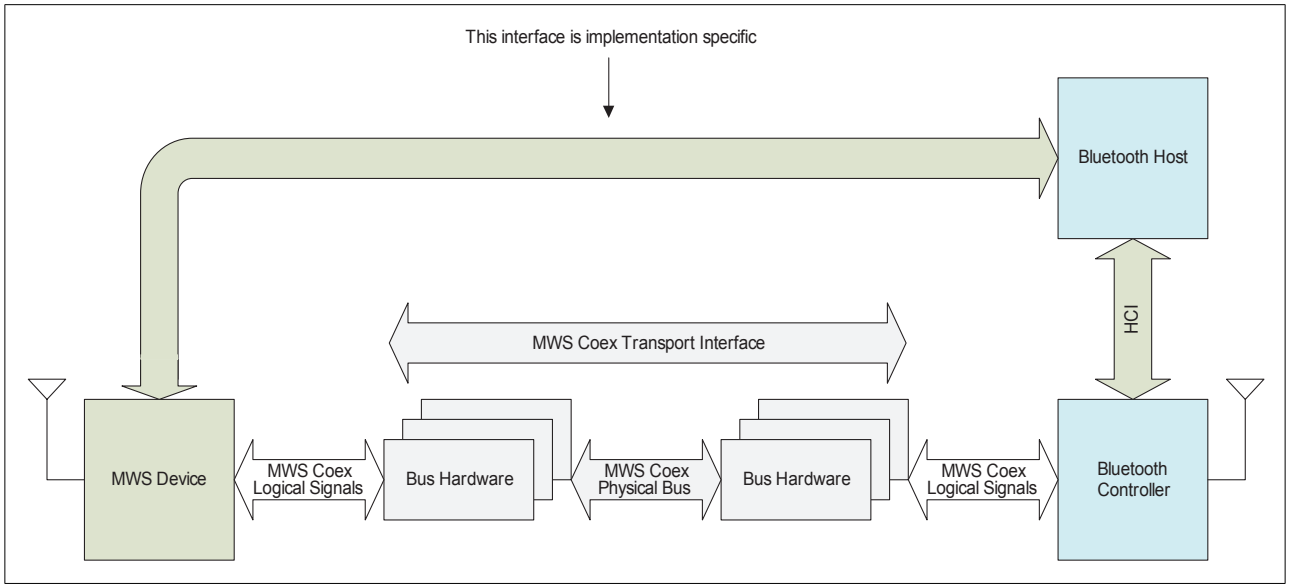

Figure 1.1: Coexistence signaling/messaging architecture

MWS Coexistence logical signaling is designed to enable a standard interface to allow an MWS device and a Bluetooth Controller to exchange information and support cooperative coexistence.

MWS Coexistence logical signaling defines a set of signals between the collocated Bluetooth Controller and MWS device. Those signals carry time critical, real-time information such as the start point of an MWS frame. The coexistence logical signaling architecture also includes a transparent data messaging mechanism to enable passing of information between the MWS device and Bluetooth Controller when such information cannot tolerate the long latency (tens of milliseconds) of the signaling path via the Bluetooth Host.

2 LOGICAL INTERFACE

2.1 Coexistence signals

Table 2.1 defines the logical signals. These logical signals assist in time alignment, protecting the MWS device and the Bluetooth Controller from mutual interference, thus maximizing the usability of the Bluetooth radio.

Name	Direction	Description
FRAME_SYNC	MWS → Bluetooth	See Section 2.1.1
MWS_RX	MWS → Bluetooth	See Section 2.1.2
BLUETOOTH_RX_PRI	Bluetooth → MWS	See Section 2.1.3
BLUETOOTH_TX_ON	Bluetooth → MWS	See Section 2.1.4
MWS_PATTERN	MWS → Bluetooth	See Section 2.1.5
MWS_TX	MWS → Bluetooth	See Section 2.1.6
802_RX_PRI	Bluetooth → MWS	See Section 2.1.7
802_TX_ON	Bluetooth → MWS	See Section 2.1.8
MWS_INACTIVITY_DURATION	MWS → Bluetooth	See Section 2.1.9
MWS_SCAN_FREQUENCY	MWS → Bluetooth	See Section 2.1.10

Table 2.1: Coexistence signals

The first 8 of these (FRAME_SYNC, MWS_RX, BLUETOOTH_RX_PRI, BLUETOOTH_TX_ON, MWS_PATTERN, MWS_TX, 802_RX_PRI, and 802_TX_ON) are also referred to as the "real-time coexistence signals".

Many of the signals have associated parameters, which are configured by the Bluetooth Host using HCI commands. There is no requirement for signals that are used internally to be connected to an external interface, although testing requires external control of the FRAME_SYNC signal. For example, a combo-device that integrates a Bluetooth Controller and an MWS radio together does not need to bring out the coexistence signals.

