Bluetooth Core Specification

***Bluetooth*® Specification**

- **Version:** v6.1
- **Version Date:** 2025-04-29
- **Prepared By:** Core Specification Working Group

Abstract

This specification defines the technologies required to create interoperable Bluetooth devices.

Disclaimer and Copyright Notice

Use of this specification is your acknowledgement that you agree to and will comply with the following notices and disclaimers. You are advised to seek appropriate legal, engineering, and other professional advice regarding the use, interpretation, and effect of this specification.

Use of Bluetooth specifications by members of Bluetooth SIG is governed by the membership and other related agreements between Bluetooth SIG and its members, including those agreements posted on Bluetooth SIG's website located at www.bluetooth.com. Any use of this specification by a member that is not in compliance with the applicable membership and other related agreements is prohibited and, among other things, may result in (i) termination of the applicable agreements and (ii) liability for infringement of the intellectual property rights of Bluetooth SIG and its members. This specification may provide options, because, for example, some products do not implement every portion of the specification. All content within the specification, including notes, appendices, figures, tables, message sequence charts, examples, sample data, and each option identified is intended to be within the bounds of the Scope as defined in the Bluetooth Patent/Copyright License Agreement ("PCLA"). Also, the identification of options for implementing a portion of the specification is intended to provide design flexibility without establishing, for purposes of the PCLA, that any of these options is a "technically reasonable non-infringing alternative."

Use of this specification by anyone who is not a member of Bluetooth SIG is prohibited and is an infringement of the intellectual property rights of Bluetooth SIG and its members. The furnishing of this specification does not grant any license to any intellectual property of Bluetooth SIG or its members. THIS SPECIFICATION IS PROVIDED "AS IS" AND BLUETOOTH SIG, ITS MEMBERS AND THEIR AFFILIATES MAKE NO REPRESENTATIONS OR WARRANTIES AND DISCLAIM ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING ANY WARRANTIES OF MERCHANTABILITY, TITLE, NON-INFRINGEMENT, FITNESS FOR ANY PARTICULAR PURPOSE, OR THAT THE CONTENT OF THIS SPECIFICATION IS FREE OF ERRORS. For the avoidance of doubt, Bluetooth SIG has not made any search or investigation as to third parties that may claim rights in or to any specifications or any intellectual property that may be required to implement any specifications and it disclaims any obligation or duty to do so.

TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, BLUETOOTH SIG, ITS MEMBERS AND THEIR AFFILIATES DISCLAIM ALL LIABILITY ARISING OUT OF OR RELATING TO USE OF THIS SPECIFICATION AND ANY INFORMATION CONTAINED IN THIS SPECIFICATION, INCLUDING LOST REVENUE, PROFITS, DATA OR PROGRAMS, OR BUSINESS INTERRUPTION, OR FOR SPECIAL, INDIRECT, CONSEQUENTIAL, INCIDENTAL OR PUNITIVE DAMAGES, HOWEVER CAUSED AND REGARDLESS OF THE THEORY OF LIABILITY, AND EVEN IF

BLUETOOTH SIG, ITS MEMBERS OR THEIR AFFILIATES HAVE BEEN ADVISED OF THE POSSIBILITY OF THE DAMAGES.

Products equipped with Bluetooth wireless technology ("Bluetooth Products") and their combination, operation, use, implementation, and distribution may be subject to regulatory controls under the laws and regulations of numerous countries that regulate products that use wireless non-licensed spectrum. Examples include airline regulations, telecommunications regulations, technology transfer controls, and health and safety regulations. You are solely responsible for complying with all applicable laws and regulations and for obtaining any and all required authorizations, permits, or licenses in connection with your use of this specification and development, manufacture, and distribution of Bluetooth Products. Nothing in this specification provides any information or assistance in connection with complying with applicable laws or regulations or obtaining required authorizations, permits, or licenses.

Bluetooth SIG is not required to adopt any specification or portion thereof. If this specification is not the final version adopted by Bluetooth SIG's Board of Directors, it may not be adopted. Any specification adopted by Bluetooth SIG's Board of Directors may be withdrawn, replaced, or modified at any time. Bluetooth SIG reserves the right to change or alter final specifications in accordance with its membership and operating agreements.

Version History

The Version History is shown in [Vol 0] Part C.

Acknowledgments

The persons who contributed to this specification are listed in [Vol 0] Part C.

Web Site

This specification can also be found on the official Bluetooth web site:

Covered Core Package Version: v6.1

Version Date: 2025-04-29

Consolidated Table Of Contents, Acknowledgments, & Core Configurations Part A

CONSOLIDATED TABLE OF CONTENTS

This table of contents (TOC) covers the entire specification.

In addition, each Part of a volume is preceded by a detailed TOC.

THE BLUETOOTH CORE SPECIFICATION CONSOLIDATED TABLE OF CONTENTS

In the following Consolidated Table of Contents:

- The TOC for each Volume starts at the top of a page.
- The Volume name in red is followed by the Volume number in black.
- A Volume contains one or more Parts (A, B, etc.); each Part can be viewed independently and has its own TOC.
- Red or blue text on the following pages provides hypertext links to the indicated sections.

VERSION HISTORY AND ACKNOWLEDGMENTS

CONTENTS

1 VERSION HISTORY

Beginning with v1.2 of the Core System Package the core Bluetooth specification documents, protocols and profiles were transferred to a new partitioning comprising volumes and individual profile specifications are each contained in an individual document instead of the two volumes (Core and Profiles) used in v1.1.

For more detailed information about changes between versions published before v1.2, see Appendix I “Revision History” in v1.1.

1.1 [Vol 0] Consolidated TOC, Acknowledgments, & Core Configurations

Rev	Date	Comments
6.1	2025-05-05	Incorporated errata; see [Vol 1] Part C, Section 15.3. Adopted by the Bluetooth SIG Board of Directors.
6.0	2024-08-27	Incorporated errata; see [Vol 1] Part C, Section 14.3. Replaced the Compliance Requirements in Part B with Core Configurations (see [Vol 0] Part D). Adopted by the Bluetooth SIG Board of Directors.
5.4	2023-01-31	Incorporated errata; see [Vol 1] Part C, Section 13.3. Updated the requirements for the Basic Rate Core Configuration, Low Energy Core Configuration, and Basic Rate and Low Energy Combined Core Configuration. Adopted by the Bluetooth SIG Board of Directors.
5.3	2021-07-13	Incorporated errata; see [Vol 1] Part C, Section 12.3. Updated the definition of the Bluetooth Host and Controller Subsystem Products. Updated the requirements for the Low Energy Core Configuration and the Basic Rate and Low Energy Combined Core Configuration. Removed the High Speed Core Configuration. Adopted by the Bluetooth SIG Board of Directors.
5.2	2019-12-31	Incorporated errata; see [Vol 1] Part C, Section 11.3. Removed references to deprecated and withdrawn versions of the Core Specification. Renamed Volumes. Updated the definition of the Bluetooth Component Product type. Adopted by the Bluetooth SIG Board of Directors.
5.1	2019-01-21	Incorporated errata; see [Vol 1] Part C, Section 10.4. Incorporated CSA6: see [Vol 0] Part B, Section 3.1.2.3 and [Vol 0] Part B, Section 3.1.3 (deleted by erratum 25429).
5.0	2016-12-06	Incorporated errata
4.2	2014-12-02	Incorporated errata

Rev	Date	Comments
4.1	2013-12-03	Clarifications for allowable complementary subsystems.
4.0	2010-06-30	Updated to support Low Energy, ATT, and GATT support for BR/EDR, and to enable High Speed Controller Subsystems.
3.0 + HS	2009-04-21	Updated to include support for the Alternative MAC/PHY feature and High Speed Core Configuration.
v2.1 + EDR	2007-07-26	No content changes. Updates to the Table of Contents.
v2.0 + EDR	2004-10-15	This version of the specification is intended to be a separate Bluetooth Specification that has all the functional characteristics of the v1.2 Bluetooth Specification that adds the Enhanced Data Rate (EDR) feature which required changes to Volume 0, Part A, Consolidated Table of Contents.
v1.2	2003-11-05	This Part was moved from the Core volume. No content changes have been made to this document since v1.1.

1.2 [Vol 1] Architecture, Change History, and Conventions

Rev	Date	Comments
6.1	2025-05-05	Updates to language conventions. Incorporated errata; see [Vol 1] Part C, Section 15.3. Adopted by the Bluetooth SIG Board of Directors.
6.0	2024-08-27	Updated to include architectural aspects of new features added. Incorporated errata; see [Vol 1] Part C, Section 14.3. Vol 1, Part D merged into Vol 0, Part D. Adopted by the Bluetooth SIG Board of Directors.
5.4	2023-01-31	Updated to include architectural aspects of new features added. Incorporated errata; see [Vol 1] Part C, Section 13.3. Adopted by the Bluetooth SIG Board of Directors.
5.3	2021-07-13	Updated to include architectural aspects of new features added. Incorporated errata; see [Vol 1] Part C, Section 12.3. Updated terminology to remove inappropriate language. Alternate MAC/PHY feature was deprecated and removed. Adopted by the Bluetooth SIG Board of Directors.
5.2	2019-12-31	Updated to include architectural aspects of new features added. Incorporated errata; see [Vol 1] Part C, Section 11.3. Vol 2, Part D moved to Vol 1, Part F. Removed references to deprecated and withdrawn versions of the Core Specification. Added definition of Resolving List. Adopted by the Bluetooth SIG Board of Directors.
5.1	2019-01-21	Updated to include architectural aspects of new features added. Incorporated errata; see [Vol 1] Part C, Section 10.4. Incorporated CSA6; see [Vol 1] Part A, Section 6.6 and [Vol 0] Part D, Table 5.1 (this was formerly [Vol 1] Part D, Table 1.3 but was moved by erratum 25429).

Rev	Date	Comments
5.0	2016-12-06	Updated to include architectural aspects of new features added. Incorporated errata.
4.2	2014-12-02	Updated to include architectural aspects of new features added. Incorporated errata.
4.1	2013-12-03	Updated to include architectural aspects of new features added to CSA2, CSA3, CSA4 and v4.1.
4.0	2010-06-30	Updated to support Low Energy. and ATT and GATT over BR/EDR.
3.0 + HS	2009-04-21	Updated to integrate the Alternate MAC/PHY and Unicast Connectionless Data features.
v2.1 + EDR	2007-07-26	Added definitions for new features: Encryption Pause and Resume, Erroneous Data reporting, Extended Inquiry Response, Link Supervision Timeout Event, Packet Boundary Flag, Secure Simple Pairing, Sniff Subrating.
v2.0 + EDR	2004-10-15	This version of the specification is intended to be a separate Bluetooth Specification that has all the functional characteristics of the v1.2 Bluetooth Specification that adds the Enhanced Data Rate (EDR) feature which incorporates changes to Volume 1, Part B, Acronyms and Abbreviations.
v1.2	2003-11-05	New volume with informational content. This volume will always be updated in parallel with the Core System volumes.

1.3 [Vols 2, 3, 5, 6 & 7] Controllers and Host

Rev	Date	Comments
6.1	2025-05-05	• Incorporated errata; see [Vol 1] Part C, Section 15.3. Adopted by the Bluetooth SIG Board of Directors.
6.0	2024-08-27	• New features added in 6.0; see [Vol 1] Part C, Section 14.1. • Incorporated errata; see [Vol 1] Part C, Section 14.3. Adopted by the Bluetooth SIG Board of Directors.
5.4	2023-01-31	• New features added in 5.4; see [Vol 1] Part C, Section 13.1. • Incorporated errata; see [Vol 1] Part C, Section 13.3. Adopted by the Bluetooth SIG Board of Directors.
5.3	2021-07-13	• New features added in 5.3; see [Vol 1] Part C, Section 12.1 • Incorporated errata; see [Vol 1] Part C, Section 12.3 • Alternate MAC/PHY feature was deprecated and removed. • Updated terminology to remove inappropriate language. Adopted by the Bluetooth SIG Board of Directors.

Rev	Date	Comments
5.2	2019-12-31	• New features added in 5.2: see [Vol 1] Part C, Section 11.1 • Incorporated erratum 11838: Encryption Key Size Updates; see [Vol 1] Part C, Section 11.2 • Incorporated other errata; see [Vol 1] Part C, Section 11.3 • Vol 2, Part D moved to Vol 1, Part F • Vol 2, Part E moved to Vol 4, Part E • Removed references to deprecated and withdrawn versions of the Core Specification Adopted by the Bluetooth SIG Board of Directors.
5.1	2019-01-21	• New features added in v5.1: see [Vol 1] Part C, Section 10.1. • Unit keys were deprecated and removed; see [Vol 1] Part C, Section 10.2 • Incorporated erratum 10734: Pairing Updates; see [Vol 1] Part C, Section 10.3 • Incorporated other errata; see [Vol 1] Part C, Section 10.4.
5.0	2016-12-06	• New features added in 5.0: – CSA 5 features (Higher Output Power) – Slot Availability Mask (SAM) – 2 Msym/s PHY for LE – LE Long Range – High Duty Cycle Non-Connectable Advertising – LE Advertising Extensions – LE Channel Selection Algorithm #2 • Park State was deprecated and removed • Errata for v2.0 + EDR, v2.1 + EDR, v3.0 + HS + 4.0 + 4.1 + 4.2 (ESR09, ESR10 and ESR11). See also [Vol 1] Part C, Section 9.4.
4.2	2014-12-02	• New features added in 4.2: – LE Data Packet Length Extension – LE Secure Connections – Link Layer Privacy – Link Layer Extended Scanner Filter Policies • Errata for v2.0 + EDR, v2.1 + EDR, v3.0 + HS + 4.0 + 4.1 (ESR08). See also [Vol 1] Part C, Section 8.2.

Rev	Date	Comments
4.1	2013-12-03	• New features added and changes made in 4.1: – CSA 2 features – CSA 3 features – CSA 4 features – Secure Connections – Train Nudging & Generalized Interlaced Scan – Low Duty Cycle Directed Advertising – 32-bit UUID Support in LE – LE Dual Mode Topology – Piconet Clock Adjustment – Removal of At Least One New Feature – LE L2CAP Connection-Oriented Channel Support – LE Privacy v1.1 – LE Link Layer Topology – LE Ping • Errata for v2.0 + EDR, v2.1 + EDR, v3.0 + HS + 4.0 (ESR05, ESR06 and ESR07)
4.0	2010-06-30	• New features added in 4.0: – Low Energy • Errata for v2.0 + EDR, v2.1 + EDR, v3.0 + HS
3.0 + HS	2009-04-21	• New features added in 3.0 + HS: – AMP Manager Protocol (A2MP) – Enhancements to L2CAP for AMP – Enhancements to HCI for AMP – Enhancements to Security for AMP – 802.11 Protocol Adaptation Layer – Enhanced Power Control – Unicast Connectionless Data – HCI Read Encryption Key Size command – Generic Test Methodology for AMP – Enhanced USB and SDIO HCI Transports • Errata for v 2.0 + EDR and v2.1 + EDR

Rev	Date	Comments
v2.1 + EDR	2007-07-26	• New features added in 2.1 + EDR: – Encryption Pause and Resume – Erroneous Data Reporting – Extended Inquiry Response – Link Supervision Timeout Changed Event – Non-Flushable Packet Boundary Flag – Secure Simple Pairing – Sniff Subrating – Security Mode 4 • Updates to IEEE language in Volume 2, Part H, Security • Errata for v2.0 + EDR
v2.0 + EDR	2004-08-01	This version of the specification is intended to be a separate Bluetooth Specification. This version was created by adding EDR and the errata.
v1.2	2003-11-05	New features added in v1.2: • Architectural overview • Faster connection • Adaptive frequency hopping • Extended SCO links • Enhanced error detection and flow control • Enhanced synchronization capability • Enhanced flow specification The Core System Package now comprises two volumes and the text has gone through a radical change both in terms of structure and nomenclature. The language is also more precise and is adapted to meet the IEEE standard. The following parts are moved from the Core System Package to other volumes or were deprecated: RFCOMM [vol 7], Object Exchange (IrDA Interoperability) [vol 8], TCS [vol 9], Interoperability Requirements for Bluetooth as a WAP Bearer [vol 6], HCI USB Transport Layer [vol 4], HCI RS232 Transport Layer [vol 4], HCI UART Transport Layer [vol 4], Bluetooth Compliance Requirements [vol 0], Optional Paging Schemes [deprecated]
1.1	2001-02-22	The specification was updated with Errata items previously published on the web site. The Bluetooth Assigned Numbers appendix was lifted out from the specification to allow continuous maintenance on the web site.

Rev	Date	Comments
1.0B	1999-12-01	The specification was updated with Errata items previously published on the web site and was revised from a linguistic point of view. The following parts were added: Interoperability Requirements for Bluetooth as a WAP Bearer, Test Control Interface, Sample Data (appendix), Bluetooth Audio (appendix), Baseband Timers (appendix) and Optional Paging Scheme (appendix)
1.0a	1999-07-26	The first version of the Bluetooth Specification published on the public web site. Added part: Bluetooth Compliance Requirements.
1.0 draft	1999-07-05	The following parts were added: Service Discovery Protocol (SDP), Telephony Control Specification (TCS), Bluetooth Assigned Numbers (appendix) and Message Sequence Charts (appendix)
0.9	1999-04-30	The following parts were added: IrDA Interoperability, HCI RS232 Transport Layer, HCI UART Transport Layer and Test Mode
0.8	1999-01-21	The following parts were added: Radio Specification, L2CAP, RFCOMM, HCI & HCI USB Transport Layer
0.7	1998-10-19	This first version only included Baseband and Link Manager Protocol

1.4 [Vol 4] Host Controller Interface

Rev	Date	Comments
6.1	2025-05-05	• New feature added in 6.1; see [Vol 1] Part C, Section 15.1. • Incorporated errata; see [Vol 1] Part C, Section 15.3. Adopted by the Bluetooth SIG Board of Directors.
6.0	2024-08-27	• New features added in 6.0; see [Vol 1] Part C, Section 14.1. • Incorporated errata; see [Vol 1] Part C, Section 14.3. Adopted by the Bluetooth SIG Board of Directors.
5.4	2023-01-31	• New features added in 5.4; see [Vol 1] Part C, Section 13.1. • Incorporated errata; see [Vol 1] Part C, Section 13.3. Adopted by the Bluetooth SIG Board of Directors.

Rev	Date	Comments
5.3	2021-07-13	• New features added in 5.3; see [Vol 1] Part C, Section 12.1 • Incorporated errata; see [Vol 1] Part C, Section 12.3 • Alternate MAC/PHY feature was deprecated and removed. • Updated terminology to remove inappropriate language. Adopted by the Bluetooth SIG Board of Directors.
5.2	2019-12-31	• New features added in 5.2: see [Vol 1] Part C, Section 11.1 • Incorporated errata; see [Vol 1] Part C, Section 11.3 • Vol 2, Part E moved to Vol 4, Part E • Added requirements for supporting HCI commands and events for BR/EDR and AMP • Removed references to deprecated and withdrawn versions of the Core Specification Adopted by the Bluetooth SIG Board of Directors.
5.1	2019-01-21	Incorporated errata; see [Vol 1] Part C, Section 10.4.
5.0	2016-12-06	Incorporated errata
4.2	2014-12-02	Incorporated errata
4.1	2013-12-03	Incorporated errata
4.0	2010-06-30	Incorporated errata
3.0 + HS	2009-04-21	Updated the USB and SDIO HCI Transport protocols for high speed, support composite BR/EDR + AMP devices, and to include errata.
v2.1 + EDR	2007-07-26	Added this volume to the specification

2 ACKNOWLEDGMENTS (UP TO V5.1)

Consolidated Table Of Contents, Acknowledgments, & Core Configurations Part D

CORE CONFIGURATIONS

This volume specifies Core Configurations for implementations based on the Bluetooth Core Specification.

CONTENTS

1 INTRODUCTION

This Part covers Core Configurations and related concepts for implementations based on the Core Specification.

A layer is one of the parts of this specification specified in the tables in Section 2. A Controller layer is any layer listed in Table 2.1 or Table 2.2. A Host layer is any layer listed in Table 2.3 or Table 2.4.

For some purposes in this Part, HCI is treated as if it were two separate layers, one only including the Upper HCI role and the other only including the Lower HCI role.

An implementation contains a complete layer if the implementation includes, for that layer, all mandatory features, all the mandatory elements of any optional feature that is included, and any features that are conditionally required. This also applies to sub-features or elements of a feature. For example, if the layer includes a requirement such as “if feature A is implemented, then feature B shall be implemented”, then any implementation of the layer that includes feature A but not all the elements of feature B is not complete.

An implementation of Bluetooth wireless technology based on the Core Specification shall include one or more complete layers of the Core Specification and may also implement one or more Bluetooth specifications that are external to the Core Specification. Such an implementation shall include all features required by dependencies between any layers included in the implementation.

Each capability of this specification shall be supported in the specified manner. This specification may provide options for design flexibility, because, for example, some products do not implement every portion of the specification. For each implementation option that is supported, it shall be supported as specified.

Using such an implementation to enable Bluetooth wireless technology end-to-end might require further integration before distribution.

2 CORE CONFIGURATIONS

A Core Configuration determines the transport and layers that an implementation shall include and any inter-layer dependency requirements that apply, as specified in other Parts of this specification.

Each implementation of a Core Configuration shall include the specific complete layers listed in the sub-section of Section 2 corresponding to that configuration. The implementation may also include other complete layers of the Core Specification and may also implement one or more Bluetooth specifications that are external to the Core Specification. It shall also implement all features required by dependencies between any layers included in the implementation. An implementation that includes all the layers of more than one Core Configuration is deemed to be an implementation of the Core Configuration that has the most layers and not of any other Core Configuration. For example, an implementation that includes all the layers in Table 2.1 and Table 2.2 implements the BR/EDR/LE Core-Controller Configuration and not either the BR/EDR Core-Controller Configuration or the LE Core-Controller Configuration.

Bluetooth wireless technology shall only be enabled end-to-end in an implementation of a Core-Complete Configuration.

2.1 Core-Controller Configuration

An implementation of a Core-Controller Configuration shall include Controller layers of this specification and the Lower HCI role of HCI and shall not include any Host layer (including the Upper HCI role of HCI) of this specification.

An implementation of a Core-Controller Configuration may also include one or more codec specifications implemented in the Controller. For example, an implementation of a Core-Controller Configuration may also support the LC3 codec implemented in the Controller.

An implementation of a Core-Controller Configuration shall not include any other layers external to the Core Specification.

2.1.1 BR/EDR Core-Controller Configuration

An implementation of the BR/EDR Core-Controller Configuration shall include the layers specified in Table 2.1.

Layer	Reference	Layer requirement
HCI	[Vol 4] Part E	Mandatory (Lower HCI role only)
SEC	[Vol 2] Part H	Mandatory
LMP	[Vol 2] Part C	Mandatory
BB	[Vol 2] Part B	Mandatory
RF	[Vol 2] Part A	Mandatory

Table 2.1: BR/EDR Core-Controller Configuration layers

2.1.2 LE Core-Controller Configuration

An implementation of the LE Core-Controller Configuration shall include the layers specified in Table 2.2.

Layer	Reference	Layer requirement
HCI	[Vol 4] Part E	Mandatory (Lower HCI role only)
ISOAL	[Vol 6] Part G	C.2
CS	[Vol 6] Part H	C.3
LESEC	[Vol 6] Part E	C.1
LL	[Vol 6] Part B	Mandatory
RFPHY	[Vol 6] Part A	Mandatory

C.1: Mandatory if LE Encryption feature (see [Vol 6] Part B, Section 4.6.1) is supported, otherwise excluded.

C.2: Mandatory if the Link Layer supports any of the following features, otherwise excluded:

- Connected Isochronous Stream – Central (see [Vol 6] Part B, Section 4.6.27)
- Connected Isochronous Stream – Peripheral (see [Vol 6] Part B, Section 4.6.27)
- Isochronous Broadcaster (see [Vol 6] Part B, Section 4.6.28)
- Synchronized Receiver (see [Vol 6] Part B, Section 4.6.29)

C.3: Optional if LE Channel Sounding feature (see [Vol 6] Part B, Section 4.6.41) is supported, otherwise excluded.

Table 2.2: LE Core-Controller Configuration layers

2.1.3 BR/EDR/LE Core-Controller Configuration

An implementation of the BR/EDR/LE Core-Controller Configuration shall include the layers specified in Table 2.1 and Table 2.2.

2.1.4 [This section is no longer used]

2.1.5 [This section is no longer used]

2.2 Core-Host Configurations

An implementation of a Core-Host Configuration shall include Host layers of the Core Specification and the Upper HCI role of HCI and shall not include any Controller layer (including the Lower HCI role of HCI) of the Core Specification.

An implementation of a Core-Host Configuration may also include one or more Bluetooth specifications that are external to the Core Specification, other than those implemented in the Controller. For example, an implementation of a Core-Host Configuration may also support A2DP, BAS, HOGP, or LC3 implemented in the Host.

2.2.1 BR/EDR Core-Host Configuration

An implementation of the BR/EDR Core-Host Configuration shall include the layers specified in Table 2.3.

Layer	Reference	Layer requirement
GATT	[Vol 3] Part G	C.1
ATT	[Vol 3] Part F	Optional
GAP	[Vol 3] Part C	Mandatory
SDP	[Vol 3] Part B	Mandatory
L2CAP	[Vol 3] Part A	Mandatory
HCI	[Vol 4] Part E	Mandatory (Upper HCI role only)
C.1: Mandatory if ATT is included, otherwise excluded.		

Table 2.3: BR/EDR Core-Host Configuration layers

2.2.2 LE Core-Host Configuration

An implementation of the LE Core-Host Configuration shall include the layers specified in Table 2.4.

Layer	Reference	Layer requirement
GATT	[Vol 3] Part G	C.1
ATT	[Vol 3] Part F	C.1
GAP	[Vol 3] Part C	Mandatory
SM	[Vol 3] Part H	C.1

Layer	Reference	Layer requirement
L2CAP	[Vol 3] Part A	C.1
HCI	[Vol 4] Part E	Mandatory (Upper HCI role only)
C.1: Mandatory if either the GAP Central role or the GAP Peripheral role is supported, otherwise excluded.		

Table 2.4: LE Core-Host Configuration layers

2.2.3 BR/EDR/LE Core-Host Configuration

An implementation of the BR/EDR/LE Core-Host Configuration shall include the layers specified in Table 2.3 and Table 2.4.

2.2.4 [This section is no longer used]

2.2.5 [This section is no longer used]

2.3 Core-Complete Configurations

An implementation of a Core-Complete Configuration may also include one or more Bluetooth specifications that are external to the Core Specification. For example, an implementation of a Core-Complete Configuration may also support A2DP, BAS, HOGP, or LC3.

An implementation of a Core-Complete Configuration may omit either or both roles of the HCI layer as specified in Table 2.1, Table 2.2, Table 2.3, and Table 2.4, except as stated in the next paragraph.

If an implementation of a Core-Complete Configuration is created by combining an implementation of a Core-Host Configuration with an implementation of a compatible Core-Controller Configuration, then the resulting implementation shall use HCI ([Vol 4] Part E) for communication between the Host and the Controller.

2.3.1 BR/EDR Core-Complete Configuration

An implementation of the BR/EDR Core-Complete Configuration shall include the layers specified in Table 2.1 and Table 2.3.

2.3.2 LE Core-Complete Configuration

An implementation of the LE Core-Complete Configuration shall include the layers specified in Table 2.2 and Table 2.4.

2.3.3 BR/EDR/LE Core-Complete Configuration

An implementation of the BR/EDR/LE Core-Complete Configuration shall include the layers specified in Table 2.1, Table 2.2, Table 2.3, and Table 2.4.

2.3.4 [This section is no longer used]

2.3.5 [This section is no longer used]

2.4 Other Core layers

An implementation may include any of the additional layers specified in Table 2.5.

Note: These layers are neither Host nor Controller layers and are not associated with a specific transport or Core Configuration.

Layer	Reference	Layer requirement
HCI-UART	[Vol 4] Part A	Optional
HCI-USB	[Vol 4] Part B	Optional
HCI-SD	[Vol 4] Part C	Optional
HCI-3W	[Vol 4] Part D	Optional
DTM	[Vol 6] Part F	Optional
MWS	[Vol 7] Part A	Optional
WCI-1	[Vol 7] Part B	Optional
WCI-2	[Vol 7] Part C	Optional

Table 2.5: Other Core layers

3 MIXING REQUIREMENTS FROM DIFFERENT VERSIONS

Subject to the requirements of this section, an implementation may mix layers that implement different versions of this specification.

All Controller layers (including Lower HCI) that are included shall implement a single version of this specification (the “Controller Version”).

All Host layers that are included (excluding Upper HCI) shall implement a single version of this specification (the “Host Version”), which may be a different version from the Controller Version.

If an implementation includes Upper HCI, then the version of Upper HCI implemented (the “Upper HCI Version”) shall be the same version or a higher version than the Host Version.

For the purposes of this section, a version of this specification mixed with one or more Core Specification Addenda (see Section 5) is the same as that version of this specification without any Core Specification Addenda.

4 FEATURES AND THEIR TYPES

Features in this specification are divided into the types listed in Table 4.1.

Type	Description
Type 1	Controller feature that cannot be configured/enabled by the Host via HCI
Type 2	Controller feature that can be configured/enabled by the Host via HCI
Type 3	Feature that exists in both the Controller and the Host and requires HCI commands/events to function
Type 4	Host feature that does not involve the Controller

Table 4.1: Feature type definitions

The behavior of a feature in an implementation of a Core-Complete Configuration depends on the feature type:

- A feature of type 1 that is specified in the Controller Version can function irrespective of the Host Version or Upper HCI Version.
- A feature of type 2 that is specified in the Controller Version can function if the Upper HCI Version is the same or a newer version than the Controller Version. Otherwise, the feature will be restricted to behavior (if any) that does not require the Host to configure/enable it; the available behavior will depend on the feature.
- A feature of type 3 can only function if it is specified in both the Controller Version and the Host Version.
- A feature of type 4 that is specified in the Host Version can function irrespective of the Controller Version or Upper HCI Version.

Table 4.2 lists the features added in versions 1.2 and higher of this specification, their types, and the version or addendum where the feature was first introduced.

Feature	Version	Type
Basic AFH operation	1.2	1
Enhanced inquiry	1.2	1
Configuration of AFH (setting channels and enabling/disabling channel assessment)	1.2	2
Enhanced synchronization capability	1.2	2
Interlaced inquiry scan	1.2	2
Interlaced page scan	1.2	2
Broadcast encryption	1.2	2

Feature	Version	Type
Enhanced flow specification and flush time-out	1.2	3
Extended SCO links	1.2	3
Inquiry Result with RSSI	1.2	3
L2CAP flow and error control	1.2	4
2 Mb/s EDR	2.0 + EDR	2
3 Mb/s EDR	2.0 + EDR	2
3 slot packets in EDR	2.0 + EDR	2
5 slot packets in EDR	2.0 + EDR	2
2 Mb/s eSCO	2.0 + EDR	2
3 Mb/s eSCO	2.0 + EDR	2
3 slot packets for EDR eSCO	2.0 + EDR	2
Erroneous Data Reporting	2.1 + EDR	3
Extended Inquiry Response	2.1 + EDR	3
Encryption Pause and Resume	2.1 + EDR	1
Link Supervision Timeout Changed Event	2.1 + EDR	3
Non-Flushable Packet Boundary Flag	2.1 + EDR	3
Sniff subrating	2.1+ EDR	3
Secure Simple Pairing	2.1.+ EDR	3
L2CAP Enhanced Retransmission Mode	Addendum 1/ 3.0 + HS	4
L2CAP Streaming Mode	Addendum 1/ 3.0 + HS	4
Enhanced Power Control	3.0 + HS	1
Generic Test Methodology	3.0 + HS	3
Unicast Connectionless Data	3.0 + HS	4
Low Energy Controller (PHY and LL)	4.0	3
Low Energy Host (L2CAP and Security Manager)	4.0	4
Attribute Protocol and Generic Attribute Profile	4.0	4
Appearance Data Type	Addendum 2	4
MWS Coexistence Signaling	Addendum 3	2
Connectionless Peripheral Broadcast	Addendum 4	3
Unencrypted UCD	Addendum 4	4
BR/EDR Secure Connections	4.1	3

Feature	Version	Type
Train Nudging	4.1	2
Generalized Interlaced Scan	4.1	2
Piconet Clock Adjustment	4.1	3
Low Duty Cycle Directed Advertising	4.1	2
32-bit UUID Support in LE	4.1	4
LE Dual Mode Topology	4.1	4
LE L2CAP Connection Oriented Channel Support	4.1	4
LE Privacy v1.1	4.1	4
LE Link Layer Topology	4.1	3
LE Ping	4.1	2
LE Data Packet Length Extension	4.2	2
LE Secure Connections	4.2	4
Link Layer Privacy	4.2	3
Link Layer Extended Filter Policies	4.2	3
Slot Availability Mask	5.0	2
LE 2M PHY	5.0	2
LE Coded PHY	5.0	3
High Duty Cycle Non-Connectable Advertising	5.0	2
LE Advertising Extensions	5.0	3
LE Channel Selection Algorithm #2	5.0	2
LE Higher Output Power	Addendum 5	1
Angle of Arrival/Angle of Departure	5.1	2
GATT Caching	5.1	4
Periodic Advertising Sync Transfer	5.1	3
Control Length Extension	5.1	1
Advertising Channel Index	5.1	1
HCI support for debug keys in LE Secure Connections	5.1	2
Sleep clock accuracy update mechanism	5.1	2
ADI field in scan response data	5.1	1
Interaction between QoS and Flow Specification	5.1	2
Host channel classification for secondary advertising	5.1	2
Allow the SID to appear in scan response reports	5.1	1
LE Isochronous Channels	5.2	3

Feature	Version	Type
Enhanced Attribute Protocol	5.2	4
LE Power Control	5.2	2
Periodic Advertising ADI support	5.3	2
Set Min Encryption Key Size command and Encryption Change [v2] event	5.3	2
Connection Subrating	5.3	3
Channel Classification	5.3	2
Advertising Coding Selection	5.4	2
Encrypted Advertising Data	5.4	4
Periodic Advertising with Responses	5.4	3
LE GATT Security Levels Characteristic	5.4	4
Channel Sounding	6.0	3
Decision-Based Advertising Filtering	6.0	3
ISOAL Unsegmented Framed Mode	6.0	2
Monitoring Advertisers	6.0	3
LE Frame Space Update	6.0	2
LL Extended Feature Set	6.0	2
Randomized RPA Updates	6.1	2

Table 4.2: Features and their types

5 CORE SPECIFICATION ADDENDA

A Core Specification Addendum (CSA) contains one or more parts of a single volume, one or more parts in multiple volumes, changes on one or more parts, or a mixture of parts and changes. Addenda are used to supersede a part in a volume or may be used to add a part to a volume according to the rules in Table 5.1.

Note: Each Change may contain changes and/or additions to one or more parts of the specification.

Addendum	Volume and Part or change name	Addition/ Changes/ Replacement	Allowed Versions & Addenda	Mandatory / Optional / Conditional	Type
1	Volume 3, Part A	Replacement	2.0 + EDR, 2.1 + EDR	O	4
2	Audio Architecture HCI changes	Change	2.1 + EDR, 3.0 + HS, 4.0	O	2
	Audio Architecture USB changes	Change	2.1 + EDR, 3.0 + HS, 4.0	O	2
	LE Limited Discovery Time Changes	Change	4.0	C.1	4
	EIR and AD Da-ta Types in GAP changes	Change	4.0	C.1	4
	EIR and AD Data Types Specification	Addition	4.0	C.1	4
	Volume 5, Part A	Replacement	3.0 + HS, 4.0	O	3
3	LE Errata	Change	4.0 with CSA2	C.2	Multiple
	GAP Connection Pa-rameters Changes	Change	4.0 with CSA2	C.1	4
	GAP Authentication and Lost Bond Changes	Change	4.0 with CSA2	C.1	4
	Common Profile and Services Error Code Range Changes	Change	4.0 with CSA2	C.1	4

Addendum	Volume and Part or change name	Addition/ Changes/ Replacement	Allowed Versions & Addenda	Mandatory / Optional / Conditional	Type
	Private Addressing Changes	Change	4.0 with CSA2	C.1	4
	Dual Mode Addressing Changes	Change	4.0 with CSA2	C.3	4
	MWS Coexistence Logical Signaling Specification	Addition	2.1 + EDR, 3.0 + HS, 4.0 with CSA2	O	2
	MWS Coexistence HCI	Addition	2.1 + EDR, 3.0 + HS, 4.0 with CSA2	C.4	2
	Wireless Coexistence Interface 1 (WCI-1) Transport Layer Specification	Addition	2.1 + EDR, 3.0 + HS, 4.0 with CSA2	C.4	2
	Wireless Coexistence Interface 2 (WCI-2) Transport Layer Specification	Addition	2.1 + EDR, 3.0 + HS, 4.0 with CSA2	C.4	2
4	Connectionless Peripheral Broadcast	Change	3.0 + HS, 4.0 with CSA3	O	3
	Unencrypted UCD	Change	3.0 + HS, 4.0 with CSA3	O	4
	Fast Advertising Interval	Change	4.0 with CSA3	C.1	4
	eSCO Reserved Slot Clarification	Change	2.1 + EDR, 3.0 + HS, 4.0 with CSA3	O	1

Addendum	Volume and Part or change name	Addition/ Changes/ Replacement	Allowed Versions & Addenda	Mandatory / Optional / Conditional	Type
5	Higher Output Power	Change	4.0 with CSA3, 4.0 with CSA4, 4.1, 4.2	O	1
6	The changes made by CSA6 have all been removed from the Core Specification and so CSA6 is withdrawn.				

C.1: Mandatory if either the Host Part of the Low Energy Core Configuration or the Host Part of the Basic Rate and Low Energy Combined Core Configuration is supported, otherwise Excluded.

C.2: Mandatory if either the Host Part of the Low Energy Core Configuration, Controller Part of the Low Energy Core Configuration, Host Part of the Basic Rate and Low Energy Combined Core Configuration, or Controller Part of the Basic Rate and Low Energy Combined Core Configuration is supported, otherwise Excluded.

C.3: Mandatory if the Host Part of the Basic Rate and Low Energy Combined Core Configuration is supported, otherwise Excluded.

C.4: Optional if MWS Coexistence Logical Signaling is supported, otherwise Excluded.

Table 5.1: Adopted specification versions to use with addenda

Architecture, Change History, And Conventions Part A

ARCHITECTURE

CONTENTS

1 GENERAL DESCRIPTION

This Part of the specification provides an overview of the Bluetooth system architecture, communication topologies, and data transport features. The text in this Part of the specification is intended to provide an introduction to Bluetooth and does not cover every detail or every corner case. In case of discrepancy with other parts of this specification, the other text is to be relied on.

Bluetooth wireless technology is a short-range communications system intended to replace the cable(s) connecting portable and/or fixed electronic devices. The key features of Bluetooth wireless technology are robustness, low power consumption, and low cost. Many features of the specification are optional, allowing product differentiation.

There are two forms of Bluetooth wireless technology systems: Basic Rate (BR) and Low Energy (LE). Both systems include device discovery, connection establishment and connection mechanisms. The Basic Rate system includes an optional Enhanced Data Rate (EDR) extension. The Basic Rate system offers synchronous and asynchronous connections with data rates of 721.2 kb/s for Basic Rate and 2.1 Mb/s for Enhanced Data Rate. The LE system includes features designed to enable products that require lower current consumption, lower complexity and lower cost than BR/EDR. The LE system is also designed for use cases and applications with lower data rates and has lower duty cycles. The LE system includes an optional 2 Mb/s physical layer data rate and also offers isochronous data transfer in a connection-oriented and connectionless mechanism that uses the isochronous transports. The LE system also includes the optional modulation of tones used to convey information useful for distance estimation. Depending on the use case or application, one system including any optional parts may be more optimal than the other.

Devices implementing both systems can communicate with other devices implementing both systems as well as devices implementing either system. Some profiles and use cases will be supported by only one of the systems. Therefore, devices implementing both systems have the ability to support the most use cases.

The Bluetooth core system consists of a Host and one or more Controllers. A Host is a logical entity defined as all of the layers below the non-core profiles and above the Host Controller interface (HCI). A Controller is a logical entity defined as all of the layers below HCI. An implementation of the Host and Controller may contain the respective parts of the HCI.

An implementation of the Bluetooth Core has only one Controller which may be one of the following configurations:

- a BR/EDR Controller including the Radio, Baseband, Link Manager and optionally HCI.
- an LE Controller including the LE PHY, Link Layer and optionally HCI.
- a combined BR/EDR Controller portion and LE Controller portion (as identified in the previous two bullets) into a single Controller.

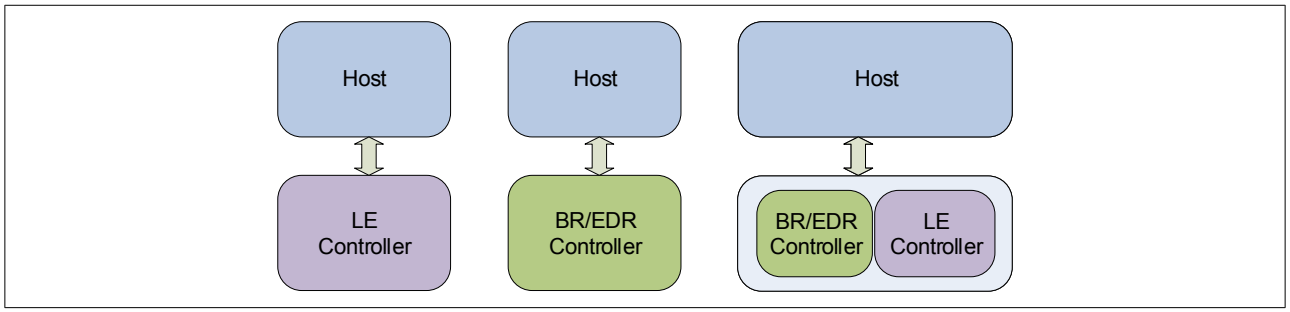

Figure 1.1: Bluetooth Host and Controller combinations: (from left to right): LE Only Controller, BR/EDR only Controller, and BR/EDR/LE Controller

1.1 Overview of BR/EDR operation

The Basic Rate / Enhanced Data Rate (BR/EDR) radio (physical layer or PHY) operates in the unlicensed ISM band at 2.4 GHz. The system employs a frequency hopping transceiver to combat interference and fading and provides many FHSS carriers. Basic Rate radio operation uses a shaped, binary frequency modulation to minimize transceiver complexity. The symbol rate is 1 megasymbol per second (Msym/s) supporting the bit rate of 1 megabit per second (Mb/s) or, with Enhanced Data Rate, a gross air bit rate of 2 Mb/s or 3 Mb/s. These modes are known as Basic Rate and Enhanced Data Rate respectively.

During typical operation a physical radio channel is shared by a group of devices that are synchronized to a common clock and frequency hopping pattern. One device provides the synchronization reference and is known as the Central. All other devices synchronized to a Central's clock and frequency hopping pattern are known as Peripherals. A group of devices synchronized in this fashion form a piconet. This is the fundamental form of communication in the Bluetooth BR/EDR wireless technology.

Devices in a piconet use a specific frequency hopping pattern, which is algorithmically determined by certain fields in the Bluetooth address and clock of the Central. The basic hopping pattern is a pseudo-random ordering of the 79 frequencies, separated by 1 MHz, in the ISM band. The hopping pattern can be adapted – on a per-Peripheral basis – to exclude a portion of the frequencies that are used by interfering devices. The

adaptive hopping technique improves Bluetooth co-existence with static (non-hopping) ISM systems when they are co-located.

The physical channel is sub-divided into time units known as slots. Data is transmitted between Bluetooth devices in packets that are positioned in these slots. When circumstances permit, a number of consecutive slots may be allocated to a single packet. Frequency hopping may take place between the transmission or reception of packets. Bluetooth technology provides the effect of full duplex transmission through the use of a Time-Division Duplex (TDD) scheme.

Above the physical channel there is a layering of links and channels and associated control protocols. The hierarchy of channels and links from the physical channel upwards is physical channel, physical link, logical transport, logical link and L2CAP channel. These are discussed in more detail in Section 3.3 to Section 3.6 but are introduced here to aid the understanding of the remainder of this section.

Typically within a physical channel, a physical link is formed between a Central and one or more Peripherals. Exceptions to this include Inquiry scan and Page scan physical channels, which have no associated physical link. The physical link provides bidirectional packet transport between the Central and Peripherals, except in the case of a Connectionless Peripheral Broadcast physical link. In that case, the physical link provides a unidirectional packet transport from the Central to a potentially unlimited number of Peripherals. Since a physical channel could include multiple Peripherals, there are restrictions on which devices may form a physical link. There is a physical link between each Peripheral and the Central. Physical links are not formed directly between the Peripherals in a piconet.

The physical link is used as a transport for one or more logical links that support unicast synchronous, asynchronous and isochronous traffic, and broadcast traffic. Traffic on logical links is multiplexed onto the physical link by occupying slots assigned by a scheduling function in the resource manager.

A control protocol for the baseband and physical layers is carried over logical links in addition to user data. This is the Link Manager protocol (LMP). Devices that are active in a piconet have a default asynchronous connection-oriented logical transport that is used to transport the LMP protocol signaling. For historical reasons this is known as the ACL logical transport. With the exception of Connectionless Peripheral Broadcast devices, the primary ACL logical transport is the one that is created whenever a device joins a piconet. Connectionless Peripheral Broadcast devices may join the piconet purely to listen to Connectionless Peripheral Broadcast packets. In that case, a Connectionless Peripheral Broadcast logical transport is created (also called a CPB logical transport) and no ACL logical transport is required. For all devices, additional logical transports may be created to transport synchronous data streams when required.

The Link Manager function uses LMP to control the operation of devices in the piconet and provide services to manage the lower architectural layers (radio and baseband). The LMP protocol is carried on the primary ACL and Active Peripheral Broadcast logical transports.

Above the baseband the L2CAP layer provides a channel-based abstraction to applications and services. It carries out segmentation and reassembly of application data and multiplexing and de-multiplexing of multiple channels over a shared logical link. L2CAP has a protocol control channel that is carried over the default ACL logical transport. Application data submitted to the L2CAP protocol may be carried on any logical link that supports the L2CAP protocol.

1.2 Overview of Bluetooth Low Energy operation

Like the BR/EDR radio, the LE radio operates in the unlicensed 2.4 GHz ISM band. The LE system employs a frequency hopping transceiver to combat interference and fading and provides many FHSS carriers. LE radio operation uses a shaped, binary frequency modulation, and optional amplitude shift keying modulation to minimize transceiver complexity. LE uses terminology that differs from BR/EDR to describe supported PHYs with regards to differences in modulation, coding that may be applied, and the resulting data rates. The mandatory symbol rate is 1 megasymbol per second (Msym/s), where 1 symbol represents 1 bit therefore supporting a bit rate of 1 megabit per second (Mb/s), which is referred to as the LE 1M PHY. The 1 Msym/s symbol rate may optionally support error correction coding, which is referred to as the LE Coded PHY. This may use either of two coding schemes: S=2, where 2 symbols represent 1 bit therefore supporting a bit rate of 500 kb/s, and S=8, where 8 symbols represent 1 bit therefore supporting a bit rate of 125 kb/s. An optional symbol rate of 2 Msym/s may be supported, with a bit rate of 2 Mb/s, which is referred to as the LE 2M PHY, when using a bandwidth-symbol time product (BT) of 0.5. An additional optional symbol rate at 2 Msym/s using a BT of 2.0 is also supported when used for the purpose of distance estimation, which is referred to as the LE 2M 2BT PHY. The 2 Msym/s symbol rate supports uncoded data only. LE 1M, LE 2M, and 2M 2BT are collectively referred to as the LE Uncoded PHYs. Section 3.2.2 describes this terminology in more detail.

The amplitude shift keying modulation scheme is employed to modulate tones for the purpose of gathering information for distance estimation. Section 3.2.3 describes amplitude shift keying in more detail.

LE employs two multiple access schemes: Frequency division multiple access (FDMA) and time division multiple access (TDMA). A TDMA-based polling scheme is used in which one device transmits a packet at a predetermined time and a corresponding device responds with a packet after a predetermined interval.

For the purposes of data transfer, 40 physical channels, separated by 2 MHz, are used in the FDMA scheme. Three are used as primary advertising channels and 37 are used as general-purpose channels (including as secondary advertising channels).

For the purpose of distance estimation, 72 physical channels, separated by 1 MHz, are used in the FDMA scheme.

The physical channel is sub-divided into time units known as events. Data is transmitted between LE devices in packets that are positioned in these events. The following types of events exist: Advertising, Extended Advertising, Periodic Advertising, Connection, Isochronous events (which are partitioned into BIS, BIG, CIS, and CIG events), and Channel Sounding events.

Devices that transmit advertising packets on the advertising PHY channels are referred to as advertisers. Devices that receive advertising packets on the advertising physical channels without the intention to connect to the advertising device are referred to as scanners. Transmissions on the advertising PHY channels occur in advertising events. At the start of each advertising event, the advertiser sends an advertising packet corresponding to the advertising event type. Depending on the type of advertising packet, the scanner may make a request to the advertiser on the same advertising PHY channel which may be followed by a response from the advertiser on the same advertising PHY channel. The advertising PHY channel changes on the next advertising packet sent by the advertiser in the same advertising event. The advertiser may end the advertising event at any time during the event. Each advertising packet in an advertising event uses a different advertising PHY channel. Each advertising event may use a different order for the advertising PHY channels.

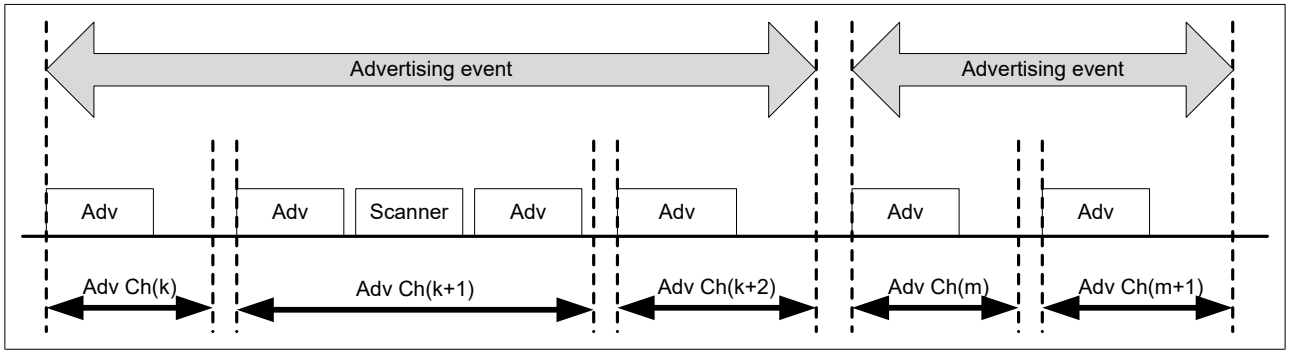

Figure 1.2: Advertising events

LE devices may fulfill the entire communication in the case of unidirectional or broadcast communication between two or more devices using advertising events. LE devices may also use advertising events to establish bi-directional connections with another device and to establish asynchronous or isochronous periodic broadcasts. Asynchronous periodic broadcasts may allow the advertiser to receive responses from

one or more devices. These additional activities make use of the general purpose channels in various ways.

Devices that need to form an ACL connection to another device listen for connectable advertising packets. Such devices are referred to as initiators. If the advertiser is using a connectable advertising event, an initiator may make a connection request using the same advertising PHY channel on which it received the connectable advertising packet. The advertising event is ended and connection events begin if the advertiser receives and accepts the request for a connection be initiated. Once a connection is established, the initiator becomes the Central in what is referred to as a piconet and the advertising device becomes the Peripheral. Connection events are used to send data packets between the Central and Peripherals. In connection events, channel hopping occurs at the start of each connection event. Within a connection event, the Central and Peripheral alternate sending data packets using the same data PHY channel. The Central initiates the beginning of each connection event and can end each connection event at any time.

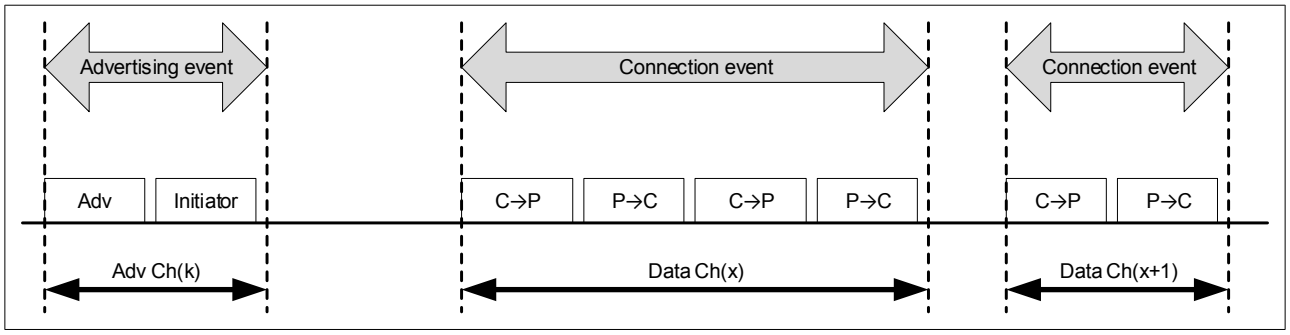

Figure 1.3: Connection events

Devices in a piconet use a specific frequency hopping pattern, which is algorithmically determined by a field contained in the connection request sent by an initiating device. The hopping pattern used on the LE data channel is a pseudo-random ordering of the 37 frequencies in the ISM band. The hopping pattern used in a Channel Sounding procedure is a pseudo-random ordering of 72 frequencies in the ISM band. The hopping pattern can be adapted to exclude a portion of the frequencies that are used by interfering devices. The adaptive hopping technique improves Bluetooth co-existence with static (non-hopping) ISM systems when these systems are co-located and have access to information about the local radio environment. A Peripheral can classify frequencies as good and bad and provide that information to the Central. The Central can take this information into consideration while adapting the hopping pattern.

Using an ACL connection, a Central can establish one or more isochronous connections that use the isochronous physical channel. An isochronous connection is used to transfer isochronous data between the Central and a Peripheral by using a logical transport, which is referred to as a Connected Isochronous Stream (CIS). A CIS

consists of CIS events that occur at regular intervals (designated ISO_Interval). Every CIS event consists of one or more subevents. In each subevent, the Central transmits once and the Peripheral responds. If the Central and Peripheral have completed transferring the scheduled isochronous data in a CIS event, all remaining subevents in that event will have no radio transmissions and the event is closed. Each subevent uses a PHY channel which is determined by using the channel selection algorithm. The PHY channel that is used for a subevent is marked as ISO Ch(eventcount, subeventcount), as shown in Figure 1.4.

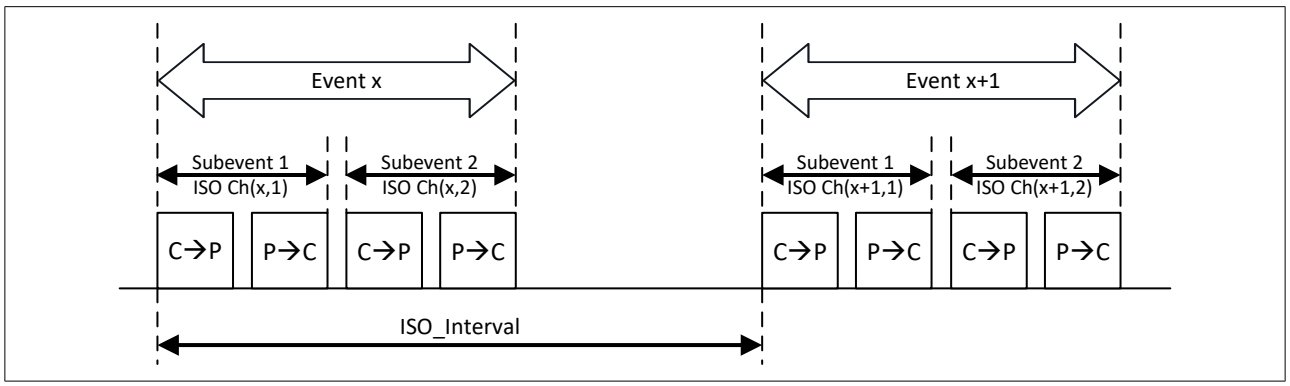

Figure 1.4: CIS events and subevents

A device can use an isochronous physical channel to broadcast isochronous data by using isochronous connectionless logical transports. An isochronous connectionless logical transport is referred to as a Broadcast Isochronous Stream (BIS). A BIS consists of BIS events that occur at regular intervals (designated ISO_Interval). Every BIS event consists of one or more subevents. In every subevent, a broadcasting device transmits an isochronous data packet. Each subevent uses a PHY channel that is determined using the channel selection algorithm.

A device can transmit several BISes with synchronized timing; this is referred to as a Broadcast Isochronous Group (BIG). The various BIS events together form a BIG event. The device can also use the isochronous physical channel to broadcast control information in a Control subevent, which is transmitted at the end of all subevents for a BIG, as shown in Figure 1.5.

A device that transmits BIG events also transmits periodic advertisement events that contain synchronization information of the BIG. A device that is scanning can synchronize to those periodic advertising events and receive the synchronization information. Using this synchronization information, the device can synchronize to one or more BISes in the BIG and receive the isochronous data. Figure 1.5 shows two BIG events: one with and one without a Control subevent. Each subevent uses a PHY channel marked as ISO Ch(eventcount, subeventcount), as shown in Figure 1.5.

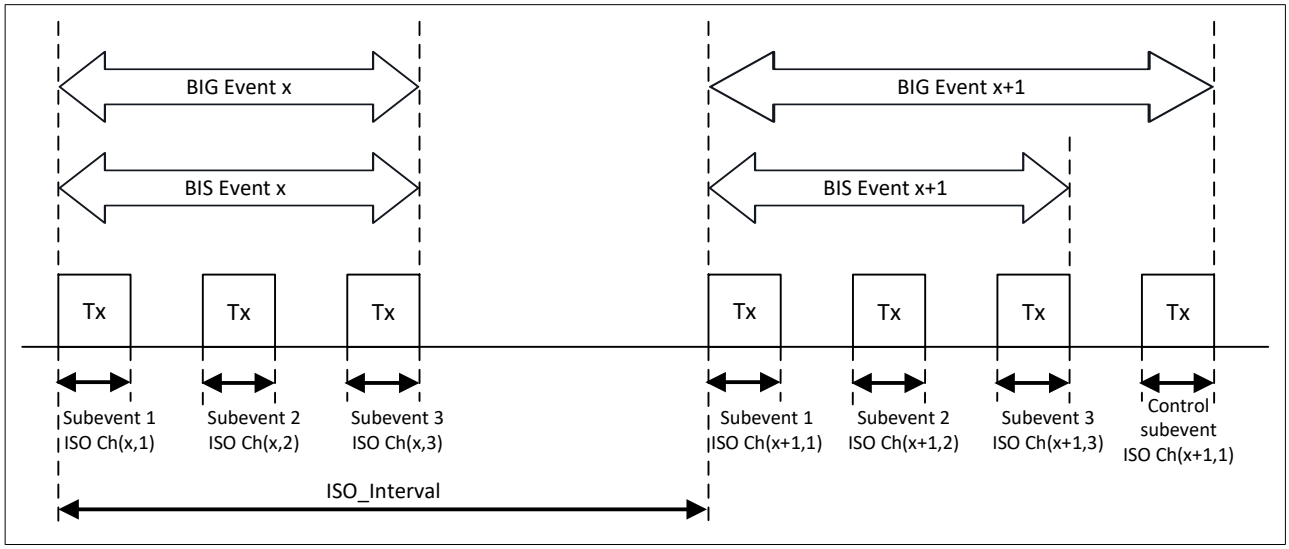

Figure 1.5: BIG and BIS events, BIS subevents, and Control subevent

Devices can use the LE Channel Sounding physical link to exchange information that can later be used for distance estimation calculations. A Channel Sounding procedure (and hence, the first Channel Sounding event within that procedure) is started at an offset from an ACL connection event anchor point. A Channel Sounding procedure exists only for a limited duration, and consists of Channel Sounding events, subevents, and steps. Channel Sounding events may contain one or more subevents. Channel Sounding subevents contain two or more Channel Sounding steps. Channel Sounding steps contain bilateral exchanges between the two Channel Sounding peers known as the initiator and reflector. The Channel Sounding initiator transmits first in each step, followed by one or more transmissions from the Channel Sounding reflector. These transmissions may be a packet-based GFSK-modulated exchange or a tone-based, amplitude shift keying modulated exchange, or both.

The general structure of Channel Sounding events and subevents is shown in Figure 1.6.

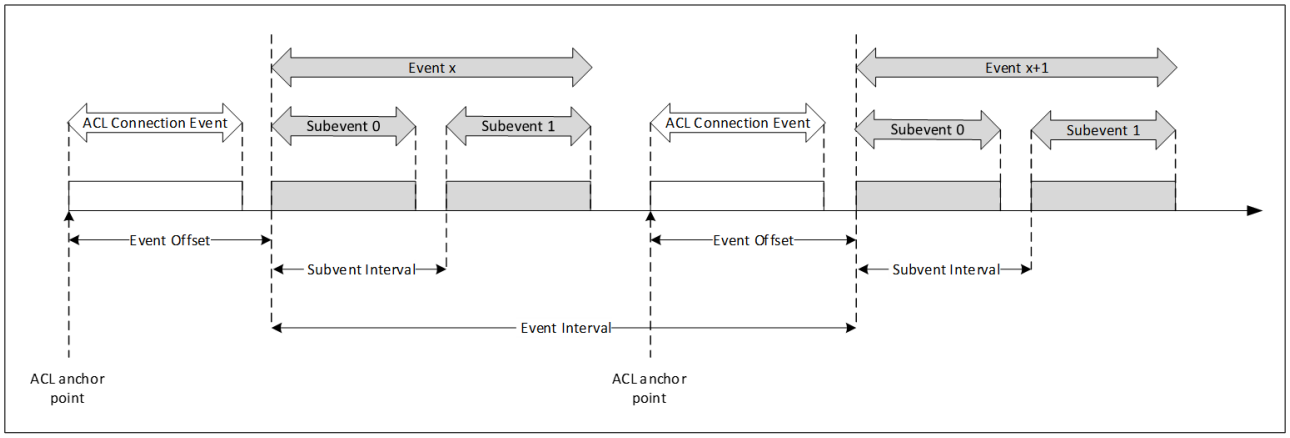

Figure 1.6: Channel Sounding events and subevents

Each exchange within a Channel Sounding step contains information that can be measured. These measurements can be further processed to produce a distance estimate. The step content is discussed in more detail in [Vol 6] Part H, Section 4.3. These exchanges also carry security-related information that may assist in the detection of an external attacker who is attempting to indirectly manipulate the measured results, which could in turn affect the distance estimate. The Channel Sounding step exchanges use a PHY channel that is determined using a channel selection algorithm. For Channel Sounding, this channel selection algorithm, as well as other security-related information, is seeded using a Deterministic Random Bit Generator (DRBG). The security key material for this DRBG is known only by the respective initiator and reflector devices.

Above the physical channel there are concepts of links, channels and associated control protocols. The hierarchy is physical channel, physical link, logical transport, logical link, and L2CAP channel. These are discussed in more detail in Section 3.3 to Section 3.6 but are introduced here to aid the understanding of the remainder of this section.

Within a physical channel, a physical link is formed between devices. The active physical link provides bidirectional packet transport between the Central and Peripherals. Centrals may have physical links to more than one Peripheral at a time and Peripherals may have physical links to more than one Central at a time. A device may be Central and Peripheral in different piconets at the same time. Role changes between a Central and Peripheral are not supported. The advertising and periodic physical links provide a unidirectional packet transport from the advertiser to a potentially unlimited number of scanners or initiators.

The physical link is used as a transport for one or more logical links that support asynchronous traffic. Traffic on logical links is multiplexed onto the physical link assigned by a scheduling function in the resource manager.

A control protocol for the link and physical layers is carried over logical links in addition to user data. This is the Link Layer protocol (LL). Devices that are active in a piconet

have a default LE asynchronous connection logical transport (LE ACL) that is used to transport the LL protocol signaling. The default LE ACL is the one that is created whenever a piconet is created.

The Link Layer function uses the LL protocol to control the operation of devices in the piconet and provide services to manage the lower architectural layers (PHY and LL).

Overall, a piconet consists of one ACL logical transport over the active physical link plus zero or more CIS logical transports over the isochronous physical link(s). In addition, zero or more transitory Channel Sounding procedures may exist over the Channel Sounding physical link.

Just as in BR/EDR, above the Link Layer the L2CAP layer provides a channel-based abstraction to applications and services. It carries out fragmentation and de-fragmentation of application data and multiplexing and de-multiplexing of multiple channels over a shared logical link. L2CAP has a protocol control channel that is carried over the primary ACL logical transport.

In addition to L2CAP, LE provides two additional protocol layers that reside on top of L2CAP. The Security Manager protocol (SMP) uses a fixed L2CAP channel to implement the security functions between devices. The other is the Attribute Protocol (ATT) that provides a method to communicate small amounts of data over a fixed L2CAP channel. The Attribute Protocol is also used by devices to determine the services and capabilities of other devices. The Attribute Protocol may also be used over BR/EDR.

The LE radio provides a means for detecting the relative direction of another LE radio by using the Angle of Arrival (AoA) or Angle of Departure (AoD) method.

1.3 [This section is no longer used]

1.4 Nomenclature

Where the following terms appear in the specification they have the meaning given in Table 1.1.