Section 2.2 provides recommended values for the defined offset and jitter parameters.

2.1.1 FRAME_SYNC

The FRAME_SYNC signal is sent by the MWS device to indicate the time of the beginning of MWS frames according to the MWS network timing. It provides the anchor point for the Bluetooth Controller to properly align Bluetooth transmission and reception activity with the MWS network frame structure. The time when FRAME_SYNC is sent

over the transport, adjusted for MWS_Frame_Sync_Assert_Offset, indicates the start time of the first Period_Duration parameter in the external frame configuration, which can be set using the HCI_Set_External_Frame_Configuration command.

The MWS device will inform the Bluetooth Controller about changes to the layout and timing of the MWS frame; e.g., by issuing new HCI_Set_External_Frame_Configuration commands.

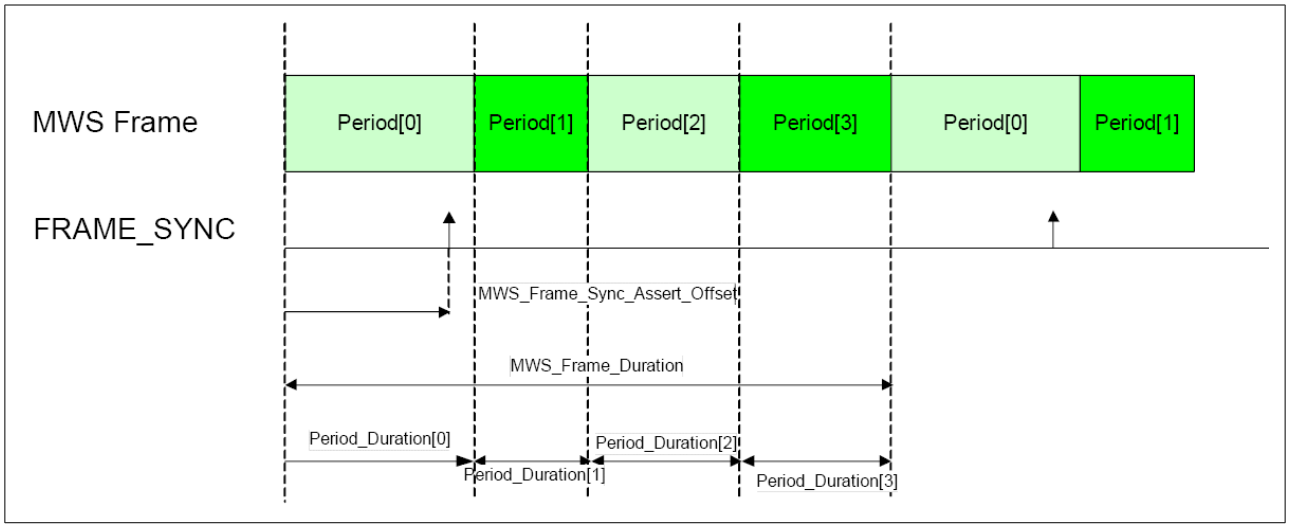

Figure 2.1: Illustration of FRAME_SYNC

2.1.2 MWS_RX

The MWS_RX signal is sent by the MWS device to indicate that an MWS reception is occurring and to request that the Bluetooth Controller cease ongoing transmission and not start a new transmission. The Bluetooth Controller can occasionally disregard the MWS_RX signal for critical transmissions.

The MWS RX signal should be de-asserted at the time an MWS device stops actively receiving. If there are multiple distinct periods of reception within an MWS downlink duration, the signal may stay asserted until the last period has finished receiving.

2.1.3 BLUETOOTH_RX_PRI

The BLUETOOTH_RX_PRI signal is used by the Bluetooth Controller to request that the MWS device cease its transmission and/or refrain from starting a transmission because the Bluetooth Controller is expecting a high priority reception.

The signal should be used minimally by the Bluetooth system so as not to adversely affect the MWS system. There is no guarantee that the MWS device will honor the signal and not transmit or abort an ongoing transmission.

2.1.4 BLUETOOTH_TX_ON

The BLUETOOTH_TX_ON signal is sent by the Bluetooth Controller to indicate that it is actively transmitting.

2.1.5 MWS_PATTERN

The MWS_PATTERN signal is sent by the MWS device to inform the Bluetooth Controller which MWS_PATTERN is in use.

Up to three different MWS_PATTERNs can be selected: 0, 1, and 2. The MWS device may indicate that the MWS_PATTERN has not changed by setting it to 3. The definitions of the patterns are communicated to the Bluetooth Controller (e.g., by using the HCI_Set_MWS_PATTERN_Configuration HCI command). If the pattern is not currently configured, the behaviour is equivalent to setting a pattern that allows unrestricted activity by the Bluetooth Controller.

At the start of each MWS Frame, as defined by the FRAME_SYNC signal plus the MWS_Frame_Sync_Assert_Offset, the most recent MWS_PATTERN value takes effect as follows.

- If it is 3, the current pattern continues in use.
- If it is the index of the current pattern, then that pattern is restarted.
- Otherwise the indicated pattern is started.

2.1.6 MWS_TX

The MWS_TX signal is sent by the MWS device to indicate its transmission state.

The signal should be asserted at the beginning of an MWS transmission and de-asserted at the end of a transmission. If there are multiple transmission periods during an uplink frame, the signal may stay asserted until the end of the last transmission period.

2.1.7 802_TX_ON

Bluetooth technology and 802.11 may be collocated and share an interface to coordinate access to the 2.4 GHz ISM band.

The 802_TX_ON is used by the 802.11 device to indicate the state of the 802.11 transmission.

Interference generated by 802.11 to the MWS device will not necessarily be distinguishable from interference created by Bluetooth transmissions.

This signal allows the MWS device to distinguish the interference generated by 802.11 transmissions from the interference generated by the Bluetooth transmissions. The MWS device can use that information to optimize its channel access.

2.1.8 802_RX_PRI

This signal requests that the MWS device stop or refrain from any transmission because the WLAN device collocated with the Bluetooth Controller is expecting a high priority reception.

The signal should be used minimally by the 802.11 system so as not to adversely affect the MWS system. There is no guarantee that the MWS device will honor the signal and not transmit or abort an ongoing transmission.

2.1.9 MWS_INACTIVITY_DURATION

The MWS_INACTIVITY_DURATION signal provides the time duration until the MWS device is active again. Subsequent MWS_INACTIVITY_DURATION signals override previously sent time durations.

MWS_INACTIVITY_DURATION may be set to zero (i.e. cancel), infinite, or a positive finite duration. The transport layer defines the value for infinite duration and the set of finite durations available.

2.1.10 MWS_SCAN_FREQUENCY

The MWS_SCAN_FREQUENCY signal provides an index to a table of RF frequencies during MWS scan operation. If the table is not currently configured, then the behavior during MWS scan operation is vendor-specific.

The MWS device signals MWS_SCAN_FREQUENCY if it starts an inter-frequency scan.

Setting MWS_SCAN_FREQUENCY to a non-zero value indicates the start of the MWS scan period. Setting MWS_SCAN_FREQUENCY to zero indicates the end of the scan period.

The Bluetooth Controller should avoid any transmissions that can interfere with the scan while a scan is active. The Bluetooth Controller can occasionally disregard the signal for critical transmissions.

2.2 Tolerances for offsets and jitter

This section lists the recommended tolerances for the signal assertion and de-assertion offsets and jitter for those signals.

Note: The transmitting side should use a value within the range and the receiving side should accept any value within the range and may accept other values.

An offset is a static advance notification or delay between the real physical event and the time when the corresponding signal is issued.

Jitter is variation in the timing of each signal from ideal timing.

Signals that are turned on and off around a period of time have specified values for both assertion and de-assertion offsets and jitter. Signals that represent a single event at a single instant in time have only assertion offset and jitter timing specified.

All jitter values are given as an unsigned value representing the maximum allowable jitter in positive and negative directions. De-assertion and MWS_Frame_Sync_Assert_Offset may be negative (i.e., signal is asserted before the event) or positive (i.e., signal is asserted after the event). All other assertion signals should be negative (i.e., signal is issued before the event).