Active Peripheral Broadcast (APB)	The logical transport that is used to transport L2CAP user traffic and some kinds of LMP traffic to all active devices in the piconet over the BR/EDR Controller. See Section 3.5.4.4
Ad Hoc Network	A network typically created in a spontaneous manner. An ad hoc network requires no formal infrastructure and is limited in temporal and spatial extent.
Advertiser	A Bluetooth Low Energy device that broadcasts advertising packets during advertising events on advertising channels

Advertising event	A series of between one and three advertising packets on different advertising physical channels sent by an advertiser.
Advertising Packet	A packet containing an advertising PDU. See [Vol 6] Part B, Section 2.3.1
Angle of Arrival (AoA)	Angle of Arrival is the relative direction at which a propagating RF wave that was transmitted by a single antenna is incident on an antenna array.
Angle of Departure (AoD)	Angle of Departure is the relative direction from which a propagating RF wave that was transmitted using an antenna array is incident on another antenna.
BD_ADDR	The Bluetooth Device Address, BD_ADDR, is used to identify a Bluetooth device.
Bluetooth	Bluetooth is a wireless communication link, operating in the unlicensed ISM band at 2.4 GHz using a frequency hopping transceiver. It allows real-time AV and data communications between Bluetooth Hosts. The link protocol is based on time slots.
Bluetooth Baseband	The part of the Bluetooth system that specifies or implements the medium access and physical layer procedures to support the exchange of real-time voice, data information streams, and ad hoc networking between Bluetooth Devices.
Bluetooth Clock	A 28 bit clock internal to a BR/EDR Controller sub-system that ticks every 312.5 µs. The value of this clock defines the slot numbering and timing in the various physical channels.
Bluetooth Controller	A generic term referring to a Controller.
Bluetooth Device	A device that is capable of short-range wireless communications using the Bluetooth system.
Bluetooth Device Address	A 48 bit address used to identify each Bluetooth device.
BR/EDR	Bluetooth basic rate (BR) and enhanced data rate (EDR).
BR/EDR Controller	A term referring to the Bluetooth Radio, Baseband, Link Manager, and HCI layers.
BR/EDR Piconet Physical Channel	A Channel that is divided into time slots in which each slot is related to an RF hop frequency. Consecutive hops normally correspond to different RF hop frequencies and occur at a standard hop rate of 1600 hops per second. These consecutive hops follow a pseudo-random hopping sequence, hopping through a 79 RF channel set, or optionally fewer channels when Adaptive Frequency Hopping (AFH) is in use.
BR/EDR/LE	Bluetooth basic rate (BR), enhanced data rate (EDR) and low energy (LE).
C-plane	Control plane
Channel	Either a physical channel or an L2CAP channel, depending on the context.

Channel Sounding	A Bluetooth Low Energy feature that measures and distributes information that can be used to approximate distances between devices.
Channel Sounding event	A group of Channel Sounding subevents that are anchored from a common LE connection event.
Channel Sounding procedure	A group of Channel Sounding events that are sequenced serially for the purpose of gathering information useful for estimating the distance between two devices.
Channel Sounding step	In Channel Sounding, an individual exchange between two devices.
Channel Sounding subevent	A group of Channel Sounding steps that are associated with a specific coherent timing.
Connect (to service)	The establishment of a connection to a service. If not already done, this also includes establishment of a physical link, logical transport, logical link and L2CAP channel.
Connectable device	A BR/EDR device in range that periodically listens on its page scan physical channel and will respond to a page on that channel. An LE device that is advertising using a connectable advertising event.
Connected devices	Two BR/EDR devices and with a physical link between them.
Connecting	A phase in the communication between devices when a connection between the devices is being established. (Connecting phase follows after the link establishment phase is completed.)
Connection	A connection between two peer applications or higher layer protocols mapped onto an L2CAP channel.
Connection establishment	A procedure for creating a connection mapped onto a channel.
Connection event	A series of one or more pairs of interleaving data packets sent between a Central and a Peripheral on the same physical channel.
Connectionless Peripheral Broadcast (CPB)	A feature that enables a Central to broadcast information to an unlimited number of Peripherals.
Connectionless Peripheral Broadcast Receiver	A Bluetooth device that receives broadcast information from a Connectionless Peripheral Broadcast Transmitter. The device is a Peripheral of the piconet.
Connectionless Peripheral Broadcast Transmitter	A Bluetooth device that sends Connectionless Peripheral Broadcast messages for reception by one or more Connectionless Peripheral Broadcast receivers. The device is the Central of the piconet.
Controller	A collective term referring to all of the layers below HCI.
Coverage area	The area where two Bluetooth devices can exchange messages with acceptable quality and performance.
Creation of a secure connection	A procedure of establishing a connection, including authentication and encryption.

Creation of a trusted relationship	A procedure where the remote device is marked as a trusted device. This includes storing a common link key for future authentication, or pairing, when a link key is not available.
Device discovery	A procedure for retrieving the Bluetooth Device Address, clock, and Class of Device from discoverable devices.
Discoverable device	A BR/EDR device in range that periodically listens on an inquiry scan physical channel and will respond to an inquiry on that channel. An LE device in range that is advertising with a connectable or scannable advertising event with a discoverable flag set in the advertising data. This device is in the discoverable mode.
Discoverable Mode	A Bluetooth device that is performing inquiry scans in BR/EDR or advertising with a discoverable or connectable advertising event with a discoverable flag set in LE.
Discovery procedure	A Bluetooth device that is carrying out the inquiry procedure in BR/EDR or scanning for advertisers using a discoverable or connectable advertising event with a discoverable flag set in LE.
HCI	The Host Controller interface (HCI) provides a command interface to the baseband Controller and link manager and access to hardware status and control registers. This interface provides a uniform method of accessing the Bluetooth baseband capabilities.
Host	A logical entity defined as all of the layers below the non-core profiles and above the Host Controller interface (HCI); i.e., the layers specified in Volume 3. A Bluetooth Host attached to a Bluetooth Controller may communicate with other Bluetooth Hosts attached to their Controllers as well.
Initiator	From the perspective of an advertising bearer, a Bluetooth Low Energy device that listens on advertising physical channels for connectable advertising events to form connections. From the perspective of Channel Sounding, the device that transmits first within a Channel Sounding step.
Inquiring device	A BR/EDR device that is carrying out the inquiry procedure. This device is performing the discovery procedure.
Inquiry	A procedure where a Bluetooth device transmits inquiry messages and listens for responses in order to discover the other Bluetooth devices that are within the coverage area.
Inquiry scan	A procedure where a Bluetooth device listens for inquiry messages received on its inquiry scan physical channel.
Interoperability	The ability of two or more devices to exchange information and to use the information that has been exchanged.
Isochronous data	Information in a stream where each information entity in the stream is bound by a time relationship to previous and successive entities.
Known device	A Bluetooth device for which at least the BD_ADDR is stored.

L2CAP	Logical Link Control and Adaptation Protocol
L2CAP Channel	A logical connection on L2CAP level between two devices serving a single application or higher layer protocol.
L2CAP Channel establishment	A procedure for establishing a logical connection on L2CAP level.
LE	Bluetooth Low Energy
Link	Shorthand for a logical link.
Link establishment	A procedure for establishing the default ACL link and hierarchy of links and channels between devices.
Link key	A secret key that is known by two devices and is used to authenticate the link.
LMP authentication	An LMP level procedure for verifying the identity of a remote device.
LMP pairing	A procedure that authenticates two devices and creates a common link key that can be used as a basis for a trusted relationship or a (single) secure connection.
Logical link	The lowest architectural level used to offer independent data transport services to clients of the Bluetooth system.
Logical transport	Shared acknowledgment protocol and link identifiers between different logical links.
Name discovery	A procedure for retrieving the user-friendly name (the Bluetooth Device Name) of a connectable device.
Packet	Format of aggregated bits that are transmitted on a physical channel.
Page	The initial phase of the connection procedure where a device transmits a train of page messages until a response is received from the target device or a time-out occurs.
Page scan	A procedure where a device listens for page messages received on its page scan physical channel.
Paging device	A Bluetooth device that is carrying out the page procedure.
Paired device	A Bluetooth device for which a link key has been created (either before connection establishment was requested or during connecting phase).
Passkey	A 6-digit number used to authenticate connections when Secure Simple Pairing is used.
Periodic advertising synchronization information	The control information describing a periodic advertisement that a Bluetooth Low Energy device uses to synchronize to the advertisement it describes.
Physical Channel	Characterized by synchronized occupancy of a sequence of RF carriers by one or more devices. A number of physical channel types exist with characteristics defined for their different purposes.

Physical link	A Baseband or Link Layer level connection between two devices.
Physical Transport	PHY packet transmission and/or reception on an RF channel using one or more modulation schemes.
Piconet	A collection of devices (up to eight devices in BR/EDR, exactly two devices in LE) occupying a shared physical channel where one of the devices is the Piconet Central and the remaining devices are connected to it.
Piconet Central	The BR/EDR device in a piconet whose Bluetooth Clock and Bluetooth Device Address are used to define the piconet physical channel characteristics. The LE device in a piconet which initiates the creation of the piconet, chooses the Access Address that identifies the piconet, and transmits first in each connection event.
Piconet Peripheral	Any BR/EDR device in a piconet that is not the Piconet Central, but is connected to the Piconet Central. The LE device in a piconet which is not the Central but communicates with it.
PIN	A user-friendly number that can be used to authenticate connections to a device before pairing has taken place.
Profile Broadcast Data (PBD)	A logical link that carries data from a Connectionless Peripheral Broadcast Transmitter to one or more Connectionless Peripheral Broadcast Receivers.
Pseudo-Noise Bit Sequence	A series of bits that are generated randomly.
Reflector	In Channel Sounding, the device that transmits second within a Channel Sounding step in response to a transmission from an initiator.
Resolving List	A list of records used to generate and resolve Resolvable Private Addresses. Each record contains a local Identity Resolving Key, a peer Identity Resolving Key, and a peer Identity Address.
Round-Trip Time	The time it takes for a packet to travel from an originating device to a responding device and back again to the originating device.
Scanner	A Bluetooth Low Energy device that listens for advertising events on the advertising physical channels.
Scatternet	Two or more piconets that have one or more devices in common.
Service discovery	Procedures for querying and browsing for services offered by or through another Bluetooth device.
Service Layer Protocol	A protocol that uses an L2CAP channel for transporting PDUs.
Silent device	A Bluetooth enabled device appears as silent to a remote device if it does not respond to inquiries made by the remote device.
Synchronization Scan Physical Channel	A physical channel that enables a Peripheral to receive synchronization train packets from a Central.

Synchronization Train	A series of packets transmitted on a set of fixed frequencies that deliver sufficient information for a receiving device to start receiving corresponding Connectionless Peripheral Broadcast packets or to recover the current piconet clock after missing a Coarse Clock Adjust.
Tick	(BR/EDR) the time between changes of the value of the Bluetooth Clock: 312.5 µs.
U-plane	User plane
Unknown device	A Bluetooth device for which no information (Bluetooth Device Address, link key or other) is stored.

Table 1.1: Nomenclature

2 CORE SYSTEM ARCHITECTURE

The Bluetooth Core system consists of a Host and a Controller. A minimal implementation of the Bluetooth BR/EDR core system covers the four lowest layers and associated protocols defined by the Bluetooth specification as well as one common service layer protocol; the Service Discovery Protocol (SDP) and the overall profile requirements are specified in the Generic Access Profile (GAP). A minimal implementation of a Bluetooth LE only core system covers the four lowest layers and associated protocols defined by the Bluetooth specification as well as two common service layer protocols; the Security Manager (SM) and Attribute Protocol (ATT) and the overall profile requirements are specified in the Generic Attribute Profile (GATT) and Generic Access Profile (GAP). Implementations combining Bluetooth BR/EDR and LE include both of the minimal implementations described above.

A complete Bluetooth application requires a number of additional service and higher layer protocols that are defined in the Bluetooth specification, but are not described here. The core system architecture is shown in Figure 2.1.

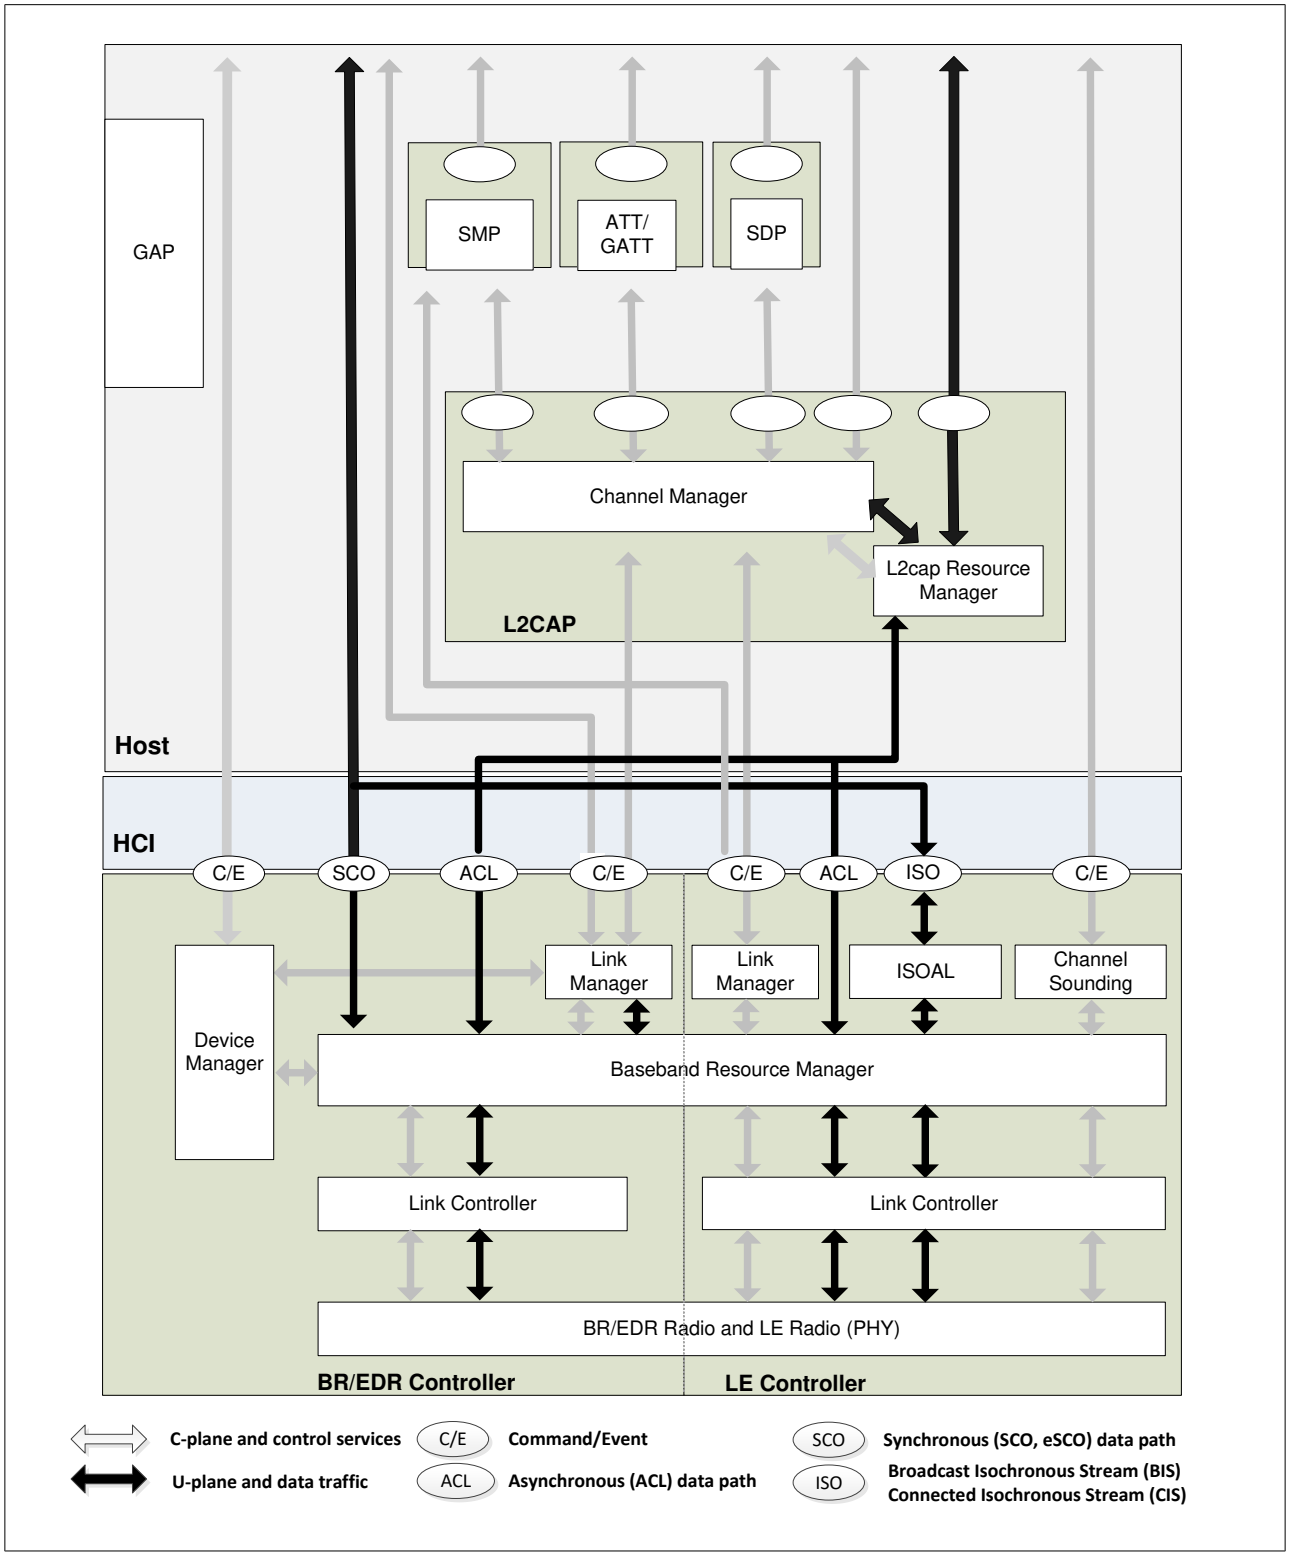

Figure 2.1: Bluetooth core system architecture

Figure 2.1 shows the Core blocks, each with its associated communication protocol. Link Manager, Link Controller and BR/EDR Radio blocks comprise a BR/EDR Controller. Link Manager, Link Controller and LE Radio blocks comprise an LE Controller. L2CAP, SDP and GAP blocks comprise a BR/EDR Host. L2CAP, SMP, Attribute Protocol, GAP and Generic Attribute Profile (GATT) blocks comprise an LE Host. A BR/EDR/LE Host combines the set of blocks from each respective Host. This is a common implementation involving a standard physical communication interface between the Controller and the Host. Although this interface is optional the architecture is designed to allow for its existence and characteristics. The Bluetooth specification enables interoperability between independent Bluetooth systems by defining the protocol messages exchanged between equivalent layers, and also interoperability between independent Bluetooth Controllers and Bluetooth Hosts by defining a common interface between Bluetooth Controllers and Bluetooth Hosts.

A number of functional blocks and the path of services and data between them are shown. The functional blocks shown in the diagram provide a set of conceptual entities that are used when describing the requirements of the specification; in general the Bluetooth specification does not define the details of implementations except where this is required for interoperability. Thus the functional blocks in Figure 2.1 are shown in order to aid description of the system behavior. An implementation may be different from the system shown in Figure 2.1.

Standard interactions are defined for all inter-device operation, where Bluetooth devices exchange protocol signaling according to the Bluetooth specification. The Bluetooth core system protocols are the Radio (PHY) protocol, Link Control (LC) and Link Manager (LM) protocol or Link Layer (LL) protocol, and Logical Link Control and Adaptation protocol (L2CAP), all of which are fully defined in subsequent parts of the Bluetooth specification. In addition, the Service Discovery protocol (SDP) and the Attribute Protocol (ATT) are service layer protocols that may be required by some Bluetooth applications.

The Bluetooth core system offers services through a number of service access points that are shown in the diagram as ellipses. These services consist of the basic primitives that control the Bluetooth core system. The services can be split into three types. There are device control services that modify the behavior and modes of a Bluetooth device, transport control services that create, modify and release traffic bearers (channels and links), and data services that are used to submit data for transmission over traffic bearers. It is common to consider the first two as belonging to the C-plane and the last as belonging to the U-plane.

A service interface to the Bluetooth Controller is defined such that the Controller may be considered a standard part. In this configuration the Bluetooth Controller operates the lowest four layers. The Bluetooth Host operates the L2CAP layer and other higher layers. The standard interface is called the Host Controller interface (HCI) and

its service access points are represented by the ellipses on the upper edge of the Bluetooth Controller in Figure 2.1. Implementation of this standard service interface is optional.

As the Bluetooth architecture is defined with the possibility of separate Host and Controller(s) communicating through one or more HCI transports, a number of general assumptions are made. Bluetooth Controllers are assumed to have limited data buffering capabilities in comparison with the Host. Therefore the L2CAP layer is expected to carry out some simple resource management when submitting L2CAP PDUs to the Controller for transport to a peer device. This includes segmentation of L2CAP SDUs into more manageable PDUs and then the fragmentation of PDUs into start and continuation packets of a size suitable for the Controller buffers, and management of the use of Controller buffers to ensure availability for channels with Quality of Service (QoS) commitments.

The BR/EDR Baseband and LE Link Layer provide the basic acknowledgment/repeat request (ARQ) protocol in Bluetooth. The L2CAP layer can optionally provide a further error detection and retransmission to the L2CAP PDUs. This feature is recommended for applications with requirements for a low probability of undetected errors in the user data. A further optional feature of L2CAP is a window-based flow control that can be used to manage buffer allocation in the receiving device. Both of these optional features augment the QoS performance in certain scenarios. Not all of the L2CAP capabilities are available when using the LE system.

Although these assumptions are not always required for embedded Bluetooth implementations that combine all layers in a single system, the general architectural and QoS models are defined with these assumptions in mind, in effect a lowest common denominator.

Automated conformance testing of implementations of the Bluetooth core system is required. This is achieved by allowing the tester to control the implementation through the PHY interface, test interfaces such as Direct Test Mode (DTM), and test commands and events over HCI which are only required for conformance testing.

The tester exchanges messages with the implementation under test (IUT) through the PHY interface to ensure the correct responses to requests from remote devices. The tester controls the IUT through HCI, DTM, or test commands to cause the IUT to originate exchanges through the PHY interface so that these can also be verified as compliant.

2.1 Core architectural blocks

This section describes the function and responsibility of each of the blocks shown in Figure 2.1. An implementation is not required to follow the architecture described above,

though every implementation is still required to conform to the protocol specifications, behaviors, and other requirements specified in subsequent parts of the Bluetooth specification.

2.1.1 Host architectural blocks

2.1.1.1 Channel manager

The channel manager is responsible for creating, managing and closing L2CAP channels for the transport of service protocols and application data streams. The channel manager uses the L2CAP protocol to interact with a channel manager on a remote (peer) device to create these L2CAP channels and connect their endpoints to the appropriate entities. The channel manager interacts with its local link manager to create new logical links (if necessary) and to configure these links to provide the required quality of service for the type of data being transported.

2.1.1.2 L2CAP resource manager

The L2CAP resource manager block is responsible for managing the ordering of submission of PDU fragments to the baseband and some relative scheduling between channels to ensure that L2CAP channels with QoS commitments are not denied access to the physical channel due to Controller resource exhaustion. This is required because the architectural model does not assume that a Controller has limitless buffering, or that the HCI is a pipe of infinite bandwidth.

L2CAP Resource Managers may also carry out traffic conformance policing to check that applications are submitting L2CAP SDUs within the bounds of their negotiated QoS settings. The general Bluetooth data transport model assumes well-behaved applications, and does not define how an implementation is expected to deal with this problem.

2.1.1.3 Security Manager Protocol

The Security Manager Protocol (SMP) is the peer-to-peer protocol used to generate encryption keys and identity keys. The protocol operates over a dedicated fixed L2CAP channel. The SMP block also manages storage of the encryption keys and identity keys and is responsible for generating random addresses and resolving random addresses to known device identities. The SMP block interfaces with the Controller to provide stored keys used for encryption and authentication during the encryption or pairing procedures.

This block is only used in LE systems. Similar functionality in the BR/EDR system is contained in the Link Manager block in the Controller. SMP functionality is in the Host on LE systems to reduce the implementation cost of the LE only Controllers.

2.1.1.4 Attribute Protocol

The Attribute Protocol (ATT) block implements the peer-to-peer protocol between an ATT Server and an ATT Client. The ATT Client communicates with an ATT Server on a remote device over a dedicated fixed L2CAP channel. The ATT Client sends commands, requests, and confirmations to the ATT Server. The ATT Server sends responses, notifications and indications to the client. These ATT Client commands and requests provide a means to read and write values of attributes on a peer device with an ATT Server.

2.1.1.5 [This section is no longer used]

2.1.1.6 Generic Attribute Profile

The Generic Attribute Profile (GATT) block represents the functionality of the ATT Server and, optionally, the ATT Client. The profile describes the hierarchy of services, characteristics and attributes used in the ATT Server. The block provides interfaces for discovering, reading, writing and indicating of service characteristics and attributes. GATT is used on LE devices for LE profile service discovery.

2.1.1.7 Generic Access Profile

The Generic Access Profile (GAP) block represents the base functionality common to all Bluetooth devices such as modes and access procedures used by the transports, protocols and application profiles. GAP services include device discovery, connection modes, security, authentication, association models and service discovery.

2.1.1.8 Service Discovery Protocol

The Service Discovery Protocol (SDP) provides a mechanism to allow clients to search for needed services based on specific attributes of the service, including search based on class of service and browsing the entire database. SDP is used on BR/EDR devices for BR/EDR profile service discovery.

SDP focuses on discovering services available from or through Bluetooth devices. It does not define methods for accessing services once they are discovered with SDP; the access method is service-specific.

2.1.2 BR/EDR/LE Controller architectural blocks

In implementations where the BR/EDR and LE systems are combined, the architectural blocks may be shared between systems or each system may have their own instantiation of the block.

2.1.2.1 Device manager

The device manager is the functional block in the baseband that controls the general behavior of the Bluetooth device. It is responsible for all operations of the Bluetooth

system that are not directly related to data transport, such as inquiring for the presence of nearby Bluetooth devices, connecting to Bluetooth devices, or making the local Bluetooth device discoverable or connectable by other devices.

The device manager requests access to the transport medium from the baseband resource Controller in order to carry out its functions.

The device manager also controls local device behavior implied by a number of the HCI commands, such as managing the device local name, any stored link keys, and other functionality.

2.1.2.2 Link manager

The link manager is responsible for the creation, modification and release of logical links (and, if required, their associated logical transports), as well as the update of parameters related to physical links between devices. The link manager achieves this by communicating with the link manager in remote Bluetooth devices using the Link Manager Protocol (LMP) in BR/EDR and the Link Layer Protocol (LL) in LE.

The LM or LL protocol allows the creation of new logical links and logical transports between devices when required, as well as the general control of link and transport attributes such as the enabling of encryption on the logical transport, the adapting of transmit power on the physical link, or the adjustment of QoS settings in BR/EDR for a logical link.

2.1.2.3 Baseband resource manager

The baseband resource manager is responsible for all access to the radio medium. It has two main functions. At its heart is a scheduler that grants time on the physical channels to all of the entities that have negotiated an access contract. The other main function is to negotiate access contracts with these entities. An access contract is effectively a commitment to deliver a certain QoS that is required in order to provide a user application with an expected performance.

The access contract and scheduling function must take account of any behavior that requires use of the Controller. This includes (for example) the normal exchange of data between connected devices over logical links, and logical transports, as well as the use of the radio medium to carry out inquiries, make connections, be discoverable or connectable, or to take readings from unused carriers during the use of adaptive frequency hopping mode.

In some cases in BR/EDR systems the scheduling of a logical link results in changing a logical link to a different physical channel from the one that was previously used. This may be (for example) due to involvement in scatternet, a periodic inquiry function, or page scanning. When the physical channels are not time slot aligned, then the resource

manager also accounts for the realignment time between slots on the original physical channel and slots on the new physical channel. In some cases the slots will be naturally aligned due to the same device clock being used as a reference for both physical channels.

2.1.2.4 Link Controller

The Link Controller is responsible for the encoding and decoding of Bluetooth packets from the data payload and parameters related to the physical channel, logical transport and logical link.

The Link Controller carries out the link control protocol signaling in BR/EDR and Link Layer protocol in LE (in close conjunction with the scheduling function of the resource manager), which is used to communicate flow control and acknowledgment and retransmission request signals. The interpretation of these signals is a characteristic of the logical transport associated with the baseband packet. Interpretation and control of the link control signaling is normally associated with the resource manager's scheduler.

2.1.2.5 PHY

The PHY block is responsible for transmitting and receiving packets of information on the physical channel. A control path between the baseband and the PHY block allows the baseband block to control the timing and frequency carrier of the PHY block. The PHY block transforms a stream of data to and from the physical channel and the baseband into required formats.

2.1.2.6 Isochronous Adaptation Layer

The Isochronous Adaptation Layer (ISOAL) enables the upper layer to send or receive isochronous data to or from the Link Layer in a flexible way such that the size and interval of data packets in the upper layer can be different from the size and interval of data packets in the Link Layer. The ISOAL uses fragmentation/recombination or segmentation/reassembly operations to convert upper layer data units into lower layer data units (or the other way around).

2.1.2.7 Channel Sounding

The Channel Sounding block is responsible for creation, modification, and release of Channel Sounding physical links. Channel Sounding related capabilities are first exchanged between peer Channel Sounding blocks and procedure configuration parameters are established. Security parameters are then set up. Thereafter, Channel Sounding exchanges are coordinated via this block, which includes Channel Sounding event, subevent, and step timing. Step transmission and reception is also generated and coordinated through this block. This data is then sent to the Host. From these exchanges, data is collected that may be used by the Host for distance estimation and attack detection.

2.1.3 [This section is no longer used]

3 TRANSPORT ARCHITECTURE

The Bluetooth data transport system follows a layered architecture. This description of the Bluetooth system describes the Bluetooth core transport layers up to and including L2CAP channels. All Bluetooth operational modes follow the same generic transport architecture, which is shown in Figure 3.1.

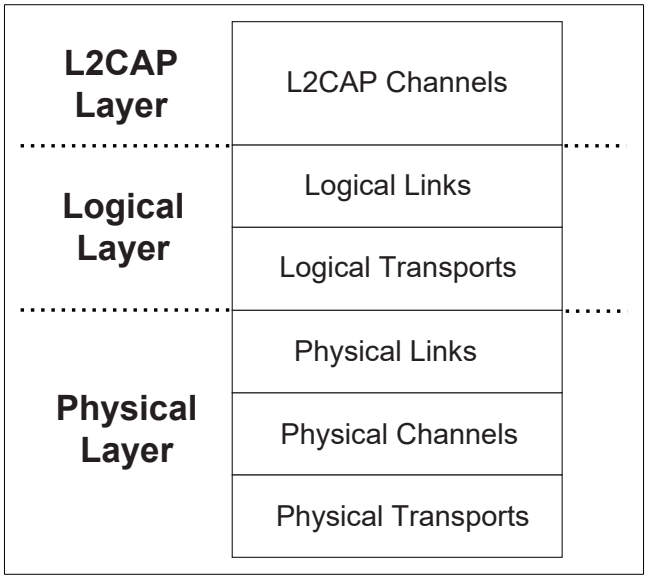

Figure 3.1: Bluetooth generic data transport architecture

For efficiency and legacy reasons, the Bluetooth transport architecture includes a sub-division of the logical layer, distinguishing between logical links and logical transports. This sub-division provides a general (and commonly understood) concept of a logical link that provides an independent transport between two or more devices. The logical transport sub-layer is required to describe the inter-dependence between some of the logical link types (mainly for reasons of legacy behavior).

The ACL, SCO, and eSCO connections are considered as logical transports but often behave as separate physical links. However, they are not as independent as might be desired, due to their shared use of resources such as the LT_ADDR and acknowledgment/repeat request (ARQ) scheme. Hence the architecture is incapable of representing these logical transports with a single transport layer. The additional logical transport layer goes some way towards describing this behavior.

3.1 Core traffic bearers

The Bluetooth core system provides a number of standard traffic bearers for the transport of service protocol and application data. These are shown in Figure 3.2 below

(for ease of representation this is shown with higher layers to the left and lower layers to the right).