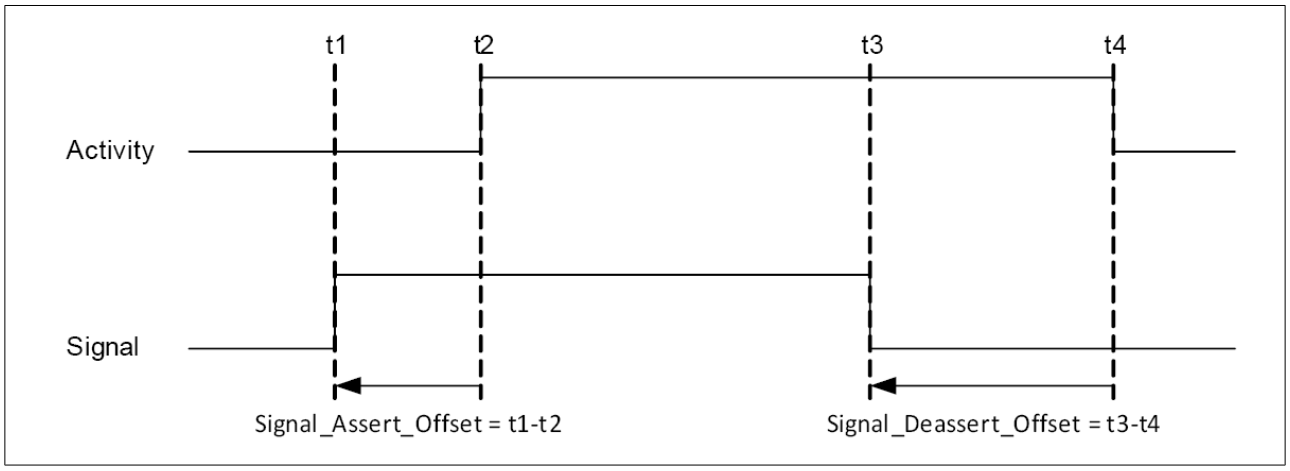

Figure 2.2: Signal with negative Assert Offset and negative De-assert Offset

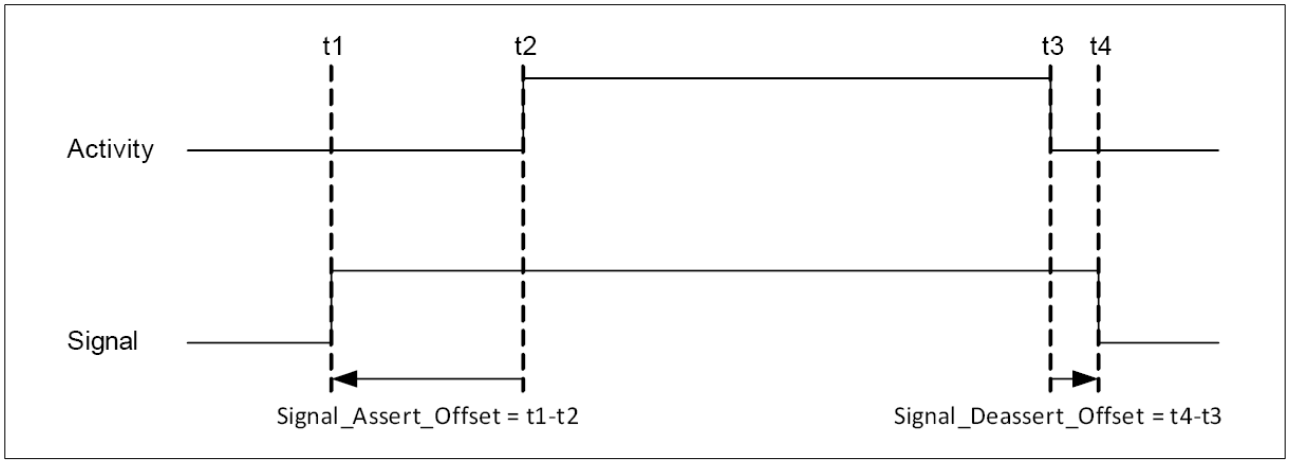

Figure 2.3: Signal with negative Assert Offset and positive De-assert Offset

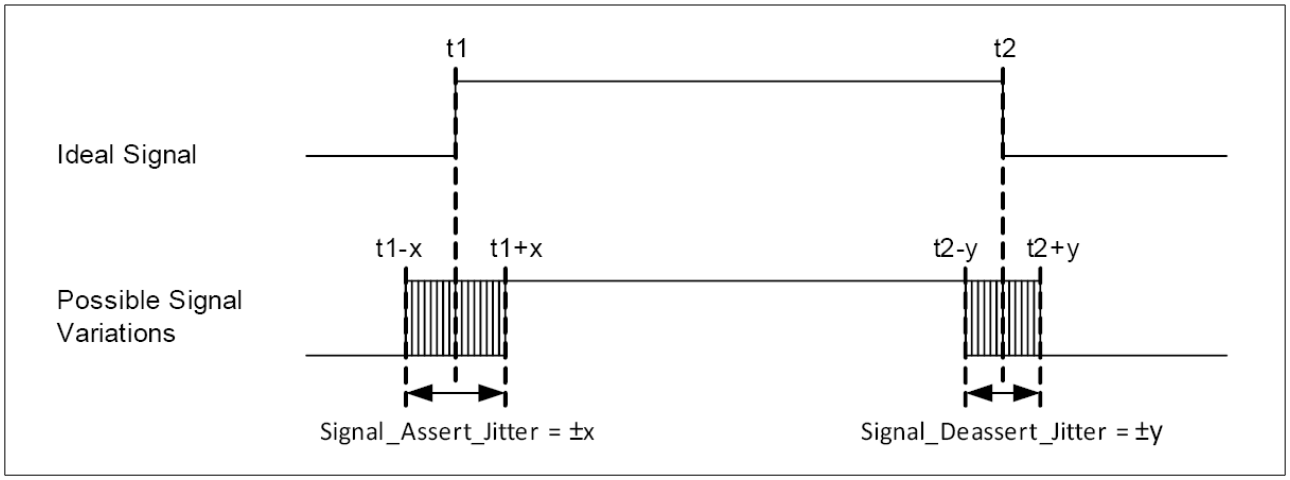

Figure 2.4: Signal assertion and de-assertion jitter

Parameter	Earliest	Latest
MWS_Frame_Sync_Assert_Offset	-MWS_Frame_Duration	+MWS_Frame_Duration
MWS_Rx_Assert_Offset	-2 ms	-20 µs
MWS_Rx_Deassert_Offset	-2 ms	0
MWS_Tx_Assert_Offset	-2 ms	0
MWS_Tx_Deassert_Offset	-2 ms	0
MWS_Pattern_Assert_Offset	0	+MWS_Frame_Duration
MWS_Inactivity_Duration_Assert_Offset	0	+MWS_Frame_Duration
MWS_Scan_Frequency_Assert_Offset	-2 ms	-20 µs
Bluetooth_Rx_Priority_Assert_Offset	-1 ms	0
Bluetooth_Rx_Priority_Deassert_Offset	-1 ms	0
802_Rx_Priority_Assert_Offset	-1 ms	0
802_Rx_Priority_Deassert_Offset	-1 ms	0
Bluetooth_Tx_On_Assert_Offset	-100 µs	0

Wireless Coexistence Signaling
And Interfaces
Part B

WIRELESS COEXISTENCE INTERFACE 1 (WCI-1) TRANSPORT SPECIFICATION

This Part specifies the MWS Wireless Coexistence Interface 1 (WCI-1) Transport Interface between the Bluetooth Controller and an MWS device.

CONTENTS

1 INTRODUCTION

This Part of the specification describes the MWS Wireless Coexistence Interface 1 (WCI-1) Transport for a Bluetooth Controller. It provides a half-duplex UART carrying logical signals framed as UART characters. Only the TXD and RXD UART signals are used.

Note: The physical layers for WCI-1 and WCI-2 (see [Vol 7] Part C) differ but the transport layers are identical.

2 PHYSICAL LAYER

The WCI-1 physical layer multiplexes the UART TXD and RXD onto a single wire, using drive strengths to resolve contention. The MWS device uses direct drive to transmit its signals, while the Bluetooth Controller uses a pull up / pull down drive to transmit its signals. The configuration is illustrated in Figure 2.1.

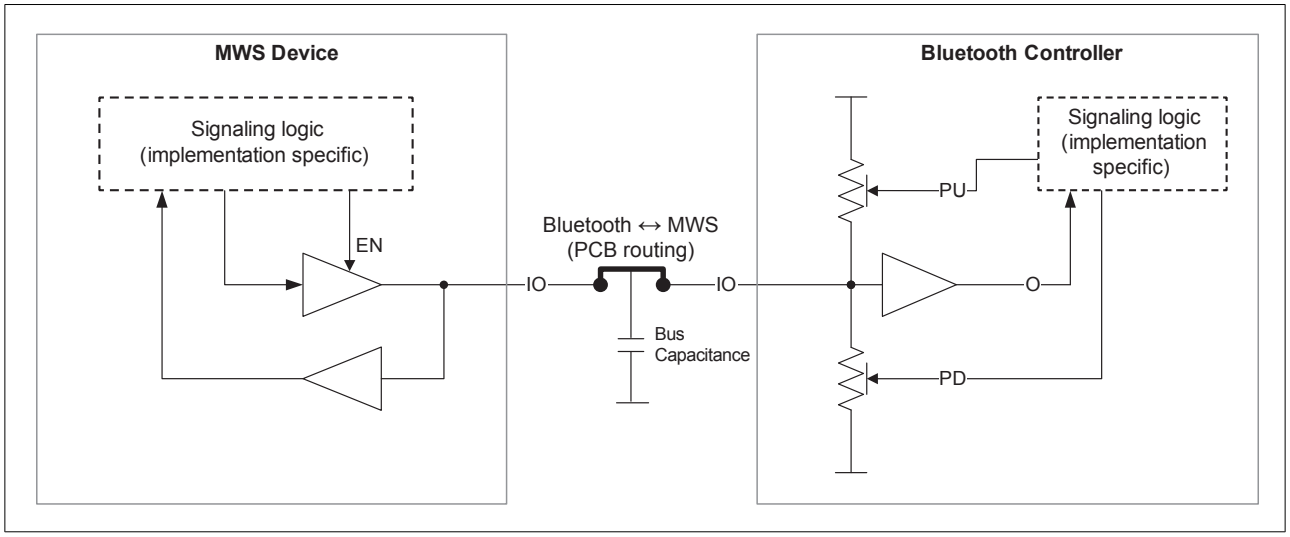

Figure 2.1: WCI-1 physical interface

A high voltage on the wire shall be interpreted as a logical 1 and a low voltage shall be interpreted as a logical 0. The actual voltage levels are vendor specific.