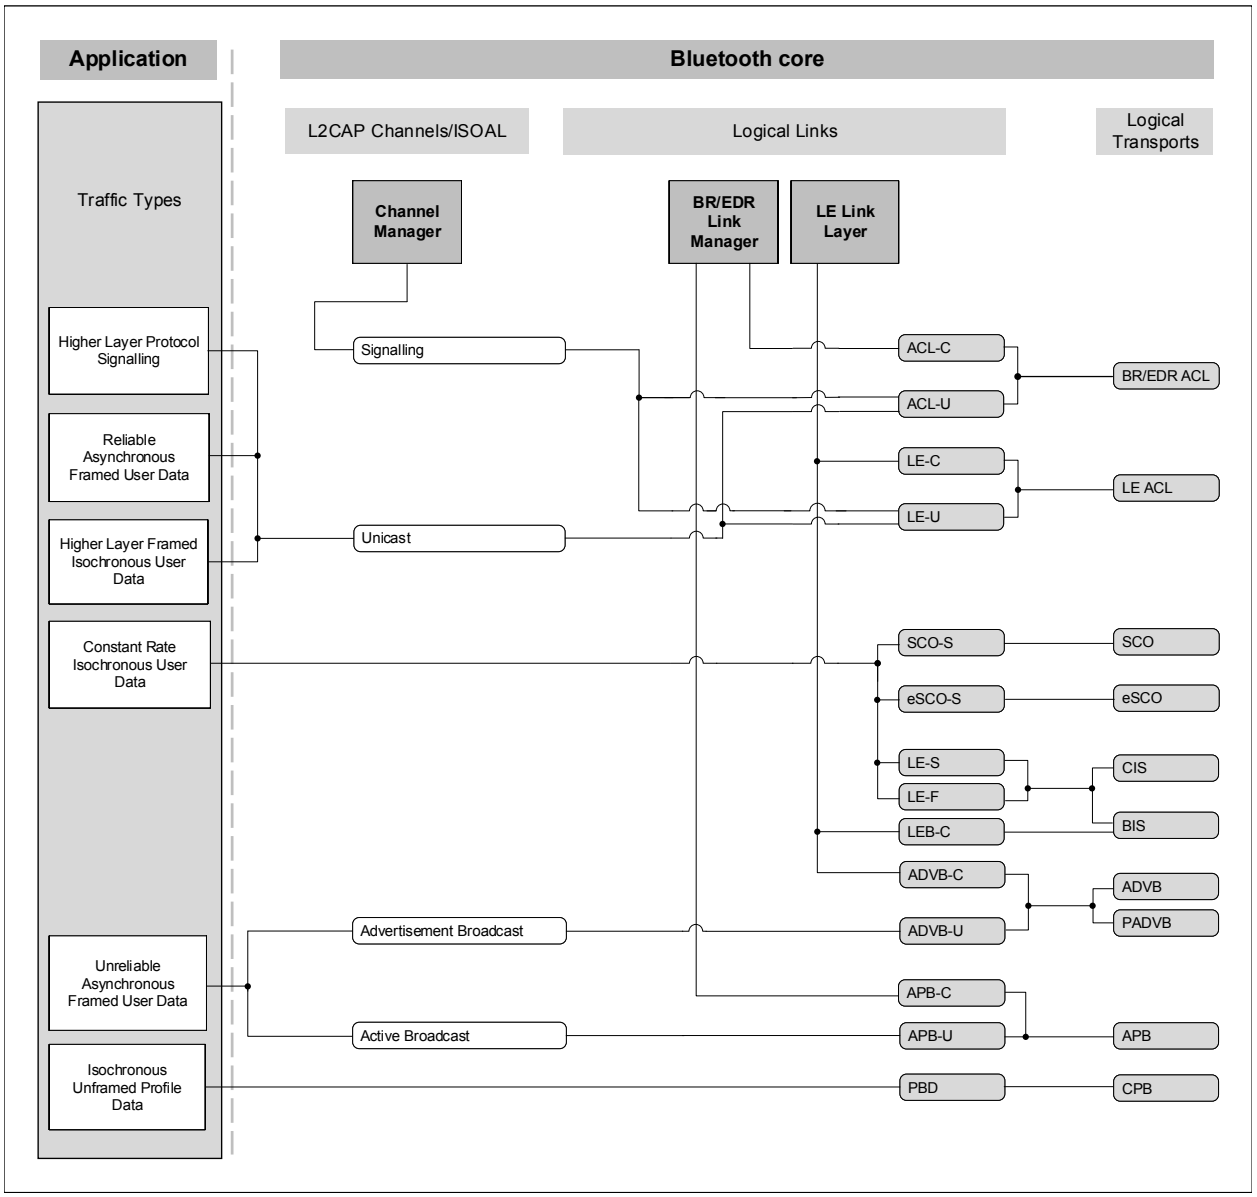

Figure 3.2: Bluetooth traffic bearers

The core traffic bearers that are available to applications are shown in Figure 3.2 as the shaded rounded rectangles. The architectural layers that are defined to provide these services are described in Section 2. A number of data traffic types are shown on the left of the diagram linked to the traffic bearers that are typically suitable for transporting that type of data traffic.

The logical links are named using the names of the associated logical transport and a suffix that indicates the type of data that is transported. (C for control links carrying LMP

or LL messages, U for L2CAP links carrying user data (L2CAP PDUs) and S for stream links carrying unformatted synchronous or isochronous data.) It is common for the suffix to be removed from the logical link without introducing ambiguity, thus a reference to the default ACL logical transport can be resolved to mean the ACL-C logical link in cases where the LMP protocol is being discussed, the LE-C logical link in cases where LL protocol is being discussed, or the ACL-U or LE-U logical links when the L2CAP layer is being discussed.

The mapping of application traffic types to Bluetooth core traffic bearers in Figure 3.2 is based on matching the traffic characteristics with the bearer characteristics. It is recommended to use these mappings as they provide the most natural and efficient method of transporting the data with its given characteristics.

However, an application (or an implementation of the Bluetooth core system) may choose to use a different traffic bearer, or a different mapping to achieve a similar result. For example, in a BR/EDR piconet with only one Peripheral, the Central may choose to transport L2CAP broadcasts over the ACL-U logical link rather than over the APB-U logical link. This will probably be more efficient in terms of bandwidth (if the physical channel quality is not too degraded). Use of alternative transport paths to those in Figure 3.2 is only acceptable if the characteristics of the application traffic type are preserved.

Figure 3.2 shows a number of application traffic types. These are used to classify the types of data that may be submitted to the Bluetooth core system. The original data traffic type can be different from the type that is submitted to the Bluetooth core system if an intervening process modifies it. For example, video data is generated at a constant rate but an intermediate coding process may alter this to variable rate, e.g. by MPEG4 encoding. For the purposes of the Bluetooth core system, only the characteristic of the submitted data is of interest.

3.1.1 Framed data traffic

The L2CAP layer services provide a frame-oriented transport for asynchronous and isochronous user data. The application submits data to this service in variable-sized frames (up to a negotiated maximum for the channel) and these frames are delivered in the same form to the corresponding application on the remote device. There is no requirement for the application to insert additional framing information into the data, although it may do so if this is required (such framing is invisible to the Bluetooth core system).

Connection-oriented L2CAP channels may be created for transport of unicast (point-to-point) data between two Bluetooth devices. Connection-oriented channels provide a context within which specific properties may be applied to data transported on the channel. For example, quality of service parameters or flow and error control modes

may be applied. Connection-oriented L2CAP channels are created using the L2CAP connection procedure.

A connectionless BR/EDR L2CAP channel exists for broadcasting data or for transport of unicast data. In the case of piconet topologies the Central is always the source of broadcast data and the Peripheral(s) are the recipients. Broadcast traffic on the connectionless L2CAP channel is uni-directional. Unicast data sent on the connectionless L2CAP channels may be uni-directional or bi-directional. Unicast data sent on the L2CAP connectionless channel provides an alternate mechanism to send data with the same level of reliability as an L2CAP connection-oriented channel operating in Basic mode but without the additional latency incurred by opening an L2CAP connection-oriented channel. LE L2CAP connectionless channels are not supported.

BR/EDR L2CAP channels have an associated QoS setting that defines constraints on the delivery of the frames of data. These QoS settings may be used to indicate (for example) that the data is isochronous, and therefore has a limited lifetime after which it becomes invalid, or that the data should be delivered within a given time period, or that the data is reliable and should be delivered without error, however long this takes.

Some L2CAP channels are fixed channels created when the ACL-U and/or LE-U logical links are established. These fixed channels have fixed channel identifiers and fixed configurations and do not permit negotiation of the configuration after they are created. These fixed channels are used for BR/EDR and LE L2CAP signaling (ACL-U or LE-U), connectionless channel (ACL-U and APB-U), Security Manager Protocol (LE-U), and Attribute Protocol (ACL-U or LE-U).

The L2CAP channel manager is responsible for arranging to transport the L2CAP channel data frames on an appropriate baseband logical link, possibly multiplexing this onto the baseband logical link with other L2CAP channels with similar characteristics.

3.1.2 Unframed data traffic

If the application does not require delivery of data in frames, possibly because it includes in-stream framing, or because the data is a pure stream, then it may avoid the use of L2CAP channels and make direct use of a baseband logical link.

The Bluetooth core system supports the direct transport of application data that is isochronous and of a constant rate (either bit-rate, or frame-rate for pre-framed data), using a SCO-S or eSCO-S logical link. These logical links reserve physical channel bandwidth and provide a constant rate transport locked to the piconet clock. Data is transported in fixed size packets at fixed intervals with both of these parameters negotiated during channel establishment. eSCO links provide a greater choice of bit-rates and also provide greater reliability by using limited retransmission in case of error. Enhanced Data Rate operation is supported for eSCO, but not for SCO logical

transports. SCO and eSCO logical transports do not support multiplexed logical links or any further layering within the Bluetooth core. An application may choose to layer a number of streams within the submitted SCO/eSCO stream, provided that the submitted stream is, or has the appearance of being, a constant rate stream.

The Bluetooth core system also supports the direct transport of application data using a Profile Broadcast Data (PBD) logical link. This logical link is similar to SCO-S and eSCO-S since it reserves physical channel bandwidth, provides a constant rate transport locked to the piconet clock, and transports data at fixed intervals. It does not support multiplexed logical links or any further layering within the Bluetooth core but, unlike SCO-S and eSCO-S, it supports broadcasting data from a single transmitter to many receivers.

The application chooses the most appropriate type of logical link from those available at the baseband, and creates and configures it to transport the data stream, and releases it when completed. (The application will normally also use a framed L2CAP unicast channel to transport its C-plane information to the peer application on the remote device.)

If the application data is isochronous and of a variable rate, then this may only be carried by the L2CAP unicast channel, and hence will be treated as framed data.

Unframed data traffic is not supported in the LE system.

3.1.3 Reliability of traffic bearers

A link or channel is characterized as reliable if the receiver is capable of detecting errors in received packets and requesting retransmission until the errors are removed. This is known as an Automatic Repeat reQuest (ARQ) scheme. Due to the error detection systems used, some residual undetected errors may still remain in the received data. The rate at which these occur depends on the details of the error detection system.

A link or channel is characterized as unreliable if the receiver is not capable of detecting errors in received packets or if it can detect errors but cannot request retransmission. In the latter case (such as with most broadcast links), the packets passed on by the receiver to higher layers may be without error but there is no guarantee that all the packets that were sent are received. Uses for unreliable links are normally dependent on techniques to improve the redundancy of the transmission, such as the use of Forward Error Connection or the repetition of data from the higher layers while the data is valid, in order to increase the probability that the receiver is able to receive at least one of the copies successfully.

3.1.3.1 BR/EDR reliability

Bluetooth is a wireless communications system. In poor RF environments, this system should be considered inherently unreliable. To counteract this the system provides

levels of protection at each layer. The baseband packet header uses forward error correcting (FEC) coding to allow error correction by the receiver and a header error check (HEC) to detect errors remaining after correction. Certain Baseband packet types include FEC for the payload. Furthermore, some Baseband packet types include a cyclic redundancy error check (CRC).

On ACL logical transports the results of the error detection algorithm are used to drive a simple ARQ protocol. This provides an enhanced reliability by re-transmitting packets that do not pass the receiver's error checking algorithm. It is possible to modify this scheme to support latency-sensitive packets by discarding an unsuccessfully transmitted packet at the transmitter if the packet's useful life has expired. eSCO links use a modified version of this scheme to improve reliability by allowing a limited number of retransmissions.

The resulting reliability gained by this ARQ scheme is only as dependable as the ability of the HEC and CRC codes to detect errors. In most cases this is sufficient, however it has been shown that for the longer packet types the probability of an undetected error is too high to support typical applications, especially those with a large amount of data being transferred.

The L2CAP layer provides an additional level of error control that is designed to detect the occasional errors not detected by the baseband and request retransmission of the affected data. This provides the level of reliability required by typical Bluetooth applications. The resulting rate of residual errors is comparable to the rate in other communication systems.

The transmitter may remove packets from the transmit queue such that the receiver does not receive all the packets in the sequence. If this happens detection of the missing packets is delegated to the L2CAP layer.

Stream links have a reliability characteristic somewhere between a reliable and an unreliable link, depending on the current operating conditions.

3.1.3.2 LE reliability

Like BR/EDR, in poor RF environments, the LE system should be considered inherently unreliable. To counteract this, the system provides levels of protection at each layer. The LL packet uses a 24-bit cyclic redundancy error check (CRC) to cover the contents of the packet payload. If the CRC verification fails on the packet payload, the packet is not acknowledged by the receiver and the packet gets retransmitted by the sender.

Because of the longer CRC and the shorter typical message compared with BR/EDR, it is not necessary for the L2CAP layer to provide a separate error detection and retransmission mechanism.

3.1.3.3 [This section is no longer used]

3.2 Transport architecture entities

The Bluetooth transport architecture entities are shown in Figure 3.3 and are described from the lowest layer upwards in the subsequent sections.

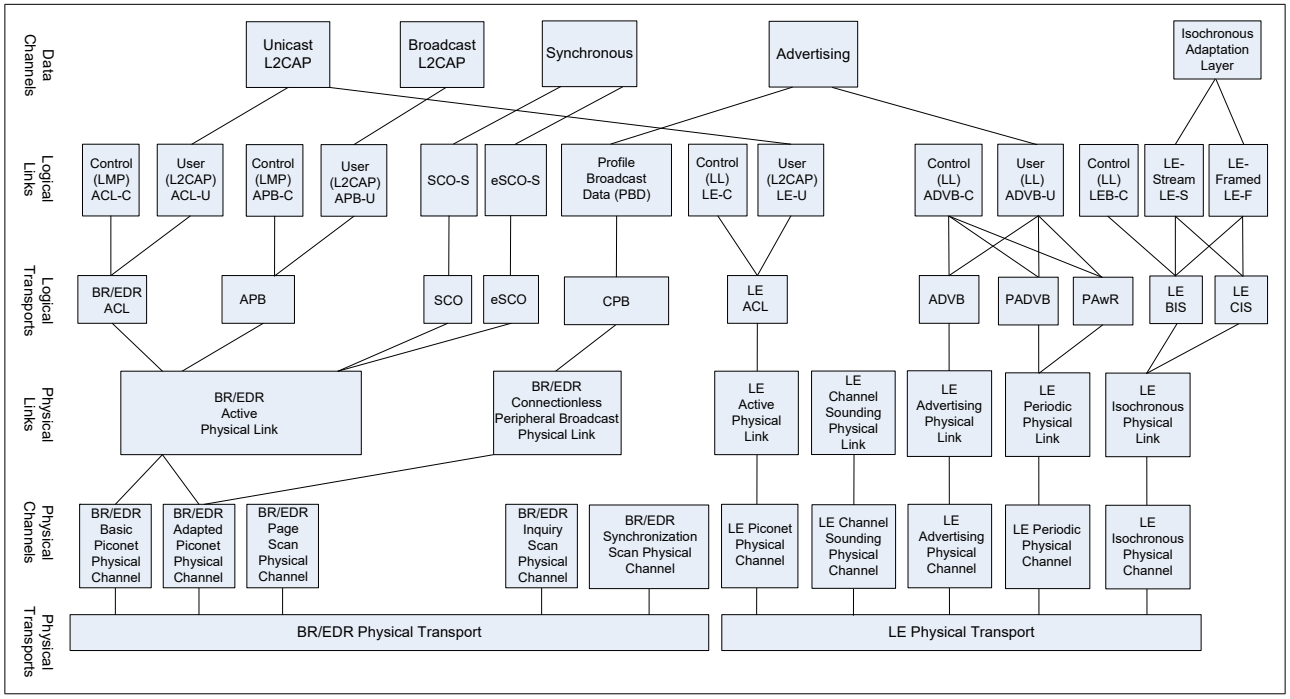

Figure 3.3: Overview of transport architecture entities and hierarchy

The BR/EDR Physical Transport encapsulates the BR/EDR Physical Channels. Transfers using the BR/EDR Physical Transport use the BR/EDR Generic Packet Structure. The LE Physical Transport encapsulates the LE Physical Channels. Transfers using the LE Physical Transport use the LE Generic Packet Structure for transferring user data and LL control information. The LE Physical Transport is also used for transfers using the Channel Sounding generic packet structure and signaling format.

3.2.1 BR/EDR generic packet structure

The generic packet structure nearly reflects the architectural layers found in the Bluetooth BR/EDR system. The BR/EDR packet structure is designed for optimal use in normal operation. It is shown in Figure 3.4.

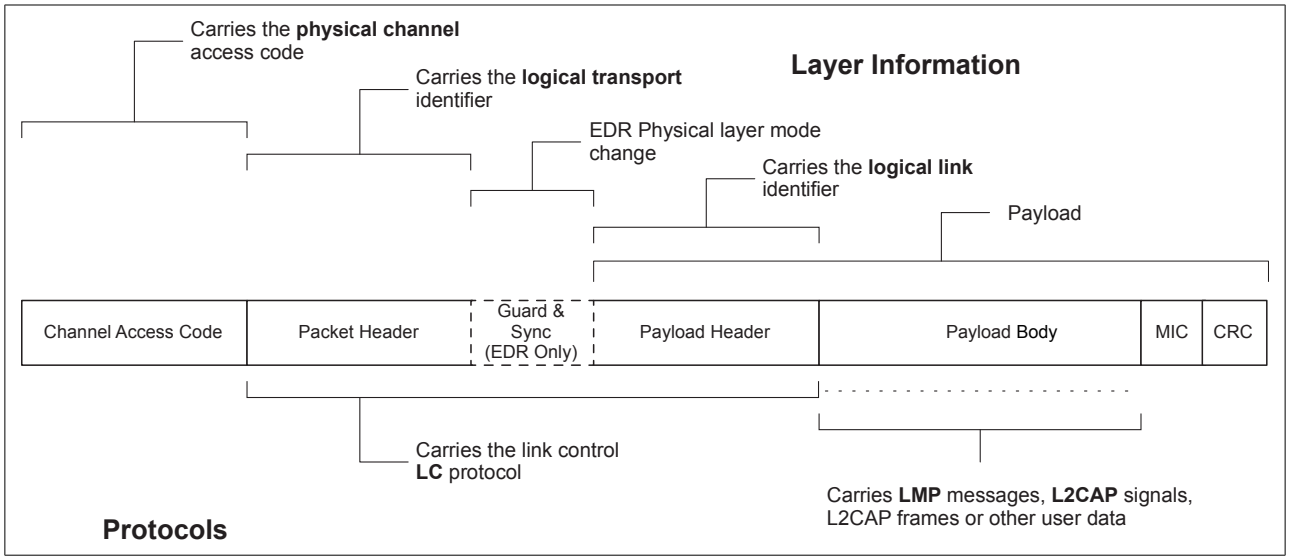

Figure 3.4: BR/EDR packet structure

Packets normally only include the fields that are necessary to represent the layers required by the transaction. Thus a simple inquiry request over an inquiry scan physical channel does not create or require a logical link or higher layer and therefore consists only of the channel access code (associated with the physical channel).

All packets include the channel access code. This is used to identify communications on a particular physical channel, and to exclude or ignore packets on a different physical channel that happens to be using the same RF carrier in physical proximity.

There is no direct field within the BR/EDR packet structure that represents or contains information relating to physical links. This information is implied by the combination of the logical transport address (LT_ADDR) carried in the packet header and the channel access code (CAC).

Most BR/EDR packets include a packet header. The packet header is always present in packets transmitted on physical channels that support physical links, logical transports and logical links. The packet header carries the LT_ADDR, which is used by each receiving device to determine if the packet is addressed to the device and is used to route the packet internally.

The BR/EDR packet header also carries part of the link control (LC) protocol that is operated per logical transport (except for ACL and SCO transports that operate a shared LC protocol carried on either logical transport).

The Enhanced Data Rate (EDR) packets have a guard time and synchronization sequence before the payload. This is a field used for physical layer change of modulation scheme.

The payload header is present in all packets on logical transports that support multiple logical links. The payload header includes a logical link identifier field used for routing the payload, and a field indicating the length of the payload body. Some packet types also include a CRC at the end of the packet payload that is used to detect most errors in received packets. When AES-CCM encryption is enabled, ACL packets include a Message Integrity Check (MIC) just prior to the CRC.

EDR packets have a trailer after the CRC.

The packet payload body is used to transport the user data. The interpretation of this data is dependent on the logical transport and logical link identifiers. For ACL logical transports Link Manager protocol (LMP) messages and L2CAP signals are transported in the packet payload body, along with general user data from applications.

For SCO, eSCO, and CPB logical transports the payload body contains the user data for the logical link.

3.2.2 LE generic packet structure

LE radio operation is based on four PHYs and makes use of two modulation symbol rates. Table 3.1 summarizes the properties of each of the LE PHYs. Each packet transmitted uses a single PHY. Three of the PHYs are uncoded - that is, each bit maps directly to a single radio symbol in the packet - while the fourth PHY is error correction coded. There are two coding schemes: S=8 and S=2, where S is the number of symbols per bit.

PHY	Modulation symbol rate	Modulation bandwidth-symbol time product (BT)	Coding scheme		Data rate
			Access Header	Payload	
LE 1M	1 Msym/s modulation	BT=0.5	Uncoded	Uncoded	1 Mb/s
LE 2M	2 Msym/s modulation	BT=0.5	Uncoded	Uncoded	2 Mb/s
LE 2M 2BT[1]	2 Msym/s modulation	BT=2.0	Uncoded	Uncoded	2 Mb/s
LE Coded	1 Msym/s modulation	BT=0.5	S=8	S=8	125 kb/s
				S=2	500 kb/s

Table 3.1: Summary of PHYs, modulation schemes, and coding schemes

[1]LE 2M 2BT is used only for Channel Sounding.

The "Access Header" referred to in Table 3.1 includes all the bits in the packet format associated with the particular PHY prior to the start of the PDU Header but not including the preamble. The preamble is excluded as this is uncoded for all PHYs.

The "Payload" referred to in Table 3.1 includes all the bits in the packet format from the PDU Header to the end of the packet.

The general structure of the Link Layer Air Interface packet closely reflects the architectural layers found in the LE system. The packet structure for the LE Uncoded PHYs is designed for optimal use in normal operation and is shown in Figure 3.5.

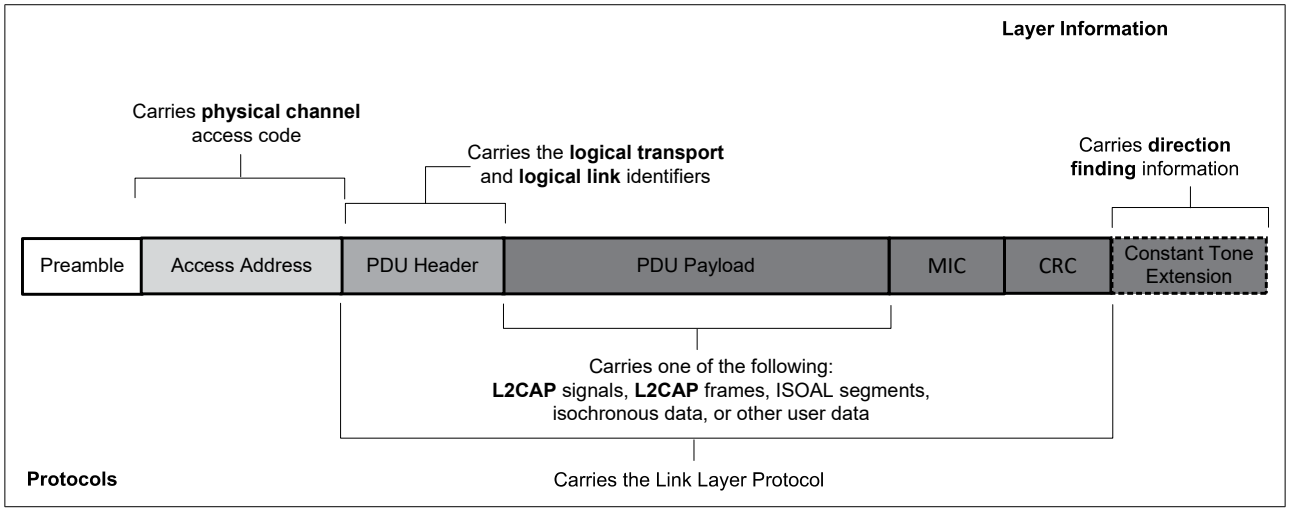

Figure 3.5: The packet structure for the LE Uncoded PHYs

The packet structure for the LE Coded PHY is designed for optimal use in extended range operation and is shown in Figure 3.6.

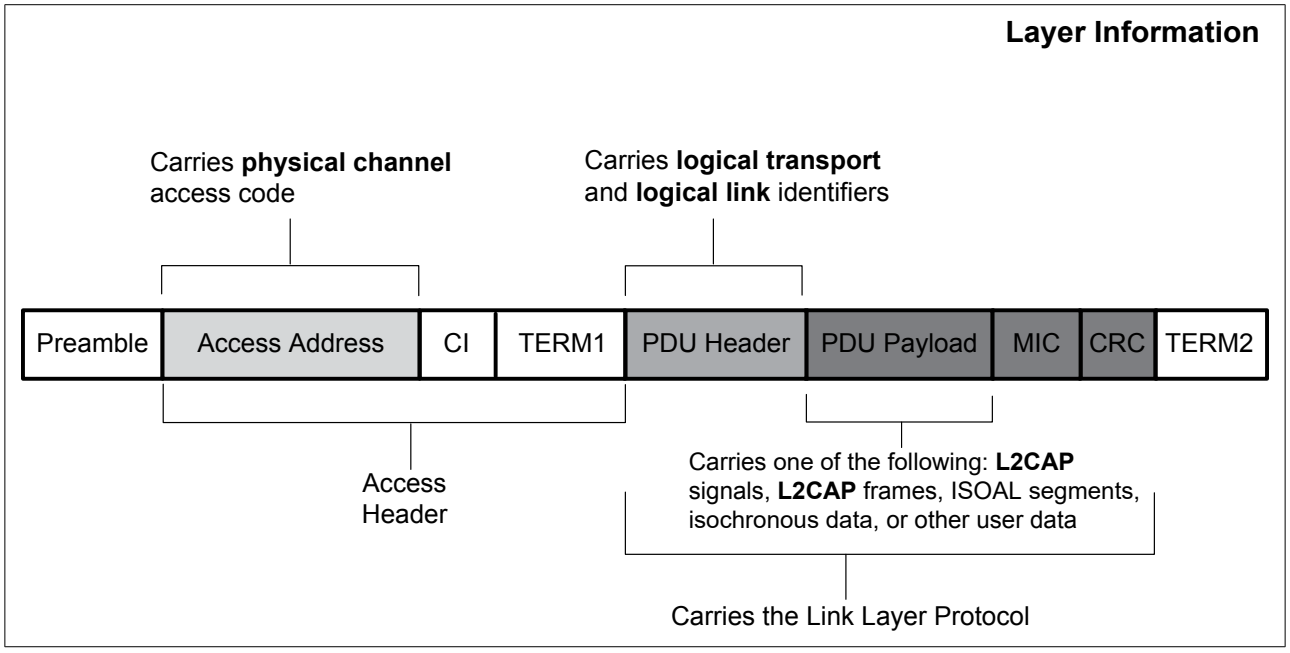

Figure 3.6: The packet structure for the LE Coded PHY

When using the LE Coded PHY, it is recommended to carefully consider the impact of radio-on time for power consumption and duty cycle for scheduling and coexistence over the air. The LE Coded PHY with S=8 coding (125 kb/s) represents the worst case,

when considering radio-on time and duty cycle, where each packet sent over the air will be approximately 8 times larger than LE 1M.

Table 3.2 illustrates the on-air time of advertising events with different sizes of AdvData. The first is using connectable and scannable undirected advertising events where the AdvData is sent on the primary advertising physical channel. The second is using events where the AdvData is offloaded to the secondary advertising physical channel. The usage of the primary and secondary advertising physical channels is described in Section 3.3.2.2. Numbers in parentheses are hypothetical and show cases that are not valid.

AdvData [Bytes]	Connectable Undirected Advertising event [µs]		Connectable Undirected Advertising event Using Offloading [µs]	
	LE 1M	LE Coded S=8	LE 1M	LE Coded S=8
0	384	(3,312)	568	4,864
15	744	(6,192)	688	5,824
31	1,128	(9,264)	816	6,848
100	(2,784)	(22,512)	1,368	11,264
245	(6,264)	(50,352)	2,528	20,544

Table 3.2: On-air time for various advertising events

Note: The events without offloading were calculated using three ADV_IND PDUs, while the events with offloading used three ADV_EXT_IND PDUs containing only the AuxPtr and ADI fields plus one AUX_ADV_IND PDU with the AdvA and ADI fields present and holding the AdvData.

Table 3.3 illustrates, for a range of payload sizes, the difference in Link Layer Data Physical Channel PDU packet durations for connections over the LE 1M PHY and LE Coded PHY with S=8 coding. Connection duty cycle for a specific implementation may be easily calculated from this information.

Payload [bytes]	LL Data Physical Channel PDU [µs]	
	LE 1M	LE Coded S=8
0	80	720
15	200	1,680
31	328	2,704
100	880	7,120
255	2,120	17,040

Table 3.3: On-air time for various data physical channel packets not containing Constant Tone Extensions

The physical link identifier is not contained in the Link Layer Air Interface packet. The physical channel identifiers are either fixed, are determined at connection setup, or are determined at periodic advertising setup. All LE packets include the Access Address. This is used to identify communications on a physical channel, and to exclude or ignore packets on different physical channels that are using the same PHY channels in physical proximity. The Access Address determines whether the packet is directed to the advertising physical channel (and thus an advertising physical link) used for non-periodic advertising, the periodic physical channel used for periodic advertising, or to a piconet physical channel (and thus an active physical link to a device). The LE advertising physical channel used for non-periodic advertising uses a fixed Access Address. The LE periodic physical channel used for periodic advertising and LE piconet physical channels use a randomly generated 32-bit value as their Access Address. This provides a high number of periodic advertising trains and a high number of active devices that can be addressed in an LE periodic advertisement or an LE piconet.

All LE packets include a PDU header. The PDU header determines the type of advertisement broadcast or logical link carried over the physical channel.

For advertising physical channel PDUs, the PDU header contains the type of advertisement payload, the device address type for addresses contained in the advertisement, and the advertising physical channel PDU payload length. Most advertising physical channel PDU payloads contain the advertiser's address and advertising data. One advertising physical channel PDU payload only contains the advertiser's device address and the initiator's device address in which the advertisement is directed. Advertising physical channel PDUs with scan requests payloads contain the scanner's device address and the advertiser's device address. Advertising physical channel PDUs with scan responses contain advertiser's device address and the scan response data. Advertising physical channel PDUs with connection request payloads contain the initiator's device address, advertiser's device address and connection setup parameters.

For Data Physical Channel PDUs, the PDU header contains the Logical Link Identifier (LLID), the Next Expected Sequence Number (NESN), Sequence Number (SN), More Data (MD), CTEInfo Present (CP), payload length, and may contain CTEInfo. For Data Physical Channel PDUs that contain control commands, the Data Channel PDU payload contains a command opcode and control data that is specific to the command. There is an optional Message Integrity Check (MIC) value that is used to authenticate the data PDU. For Data Physical Channel PDUs that are data, the Data Physical Channel PDU payload contains L2CAP data.

An Isochronous Physical Channel PDU can be either a Connected Isochronous or Broadcast Isochronous PDU. A Connected Isochronous PDU contains a header and may contain an isochronous payload. The header field contains the Logical Link Identifier (LLID), Sequence Number (SN), Next Expected Sequence Number (NESN),

Close Isochronous Event (CIE), Null PDU Indicator (NPI), and the payload length. A Connected Isochronous PDU may also contain a Message Integrity Check (MIC) field.

A Broadcast Isochronous PDU contains a header and either isochronous or control data. The header field contains the Logical Link Identifier (LLID), the Control Subevent Sequence Number (CSSN), the Control Subevent Transmission Flag (CSTF), and the payload length. The Broadcast Isochronous PDU may also contain a Message Integrity Check (MIC) field.

Both advertising physical channel packets and data physical channel packets can contain a Constant Tone Extension, which can be used for determining the relative direction of a received radio signal.

3.2.3 LE Channel Sounding generic packet structure and signaling format

An LE Channel Sounding (CS) operation employs two types of packet structures. The first packet structure makes use of the LE 1M, LE 2M, and LE 2M 2BT PHYs described in Section 3.2.2 and uses the same modulation described for those PHYs. The second packet structure employs the carrier tone modulated with amplitude shift keying.

The first packet structure used with the LE 1M, LE 2M, and LE 2M 2BT PHYs contains a preamble, an Access Address with trailer bits, and an optional payload as shown in Figure 3.7. Unlike the packet formats described in Section 3.2.2, a PDU header is not needed, because the presence and the content type of the optional payload are pre-negotiated.

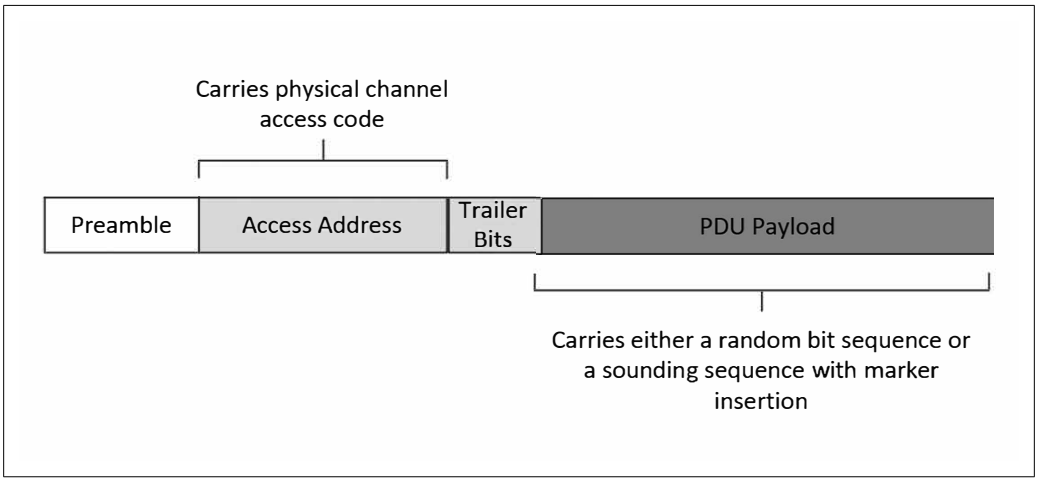

Figure 3.7: The Channel Sounding packet structure for LE 1M and 2M PHYs

The Preamble is the same as the preamble described for LE Uncoded PHYs in Section 3.2.2.

Similarly for CS, the Access Address is also the same as described in Section 3.2.2 but contains a bit sequence known only to the CS initiator and reflector pair. This CS Access Address is changed on every transmission.