The MWS device output buffer shall be in the high impedance state when it is not transmitting. The Bluetooth Controller shall be in the pulled-up state when it is not transmitting.

The MWS device may transmit at any time, using the waveform illustrated in Figure 2.2.

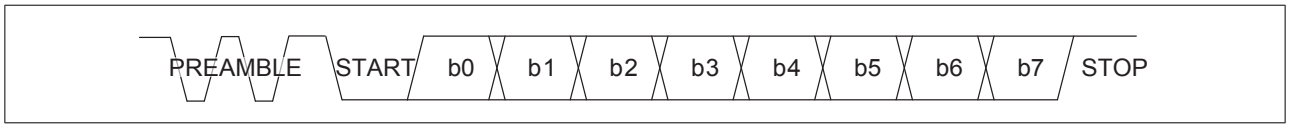

Figure 2.2: UART waveform for MWS-to-Bluetooth signals

Every MWS-to-Bluetooth message shall be preceded by a preamble, which consists of 5 bits ‘01011’ (in transmission order). The preamble is sent at a baud rate that is at least twice the baud rate of Bluetooth-to-MWS signals[1]. The nominal drive strength for the preamble should be targeted at no more than 250 Ω equivalent output

[1]The preamble baud rate should be one that is supported by the underlying UART of the Bluetooth device.

resistance. The Bluetooth Controller shall be able to detect the preamble and go into the reception mode to receive the message that follows. If the Bluetooth Controller detects a preamble while it is transmitting, it shall stop the transmission and go into the reception mode. After completion of the reception, it may retransmit the message that was interrupted.

When the Bluetooth Controller is not in the reception mode, it may transmit a message using the pull up / pull down mechanism. The nominal pull strength should be targeted at 4 kΩ ± 1 kΩ equivalent resistance for both pull up and pull down. The Bluetooth-to-MWS waveform is illustrated in Figure 2.3.

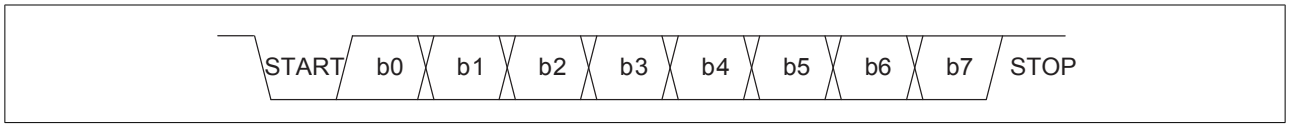

Figure 2.3: UART waveform for Bluetooth-to-MWS signals

2.1 Physical signal specifications

Table 2.1 and Table 2.2 provide more complete specifications for the physical signals. They are provided as a reference to device makers:

Symbol	Parameter	Condition	Value	
			Min	Max
V_{IL}	Low level input voltage	V_{DD} in the range 1.8 V to 2.5 V[1]	-0.5 V	0.2 × V_{DD}
V_{IH}	High level input voltage	V_{DD} in the range 1.8 V to 2.5 V[1]	0.8 × V_{DD}	V_{DD} + 0.5 V
V_{OL}	Low level output voltage (with extra pull high R_B)	V_{DD} in the range 1.8 V to 2.5 V[1] R_B = 2.5 kΩ	0 V	0.1 × V_{DD}
V_{OH}	High level output voltage (with extra pull low R_B)	V_{DD} in the range 1.8 V to 2.5 V[1] R_B = 2.5 kΩ	0.9 × V_{DD}	V_{DD}
C_{IO}	Capacitance for I/O	*none*	0 F	5 pF
CB	Capacitive load for bus	*none*	0 F	10 pF
R_{ON}	Turn on impedance	*none*	0 Ω	250 Ω
T_R	Rise time (10% to 90% swing time, with extra pull low R_B and capacitive load C_L = C_B + other IO)	R_B = 2.5 kΩ C_L = 15 pF	0 s	50 ns

Symbol	Parameter	Condition	Value	
			Min	Max
T_F	Fall time (90% to 10% swing time, with extra pull high R_B and capacitive load $C_L = C_B$ + other IO)	R_B = 2.5 kΩ C_L = 15 pF	0 s	50 ns
CLK_j	Clock jitter	*none*	*none*	1%

Table 2.1: WCI-1 UART physical signal specification for the MWS device

Symbol	Parameter	Condition	Value	
			Min	Max
V_{IL}	Low level input voltage	V_{DD} in the range 1.8 V to 2.5 V[1]	-0.5 V	0.2 × V_{DD}
V_{IH}	High level input voltage	V_{DD} in the range 1.8 V to 2.5 V[1]	0.8 × V_{DD}	V_{DD} + 0.5 V
V_{OL}	Low level output voltage	V_{DD} in the range 1.8 V to 2.5 V[1]	0 V	0.1 × V_{DD}
V_{OH}	High level output voltage	V_{DD} in the range 1.8 V to 2.5 V[1]	0.9 × V_{DD}	V_{DD}
C_{IO}	Capacitance for I/O	*none*	0 F	5 pF
CB	Capacitive load for bus	*none*	0 F	10 pF
R_P	Pull up/pull down resistance	*none*	3 kΩ	5 kΩ
T_R	Rise time (10% to 90% swing time, with capacitive load $C_L = C_B$ + other IO)	C_L = 15 pF	0 s	220 ns
T_F	Fall time (90% to 10% swing time, with capacitive load $C_L = C_B$ + other IO)	C_L = 15 pF	0 s	220 ns
CLK_j	Clock jitter	*none*	*none*	1%

Table 2.2: WCI-1 UART physical signal specification for the Bluetooth Controller

Notes:

1. The voltage levels are vendor specific. Table 2.1 and Table 2.2 do not cover all possible ranges of voltage for all devices, nor is it required that a single device be able to operate in the full range indicated here.
2. The values in these tables are based on a MWS-to-Bluetooth baud rate of 4 megabits per second and a Bluetooth-to-MWS baud rate of 1 megabit per second, in each case ±1%. The actual baud rates used are vendor-specific.

3 TRANSPORT LAYER

The transport layer defines the mapping of the logical coexistence signals (see [Vol 7] Part A) onto the physical transport channel.

The 8-bit UART character is divided into two portions with three bits for the message type indicator and five bits for the message body. The bit with index 0 is the LSB and shall be transmitted first.

6	Vendor-specific	
7	Vendor-specific	

Table 3.2: Message types

The logical coexistence signals are listed in Table 3.3.

Signal Name	Description
FRAME_SYNC	See [Vol 7] Part A, Section 2.1.1
MWS_RX	See [Vol 7] Part A, Section 2.1.2
BLUETOOTH_RX_PRI	See [Vol 7] Part A, Section 2.1.3

Signal Name	Description
BLUETOOTH_TX_ON	See [Vol 7] Part A, Section 2.1.4
MWS_PATTERN	See [Vol 7] Part A, Section 2.1.5
MWS_TX	See [Vol 7] Part A, Section 2.1.6
802_TX_ON	See [Vol 7] Part A, Section 2.1.7
802_RX_PRI	See [Vol 7] Part A, Section 2.1.8
MWS_INACTIVITY_DURATION	See [Vol 7] Part A, Section 2.1.9
MWS_SCAN_FREQUENCY	See [Vol 7] Part A, Section 2.1.10

Table 3.3: Coexistence signals

3.1.1 Real-time Signal message (Type 0)

The Real-time Signal message is used to transport the real-time coexistence signals (see [Vol 7] Part A) over the WCI-1 transport interface.

The Real-time Signal message conveys all the real-time coexistence signals in one message. The time reference point for the Real-time Signal message is the end of MSG[4] (i.e. the transition to the STOP bit).

Two Real-time Signal messages are defined, one from the Bluetooth Controller to the MWS device and another from the MWS device to the Bluetooth Controller.

3.1.2 Transport Control message (Type 1)

The Transport Control message can request state information from the MWS device's coexistence interface.

MSG[0]	MSG[1]	MSG[2]	MSG[3]	MSG[4]
RESEND_REAL_TIME	RFU	RFU	RFU	RFU

Table 3.6: Transport Control message

Signal Name	Description
RESEND_REAL_TIME	This bit is set if a device wants to get a status update of the real-time coexistence signals. The signal is usually used after wake-up from sleep of the transport interface. If the receiving device's transport interface is awake it shall send a Real-time message with the current status of the real-time coexistence signals within 4 UART character periods. If the signal is not received within 4 UART character periods the device is considered asleep.

Table 3.7: Transport Control signals

3.1.3 Transparent Data message (Type 2)

The Transparent Data message can be used to exchange non-time critical signals between the MWS device and the Bluetooth Controller. The interface does not guarantee the delivery of a message. Protocol and content of the message are vendor specific.

Each octet to be transmitted is split into two 4-bit parts, called "nibbles". The least significant nibble consists of bits 0 to 3 of the octet and shall be transmitted first. The most significant nibble consists of bits 4 to 7 of the octet and shall be transmitted after the least significant nibble.