The Trailer is a 4-bit sequence, alternating between 0 and 1 bits.

The “Payload” also follows the coding scheme rules described in Section 3.2.2. However, its content format is pre-selected and consists of either a bit sequence known only to the initiator and reflector pair, or a repeating [0 1] sounding sequence, with intermittent insertion of markers.

The second packet structure which is modulated using amplitude shift keying consists of one or more transmissions at the channel carrier frequency followed by an optional carrier transmission, over a selected antenna path. An antenna path is defined as single communication path between a specific physical antenna element on a transmitter to a specific physical antenna element on a receiver. The first set of transmissions can repeat over several antenna paths. The presence or non-presence of the final transmission extension concludes this transmission sequence. This format is shown in Figure 3.8.

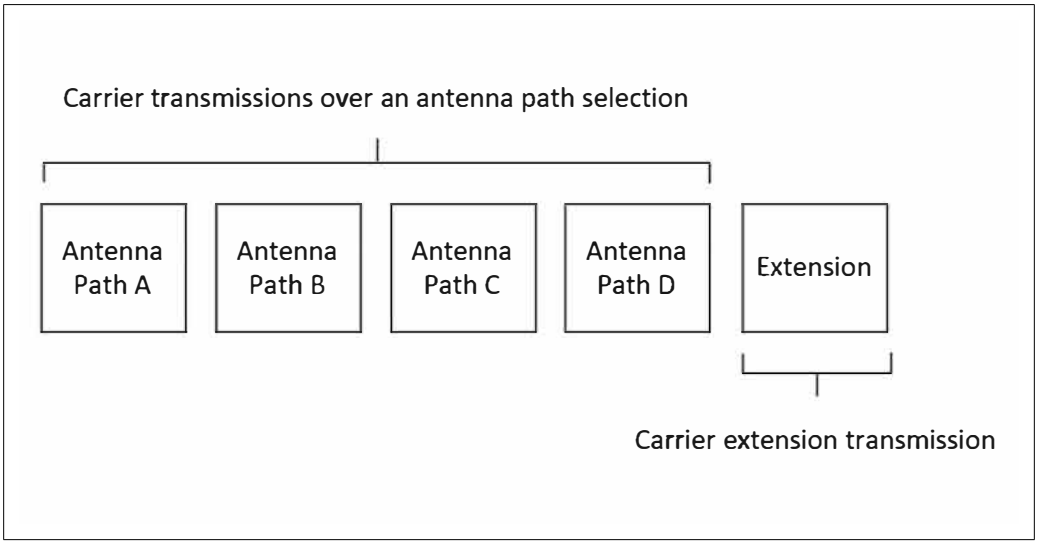

Figure 3.8: The Channel Sounding packet structure for modulated carrier transmissions.

3.3 Physical channels

A number of types of physical channel are defined. All Bluetooth physical channels are characterized by a set of PHY frequencies combined with temporal parameters and restricted by spatial considerations. For the basic and adapted piconet physical channels frequency hopping is used to change frequency periodically to reduce the effects of interference and for regulatory reasons.

The Bluetooth BR/EDR system and LE system differ slightly in the way they use physical channels.

3.3.1 BR/EDR physical channels

In the BR/EDR core system, peer devices use a shared physical channel for communication. To achieve this their transceivers need to be tuned to the same PHY frequency at the same time, and they need to be within a nominal range of each other.

Given that the number of RF carriers is limited and that many Bluetooth devices may be operating independently within the same spatial and temporal area there is a strong likelihood of two independent Bluetooth devices having their transceivers tuned to the same RF carrier, resulting in a physical channel collision. To mitigate the unwanted effects of this collision each transmission on a physical channel starts with an access code that is used as a correlation code by devices tuned to the physical channel. This channel access code is a property of the physical channel. The access code is present at the start of every transmitted packet.

Several BR/EDR physical channels are defined. Each is optimized and used for a different purpose. Two of these physical channels (the basic piconet channel and adapted piconet channel) are used for communication between connected devices and are associated with a specific piconet. Other BR/EDR physical channels are used for discovering (the inquiry scan channel) and connecting (the page scan channel) Bluetooth devices. The synchronization scan physical channel is used by devices to obtain timing and frequency information about the Connectionless Peripheral Broadcast physical link or to recover the current piconet clock.

A Bluetooth device can only use one BR/EDR physical channel at any given time. In order to support multiple concurrent operations the device uses time-division multiplexing between the channels. In this way a Bluetooth device can appear to operate simultaneously in several piconets, as well as being discoverable and connectable.

Whenever a Bluetooth device is synchronized to the timing, frequency and access code of a physical channel it is said to be ‘connected’ to this channel (whether or not it is actively involved in communications over the channel). The Bluetooth specification assumes that a device is only capable of connecting to one physical channel at any time. Advanced devices may be capable of connecting simultaneously to more than one physical channel, but the specification does not assume that this is possible.

3.3.1.1 Basic piconet channel

3.3.1.1.1 Overview

The basic piconet channel is used for communication between connected devices during normal operation.

3.3.1.1.2 Characteristics

The basic piconet channel is characterized by a pseudo-random sequence hopping through the PHY channels. The hopping sequence is unique for the piconet and is determined by the Bluetooth Device Address of the Central. The phase in the hopping sequence is determined by the Bluetooth clock of the Central. All Bluetooth devices participating in the piconet are time- and hop-synchronized to the channel.

The channel is divided into time slots where each slot corresponds to an PHY hop frequency. Consecutive hops correspond to different PHY hop frequencies. The time slots are numbered according to the Bluetooth clock of the piconet Central. Packets are transmitted by Bluetooth devices participating in the piconet aligned to start at a slot boundary. Each packet starts with the channel access code, which is derived from the Bluetooth Device Address of the piconet Central.

On the basic piconet channel the Central controls access to the channel. The Central starts its transmission in even-numbered time slots only. Packets transmitted by the Central are aligned with the slot start and define the piconet timing. Packets transmitted by the Central may occupy up to five time slots depending on the packet type.

Each Central transmission is a packet carrying information on one of the logical transports. Peripherals may transmit on the physical channel in response. The characteristics of the response are defined by the logical transport that is addressed.

For example, on the asynchronous connection-oriented logical transport (ACL), the addressed Peripheral responds by transmitting a packet containing information for the same logical transport that is nominally aligned with the next (odd-numbered) slot start. Such a packet may occupy up to five time slots, depending on the packet type. On a broadcast logical transport no Peripherals are allowed to respond.

3.3.1.1.3 Topology

A basic piconet channel may be shared by any number of Bluetooth devices, limited only by the resources available on the piconet Central. Only one device is the piconet Central, all others being piconet Peripherals. All communication is between the Central and Peripherals. There is no direct communication between Peripherals on the piconet channel.

There is, however, a limitation on the number of logical transports that can be supported within a piconet. This means that although there is no theoretical limit to the number of Bluetooth devices that share a channel there is a limit to the number of these devices that can be actively involved in exchanging data with the Central.

3.3.1.1.4 Supported layers

The basic piconet channel supports a number of physical links, logical transports, logical links and L2CAP channels used for general purpose communications.

3.3.1.2 Adapted piconet channel

3.3.1.2.1 Overview

The adapted piconet channel differs from the basic piconet channel in two ways. First, the frequency on which a Peripheral transmits is the same as the frequency used by its Central in the preceding transmission. In other words the frequency is not recomputed between Central and subsequent Peripheral packets. Second, the adapted piconet channel may be based on fewer than the full 79 frequencies. A number of frequencies may be excluded from the hopping pattern by being marked as “unused”. The remainder of the 79 frequencies are included. The two sequences are the same except that whenever the basic pseudo-random hopping sequence selects an unused frequency, it is replaced with an alternative chosen from the used set. The set of frequencies used may vary between different physical links on the same adapted piconet channel.

Because the adapted piconet channel uses the same timing and access code as the basic piconet channel, physical links on the two channels are often coincident. This provides a deliberate benefit as it allows Peripherals in either the basic piconet channel or the adapted piconet channel to adjust their synchronization to the Central.

The topology and supported layers of the adapted piconet physical channel are identical to the basic piconet physical channel with one exception: on the adapted piconet physical channel, it is possible for a single Central to transmit data to an unlimited number of Peripherals using a single CPB logical transport. In this case, however, data is only transferred from Central to Peripheral and not from Peripheral to Central.

3.3.1.3 Inquiry scan channel

3.3.1.3.1 Overview

In order for a device to be discovered, an inquiry scan channel is used. A discoverable device listens for inquiry requests on its inquiry scan channel and then sends a response to that request. In order for a device to discover other devices, it iterates (hops) through all possible inquiry scan channel frequencies in a pseudo-random fashion, sending an inquiry request on each frequency and listening for any response.

3.3.1.3.2 Characteristics

Inquiry scan channels follow a slower hopping pattern and use an access code to distinguish between occasional occupancy of the same radio frequency by two co-located devices using different physical channels.

The access code used on the inquiry scan channel is taken from a reserved set of inquiry access codes that are shared by all Bluetooth devices. One access code is used for general inquiries, and a number of additional access codes are reserved for limited inquiries. Each device has access to a number of different inquiry scan channels. As all of these channels share an identical hopping pattern, a device may concurrently occupy more than one inquiry scan channel if it is capable of concurrently correlating more than one access code.

A device using one of its inquiry scan channels remains passive on that channel until it receives an inquiry message on this channel from another Bluetooth device. This is identified by the appropriate inquiry access code. The inquiry scanning device will then follow the inquiry response procedure to return a response to the inquiring device.

In order for a device to discover other Bluetooth devices it uses the inquiry scan channel to send inquiry requests. As it has no prior knowledge of the devices to discover, it cannot know the exact characteristics of the inquiry scan channel.

The device takes advantage of the fact that inquiry scan channels have a reduced number of hop frequencies and a slower rate of hopping. The inquiring device transmits inquiry requests on each of the inquiry scan hop frequencies and listens for an inquiry response. Transmissions are done at a faster rate, allowing the inquiring device to cover all inquiry scan frequencies in a reasonably short time period.

3.3.1.3.3 Topology

Inquiring and discoverable devices use a simple exchange of packets to fulfill the inquiring function. The topology formed during this transaction is a simple and transient point-to-point connection.

3.3.1.3.4 Supported layers

During the exchange of packets between an inquiring and discoverable device it may be considered that a temporary physical link exists between these devices. However, the concept is quite irrelevant as it has no physical representation but is only implied by the brief transaction between the devices. No further architectural layers are considered to be supported.

3.3.1.4 Page scan channel

3.3.1.4.1 Overview

A connectable device (one that is prepared to accept connections) does so using a page scan channel. A connectable device listens for a page request on its page scan channel and, once received, enters into a sequence of exchanges with this device. In order for a device to connect to another device, it iterates (hops) through all page scan channel frequencies in a pseudo-random fashion, sending a page request on each frequency and listening for a response.

3.3.1.4.2 Characteristics

The page scan channel uses an access code derived from the scanning device's Bluetooth Device Address to identify communications on the channel. The page scan channel uses a slower hopping rate than the hop rate of the basic and adapted piconet channels. The hop selection algorithm uses the Bluetooth device clock of the scanning device as an input.

A device using its page scan channel remains passive until it receives a page request from another Bluetooth device. This is identified by the page scan channel access code. The two devices will then follow the page procedure to form a connection. Following a successful conclusion of the page procedure both devices switch to the basic piconet channel that is characterized by having the paging device as Central.

In order for a device to connect to another Bluetooth device it uses the page scan channel of the target device in order to send page requests. If the paging device does not know the phase of the target device's page scan channel it therefore does not know the current hop frequency of the target device. The paging device transmits page requests on each of the page scan hop frequencies and listens for a page response. This is done at a faster hop rate, allowing the paging device to cover all page scan frequencies in a reasonably short time period.

The paging device may have some knowledge of the target device's Bluetooth clock (indicated during a previous inquiry transaction between the two devices, or as a result of a previous involvement in a piconet with the device), in this case it is able to predict the phase of the target device's page scan channel. It may use this information to optimize the synchronization of the paging and page scanning process and speed up the formation of the connection.

3.3.1.4.3 Topology

Paging and connectable devices use a simple exchange of packets to fulfill the paging function. The topology formed during this transaction is a simple and transient point-to-point connection.

3.3.1.4.4 Supported layers

During the exchange of packets between a paging and connectable device it may be considered that a temporary physical link exists between these devices. However, the concept is quite irrelevant as it has no physical representation but is only implied by the brief transaction between the devices. No further architectural layers are considered to be supported.

3.3.1.5 Synchronization scan channel

3.3.1.5.1 Overview

In order to receive packets sent on the CPB logical transport, a device must first obtain information about the timing and frequency channels of those packets. If a device misses a Coarse Clock Adjustment notification, it needs to recover the current piconet clock. The synchronization scan channel is provided for these purposes. A scanning device listens for synchronization train packets on the synchronization scan channel. Once a synchronization train packet is received, the device may stop listening for synchronization train packets because it has the timing and frequency information necessary to start receiving packets sent on the CPB logical transport or to recover the piconet clock.

3.3.1.5.2 Characteristics

The synchronization scan channel uses an access code derived from the Bluetooth Device Address of the synchronization train transmitter to identify synchronization train packets on the channel. Once a synchronization train packet is received, the scanning BR/EDR Controller may start receiving packets sent on the CPB logical transport, depending on the needs of the Host and any applicable profile(s).

3.3.1.5.3 Topology

The topology formed during this scan is transient and point-to-multipoint. There can be an unlimited number of scanning devices simultaneously receiving synchronization train packets from the same synchronization train transmitter.

3.3.1.5.4 Supported layers

There is a one-way flow of packets from the synchronization train transmitting device to the scanning device(s). This may be considered a temporary physical link that exists only until the scanning device receives the required information. No further architectural layers are considered to be supported.

3.3.2 LE physical channels

In the LE core system, two Bluetooth devices use a shared physical channel for communication. To achieve this, their transceivers need to be tuned to the same PHY frequency at the same time, and they need to be within a nominal range of each other.

Given that the number of PHY channels is limited, and many Bluetooth devices can be operating independently within the same spatial and temporal area, there is a strong likelihood of two pairs of independent Bluetooth devices having their transceivers tuned to the same PHY channel, resulting in a collision. Unlike BR/EDR, where an access code is used to identify the piconet, LE uses a randomly generated Access Address to identify a physical channel between devices. In the event that two devices happen to share the same PHY channel in the same area, the targeted device Access Address is used as a correlator to determine to which device the communication is directed.

Five LE physical channels are defined. Each is optimized and used for a different purpose. The LE piconet physical channel is used for communication between connected devices and is associated with a specific piconet. The LE advertising physical channel is used for broadcasting advertisements to LE devices. These advertisements can be used to discover, connect, or send user data to scanner or initiator devices. The periodic physical channel is used to send user data to scanner devices in periodic advertisements at a specified interval. The LE isochronous physical channel is used to transfer isochronous data between LE devices in an LE piconet or to transfer isochronous data between unconnected LE devices. The LE Channel Sounding physical channel carries security-related information, as well as content used for the purpose of measuring the time, phase, and amplitude of the communication channel between two LE devices in an LE piconet.

An LE device can only use one of these LE physical channels at any given time. In order to support multiple concurrent operations the device uses time-division multiplexing between the channels. In this way a Bluetooth device can appear to support connected devices while simultaneously sending advertising broadcasts.

Whenever an LE device is synchronized to the timing and frequency of the physical channel it is said to be connected or synchronized to this channel (whether or not it is actively involved in communications over the channel). The Bluetooth specification assumes that a device is only capable of connecting to one physical channel at a time. Advanced devices may be capable of connecting or synchronizing simultaneously to more than one physical channel, but the specification does not make this assumption.

Packets on both the LE piconet physical channel and the LE advertisement broadcast channel can contain a Constant Tone Extension that can be used for the purpose of direction finding.

3.3.2.1 LE piconet physical channel

3.3.2.1.1 Overview

The LE piconet physical channel is used for communication between connected LE devices during normal operation.

3.3.2.1.2 Characteristics

The LE piconet physical channel is characterized by the access address, a pseudo-random sequence of PHY channels, and three additional parameters provided by the Central. The first is the channel map that indicates the set of PHY channels used in the piconet. The second is a pseudo random number used as an index into the complete set of PHY channels. The third is the timing of the first data packet sent by the Central after the connection request.

The channel is divided into connection events where each connection event corresponds to a PHY hop channel. Consecutive connection events correspond to different PHY hop channels. The first packet sent by the Central after the connection establishment sets an anchor point for the timing of all future connection events. In a connection event the Central transmits packets to a Peripheral in the piconet and the Peripheral may respond with a packet of its own.

On the LE piconet physical channel the Central controls access to the channel. The Central starts its transmission in a connection event that occurs at regular intervals. Packets transmitted by the Central are aligned with the connection event start and define the piconet timing.

Each Central transmission contains a packet carrying information on one of the logical transports. The Peripheral can transmit on the physical channel in response.

The LE piconet physical channel is similar to the BR/EDR adapted piconet channel in that the set of PHY channels used can be modified to avoid interference. The set of used channels in the channel map is established by the Central during connection setup. While in a connection the Central can change the channel map when necessary to avoid new interferers. The Peripheral can provide channel classification information to the Central.

There are 37 LE piconet channels. The Central can reduce this number through the channel map indicating the used channels. When the hopping pattern hits an unused channel the unused channel is replaced with an alternate from the set of used channels. The LE Piconet physical channel can use any LE PHY.

3.3.2.1.3 Topology

An LE piconet physical channel is shared by exactly two LE devices.

An LE device may belong to one or more piconets at a time, that is, an LE device may be a Peripheral in zero or more piconets and may also be a Central in zero or more piconets.

Only one LE piconet physical channel can exist between two LE device identities or non-resolvable private addresses.

3.3.2.1.4 Supported layers

The LE piconet physical channel supports L2CAP channels used for general purpose communications.

3.3.2.2 Advertising physical channels

3.3.2.2.1 Overview

An LE advertising physical channel is used to set up connections between two devices or to communicate broadcast information between unconnected devices.

3.3.2.2.2 Characteristics

There are two LE advertising physical channels: the primary advertising physical channel and the secondary advertising physical channel.

The primary advertising physical channel is a set of three fixed PHY channels spread evenly across the LE frequency spectrum. The number of primary advertising PHY channels can be reduced by the advertising device in order to reduce interference. The primary advertising physical channel can use either the LE 1M or LE Coded PHY.

The primary advertising physical channel is divided into advertising events where each advertising event can hop on all primary advertising PHY channels. The advertising events occur at regular intervals which are slightly modified with a random delay to aid in interference avoidance.

On the primary advertising physical channel the advertising device controls access to the physical channel. The advertising device starts its transmission in an advertising event and transmits advertising packets on one or more of the primary advertising PHY channels. Each advertising packet is sent on a different advertising PHY channel at a fixed interval. Seven types of advertising events can be used, with each advertising event type having different sized advertising packets. The PDU payloads of these advertising packets can vary in length from 6 to 37 octets.

Some advertising events sent by the advertising device permit the listening device to concurrently send scan requests or connection requests packets on the same advertising PHY channel in which the advertising packet was received. The advertising device can send a scan response packet again on the same advertising PHY channel within the same advertising event. The payload of the scan response packet can vary in length from 6 to 37 octets.

The secondary advertising physical channel is a set of 37 fixed PHY channels spread across the LE frequency spectrum. These are the same fixed LE PHY channels used by the data physical channel. The secondary advertising physical channel uses the same channel indices as the data physical channel. The payload of advertising packets used on the secondary advertising physical channel can vary in length from 0 to 255 octets. Advertising packets on the secondary advertising physical channel are not part of the advertising event but are part of the extended advertising event. These extended advertising events begin at the same time as the advertising event on the primary advertising physical channel and conclude with the last packet on the secondary advertising physical channel.

The secondary advertising physical channel is used to offload data that would otherwise be transmitted on the primary advertising physical channel. Advertising packets on the secondary advertising physical channel ("auxiliary packets") are scheduled by the advertiser when sufficient over-the-air time is available. The advertising packet on the primary advertising physical channel contains the PHY channel and the offset to the start time of the auxiliary packet.

The secondary advertising physical channel can use any LE PHY. All advertising packets on the secondary advertising physical channel in the same extended advertising event use the same PHY, which is specified in the advertising packet on the primary advertising physical channel.

3.3.2.2.3 Topology

An LE advertising physical channel can be shared by any number of LE devices. Any number of LE devices can transmit advertising packets while sharing the advertising physical channel. Any number of scanning devices can listen on the advertising physical channel. An advertising device can advertise and be connected on an LE piconet physical channel simultaneously. Scanning devices may also be connected to one or more LE piconet physical channels simultaneously.

3.3.2.3 Periodic physical channel

3.3.2.3.1 Overview

An LE periodic physical channel is used to set up a periodic broadcast between unconnected devices.

3.3.2.3.2 Characteristics

The periodic physical channel is characterized by a pseudo-random sequence of PHY channels and additional parameters provided by the advertiser. These are the channel map that indicates the set of PHY channels used in the periodic broadcast, the event counter used to determine the channel hopping sequence, the offset indicating the timing of the first periodic broadcast packet, and the interval between successive periodic broadcasts.

The channel is divided into periodic advertising events where the start of a periodic advertising event corresponds to a PHY hop channel. The start of consecutive periodic advertising events corresponds to different PHY hop channels. The first packet sent by the advertiser after the broadcast is established sets an anchor point for the timing of all future periodic advertising events.

On the periodic physical channel, the advertising device controls access to the physical channel. The advertiser starts its transmission in a periodic advertising event that occurs at regular intervals. Packets transmitted by the advertiser are aligned with the periodic advertising event and specified broadcast timing. Additional packets may also be transmitted between the periodic advertising events. The payload of packets sent by the advertiser may vary in length from 0 octets to 255 octets.

Each advertiser transmission contains a packet carrying information on the PADVB logical transports. Scanners cannot transmit on the physical channel.

There are 37 PHY channels. The advertiser can reduce this number through the channel map indicating the used channels. When the hopping pattern hits an unused channel, the unused channel is replaced with an alternate from the set of used channels. The periodic physical channel can use any PHY. All periodic advertising events use the same PHY used by the advertiser in the packet describing the characteristics of the periodic physical channel.

3.3.2.3.3 Topology

An LE periodic physical channel can be shared by any number of LE devices. Any number of LE devices can transmit periodic advertising packets while sharing the same periodic physical PHY channels. Any number of scanning devices can listen on the periodic physical channel. An advertising device can advertise and be synchronized on an LE periodic physical channel simultaneously. Scanning devices may also be synchronized to one or more LE periodic physical channels simultaneously.

3.3.2.4 LE Isochronous physical channel

The LE isochronous physical channel can be created to transfer isochronous data between LE devices.

3.3.2.4.1 Overview

The LE isochronous physical channel is used to transfer isochronous data between connected or unconnected LE devices.

3.3.2.4.2 Characteristics

The LE isochronous physical channel is characterized by a pseudo-random sequence of PHY channels and by three additional parameters that are provided by a Central or a connectionless broadcaster. The first parameter is the channel map that indicates the set of PHY channels. The second parameter is a pseudo random number that is used as an index into the complete set of PHY channels. The third parameter is the timing of the first data packet. The timing of the first packet of a CIS is provided in the Link Layer message that is sent in the associated ACL connection by the Central during the CIS establishment phase. The timing of the first packet of a BIS is referenced from a periodic advertising event associated with the BIS.

The LE isochronous physical channel is used to transfer isochronous data in isochronous events that occur at regular intervals. Each isochronous event is divided into one or more subevents. Each subevent uses a PHY channel that is selected by the channel selection algorithm.

In any subevent in an isochronous connection, the Central transmits a packet to the Peripheral and the Peripheral may respond with a packet of its own. The Central controls the access to the LE isochronous physical channel. In every CIS event, the Central starts its transmission at the start of the first subevent. Packets that are transmitted by the Central are time aligned with the start of every subevent.

A Broadcasting Isochronous transmitter transmits isochronous data packets and control packets. Any device that is synchronized to the BIS can receive these packets. The broadcasting device controls access to the LE isochronous physical channel. Within BIS events, the broadcasting device starts its transmission in the first subevent. Packets that are transmitted by the broadcasting device are aligned with the start of every subevent.

There are 37 PHY channels. The Central or the isochronous stream transmitter can reduce this number through the channel map that indicates the used channels. When the channel selection algorithm selects an unused channel, the unused channel is replaced with an alternate from the set of used channels. For CISes, the LE isochronous physical channel uses the set of PHY channels that are enabled on the LE piconet physical channel. The LE isochronous physical channel can use any LE PHY.

3.3.2.4.3 Topology

The LE isochronous physical channel in a CIS can be used for one-to-one communication between the devices that are in the LE piconet. The Central may

establish one or more CISes with the Peripheral in the LE piconet; that is, the LE isochronous physical channel can carry one or more CIS logical transports between a given Central and Peripheral. The LE isochronous physical channel and all the CISes it carries are terminated when the associated LE piconet physical channel is terminated. If a Central has established piconets with more than one Peripheral, it can establish LE isochronous physical channels with more than one of these Peripherals at the same time.

The LE isochronous physical channel can be used for one-to-many communication topologies of unconnected LE devices. Each LE isochronous physical channel can carry one or more BIS logical transports.

3.3.2.5 LE Channel Sounding physical channel

The LE CS physical channel can be created to transfer time and phase information that can be used to generate a distance estimate.

3.3.2.5.1 Overview

An LE CS physical channel is used to exchange time-interleaved modulated tones and packets that allow a pair of devices to measure the time of flight, amplitude, and phase of signals sent over the communication channel. This information can be used to estimate the distance between two LE devices.

3.3.2.5.2 Characteristics

The LE CS physical channel is characterized by a pre-negotiated sequence of exchanges that make up a CS procedure. Characteristics and content of these exchanges is derived from the output of a Deterministic Random Bit Generator (DRBG). The DRBG is used to generate the content of the CS Access Address and payload content. It is also used to influence the modulated content of tone transmissions. Finally, the DRBG is used to seed the selection of the pseudo-random sequence of the PHY channels used in the channel hop sequence of a Channel Sounding procedure.

The duration of a CS procedure is determined by the time it takes for a predetermined number of CS steps to be exchanged. Additional time may be required to partition the CS steps into subevents in order to coexist with other activities using the same radio or spectrum.

CS steps are defined as a bidirectional exchange between initiator and reflector devices. These steps are further aggregated into a related timing group known as a CS subevent. These subevents are timed from an offset of the underlying LE piconet physical channel connection event anchor point. A CS event is defined as the group of all CS subevents offset from the same LE piconet physical channel connection event anchor point.

Each step exchange may include a modulated packet, a modulated tone, or both. The initiator device transmits first, followed by at least one transmission from the reflector. A modulated tone may be transmitted more than once in each direction in cases where multiple antenna paths are employed.

3.3.2.5.3 Topology

An LE Channel Sounding physical channel is used for one-to-one communication between two devices that are in the same piconet, where one is in the initiator role and the other is in the reflector role. In the context of CS, an initiator is the device that starts the CS procedure, and a reflector is the device that responds. The procedure's operating parameters are exchanged in Link Layer control messages. LE CS physical channel timing depends on the timing of the initiator device, which is followed by the reflector device. The LE Central device may assume either the initiator or reflector role. Likewise, the LE Peripheral device may assume either role.

An LE device can use only one LE Channel Sounding physical channel at a time. To support multiple concurrent Channel Sounding operations, the device uses time-division multiplexing between multiple LE Channel Sounding physical channels, which allows a device to appear to support multiple connected devices with Channel Sounding physical channels.

3.3.3 [This section is no longer used]

3.4 Physical links

A physical link represents a baseband connection between Bluetooth devices. A physical link is always associated with exactly one physical channel (although a physical channel may support more than one physical link). Within the Bluetooth system a physical link is a virtual concept that has no direct representation within the structure of a transmitted packet.

In BR/EDR the access code packet field, together with the clock and address of the Central Bluetooth device, is used to identify a physical channel. In LE, the access address and channel map, including *hopIncrement* in the case of Channel Selection Algorithm #1 or an event counter in the case of Channel Selection Algorithm #2, are used to identify a physical channel. For BR/EDR and LE, there is no subsequent part of the packet that directly identifies the physical link. Instead, the physical link may be identified by association with the logical transport, as each logical transport is only received on one physical link.

Some physical link types have properties that may be modified. An example of this is the transmit power for the link. Other physical link types have no modifiable properties. In the case of BR/EDR physical links with modifiable properties the LM protocol is used to adapt these properties. In the case of LE physical links with modifiable properties

the LL protocol is used to adapt these properties. As the LM protocol (BR/EDR) or LL protocol (LE) is supported at a higher layer (by a logical link) the appropriate physical link is identified by implication from the logical link that transports the LM or LL signaling.

In the situation where a transmission is broadcast over a number of different physical links, then the transmission parameters are selected to be suitable for all of the physical links.

3.4.1 BR/EDR links supported by the basic and adapted piconet physical channels

The basic piconet physical channel supports a physical link which may only be active. The adapted piconet physical channel may support several physical links, including active and Connectionless Peripheral Broadcast. An active physical link is a point-to-point link between the Central and a Peripheral. A Connectionless Peripheral Broadcast physical link is a point-to-multipoint link between the Transmitter (Central) and zero or more Receivers (Peripherals). At least one physical link on the piconet physical channel is always present when a Peripheral is synchronized in the piconet.

3.4.1.1 Active physical link

The physical link between a Central and a Peripheral is active if a default ACL logical transport exists between the devices. Active physical links have no direct identification of their own, but are identified by association with the default ACL logical transport ID with which there is a one-to-one correspondence.

An active physical link has the associated property of radio transmit power in each direction. Transmissions from Peripherals are always directed over the active physical link to the Central, and use the transmit power that is a property of this link in the Peripheral to Central direction. Transmissions from the Central may be directed over a single active physical link (to a specific Peripheral) or over a number of physical links (to a group of Peripherals in the piconet). In the case of point-to-point transmissions the Central uses the appropriate transmit power for the physical link in question. (In the case of point-to-multipoint transmissions the Central uses a transmit power appropriate for the set of devices addressed.)

Active physical links may be placed into Hold or Sniff mode. The effect of these modes is to modify the periods when the physical link is active and may carry traffic. Logical transports that have defined scheduling characteristics are not affected by these modes and continue according to their pre-defined scheduling behavior. The default ACL logical transport and other links with undefined scheduling characteristics are subject to the mode of the active physical link.

3.4.1.2 [This section is no longer used]

3.4.1.3 Connectionless Peripheral Broadcast physical link

A Connectionless Peripheral Broadcast physical link is present on a Receiver (Peripheral) when it is synchronized in the piconet where a CPB logical transport exists. On a Transmitter (Central), a Connectionless Peripheral Broadcast physical link is present when a CPB logical transport exists whether or not any Receivers are synchronized. The Connectionless Peripheral Broadcast physical link is a point-to-multipoint unidirectional link between a Transmitter and zero or more Receivers.

Connectionless Peripheral Broadcast physical links do not support power control because there is no feedback from Receivers to the Transmitter. Traffic is always directed from a single Transmitter to zero or more Receivers.

Connectionless Peripheral Broadcast packets are sent at regular intervals. The BR/EDR Controller selects an interval within a range requested by the Host.

3.4.2 BR/EDR links supported by the scanning physical channels

In the case of inquiry scan and page scan channels, the physical link exists for a relatively short time and cannot be controlled or modified in any way. These types of physical links are not further elaborated.

3.4.3 LE links supported by the LE physical channels

The LE piconet physical channels support an LE active physical link. The physical link is a point-to-point link between the Central and a Peripheral. It is always present when the Peripheral is in a connection with the Central.

The LE advertising physical channels support an LE advertising physical link. The physical link is a broadcast between the advertiser device and one or more scanner or initiator devices. It is always present when the advertiser is broadcasting advertisement events.

The LE periodic physical channels support an LE periodic physical link. The physical link is a broadcast between the advertiser device and one or more scanner devices. It is always present when the advertiser is broadcasting periodic advertising events.

The LE isochronous physical channels support LE isochronous physical links. An LE isochronous physical link can be a point-to-point link between a Central and a Peripheral or a connectionless link between a broadcast isochronous transmitter and multiple receiving devices.

3.4.3.1 Active physical link

The physical link between a Central and a Peripheral is active if a default LE ACL logical transport exists between the devices. Active physical links are each associated

with a separate piconet physical channel, which in turn is identified by the randomly generated Access Address used in the Link Layer packet. Each Access Address has a one-to-one relationship with the Central and the Peripheral of the active physical link.

An active physical link has the associated property of radio transmit power in each direction, which may be different in each direction. A device uses the appropriate transmit power for the physical link in question.

3.4.3.2 Advertising physical link

An advertising physical link between an advertising device and an initiating device for the purposes of forming a connection (active physical link) can exist for a relatively short period of time. These advertising physical links cannot be controlled or modified in any way and these types of physical links are not further elaborated.

An advertising physical link between an advertising device and a scanning device used for periodic broadcasting of user data can exist for longer periods of time. There is no identification information about the physical link within the protocol. The relationship between the advertising and scanning device is established through the use of the Bluetooth Device Address.

3.4.3.3 Periodic physical link

A periodic physical link between an advertising device and one or more scanning devices normally exists for a prolonged period of time. Periodic physical links are each associated with a separate periodic physical channel, which in turn is identified by the randomly generated Access Address used in the Link Layer packet. Each Access Address has a one-to-one relationship with the advertiser of the periodic physical link.

3.4.3.4 Isochronous physical links

The isochronous physical link uses an isochronous physical channel and carries CIS and BIS logical transports.