A least significant nibble shall be discarded if the next nibble is a least significant nibble. A most significant nibble shall only be accepted if the preceding nibble was a least significant nibble.

Table 3.9: Transparent Data bits

3.1.4 MWS Inactivity Duration message (Type 3)

The MWS Inactivity Duration message is used to send the MWS_INACTIVITY_DURATION signal from the MWS device to the Bluetooth Controller.

The message is sent at the beginning of an MWS inactivity period.

MSG[0]	MSG[1]	MSG[2]	MSG[3]	MSG[4]
DURATION[0]	DURATION[1]	DURATION[2]	DURATION[3]	DURATION[4]

Table 3.10: MWS Inactivity Duration message

The MWS Inactivity Duration is encoded in 5 bits. DURATION is unsigned.

When DURATION = 0, MWS_INACTIVITY_DURATION is cancelled.

When DURATION = 31, MWS_INACTIVITY_DURATION is infinite.

Otherwise, MWS_INACTIVITY_DURATION is given by the formula:

MWS_INACTIVITY_DURATION = DURATION × 5 ms

3.1.5 MWS Scan Frequency message (Type 4)

The MWS Scan Frequency message is used to send the MWS_SCAN_FREQUENCY signal from the MWS device to the Bluetooth Controller.

Part C

WIRELESS COEXISTENCE INTERFACE 2 (WCI-2) TRANSPORT SPECIFICATION

This Part specifies the MWS Wireless Coexistence Interface 2 (WCI-2) Transport Interface between the Bluetooth Controller and an MWS device.

CONTENTS

1 INTRODUCTION

This Part of the specification describes the MWS Wireless Coexistence Interface 2 (WCI-2) Transport Interface for a Bluetooth Controller.

Note: The physical layers for WCI-2 and WCI-1 (see [Vol 7] Part B) differ but the transport layers are identical.

2 PHYSICAL LAYER

The WCI-2 Transport is based on a standard full duplex UART carrying logical signals framed as UART characters. Only the TXD and RXD UART signals are used. The interface supports multiple logical channels.

The messaging is based on a standard UART format.

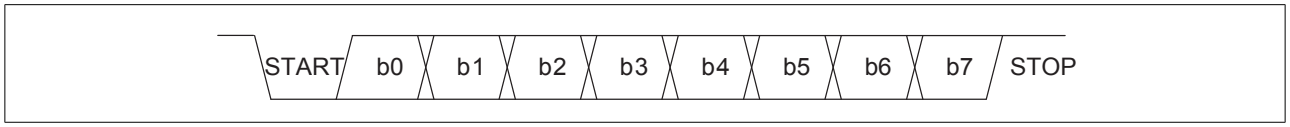

Figure 2.1: UART waveform

The UART signals shall be connected in a null-modem fashion; i.e. the local TXD shall be connected to the remote RXD and vice versa.

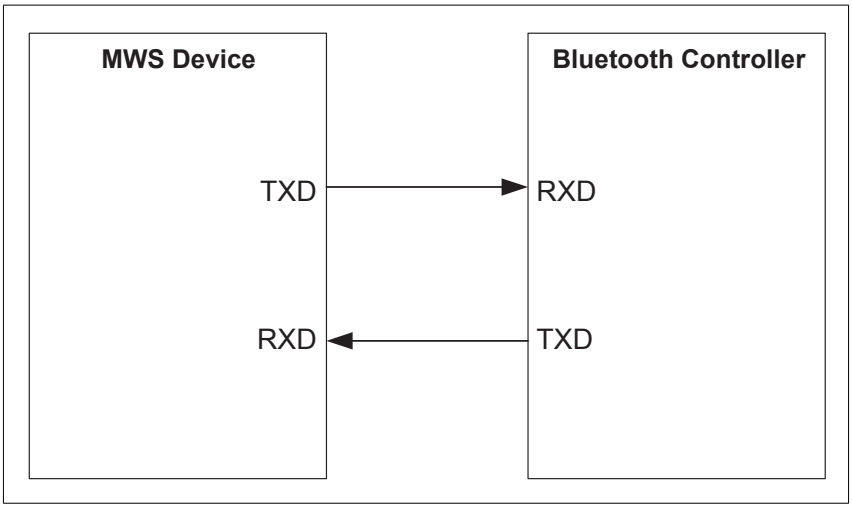

Figure 2.2: WCI-2 physical interface

3 TRANSPORT LAYER

The transport layer defines the mapping of the logical signals (see [Vol 7] Part A) onto the physical transport channel.

The 8 bit UART character is divided into two portions with three bits for the message type indicator and five bits for the message body. The bit with index 0 is the LSB and shall be transmitted first.