Isochronous physical links carrying CIS(es) use the appropriate transmit power level for the physical link in question. Devices use power control on the associated ACL-C logical link to adapt the transmit power level for the physical link.

Isochronous physical links carrying BIS(es) do not support power control because there is no feedback from Observers to the Broadcaster. Traffic is always directed from a single Broadcaster to zero or more Observers.

3.4.3.5 Channel Sounding physical link

Channel Sounding procedures exist within an LE Channel Sounding physical link and are characterized by their transitory existence as well as their unique timing

characteristics relative to an LE active physical link. Channel Sounding procedures are based on a preexisting LE active physical link. A CS procedure's start timing is also dependent on the timing of the corresponding LE active physical link.

A Channel Sounding physical channel supports a Channel Sounding physical link.

3.4.4 [This section is no longer used]

3.5 Logical links and logical transports

A variety of logical links are available to support different application data transport requirements. Each logical link is associated with a logical transport, which has a number of characteristics. These characteristics include flow control, acknowledgment/repeat mechanisms, sequence numbering and scheduling behavior. Logical transports are able to carry different types of logical links (depending on the type of the logical transport). In the case of some of the Bluetooth logical links these are multiplexed onto the same logical transport. Logical transports may be carried by active physical links on either the basic or the adapted piconet physical channel.

Logical transport identification and real-time (link control) signaling are carried in the packet header, and for some logical links identification is carried in the payload header. Control signaling that does not require single slot response times is carried out using the LMP protocol.

Table 3.4 lists all of the logical transport types, the supported logical link types, which type of physical links and physical channels can support them, and a brief description of the purpose of the logical transport.

Logical transport	Links supported	Supported by	Bearer	Overview
Asynchronous Connection-Oriented (ACL)	Control (LMP) ACL-C User (L2CAP) ACL-U	BR/EDR active physical link, BR/EDR basic or adapted piconet physical channel	BR/EDR	Reliable or time-bounded, bi-directional, point-to-point
Synchronous Connection-Oriented (SCO)	Stream (unframed) SCO-S	BR/EDR active physical link, BR/EDR basic or adapted piconet physical channel	BR/EDR	Bi-directional, symmetric, point-to-point, AV channels. Used for 64 kb/s constant rate data.

Logical transport	Links supported	Supported by	Bearer	Overview
Extended Synchronous Connection-Oriented (eSCO)	Stream (unframed) eSCO-S	BR/EDR active physical link, BR/EDR basic or adapted piconet physical channel	BR/EDR	Bi-directional, symmetric or asymmetric, point-to-point, general regular data, limited retransmission. Used for constant rate data synchronized to the Central's clock.
Active Peripheral Broadcast (APB)	Control (LMP) APB-C User (L2CAP) APB-U	BR/EDR active physical link, basic or adapted physical channel	BR/EDR	Unreliable, uni-directional broadcast to any devices synchronized with the physical channel. Used for broadcast L2CAP groups and certain LMP messages.
Connectionless Peripheral Broadcast (CPB)	Profile Broadcast Data (PBD)	Connectionless Peripheral Broadcast physical link, BR/EDR adapted piconet physical channel	BR/EDR	Unreliable, unidirectional, point-to-multipoint, periodic transmissions to zero or more devices.
LE asynchronous connection (LE ACL	Control (LL) LE-C, User (L2CAP) LE-U	LE active physical link, LE piconet physical channel	LE	Reliable, bi-directional, point-to-point.
LE Advertising Broadcast (ADVB)	Control (LL) ADVB-C, User (LL) ADVB-U	LE advertising physical link, LE advertising physical channel	LE	Unreliable, uni-directional broadcast to all devices in a given area or directed to one recipient. Used to carry data and Link Layer signaling between unconnected devices.
LE Periodic Advertising Broadcast (PADVB)	Control (LL) ADVB-C, User (LL) ADVB-U	LE periodic physical link, LE periodic physical channel	LE	Unreliable, periodic, unidirectional broadcast to all devices in a given area.
Periodic Advertising with Responses (PAwR)	Control (LL) ADVB-C, User (LL) ADVB-U	LE periodic physical link, LE periodic physical channel	LE	Unreliable, periodic broadcast to all devices or a subset of devices in a given area with optional responses from the devices.

Logical transport	Links supported	Supported by	Bearer	Overview
Connected Isochronous Stream	Low Energy Stream (LE-S) and Low Energy Framed data (LE-F)	LE isochronous physical link	LE	Unidirectional or bidirectional transport in a point-to-point connection for transferring isochronous data.
Broadcast Isochronous Stream	Low Energy Stream (LE-S), Low Energy Framed data (LE-F) and Low Energy Broadcast Control (LEB-C)	LE isochronous physical link	LE	Unidirectional transport for broadcasting data in a point to multipoint configuration and unidirectional transport for controlling the broadcast data.

Table 3.4: Logical transport types

The classification of each link type follows from a selection procedure within three categories.

3.5.1 Casting

The first category is that of casting. This may be either unicast or broadcast.

- Unicast links exist between exactly two endpoints. Traffic may be sent in either direction on unicast links.
- Broadcast links exist between one source device and zero or more receiver devices. Traffic is unidirectional, i e., only sent from the source devices to the receiver devices. Broadcast links are connectionless, meaning there is no procedure to create these links, and data may be sent over them at any time. Broadcast links are unreliable, and there is no guarantee that the data will be received.

3.5.2 Scheduling and acknowledgment scheme

The second category relates to the scheduling and acknowledgment scheme of the link, and implies the type of traffic that is supported by the link. These are synchronous, isochronous or asynchronous. There are no specific isochronous links defined, though the default ACL link can be configured to operate in this fashion.

- Synchronous links provide a method of associating the transported data with the Bluetooth piconet clock. This is achieved by reserving regular slots on the physical channel, and transmitting fixed size packets at these regular intervals. Such links are suitable for constant rate isochronous data.
- Asynchronous links provide a method for transporting data that has no time-based characteristics. The data is normally expected to be retransmitted until successfully received, and each data entity can be processed at any time after receipt, without

reference to the time of receipt of any previous or successive entity in the stream (providing the ordering of data entities is preserved).

- Isochronous links provide a method for transporting data that has time-based characteristics. The data may be retransmitted until received or expired. The data rate on the link need not be constant (this being the main difference from synchronous links).

3.5.3 Class of data

The final category is related to the class of data that is carried by the link. This is either control data or user data. The user data category is sub-divided into L2CAP data, stream data, and periodic broadcast data.

- Control links are only used for transporting LMP or Link Layer messages between two Controllers. These links are invisible above the baseband layer or Link Layer and cannot be directly instantiated, configured, or released by applications, other than by the use of the services, such as connection and disconnection, that have this effect implicitly. Control links are always multiplexed with an equivalent L2CAP data link onto a logical transport. For example, ACL-C and ACL-U are multiplexed onto an ACL logical transport, whereas ADVB-C and ADVB-U are multiplexed onto ADVB and PADVB logical transports. Subject to the rules defining the acknowledgment scheme, the control link traffic normally takes priority over the L2CAP link traffic.
- L2CAP links are used to transport L2CAP PDUs, which may carry the L2CAP signaling channel or framed user data submitted to user-instantiated L2CAP channels. L2CAP frames submitted to the baseband may be larger than the available Baseband packets. A link control protocol embedded within the LLID field preserves the frame-start and frame-continuation semantics when the frame is transmitted in a number of fragments to the receiver. Normally, L2CAP links give reliable delivery of data priority over timely delivery.
- Stream links are used to transport user data when timely delivery of the latest data has priority over reliability. Lost data may be replaced by padding at the receiver. On BR/EDR, these links (SCO and eSCO) have a fixed bandwidth and are always bidirectional between two devices; on LE, they have a variable bandwidth with a specified maximum and may be either bidirectional between two devices (CIS) or unidirectional broadcast (BIS).
- Periodic broadcast data is transmitted at regular intervals, possibly with jitter, by a device. It has no acknowledgment mechanism. The same data is transmitted until it is explicitly changed. This is sent on the PBD logical link on BR/EDR and on the ADVB-U logical link on LE.

3.5.4 Logical transports

3.5.4.1 BR/EDR asynchronous connection-oriented (ACL)

The asynchronous connection-oriented (ACL) logical transport is used to carry LMP and L2CAP control signaling and best effort asynchronous user data. The ACL logical transport uses a 1-bit ARQN/SEQN scheme to provide simple channel reliability. Every active Peripheral within a piconet has one ACL logical transport to the piconet Central, known as the default ACL.

The default ACL is created between the Central and the Peripheral when a device joins a piconet (connects to the basic piconet physical channel). This default ACL is assigned a logical transport address (LT_ADDR) by the piconet Central. This LT_ADDR is also used to identify the active physical link when required (or as a piconet active member identifier, effectively for the same purpose).

The LT_ADDR for the default ACL is reused for synchronous connection-oriented logical transports between the same Central and Peripheral. Thus the LT_ADDR is not sufficient on its own to identify the default ACL. However the packet types used on the ACL are different from those used on the synchronous connection-oriented logical transport. Therefore, the ACL logical transport can be identified by the LT_ADDR field in the packet header in combination with the packet type field.

The default ACL may be used for isochronous data transport by configuring it to automatically flush packets after the packets have expired. Asynchronous traffic can be sent over an ACL logical transport configured for isochronous traffic by marking the asynchronous packets as non-automatically-flushable. This allows both isochronous and asynchronous traffic to be transferred at the same time to a single device.

If the default ACL is removed from the active physical link then all other logical transports that exist between the Central and the Peripheral are also removed. In the case of unexpected loss of synchronization to the piconet physical channel the physical link and all logical transports and logical links cease to exist at the time that this synchronization loss is detected.

3.5.4.2 BR/EDR synchronous connection-oriented (SCO)

The synchronous connection-oriented (SCO) logical transport is a symmetric, point-to-point transport between the Central and a specific Peripheral. The SCO logical transport reserves slots on the physical channel and can therefore be considered as a circuit-switched connection between the Central and the Peripheral. SCO logical transports carry 64 kb/s of information synchronized with the piconet clock. Typically this information is an encoded voice stream. Three different SCO configurations exist, offering a balance between robustness, delay and bandwidth consumption.

Each SCO-S logical link is supported by a single SCO logical transport, which is assigned the same LT_ADDR as the default ACL logical transport between the devices. Therefore the LT_ADDR field is not sufficient to identify the destination of a received packet. Because the SCO links use reserved slots, a device uses a combination of the LT_ADDR, the slot numbers (a property of the physical channel) and the packet type to identify transmissions on the SCO link.

Although slots are reserved for the SCO, it is permissible to use a reserved slot for traffic from another channel that has a higher priority. This may be required as a result of QoS commitments, or to send LMP signaling on the default ACL when the physical channel bandwidth is fully occupied by SCOs. As SCOs carry different packet types to ACLs, the packet type is used to identify SCO traffic (in addition to the slot number and LT_ADDR).

There are no further architectural layers defined by the specification that are transported over a SCO link. A number of standard formats are defined for the 64 kb/s stream that is transported, or an unformatted stream is allowed where the application is responsible for interpreting the encoding of the stream.

3.5.4.3 BR/EDR extended synchronous connection-oriented (eSCO)

The extended synchronous connection-oriented (eSCO) logical transport is a symmetric or asymmetric, point-to-point transport between the Central and a specific Peripheral. The eSCO reserves slots on the physical channel and can therefore be considered as a circuit-switched connection between the Central and the Peripheral. eSCO links offer a number of extensions over the standard SCO links, in that they support a more flexible combination of packet types and selectable data contents in the packets and selectable slot periods, allowing a range of synchronous bit rates to be supported.

eSCO links also can offer limited retransmission of packets (unlike SCO links where there is no retransmission). If these retransmissions are required they take place in the slots that follow the reserved slots, otherwise the slots may be used for other traffic.

Each eSCO-S logical link is supported by a single eSCO logical transport, identified by a LT_ADDR that is unique within the piconet for the duration of the eSCO. eSCO-S links are created using LM signaling and follow scheduling rules similar to SCO-S links.

There are no further architectural layers defined by the specification that are transported over an eSCO-S link. Instead applications may use the data stream for whatever purpose they require, subject to the transport characteristics of the stream being suitable for the data being transported.

3.5.4.4 BR/EDR active Peripheral broadcast (APB)

The active Peripheral broadcast logical transport is used to transport LMP control signaling and connectionless L2CAP user traffic to all devices in the piconet that are

currently connected to the physical channel that is used by the APB. There is no acknowledgment protocol and the traffic is uni-directional from the piconet Central to the Peripherals. The APB channel may be used for L2CAP group traffic (a legacy of the 1.1 specification), and is never used for L2CAP connection-oriented channels or L2CAP control signaling.

The APB logical transport is inherently unreliable because of the lack of acknowledgment. To improve the reliability, each packet is transmitted a number of times. An identical sequence number is used to assist with filtering retransmissions at the Peripheral.

The APB logical transport is identified by a reserved LT_ADDR.

An APB is implicitly created whenever a piconet exists, and there is always one APB associated with each of the active physical links (whether operating over the basic or adapted piconet physical channel) that exist within the piconet. Because the basic and adapted piconet physical channels, and different channel maps on the adapted piconet physical channel, are mostly coincident, a Peripheral cannot always distinguish which of the APB channels is being used to transmit the packets. This adds to the general unreliability of the APB channel. (Although it is, perhaps, no more unreliable than general missed packets.)

A Central may decide to use only one of its two possible APBs (when it has both a basic and adapted piconet physical channel), or only one of the channel maps in use on the adapted piconet physical channel (when it has more than one map), as with sufficient retransmissions or careful selection of which slots to transmit on it is possible to address all Peripherals.

The APB channel is never used to carry L2CAP control signals.

3.5.4.5 [This section is no longer used]

3.5.4.6 LE asynchronous connection (LE ACL)

The LE asynchronous connection (LE ACL) logical transport is used to carry LL and L2CAP control signaling and best effort asynchronous user data. The LE ACL logical transport uses a 1-bit NESN/SN scheme to provide simple channel reliability. Every active Peripheral has one LE ACL logical transport to the piconet Central, known as the default LE ACL.

The default LE ACL is automatically created between the Central and the Peripheral when the piconet connecting them is created. This default LE ACL is assigned an Access Address by the piconet Central. This Access Address is also used to identify the active physical link and active piconet physical channel when required.

If the default LE ACL is removed from the LE active physical link then all other LE logical transports that exist between the Central and the Peripheral are also removed. In the case of unexpected loss of synchronization to the LE piconet physical channel the LE physical link and all LE logical transports and LE logical links cease to exist at the time that this synchronization loss is detected.

3.5.4.7 LE advertising broadcast (ADVB)

The LE advertising broadcast logical transport is used to transport broadcast control and user data to all scanning devices in a given area. There is no acknowledgment protocol and the traffic is predominately unidirectional from the advertising device. A scanning device can send requests over the logical transport to get additional broadcast user data, or to form an LE ACL logical transport connection. The LE Advertising Broadcast logical transport data is carried only over the LE advertising broadcast link.

The ADVB logical transport is inherently unreliable because of the lack of acknowledgment. To improve the reliability, each packet is transmitted a number of times over the LE advertising broadcast link.

An ADVB is created whenever an advertising device begins advertising. The ADVB logical transport is identified by the advertiser's Bluetooth Device Address and advertising set.

3.5.4.8 Connectionless Peripheral Broadcast (CPB)

The CPB logical transport is used to transport profile broadcast data to all devices connected to the Connectionless Peripheral Broadcast logical transport. There is no acknowledgment scheme and the traffic is unidirectional from a Transmitter to zero or more Receivers. To improve reliability, profile broadcast data may be transmitted multiple times.

The CPB logical transport is created on the transmitter whenever the Connectionless Peripheral Broadcast is started. The CPB logical transport is created on the receiver whenever Connectionless Peripheral Broadcast reception is configured. The CPB logical transport is identified by a unique LT_ADDR within the piconet that is reserved specifically for that purpose by the Connectionless Peripheral Broadcast Transmitter.

3.5.4.9 LE periodic advertising

3.5.4.9.1 LE periodic advertising broadcast (PADVB)

The LE periodic advertising broadcast logical transport is used to transport periodic broadcast control and user data to all scanning devices in a given area. The data may be constant for several periods or may change frequently. There is no acknowledgment protocol and the traffic is unidirectional from the advertising device. The LE Periodic

Advertising Broadcast logical transport data is carried only over the LE periodic physical link.

The PADVB logical transport is inherently unreliable because of the lack of acknowledgment. To improve the reliability, the period between transmissions can be shorter than the interval between changes to the data so that each packet can be transmitted a number of times over the LE periodic physical link.

A PADVB is created whenever an advertising device begins periodic advertising. The PADVB logical transport is identified by the advertiser's Bluetooth Device Address, timing, and advertising set.

3.5.4.9.2 Periodic advertising with responses (PAwR)

The LE periodic advertising with responses logical transport is used to transport periodic broadcast control and user data to all scanning devices in a given area. These broadcasts are grouped into subevents, allowing a subset of the devices to be synchronized with each subevent. Each subevent can then contain information that is directed to the subset of devices synchronized to that subevent. This allows the broadcasting device to send data to many devices and the synchronized devices to only have to listen very infrequently for information directed to them. The data may be constant for several periods or may change frequently. The PAwR logical transport data is carried only over the LE periodic physical link.

The PAwR logical transport also includes response slots. The devices that have been directly addressed by the advertising device use response slots to send back responses. A higher layer specification determines the set of devices that can respond and when they respond. The PAwR logical transport is inherently unreliable, but the ability to use response slots allows higher layer acknowledgments to be used to provide reliability.

A PAwR logical transport is created whenever an advertising device begins periodic advertising configured to use subevents and responses. The PAwR logical transport is identified by the advertiser's Bluetooth Device Address, timing, and advertising set.

3.5.4.10 Connected Isochronous Stream (CIS)

The CIS is a data-symmetric or data-asymmetric, point-to-point logical transport between the Central and a specific Peripheral. A CIS reserves transmission/reception (Tx/Rx) periods, known as subevents, on the isochronous physical channel and can be considered as a circuit switched connection between the Central and the Peripheral. The CIS supports a variable flushing period for payloads, variable size data contents in the packets, and a variable number of subevents, allowing a range of isochronous data rates, latencies, and re-transmissions to be supported. A CIS can be configured to retransmit packets by providing more subevents than required for transmitting the

data. If retransmissions are required, they take place in the subevents (of the current or subsequent events) that follow.

Each LE-S or LE-F logical link is supported by a single CIS that is identified by a unique access address for the lifetime of the CIS. The LE-S or LE F links are created by using Link Layer procedures. The higher layer may use the data stream for whatever purpose it requires, as long as the transport characteristics of the stream are suitable for the data that is being transported. All isochronous connections are terminated when the associated LE piconet physical channel is terminated.

3.5.4.11 Connected Isochronous Group (CIG)

Each CIS is part of a CIG. A CIG may have one or more CISes, all with the same Central but possibly different Peripherals. Multiple CISes in a CIG have a common timing reference based on the Central timing and are synchronized in time. The common timing reference of multiple CISes helps devices to synchronize their input or output data. For example, when the left and right channels of an audio stereo stream, which are received by separate devices, need to be rendered at the same time. Multiple CISes in a CIG can be scheduled sequentially or in an interleaved arrangement.

3.5.4.12 Broadcast Isochronous Stream (BIS)

The BIS logical transport is used to transport one or more isochronous data streams to all devices for a BIS within range. The data may be fixed or variable size, framed or unframed. A BIS has one or more subevents for transmitting isochronous data packets. A BIS supports transmission of multiple new isochronous data packets in every BIS event. There is no acknowledgment protocol and the traffic is unidirectional from the broadcasting device. The BIS logical transport is inherently unreliable because of the lack of acknowledgment. To improve the reliability of delivery, the isochronous data packets can be unconditionally re-transmitted by increasing the number of subevents in every event. The reliability of delivery can also be improved by transmitting packets in intervals earlier than the intervals they are associated with; this is called "pre-transmission". A BIS supports LE-S or LE-F logical links. A BIS is identified by a unique access address and the timing information. The access address and the timing information is transmitted in the packet that is sent using the associated Periodic Advertising Broadcast (PADVB) logical transport. A scanning device that supports the Synchronized Receiver role feature may receive isochronous data from a BIS after synchronizing to the BIS by using the timing information from the periodic advertising train.

3.5.4.13 Broadcast Isochronous Group (BIG)

Each BIS is part of a BIG. A BIG may have one or more BISes. Multiple BISes in a BIG have a common timing reference based on the broadcaster and are synchronized in time. For example, when the left and right channels of an audio stereo stream, which

are received by separate devices, need to be rendered at the same time. Multiple BISes in a BIG can be scheduled sequentially or in an interleaved arrangement. A BIG also supports a Low Energy Broadcast Control (LEB-C) logical link.

3.5.5 Logical links

Some logical transports are capable of supporting different logical links, either concurrently multiplexed, or one of the choice.

3.5.5.1 BR/EDR logical links

Within BR/EDR logical transports, the logical link is identified by the logical link identifier (LLID) bits in the payload header of Baseband packets that carry a data payload. The logical links distinguish between a limited set of core protocols that are able to transmit and receive data on the logical transports. Not all of the logical transports are able to carry all of the logical links (the supported mapping is shown in Figure 3.2). In particular the BR/EDR SCO and eSCO logical transports are only able to carry constant data rate streams, and these are uniquely identified by the LT_ADDR. Such logical transports only use packets that do not contain a payload header, as their length is known in advance, and no LLID is necessary.

3.5.5.1.1 ACL control logical links (ACL-C and APB-C)

The ACL Control Logical Links (ACL-C and APB-C) are used to carry BR/EDR LMP signaling between devices in the piconet. The ACL-C control link is normally only carried on the default ACL logical transport (though can also be carried in DV packets on the SCO logical transport) while the APB-C control link is only carried on the APB logical transport. Each control link is always given priority over the corresponding data link carried on the same logical transport.

3.5.5.1.2 User asynchronous/isochronous logical links (ACL-U and APB-U)

The user asynchronous/isochronous logical links (ACL-U and APB-U) are used to carry all asynchronous and isochronous framed user data. The ACL-U link is normally only carried on the default ACL logical transport (though can also be carried in DV packets on the SCO logical transport) while the APB-U link is only carried on the APB logical transport. Packets on the ACL-U and APB-U link are identified by one of two reserved LLID values. One value is used to indicate that the Baseband packet contains the start of an L2CAP frame and the other indicates a continuation of a previous frame. This ensures correct synchronization of the L2CAP reassembler following flushed packets. The use of this technique removes the need for a more complex L2CAP header in every Baseband packet (the header is only required in the L2CAP start packets) because each L2CAP frame is completely transmitted before the next one starts. (An exception to this rule being the ability to flush a partially transmitted L2CAP frame in favor of another L2CAP frame.)

3.5.5.1.3 User synchronous/extended synchronous logical links (SCO-S/eSCO-S)

Synchronous (SCO-S) and extended synchronous (eSCO-S) logical links are used to support isochronous data delivered in a stream without framing. These links are associated with a single logical transport, where data is delivered in constant sized units at a constant rate. There is no LLID within the packets on these transports, as only a single logical link can be supported, and the packet length and scheduling period are pre-defined and remain fixed during the lifetime of the link.

Variable rate isochronous data cannot be carried by the SCO-S or eSCO-S logical links. In this case the data must be carried on ACL-U or APB-U logical links, which use packets with a payload header.

3.5.5.1.4 Profile Broadcast Data (PBD) logical link

The PBD logical link is used to broadcast isochronous unframed data to multiple receivers and resides on the CPB logical transport.

3.5.5.2 LE logical links

Within LE logical transports, the logical link is identified by the logical link identifier (LLID) bits in the payload header of Baseband packets that carry a data payload. The logical links distinguish between a limited set of core protocols that are able to transmit and receive data on the logical transports. Not all of the logical transports are able to carry all of the logical links (the supported mapping is shown in Figure 3.2).

3.5.5.2.1 Control logical link (LE-C)

The LE ACL Control Logical Link (LE-C) is used to carry LE LL signaling between the two devices in the piconet. The control link is only carried on the default LE ACL logical transport.

3.5.5.2.2 User asynchronous logical link (LE-U)

The user asynchronous logical link (LE-U) is used to carry all asynchronous and framed user data. The LE-U link is carried on the LE logical transport. Packets on the LE-U link are identified by one of two reserved LLID values. One value is used to indicate that the Baseband packet contains the start of an L2CAP frame and the other indicates a continuation of a previous frame or empty PDU. This ensures correct synchronization of the L2CAP re-assembler. The use of this technique removes the need for a more complex L2CAP header in every Baseband packet because each L2CAP frame is completely transmitted before the next one starts.

3.5.5.2.3 Advertising Broadcast Control logical link (ADVB-C)

The LE Advertising Broadcast Control Logical Link (ADVB-C) is used to carry LE LL signaling between unconnected devices in a given area. This signaling is the control

commands for gathering additional broadcast user data (scan requests) or connection requests. The control link is carried on the LE Advertising Broadcast and LE Periodic Advertising Broadcast logical transports.

3.5.5.2.4 Advertising Broadcast User Data logical link (ADVB-U)

The LE Advertising Broadcast User Data Logical Link (ADVB-U) is used to carry LE Advertising Broadcast and LE Periodic Advertising Broadcast user data used between devices without the need for a connection or LE-U between the devices. The user data link is carried on the LE Advertising Broadcast logical transport for LE Advertising Broadcast user data and the LE Periodic Advertising Broadcast logical transport for LE Periodic Advertising Broadcast user data.

3.5.5.2.5 Low Energy Stream (LE-S)

An LE-S is a logical link that is used to carry the unframed isochronous data packets of an isochronous data stream in a CIS or a BIS logical transport.

3.5.5.2.6 Low Energy Framed (LE-F)

An LE-F is a logical link that is used to carry the framed isochronous data packets of an isochronous data stream in a CIS or a BIS logical transport.

3.5.5.2.7 Low Energy Broadcast Control (LEB-C)

An LEB-C is a logical link that uses the BIS logical transport to carry the control information for all the BISes in a BIG.

3.5.5.3 [This section is no longer used]

3.6 L2CAP channels

L2CAP provides a multiplexing role allowing many different applications to share an ACL-U, APB-U, or LE-U logical link. Applications and service protocols interface with L2CAP using a channel-oriented interface to create connections to equivalent entities on other devices.

L2CAP channel endpoints are identified to their clients by a Channel Identifier (CID). This is assigned by L2CAP, and each L2CAP channel endpoint on any device has a different CID.

L2CAP channels may be configured to provide an appropriate Quality of Service (QoS) to the application. L2CAP maps the channel onto the ACL-U, APB-U, or LE-U logical link.

L2CAP supports channels that are connection-oriented and others that are group-oriented. Group-oriented channels may be mapped onto the APB-U logical link, or

implemented as iterated transmission to each member in turn over an ACL-U logical link.

Apart from the creation, configuration and dismantling of channels, the main role of L2CAP is to multiplex service data units (SDUs) from the channel clients onto the ACL-U, APB-U, or LE-U logical link, and to carry out a simple level of scheduling, selecting SDUs according to relative priority.

L2CAP can provide per channel flow control with the peer L2CAP layer (except on the APB-U logical link). This option is selected by the application when the channel is established. L2CAP can also provide enhanced error detection and retransmission to (a) reduce the probability of undetected errors being passed to the application and (b) recover from loss of portions of the user data when the Baseband performs a flush on the ACL-U logical link.

In the case where an HCI is present, the L2CAP is also required to segment L2CAP SDUs into fragments that will fit into the baseband buffers, and also to operate a token based flow control procedure over the HCI, submitting fragments to the baseband only when allowed to do so. This may affect the scheduling algorithm.

3.7 Isochronous Adaptation Layer (ISOAL)

The ISOAL provides a mechanism such that the timing used to generate or receive isochronous data in the upper layer can be independent of the timing used in the CIS or BIS logical transport used to carry the isochronous data. For example, audio codec data can be generated at a 10 ms interval while the value of ISO_Interval for the CIS can be 11.25 ms. The ISOAL converts upper layer isochronous data units to lower layer isochronous data packets (or the other way around). For more information, see [Vol 6] Part G.

3.8 Power control

The power control feature provides a mechanism to request a remote device to adjust its transmit power level based on local signal quality information. The feature is supported on BR/EDR active physical links (see Section 3.4.1.1) and on LE active physical links (see Section 3.4.3.1).

3.8.1 Power control in BR/EDR

In BR/EDR, two power control mechanisms (legacy and enhanced power control) are available. Both mechanisms support requesting an incremental change in transmit power level. The enhanced power control mechanism also allows requesting a change to maximum transmit power level. The requested change is applied on all supported modulations at once since the modulation can change dynamically between packets.

3.8.2 Power control in LE

In LE, a device can request a remote device to make a specified change in the remote device's power level on a given PHY. This allows a faster transition to the desired power level compared to incremental changes. A responding device can also return a value to indicate an acceptable reduction in the power level that allows the requesting device to further reduce its transmit power level to the minimum level possible and hence conserve energy. The local and remote devices can also share their current transmit power levels during this exchange to enable devices to calculate the link path loss between them. Devices are also allowed to do autonomous local transmit power level changes and indicate the change to the remote device.

In LE, an ACL connection can have associated connections like CIS(es). The power control for all the PHYs used on the ACL and associated connections is managed over the ACL connection. The Host can use the connection handle of the ACL connection to retrieve information for all PHYs used on the ACL and associated connections.

4 COMMUNICATION TOPOLOGY AND OPERATION

4.1 Piconet topology

4.1.1 BR/EDR topology

Any time a link is created using the BR/EDR Controller it is within the context of a piconet. Each link connects two devices, called the “Central” and “Peripheral”. A piconet consists of a single Central, known as the Central of the piconet, and all the Peripherals linked to it, known as the Peripherals in the piconet.

Connected BR/EDR devices communicate on the same physical channel by synchronizing with a common clock and hopping sequence. The common (piconet) clock is identical to the Bluetooth clock of the Central of the piconet and the hopping sequence is derived from the Central’s clock and the Central’s Bluetooth Device Address (different hopping sequences may be used for different Peripherals).

The terms Central and Peripheral are only used when describing these roles in a piconet.

A number of independent piconets may exist in close proximity. Each piconet has a different physical channel (that is a different Central and an independent timing and hopping sequence).

A Bluetooth device may participate concurrently in two or more piconets. It does this on a time-division multiplexing basis. A Bluetooth device can never be a Central of more than one piconet. (Since in BR/EDR the piconet is defined by synchronization to the Central’s Bluetooth clock it is impossible to be the Central of two or more piconets.) A Bluetooth device may be a Peripheral in many independent piconets.

A Bluetooth device that is a member of two or more piconets is said to be involved in a scatternet. Involvement in a scatternet does not necessarily imply any network routing capability or function in the Bluetooth device. The Bluetooth core protocols do not, and are not intended to offer such functionality, which is the responsibility of higher level protocols and is outside the scope of the specification.

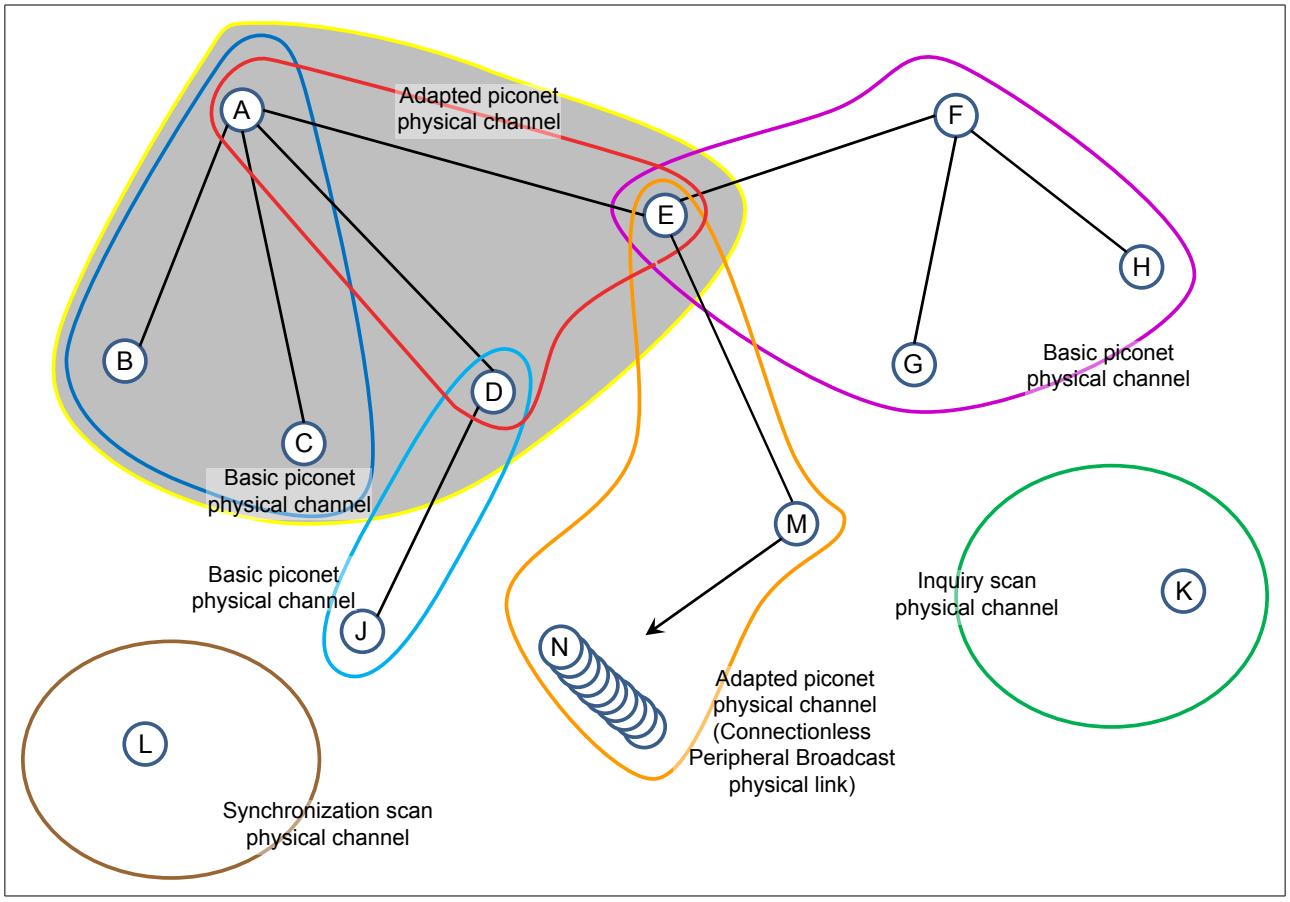

Figure 4.1: Example Bluetooth BR/EDR topology

In Figure 4.1 an example topology is shown that demonstrates a number of the architectural features described below. Device A is a Central in a piconet (represented by the shaded area, and known as piconet A) with devices B, C, D and E as Peripherals. Three other piconets are shown: a) one piconet with device F as Central (known as piconet F) and devices E, G and H as Peripherals, b) one piconet with device D as Central (known as piconet D) and device J as Peripheral, and c) one piconet with device M as Central (known as piconet M) and device E as a Peripheral and many devices N as Peripherals.

In piconet A there are two physical channels. Devices B and C are using the basic piconet physical channel (represented by the blue enclosure) as they do not support adaptive frequency hopping. Devices D and E are capable of supporting adaptive frequency hopping, and are using the adapted piconet physical channel (represented by the red enclosure). Device A is capable of adaptive frequency hopping, and operates in a TDM basis on both physical channels according to which Peripheral is being addressed.

Piconet D and piconet F are both using only a basic piconet physical channel (represented by the cyan and magenta enclosures respectively). In the case of piconet

D this is because device J does not support the adaptive hopping mode. Although device D supports adaptive hopping it cannot use it in this piconet. In piconet F device F does not support adaptive hopping, and therefore it cannot be used in this piconet.

Piconet M (represented by the orange enclosure) uses a Connectionless Peripheral Broadcast physical link over the adaptive piconet physical channel to send Profile Broadcast Data from the transmitter device M to many Receiver devices including E and N.

Device K is shown in the same locality as the other devices. It is not currently a member of a piconet, but has services that it offers to other Bluetooth devices. It is currently listening on its inquiry scan physical channel (represented by the green enclosure), awaiting an inquiry request from another device.

Device L is shown in the same locality as the other devices. It is not currently a member of a piconet, but is currently listening on its synchronization scan physical channel (represented by the brown enclosure), awaiting a synchronization train from another device.

4.1.2 LE topology

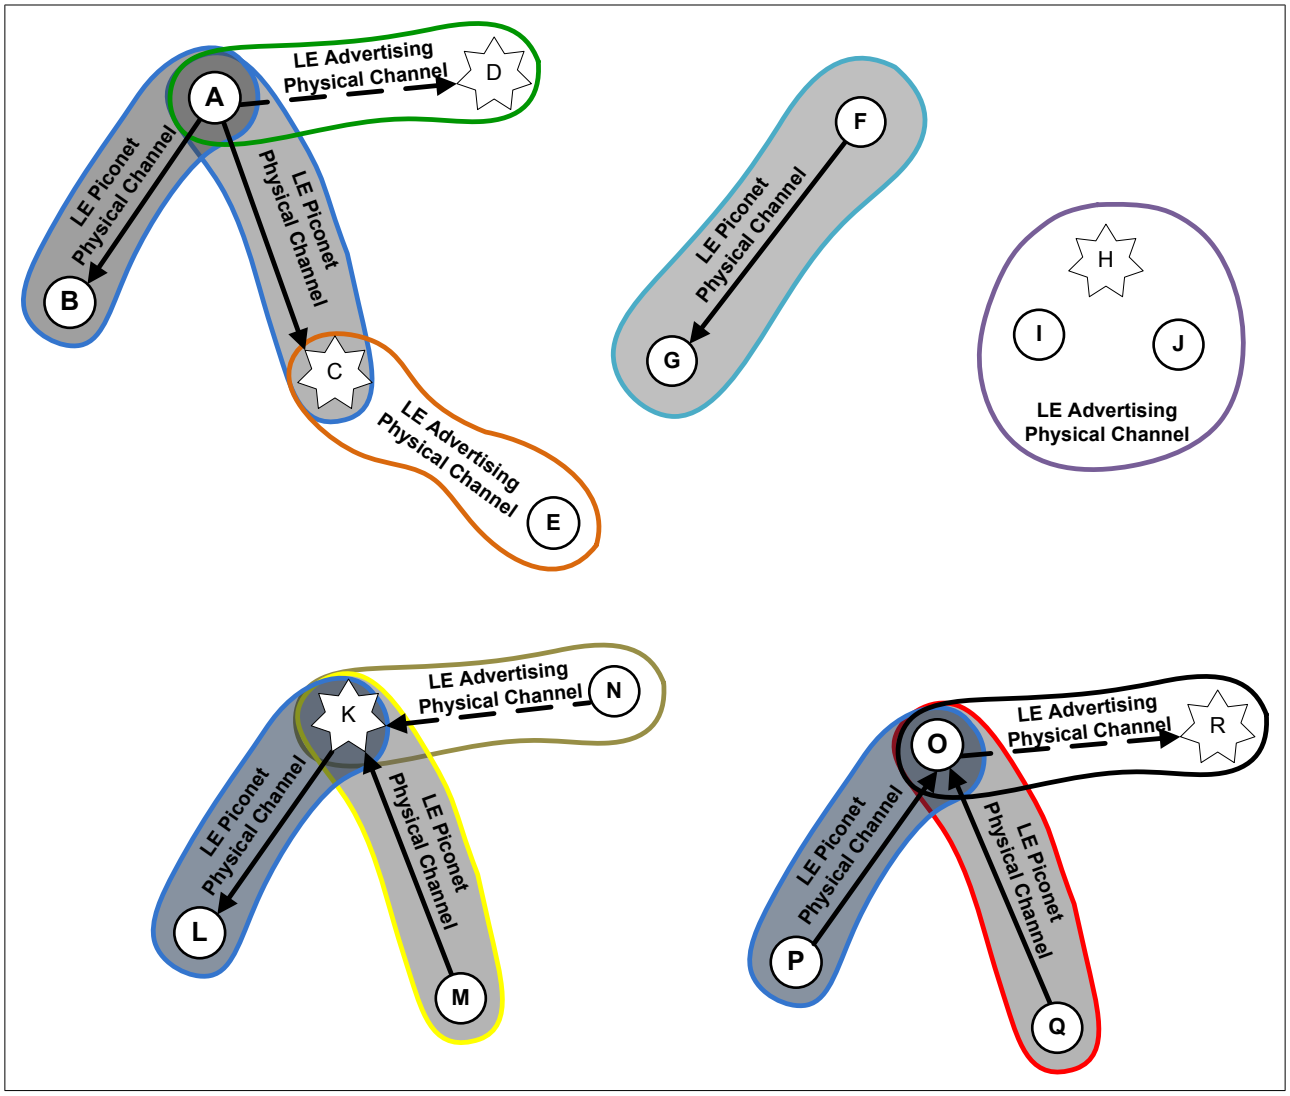

Figure 4.2: Example of Bluetooth LE topology

In Figure 4.2 an example topology is shown that demonstrates a number of the LE architectural features described below. Device A is a Central in two piconets (represented by the shaded areas) with devices B and C as the respective Peripherals. Unlike BR/EDR Peripherals, LE Peripherals do not share a single piconet or a common physical channel with the Central. Each Peripheral communicates on a separate physical channel with the Central. One other piconet is shown with device F as Central and device G as a Peripheral. Device K is in a scatternet. Device K is Central of one piconet with device L as the Peripheral and is Peripheral of a second piconet with device M as the Central. Device O is also in a scatternet. Device O is the Peripheral of two piconets, one with device P as the Central and the other with device Q as the Central. In the figure, solid arrows point from Central to Peripheral; dashed arrows,

indicating a connection initiation, point from initiator to advertiser using a connectable advertising event; devices that are advertising are indicated using stars.

There are five other groups of devices shown:

1. Device D is an advertiser and device A is also an initiator.
2. Device E is a scanner and device C is also an advertiser.
3. Device H is an advertiser and devices I and J are scanners.
4. Device K is also an advertiser and device N is an initiator.
5. Device R is an advertiser and device O is also an initiator.

Devices A and B are using one LE piconet physical channel (represented by the blue enclosure and a dark gray background). Devices A and C are using another LE piconet physical channel (represented by the blue enclosure and a lighter gray background). Device D is advertising using a connectable advertising event on the advertising physical channel (represented by the green enclosure) and device A is an initiator. Device A can form a connection with device D, creating a new piconet. Device C is also advertising on the advertising physical channel (represented by the orange enclosure) using any type of advertising events that are being captured by device E as a scanner. Devices C and D may be using different advertising PHY channels or different timings to avoid collisions.

Devices F and G are using a piconet and an LE piconet physical channel (represented by the aqua enclosure). Device F is the Central and device G is the Peripheral.

Devices H, I and J are using the LE advertising physical channel (represented by the purple enclosure). Device H is an advertiser and devices I and J are scanners.

In the scatternet involving device K, devices K and L are using one piconet and LE piconet physical channel. Devices K and M are using another piconet and LE piconet physical channel. Device K is also advertising using a connectable advertising event on the advertising physical channel and device N is an initiator. Device N can form a connection with device K resulting in device K being Peripheral of two devices and Central of one device at the same time.

In the scatternet involving device O, devices O and P are using one piconet and LE piconet physical channel. Devices O and Q are using another piconet and LE piconet physical channel. Device R is advertising using a connectable advertising event on the advertising physical channel and device O is an initiator. Device O can form a connection with device R resulting in device O being Peripheral of two devices and Central of one device at the same time.

4.2 Operational procedures and modes

The typical operational mode of a Bluetooth device is to be connected to other Bluetooth devices (in a piconet) and exchanging data with those Bluetooth devices. As Bluetooth is an ad-hoc wireless communications technology, there are a number of operational procedures that enable piconets to be formed so that the subsequent communications can take place. Procedures and modes are applied at different layers in the architecture and therefore a device may be engaged in a number of these procedures and modes concurrently.

4.2.1 BR/EDR procedures

4.2.1.1 Inquiry (discovering) procedure

Bluetooth devices use the inquiry procedure to discover nearby devices, or to be discovered by devices in their locality.

The inquiry procedure is asymmetrical. A Bluetooth device that tries to find other nearby devices is known as an inquiring device and actively sends inquiry requests. Bluetooth devices that are available to be found are known as discoverable devices and listen for these inquiry requests and send responses. The inquiry procedure uses a special physical channel for the inquiry requests and responses.

Both inquiring and discoverable devices may already be connected to other Bluetooth devices in a piconet. Any time spent inquiring or occupying the inquiry scan physical channel needs to be balanced with the demands of the QoS commitments on existing logical transports.

The inquiry procedure does not make use of any of the architectural layers above the physical channel, although a transient physical link may be considered to be present during the exchange of inquiry and inquiry response information.

4.2.1.1.1 Extended Inquiry response

An Extended Inquiry Response can be used to provide miscellaneous information during the inquiry response procedure. Data types are defined for such things as local name and supported services, information that otherwise would have to be obtained by establishing a connection. A device that receives a local name and a list of supported services in an extended inquiry response does not have to connect to do a remote name request and an SDP service search, thereby shortening the time to useful information. It is recommended that a device includes all supported services and a significant portion of its local name, if that name is too long to be sent in its entirety, in the extended inquiry response.

Extended inquiry response data can be transmitted encrypted or unencrypted. Unencrypted data can be interpreted by any device. Encrypted data can be received by

any device but can only be decrypted and authenticated by devices that have previously shared the session key used to encrypt the data.

The extended inquiry response procedure is backwards compatible with the standard inquiry response procedure.

4.2.1.2 Paging (connecting) procedure

The procedure for forming connections is asymmetrical and requires that one Bluetooth device carries out the page (connection) procedure while the other Bluetooth device is connectable (page scanning). The procedure is targeted, so that the page procedure is only responded to by one specified Bluetooth device.

The connectable device uses a special physical channel to listen for connection request packets from the paging (connecting) device. This physical channel has attributes that are specific to the connectable device, hence only a paging device with knowledge of the connectable device is able to communicate on this channel.

Both paging and connectable devices may already be connected to other Bluetooth devices. Any time spent paging or occupying the page scan physical channel needs to be balanced with the demands of the QoS commitments on existing logical transports.

4.2.1.3 Connected mode

After a successful connection procedure over the BR/EDR Controller, there is a piconet physical channel to which both devices are connected, there is a physical link between the devices, and there are default ACL-C, ACL-U, APB-C, and APB-U logical links. Two of these links (ACL-C and APB-C) transport the LMP control protocol and are invisible to the layers above the Link Manager. The ACL-U link transports the L2CAP signaling protocol and any multiplexed L2CAP best-effort channels. The APB-U link transports L2CAP channels that are broadcast to all Peripherals on the piconet. It is common to refer to a default ACL logical transport, which can be resolved by context, but typically refers to the default ACL-U logical link.

When in the connected mode it is possible to create and release additional logical links and to change the modes of the physical and logical links while remaining connected to the piconet physical channel. It is also possible for the device to carry out inquiry, paging or scanning procedures or to be connected to other piconets without needing to disconnect from the original piconet physical channel. These actions are done using the Link Manager, which exchanges Link Manager protocol messages with the remote Bluetooth device.

During the time that a Peripheral is actively connected to a piconet there is always a default ACL logical transport between the Peripheral and the Central. The only method of deleting the default ACL logical transport is to detach the device from the piconet

physical channel, at which time the entire hierarchy of L2CAP channels, logical links, and logical transports between the devices is deleted.

4.2.1.4 Hold mode

Hold mode is not a general device mode, but applies to unreserved slots on the physical link. When in this mode, the physical link is only active during slots that are reserved for the operation of the synchronous link types SCO and eSCO. All asynchronous links are inactive. Hold modes operate once for each invocation and are then exited when complete, returning to the previous mode.

4.2.1.5 Sniff mode

Sniff mode is not a general device mode, but applies to the default ACL logical transports. When in this mode the availability of these logical transports is modified by defining a duty cycle consisting of periods of presence and absence. Devices that have their default ACL logical transports in Sniff mode may use the absent periods to engage in activity on another physical channel, or to enter reduced power mode. Sniff mode only affects the default ACL logical transports (i.e. their shared ACL logical transport), and does not apply to any additional SCO or eSCO logical transports that may be active. The periods of presence and absence of the physical link on the piconet physical channel is derived as a union of all logical transports that are built on the physical link.

Sniff subrating provides a mechanism for further reducing the active duty cycle, thereby enhancing the power-saving capability of Sniff mode, by allowing a Host to specify maximum transmit and receive latencies. This allows the basebands to optimize the low power performance without having to exit and re-enter Sniff mode using Link Manager commands.

Broadcast logical transports have no defined expectations for presence or absence. A Central should aim to schedule broadcasts to coincide with periods of physical link presence within the piconet physical channel, but this is not always possible or practical. Repetition of broadcasts is defined to improve the possibilities for reaching multiple Peripherals without overlapping presence periods. However, broadcast logical transports cannot be considered to be reliable.

4.2.1.6 [This section is no longer used]

4.2.1.7 Role switch procedure

The role switch procedure is a method for swapping the roles of two devices connected in a piconet. The procedure involves moving from the physical channel that is defined by the original Central to the physical channel that is defined by the new Central. In the process of swapping from one physical channel to the next, the hierarchy of physical links and logical transports over the BR/EDR Controller are removed and rebuilt, with

the exception of the APB logical transport that is implied by the topology and is not preserved. After the role switch, the original piconet physical channel may cease to exist or may be continued if the original Central had other Peripherals that are still connected to the channel.

The procedure only moves the default ACL logical links and supporting layers to the new physical channel. Any additional logical transports are not copied by this procedure, and if required this must be carried out by higher layers. The LT_ADDRs of any affected transports will be reassigned on the new physical channel and, therefore, may change.

If there are any QoS commitments on the original logical transports, then these are not preserved after a role switch. These must be renegotiated after the role switch has completed.

4.2.1.8 Enhanced Data Rate

Enhanced Data Rate is a method of extending the capacity and types of Bluetooth packets for the purposes of increasing the maximum throughput, providing better support for multiple connections, and lowering power consumption, while the remainder of the architecture is unchanged.

Enhanced Data Rate may be selected as a mode that operates independently on each logical transport. Once enabled, the packet type bits in the packet header are interpreted differently from their meaning in Basic Rate mode. This different interpretation is clarified in conjunction with the logical transport address field in the header. The result of this interpretation allows the packet payload header and payload to be received and demodulated according to the packet type. Enhanced Data Rate can be enabled only for the ACL and eSCO logical transports and cannot be enabled for the SCO and broadcast logical transports.

4.2.1.9 Connectionless Peripheral Broadcast mode

Connectionless Peripheral Broadcast mode allows a piconet Central to transmit profile broadcast data to any number of connected Peripherals using the BR/EDR adapted piconet physical channel. To enter this mode, the Central reserves a specific logical transport address for the CPB logical transport and starts broadcasting data using the Connectionless Peripheral Broadcast physical link and the synchronization train procedure. A single Profile Broadcast Data logical link is defined, which carries profile broadcast data using the Connectionless Peripheral Broadcast logical transport. The profile broadcast data is unframed and bypasses L2CAP.

To receive the Connectionless Peripheral Broadcast packets, a device must connect with the Connectionless Peripheral Broadcast Transmitter which has already established a CPB logical transport. To connect, a device follows the Synchronization

Scan procedure to obtain the time schedule of the physical link and then starts receiving the Connectionless Peripheral Broadcast packets. Once connected, Connectionless Peripheral Broadcast receivers can receive profile broadcast data on the dedicated CPB logical transport and PBD logical link.

4.2.2 LE procedures

4.2.2.1 Device filtering procedure

The device filtering procedure is a method for Controllers to reduce the number of devices requiring communication responses. Since it is not required to respond to requests from every device, it reduces the number of transmissions an LE Controller is required to make which reduces power consumption. It also reduces the communication the Controller would be required to make with the Host. This results in additional power savings since the Host does not have to be involved.

An advertising or scanning device may employ device filtering to restrict the devices from which it receives advertising packets, scan requests or connection requests. In LE, some advertising packets received by a scanning device require that the scanning device send a request to the advertising device. This advertisement can be ignored if device filtering is used and the advertising device is being filtered. A similar situation occurs with connection requests. Connection requests must be responded to by advertisers unless a device filter is used to limit the devices to which the advertiser is required to respond. Advertisers can also use device filters to limit the devices in which it will accept a scan request or connection request.

This device filtering is accomplished through the use of a “Filter Accept List” located in the LL block of the Controller. A Filter Accept List enumerates the remote devices that are allowed to communicate with the local device. When a Filter Accept List is in effect, transmissions from devices that are not in the Filter Accept List will be ignored by the LL. Since device filtering occurs in the LL it can have a significant impact on power consumption by filtering (or ignoring) advertising packets, scan requests or connection requests from being sent to the higher layers for handling.

The use of device filtering during certain procedures needs to be evaluated carefully to ensure devices are not unintentionally ignored, which may cause interoperability problems when attempting to establish connections or receive advertising broadcasts.

4.2.2.2 Advertising procedure

An advertiser uses the advertising procedure to perform unidirectional broadcasts to devices in the area. The unidirectional broadcast occurs without a connection between the advertising device and the listening devices. The advertising procedure can be used to establish connections with nearby initiating devices or used to provide periodic broadcast of user data to scanning devices listening on the advertising physical

channel. The advertising procedure uses the primary advertising physical channel for all advertising broadcasts. However, the data may be offloaded on to the secondary advertising physical channel in one or more auxiliary packets to reduce both the occupancy of the primary advertising physical channel and the total on-air time and also to allow the data to be longer than the maximum that will fit into a single packet.

Advertising data can be transmitted encrypted or unencrypted. Unencrypted data can be interpreted by any scanning device. Encrypted data can be received by any scanning device but can only be decrypted and authenticated by devices that have previously obtained the session key used to encrypt the data.

An LE device connected in an LE piconet may also advertise using any type of advertising event. Time spent advertising while connected needs to be balanced with the connection requirements needed to maintain the already established connection(s).

Advertising devices may receive scan requests from listening devices in order to get additional user data from the advertising device. Scan responses are sent by the advertising device to the device making the scan request.

An advertising device may receive connection requests from initiator devices. If the advertising device was using a connectable advertising event and the initiating device is not being filtered by the device filtering procedure, the advertising device ceases advertising and enters the connected mode. The device can begin advertising again after it is in the connected mode.

When advertising on the LE Uncoded PHYs, scan requests and scan responses can take place on the same PHY channel as the original advertisement or can be offloaded to the secondary advertising physical channel. In some cases when advertising on the LE Uncoded PHYs, connection request and connection responses are offloaded to the secondary advertising physical channel. When advertising on the LE Coded PHY, scan requests, scan responses, connection requests, and connection responses are always offloaded. As with advertising data, offloading is carried out by having the initial advertisement on the primary advertising physical channel point to an auxiliary packet on the secondary advertising physical channel. Scan requests and scan responses, connection requests, and connection responses are made on the same PHY and same physical channel as the auxiliary packet.

4.2.2.3 Scanning procedure

A scanning device uses the scanning procedure to listen for unidirectional broadcasts of user data from advertising devices using the advertising physical channel. A scanning device can request additional user data from an advertising device by making a scan request. The advertising device responds to these requests with additional user data sent to the scanning device over the advertising physical channel.

The scanning procedure can be used while connected to other LE devices. Time spent scanning while connected needs to be balanced with the connection requirements needed to maintain the already established connection with the other LE device in each piconet.

If the broadcasts are connectable advertising events and the scanning device is in the initiator mode, it can initiate a connection by sending a connection request on the primary advertising physical channel or secondary advertising physical channel to the advertising device. Once the connection request is sent on the primary advertising physical channel, the scanning device ceases the initiator mode scanning for additional broadcasts and enters the connected mode. When the connection request is sent on the secondary advertising physical channel, the scanning device leaves the initiator mode, ceasing scanning for additional broadcasts, and enters the connected mode when it receives the connection response. The device can use the scanning procedure after it enters the connected mode, allowing it to be the Central in more than one piconet at a time.

4.2.2.4 Discovering procedure

Bluetooth devices use the advertising procedure and scanning procedure to discover nearby devices, or to be discovered by devices in a given area.

The discovery procedure is asymmetrical. A Bluetooth device that tries to find other nearby devices is known as a discovering device and listens for devices advertising scannable advertising events. Bluetooth devices that are available to be found are known as discoverable devices and actively broadcast scannable advertising events over the advertising broadcast physical channel.

Both discovering and discoverable devices may already be connected to other Bluetooth devices. Any time spent inquiring or occupying the advertising broadcast physical channel needs to be balanced with the connection requirements needed to maintain the already established connection with these other LE devices.

Using device filtering by the scanning device can prevent the scanning device from discovering all the devices in a given area.

4.2.2.5 Connecting procedure

The procedure for forming connections is asymmetrical and requires that one Bluetooth device carries out the advertising procedure while the other Bluetooth device carries out the scanning procedure. The advertising procedure can be targeted, so that only one device will respond to the advertising. The scanning device can also target an advertising device by first discovering that the advertising device is present in a connectable manner, and in the given area, and then scanning only connectable advertising events from that device using the device filter. After receiving connectable

advertising events from the targeted advertising device, it can initiate a connection by sending the connection request to the targeted advertising device over the primary advertising physical channel or secondary advertising physical channel.

Time spent scanning while connected needs to be balanced with the connection requirements needed to maintain the already established connection with other LE devices.

4.2.2.6 Connected mode

After a successful connection procedure, the devices are physically connected to each other within a piconet. This means that there is a piconet physical channel to which they are both connected, there is a physical link between the devices, and there are default LE-C and LE-U logical links. When in the connected mode it is possible to change the properties of the physical and logical links while remaining connected to the piconet physical channel, such as changing the adaptive frequency hopping sequence or changing the maximum length of data packets. It is also possible for the device to carry out advertising, scanning or discovery procedures without needing to disconnect from the original piconet physical channel.

Additional logical links are created using the Link Manager that exchanges LL Protocol messages with the remote Bluetooth device to negotiate the creation and settings for these links. One of these links (LE-C) transports the LL control protocol and is invisible to the layers above the Link Manager. The other link (LE-U) transports the L2CAP signaling protocol and any multiplexed L2CAP best-effort channels. It is common to refer to a default LE ACL logical transport, which can be resolved by context, but typically refers to the default LE-U logical link.

These two logical links share a logical transport.

During the time that a Peripheral is actively connected to a piconet there is always a default LE ACL logical transport between the Peripheral and the Central. The method of deleting the default LE ACL logical transport is to detach the device from the piconet physical channel, at which time the entire hierarchy of L2CAP channels, logical links, and logical transports between the devices is deleted.

4.2.2.6.1 Connection Subrating

Connection subrating is a means of quickly modifying the effective connection interval of an existing LE ACL connection. It is accomplished by the Central and Peripheral skipping most of the underlying connection events; for example, if the subrating factor is set to 7 then only every 7^{th} connection event is used.

When connection subrating is applied to an existing connection, the active duty cycle may be quickly reduced, saving power, but the original connection interval can

be quickly restored for improved throughput when needed. Subrated connections rely on an underlying connection interval which is understood by both Central and Peripheral and, in so doing, allow reliable and immediate reductions and changes to the connection interval without waiting for connection updates which rely on an instant several connection events in the future. Devices that have subrated their default LE ACL logical transports may use the absent periods to engage in activity on another logical transport, or to enter reduced power mode. An LE subrated connection interval only affects the specified LE ACL logical transport and does not apply to any associated LE CIS logical transports that may be active.

4.2.2.7 Periodic advertising procedure

An advertiser uses the periodic advertising procedure to perform unidirectional periodic broadcasts to devices in the area. The unidirectional broadcast occurs without a connection between the advertising device and the listening devices. The periodic advertising procedure can be used to synchronize with nearby devices to provide deterministic periodic broadcast of user data to scanning devices listening on the advertising physical channel. The advertising procedure uses the primary and secondary advertising physical channel to broadcast control information about the periodic advertising, referred to as the periodic advertising synchronization information. The advertiser can also pass the periodic advertising synchronization information to another connected device over the LE-C logical link.

An LE device synchronized with other LE devices on the periodic physical channel uses the periodic advertising event. Time spent periodic advertising while connected or synchronized with other LE devices needs to be balanced with the connection and synchronization requirements needed to maintain the already established connection(s) or synchronizations.

4.2.2.8 Periodic advertising synchronization procedure

The procedure for synchronizing to periodic advertising consists of two parts: obtaining the periodic advertising synchronization information and then listening for the periodic advertisements. The first part may be done using either of two methods.

The first method requires that one Bluetooth device carries out the advertising procedure while the other Bluetooth device carries out the scanning procedure. The scanning device can target an advertising device by first discovering that the advertising device is present and broadcasting periodic advertisements in the given area. The scanning device then needs to receive the advertising events containing the periodic advertising synchronization information from the targeted advertising device.

The second method requires that a device that already has the periodic advertising synchronization information passes it to another connected device over the LE-C logical link.

Once the receiving device has obtained the periodic advertising synchronization information, the second part of the procedure is for it to listen directly for those periodic advertising events; the receiving device is synchronized when it has successfully received one such event.

Synchronizing devices may already be advertising, scanning, or be connected to other Bluetooth devices in a piconet or synchronized to other periodic advertisements. Any time spent synchronizing to periodic advertising needs to be balanced with the requirements needed to maintain already established connections or synchronizations.

4.2.2.9 Periodic advertising synchronized mode

After a successful periodic advertising synchronization procedure, the devices are physically synchronized to each other. This means that there is a periodic physical channel to which they are both synchronized, there is a periodic physical link between the devices, and there is an ADVB-U and an ADVB-C logical link. It is also possible for the device to carry out advertising, scanning, or discovery procedures without needing to disconnect from the LE periodic physical channel.

A Link Layer that is listening to periodic advertising may report the data in the periodic advertisements to the Host. When it is not reporting the data to the Host, the Link Layer does not need to listen to as many events to maintain synchronization, thereby potentially providing more time for other procedures or reducing power consumption.

4.2.2.10 Decision-based scanning

When advertising data is being offloaded to the secondary advertising physical channel, the advertiser can include information about the content of the auxiliary advertising packet in the packets on the primary advertising physical channel. This information (the “decision data”) can be provided by the Host to the Controller on the advertising device.

A scanning device can use the decision data provided by the advertiser to filter out auxiliary packets that its host would not make use of. It does this by deciding, based on the decision data, whether or not to listen to those packets. This results in the scanning device maximizing the time that it spends scanning for packets on the primary advertising physical channel, which in turn leads to lower latency in discovery and connection procedures.

On the scanning device, the Host can provide instructions to its Controller on how to process the decision data to determine whether to accept or reject the received packet.

4.2.3 [This section is no longer used]

5 SECURITY OVERVIEW

5.1 Security architecture

The Bluetooth security model includes five distinct security features: pairing, bonding, device authentication, encryption and message integrity.

- Pairing: the process for creating one or more shared secret keys
- Bonding: the act of storing the keys created during pairing for use in subsequent connections in order to form a trusted device pair
- Device authentication: verification that the two devices have the same keys
- Encryption: message confidentiality
- Message integrity: protects against message forgeries

The Bluetooth Core security architecture has evolved over time and therefore there are several security mechanisms.

BR/EDR Legacy Pairing utilizes the E21 or E22 algorithms based on SAFER+. Device authentication is based on the E1 algorithm, which is also based on SAFER+. Encryption utilizes the E0 algorithm derived from the Massey-Rueppel algorithm. There is no provision for cryptographic message integrity. While the CRC provides some integrity protection, it is not considered to provide cryptographic integrity as it can be easily forged.

Secure Simple Pairing utilizes FIPS-approved algorithms (SHA-256, HMAC-SHA-256 and the P-192 elliptic curve) and four association models: Just Works, Numeric Comparison, Passkey Entry and Out-Of-Band (see Section 5.2). Device authentication and encryption are the same as BR/EDR Legacy Pairing.

LE Legacy Pairing uses AES-CCM encryption and four association models similar to, though not the same as, those in Secure Simple Pairing. It also provides signed data and a privacy feature.

Secure Connections on the BR/EDR physical transport upgrades Secure Simple Pairing to utilize the P-256 elliptic curve and device authentication to use FIPS-approved algorithms (HMAC-SHA-256 and AES-CTR). Secure Connections also adds message integrity (AES-CCM).

Secure Connections on the LE physical transport upgrades LE Legacy Pairing to utilize FIPS-approved algorithms (AES-CMAC and P-256 elliptic curve) and adapts the Numeric Comparison association model of Secure Simple Pairing to be used on the Bluetooth LE physical transport. It also includes provisions for a key generated using

Secure Connections on either physical transport to preclude the need for the user to pair a second time on the other physical transport.

The security key hierarchy for BR/EDR is shown in Figure 5.1. The key hierarchy is different depending on whether a physical link is using Secure Connections or legacy security procedures and algorithms.

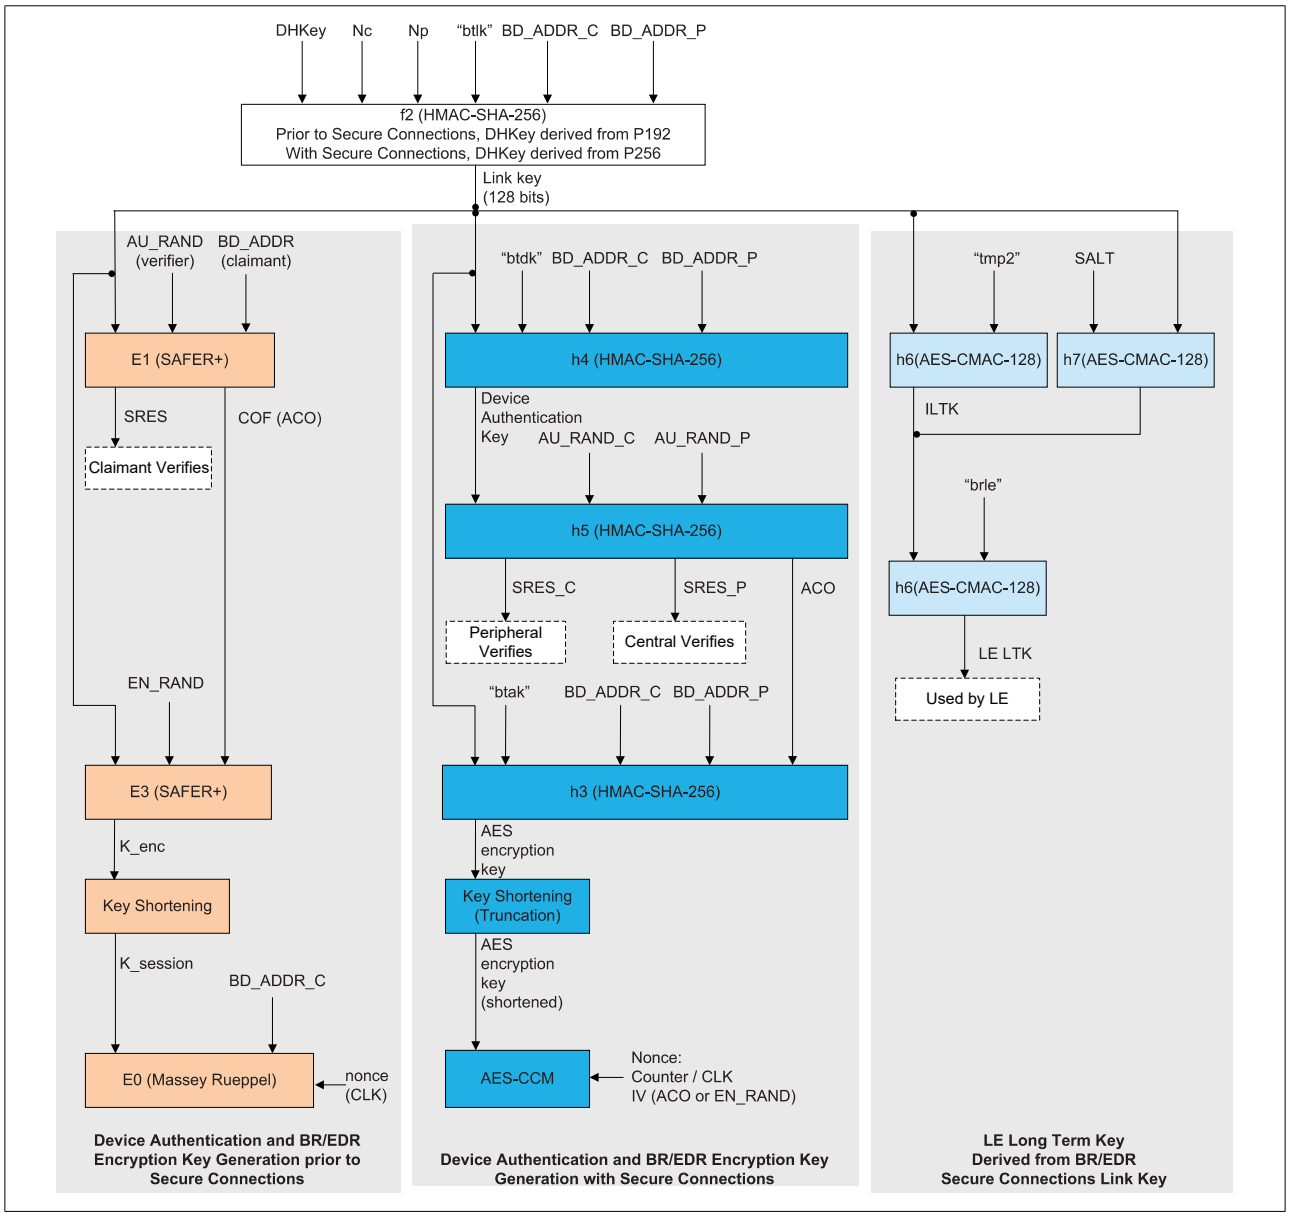

Figure 5.1: BR/EDR key hierarchy

The security key hierarchy for LE is shown in Figure 5.2. The key hierarchy is different depending on whether a physical link is using LE Secure Connections or LE legacy pairing procedures and algorithms.

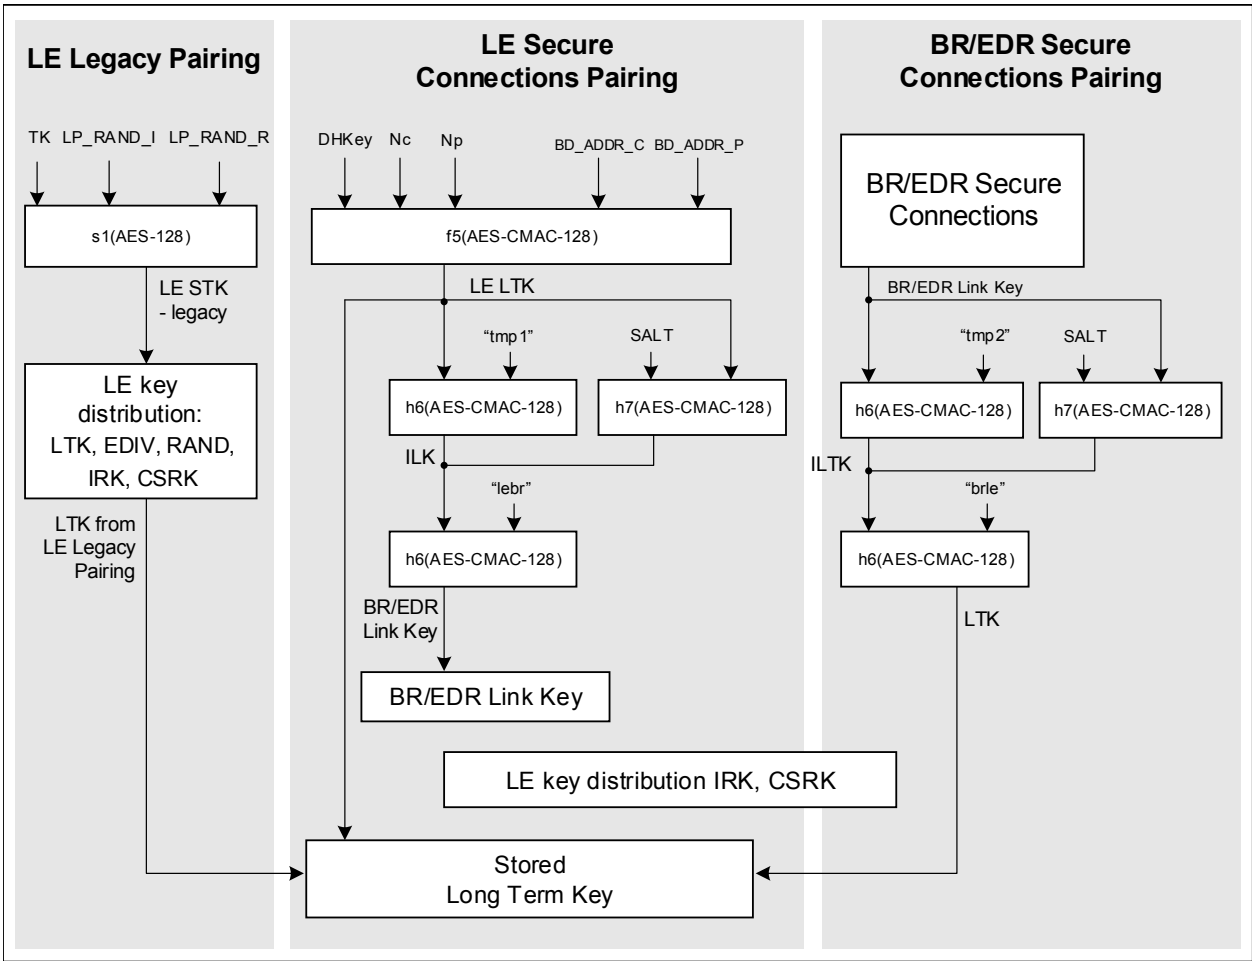

Figure 5.2: LE key hierarchy

The 5.2 version of the Core Specification adds a new LE security mode that enables transmission and reception of encrypted isochronous data over the Broadcast Isochronous Stream (BIS) logical transport.

Channel Sounding uses an AES-128 block based DRBG to exchange content that is used for reverification of Channel Sounding peers. The security features related to Channel Sounding are described in Section 9.4.

5.2 BR/EDR Secure Simple Pairing

The primary goal of Secure Simple Pairing is to simplify the pairing procedure for the user. Secondary goals are to maintain or improve the security in Bluetooth wireless technology. Since high levels of security and ease-of-use are often at opposite ends of the spectrum in many technologies and products, much care has been taken to maximize security while minimizing complexity from the end user's point of view.

5.2.1 Security goals

Secure Simple Pairing has two security goals: protection against passive eavesdropping and protection against man-in-the-middle (MITM) attacks (active eavesdropping). It is a goal of Secure Simple Pairing to exceed the maximum security level provided by the use of a 16 character, alphanumeric, case-sensitive PIN with BR/EDR Legacy Pairing, which often used a 4-digit PIN or a fixed PIN of commonly known values significantly limiting the security on the link.

5.2.2 Passive eavesdropping protection

A strong link key coupled with a strong encryption algorithm is necessary to give the user protection against passive eavesdropping. The strength of the link key is based on the amount of entropy (or randomness) in its generation process which would not be known by an attacker. Using legacy pairing, the only source of entropy is the PIN which, in many use cases, is typically four digits either selected by the user or fixed for a given product. Therefore, if the pairing procedure and one authentication exchange is recorded one can run an exhaustive search to find the PIN in a very short amount of time on commonly available computing hardware. With Secure Simple Pairing, the recording attack becomes much harder as the attacker must have solved a hard problem in public key cryptography in order to derive the link key from the recorded information. This protection is independent of the length of the passkey or other numeric values that the user must handle. Secure Simple Pairing gives the same resistance against the recording and passive eavesdropping attacks even when the user is not required to do anything.

Secure Simple Pairing uses Elliptic Curve Diffie Hellman (ECDH) public key cryptography as a means to thwart passive eavesdropping attacks. ECDH provides a very high degree of strength against passive eavesdropping attacks but it may be subject to MITM attacks, which however, are much harder to perform in practice than the passive eavesdropping attack (see Section 5.2.3).

Using BR/EDR Legacy Pairing with a 16 numeric digit PIN achieves about 53 bits of entropy whereas a 16 character, alphanumeric, case sensitive PIN yields about 95 bits of entropy when the entire 62 character set is used ([0, ... 9, 'A', ... 'Z', 'a', ... 'z']). For devices that do not support the Secure Connections feature, Secure Simple Pairing has approximately 96 bits of entropy using the FIPS approved P-192 elliptic curve which is at least as good as the entropy in BR/EDR Legacy Pairing using a 16 character, alphanumeric, case sensitive PIN. For devices that do support the Secure Connections feature, Secure Simple Pairing has approximately 128 bits of entropy using the FIPS-approved P-256 elliptic curve.

5.2.3 Man-in-the-middle protection

A man-in-the-middle (MITM) attack occurs when a user wants to connect two devices but instead of connecting directly with each other they unknowingly connect to a third (attacking) device that plays the role of the device they are attempting to pair with. The third device then relays information between the two devices giving the illusion that they are directly connected. The attacking device may even eavesdrop on communication between the two devices (known as active eavesdropping) and is able to insert and modify information on the connection. In this type of attack, all of the information exchanged between the two devices are compromised and the attacker may inject commands and information into each of the devices thus potentially damaging the function of the devices. Devices falling victim to the attack are capable of communicating only when the attacker is present. If the attacker is not active or out range, the two victim devices will not be able to communicate directly with each other and the user will notice it.

To prevent MITM attacks, Secure Simple Pairing offers two user assisted numeric methods: numeric comparison or passkey entry. If Secure Simple Pairing would use 16 decimal digit numbers, then the usability would be the same as using legacy pairing with 16 decimal digit PIN. The chance for a MITM to succeed inserting its own link keys in this case is a 1 in $10^{16} = 2^{53}$ pairing instances, which is an unnecessarily low probability.

Secure Simple Pairing protects the user from MITM attacks with a goal of offering a 1 in 1,000,000 chance that a MITM could mount a successful attack. The strength of the MITM protections was selected to minimize the user impact by using a six digit number for numeric comparison and Passkey entry. This level of MITM protection was selected since, in most cases, users can be alerted to the potential presence of a MITM attacker when the connection process fails as a result of a failed MITM attack. While most users feel that if they have not compromised their passkey, a 4-digit key is sufficient for authentication (i.e., bank card PIN codes), the use of six digits allows Secure Simple Pairing to be FIPS-compliant and this was deemed to have little perceivable usability impact.

5.2.4 Association models

Secure Simple Pairing uses four association models referred to as Numeric Comparison, Just Works, Out Of Band, and Passkey Entry. Each of these association models are described in more detail in the following sections.

The association model used is deterministic based on the IO capabilities of the two devices.

5.2.4.1 Numeric Comparison

The Numeric Comparison association model is designed for scenarios where both devices are capable of displaying a six digit number and both are capable of having the user enter "yes" or "no". A good example of this model is the cell phone / PC scenario.

The user is shown a six digit number (from "000000" to "999999") on both displays and then asked whether the numbers are the same on both devices. If "yes" is entered on both devices, the pairing is successful.

The numeric comparison serves two purposes. First, since many devices do not have unique names, it provides confirmation to the user that the correct devices are connected with each other. Second, the numeric comparison provides protection against MITM attacks (see Section 5.2.3).

There is a significant difference from a cryptographic point of view between Numeric Comparison and the PIN entry model used by BR/EDR Legacy Pairing. In the Numeric Comparison association model, the six digit number is an artifact of the security algorithm and not an input to it, as is the case in the PIN entry model. Knowing the displayed number is of no benefit in decrypting the encoded data exchanged between the two devices.

5.2.4.2 Just Works

The Just Works association model is primarily designed for scenarios where at least one of the devices does not have a display capable of displaying a six digit number nor does it have a keyboard capable of entering six decimal digits. A good example of this model is the cell phone/mono headset scenario where most headsets do not have a display.

The Just Works association model uses the Numeric Comparison protocol but the user is never shown a number and the application may simply ask the user to accept the connection (exact implementation is up to the manufacturer).

The Just Works association model provides the same protection as the Numeric Comparison association model against passive eavesdropping but offers no protection against the MITM attack.

When compared against today's experience of a headset with a fixed PIN, the security level of the Just Works association model is considerably higher since a high degree of protection against passive eavesdropping is realized.

5.2.4.3 Out of Band

The Out of Band (OOB) association model is primarily designed for scenarios where an Out of Band mechanism is used to both discover the devices as well as to exchange or

transfer cryptographic numbers used in the pairing process. In order to be effective from a security point of view, the Out of Band channel should provide different properties in terms of security compared to the Bluetooth radio channel. The Out of Band channel should be resistant to MITM attacks. If it is not, security may be compromised during authentication.

The user's experience differs a bit depending on the Out of Band mechanism. As an example, with a Near Field Communication (NFC) solution, the user(s) will initially touch the two devices together, and is given the option to pair the first device with the other device. If "yes" is entered, the pairing is successful. This is a single touch experience where the exchanged information is used in both devices. The information exchanged includes discovery information (such as the Bluetooth Device Address) as well as cryptographic information. One of the devices will use a Bluetooth Device Address to establish a connection with the other device. The rest of the exchanged information is used during authentication.

The OOB mechanism may be implemented as either read only or read/write. If one side is read only, a one-way authentication is performed. If both sides are read/write, a two-way authentication is performed.

The OOB protocol is selected only when the pairing process has been activated by previous OOB exchange of information and one (or both) of the device(s) gives OOB as the IO capabilities. The protocol uses the information which has been exchanged and simply asks the user to confirm connection.

The OOB association model supports any OOB mechanism where cryptographic information and the Bluetooth Device Address can be exchanged. The OOB association model does not support a solution where the user has activated a Bluetooth connection and would like to use OOB for authentication only.

5.2.4.4 Passkey Entry

The Passkey Entry association model is primarily designed for the scenario where one device has input capability but does not have the capability to display six digits and the other device has output capabilities. A good example of this model is the PC and keyboard scenario.

The user is shown a six digit number (from "000000" to "999999") on the device with a display, and is then asked to enter the number on the other device. If the value entered on the second device is correct, the pairing is successful.

There is a significant difference from a cryptographic point of view between Passkey Entry and the PIN entry model used by BR/EDR Legacy Pairing. In the Passkey Entry association model, the six digit number is independent of the security algorithm and not

an input to it, as is the case in the PIN entry model. Knowing the entered number is of no benefit in decrypting the encoded data exchanged between the two devices.

5.2.4.5 Association model overview

The following diagram shows Secure Simple Pairing from the point of view of the technology used for discovery and then the different association possibilities.

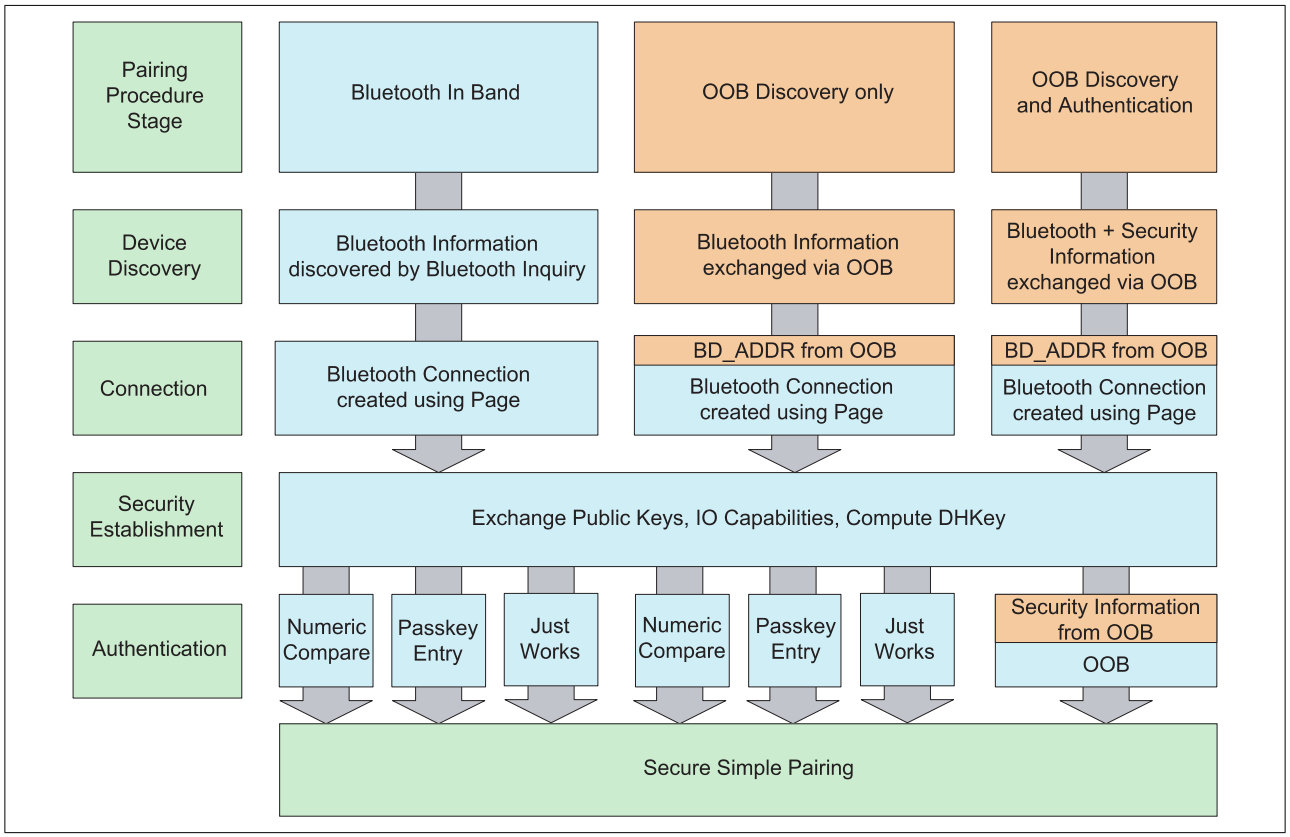

Figure 5.3: Secure Simple Pairing association models

5.3 Secure Connections Only mode

When a device requires that only FIPS-approved algorithms are used on the BR/EDR or LE physical transport, it should enter Secure Connections Only Mode. Secure Connections Only Mode is sometimes called a "FIPS Mode". This mode should be used when it is more important for a device to have high security than it is for it to maintain backwards compatibility with devices that do not support Secure Connections. The Host will enforce that the P-256 elliptic curve is used during pairing and that, on the BR/EDR physical transport, the secure authentication sequences are used and AES-CCM is used for encryption.

If a BR/EDR/LE device is configured in Secure Connections Only Mode, then both the BR/EDR and the LE transports will be in Secure Connections Only Mode.

5.4 LE security

LE Legacy Pairing has some differences in security aspects compared to BR/EDR security features such as Secure Simple Pairing. The association models are similar to BR/EDR Secure Simple Pairing from the user perspective and have the same names but have differences in the quality of the protection provided.

5.4.1 Association models

Bluetooth LE uses four association models referred to as Just Works, Numeric Comparison, Out of Band and Passkey Entry. LE legacy pairing does not have an equivalent of Numeric Comparison.

In LE legacy pairing, each of these association models is similar to BR/EDR Secure Simple Pairing with the following exceptions.

- Just Works and Passkey Entry do not provide any passive eavesdropping protection. This is because Secure Simple Pairing uses Elliptic Curve Diffie-Hellman and LE legacy pairing does not.

In LE Secure Connections pairing, the four association models are functionally equivalent to BR/EDR Secure Connections.

The use of each association model is based on the IO capabilities of the devices.

5.4.2 Key generation

Key generation in Bluetooth LE is performed by the Host on each LE device independent of any other LE device. By performing key generation in the Host, the key generation algorithms can be upgraded without the need to change the Controller.

Note: Key generation in BR/EDR is performed in the Controller.

Bluetooth LE uses multiple keys, each for a specific purpose, as follows:

- Confidentiality of data and device authentication
- Authentication of unencrypted data
- Device Identity

In LE, the key used to provide confidentiality and authentication is generated by combining contributions from each device during pairing.

5.4.3 Encryption

Encryption in Bluetooth LE uses AES-CCM cryptography. Like BR/EDR, in LE encryption is performed in the Controller.

5.4.4 Signed Data

Bluetooth LE supports the ability to send authenticated data over an unencrypted ATT bearer between two devices with a trusted relationship. This is accomplished by signing the data with a Connection Signature Resolving Key (CSRK). The sending device places a signature after the Data PDU. The receiving device verifies the signature and if the signature is verified the Data PDU is assumed to come from the trusted source. The signature is composed of a Message Authentication Code generated by the signing algorithm and a counter. The counter is used to protect against a replay attack and is incremented on each signed Data PDU sent.

5.4.5 Privacy feature

Bluetooth LE supports a feature that reduces the ability to track a LE device over a period of time by changing the Bluetooth Device Address on a frequent basis.

In order for a device using the privacy feature to reconnect to known devices, the device address, referred to as the private address, must be resolvable by the other device. The private address is generated using the device's identity resolving key (IRK) exchanged during the bonding procedure.

The term "resolution" means a process used by a device to calculate the device Identity Address from the received private address and the IRK, while the state "resolved" is the successful result of a resolution.

There are two variants of the privacy feature. In the first variant, private addresses are resolved and generated by the Host. In the second variant, private addresses are resolved and generated by the Controller without involving the Host after the Host provides the Controller device identity information. In addition, the second variant may involve the Host when the resolving list in the Controller cannot store all the device identity resolving keys necessary for bonded devices.

There are two modes of privacy: device privacy mode and network privacy mode. A device in device privacy mode is only concerned about the privacy of the device and will accept advertising packets from peer devices that contain their Identity Address as well as ones that contain a private address, even if the peer device has distributed its IRK in the past. In network privacy mode, a device will only accept advertising packets from peer devices that contain private addresses. By default, network privacy mode is used when private addresses are resolved and generated by the Controller.

The Host maintains a resolving list by adding and removing device identities. The Host may provide the Controller with a complete resolving list or a subset of the resolving list. A device identity consists of the peer's Identity Address and a local and peer's IRK pair.

When the Controller performs address resolution and the Host needs to refer to a peer device that is included in the resolving list, it uses the peer's device Identity Address.

Likewise, all incoming events from the Controller to the Host will use the peer's device identity, provided that the peer's device address has been resolved. If the Controller cannot resolve the peer's device Identity Address in an advertisement, it may pass the event to the Host for resolution in the Host.

Device filtering becomes possible when address resolution is performed in the Controller because the peer's device Identity Address can be resolved prior to checking whether it is in the Filter Accept List.

Figure 5.4 shows a logical representation of the relationship between the Controller resolving list and the Controller Filter Accept List. Actual implementations of the resolving list and Filter Accept List are not required to follow this model. The resolving list may be independent of the Filter Accept List.

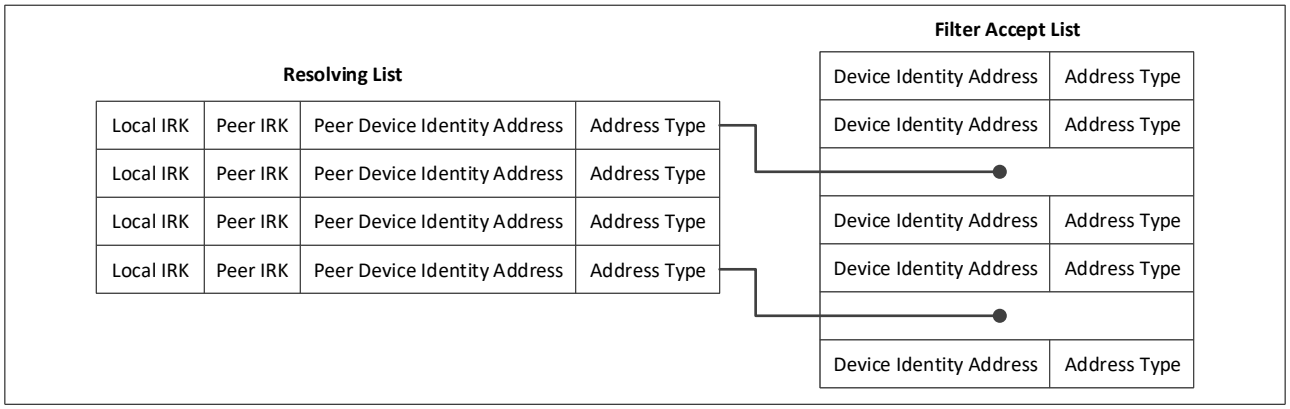

Figure 5.4: Logical representation of the resolving list and Filter Accept List

Note: Not all devices in the Filter Accept List are device Identity Addresses.

5.4.6 Encrypted Advertising Data

The privacy feature described in Section 5.4.5 allows the Bluetooth Device Address to be changed periodically while still allowing the fingerprinting of devices based on the contents of their advertising data. It is possible to encrypt advertising data by encapsulating the normal advertising data within an Encrypted Data data type using a pre-shared session key and a nonce. Because the encrypted advertising data nonce is changed whenever the private address is changed, the encrypted data before and after the change is also different. This approach prevents the tracking of devices based solely on the private address and advertising data.

The encrypted advertising data pre-shared session key is communicated only to peer devices that are authorized to receive such information. Only devices that have the key material can decrypt and authenticate messages and track the advertising device.

5.5 [This section is no longer used]

5.6 Key generation between BR/EDR and LE physical transports

When two BR/EDR/LE devices support Secure Connections over both transports, keys for both transports may be generated during a single pairing procedure. The ability to convert keys from one transport to the other prevents the need to pair twice, thus enabling a better user experience.

The link key for BR/EDR generated during Phase 4 of Secure Simple Pairing on the BR/EDR physical transport may be converted to a Long Term Key (LTK) for use on the LE transport. Similarly, an LTK generated during Phase 2 of pairing on the LE physical transport may be converted to the BR/EDR Link Key for use on the BR/EDR physical transport.

6 BLUETOOTH APPLICATION ARCHITECTURE

6.1 Bluetooth profiles

Application interoperability in the Bluetooth system is accomplished by Bluetooth profiles. Bluetooth profiles define the required functions and features of each layer in the Bluetooth system from the PHY to L2CAP and any other protocols outside of this specification. The profile defines the vertical interactions between the layers as well as the peer-to-peer interactions of specific layers between devices.

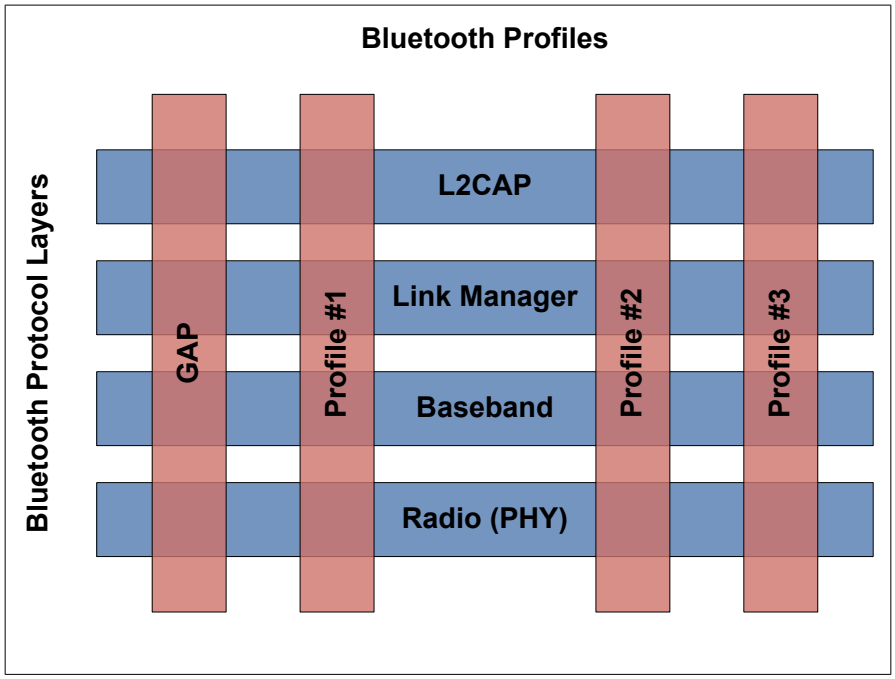

Figure 6.1: Bluetooth profiles

In addition, application behaviors and data formats are also defined by the profile. When two devices comply with all the requirements of a Bluetooth profile, interoperability of an application is enabled.

All profiles describe service discovery requirements necessary for devices to connect, find available application services and connection information necessary for making application level connections.

6.2 Generic Access Profile

The Bluetooth system defines a base profile which all Bluetooth devices implement. This profile is the Generic Access Profile (GAP), which defines the basic requirements of a Bluetooth device. For instance, for BR/EDR, it defines a Bluetooth device to

include the Radio, Baseband, Link Manager, L2CAP, and the Service Discovery protocol functionality; for LE, it defines the Physical Layer, Link Layer, L2CAP, Security Manager, Attribute Protocol and Generic Attribute Profile. This ties all the various layers together to form the basic requirements for a Bluetooth device. It also describes the behaviors and methods for device discovery, connection establishment, security, authentication, association models and service discovery.

In BR/EDR, GAP defines a single role with functionality that may be present in each device. This functionality includes how devices discovery each other, establish connections and describes security association models used for authentication. In BR/EDR this functionality may be present in both devices. It may be necessary for a device to implement both the initiating and accepting functionality if the device wants to discover or establish connections with all devices. A device may only include either the initiating or the accepting functionality but it requires the remote device to support the complimentary functionality to discovery or establish connections with the device. For BR/EDR, the Controller is required to support all the functionality, however the Host may limit this functionality based on the other profiles or use cases supported by the device.

In LE, GAP defines four specific roles: Broadcaster, Observer, Peripheral, and Central. A device may support multiple LE GAP roles provided that the underlying Controller supports those roles or role combinations. Each role specifies the requirements for the underlying Controller. This allows for Controllers to be optimized for specific use cases.

The Broadcaster role is optimized for transmitter only applications. Devices supporting the Broadcaster role use advertising to broadcast data. The Broadcaster role does not support connections. The Observer role is optimized for receiver only applications. Devices supporting the Observer role are the complementary device for a Broadcaster and receives broadcast data contained in advertisements. The Observer role does not support connections. The Peripheral role is optimized for devices that support a single connection and are less complex than Centrals; it uses the Link Layer Peripheral role within the connection. The Central role supports multiple connections and is the initiator for all connections with devices in the Peripheral role; it uses the Link Layer Central role within the connection. Devices supporting the Central role generally support more complex functions compared to the other LE GAP roles.

6.3 Profile hierarchy

Since all Bluetooth devices are required to implement GAP, any additional profiles implemented by a Bluetooth device become supersets of GAP. Depending on the complexity of an application or the ability to reuse common requirements of functionality of the Bluetooth system between many applications, additional generic profiles can be created that depend on GAP or other generic profiles, as well as enabling other profiles. A top level profile that describes application interoperability is called an Application Profile.

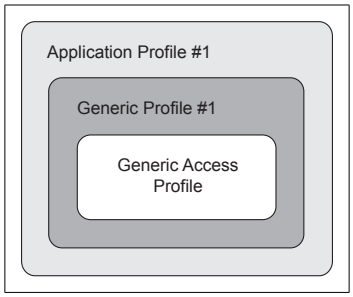

Figure 6.2: Profile hierarchy

Application profiles contain by reference GAP and any other generic profile that describes a set of common requirements of the Bluetooth system.

6.4 Generic Attribute Architecture

6.4.1 Attribute Protocol

To allow devices to read and write small data values held on a server, an Attribute Protocol (ATT) is defined. Each stored value, typically only a few octets, is known as an attribute. This protocol allows each attribute to be self-identifying using UUIDs to identify the type of data. These UUIDs can be well-known assigned numbers defined in the Assigned Numbers document and associated specifications, or a vendor assigned 128-bit UUID.

Attribute Protocol messages are sent over L2CAP channels, known as the ATT bearers.

Attribute Protocol defines two roles: Client and Server. A device can be both an ATT Client and an ATT Server at the same time. Attribute Protocol messages on a single ATT bearer allow a single transaction in each direction to be outstanding at a time. When a response to a message is received, the next transaction can be initiated. When multiple ATT bearers are created, each ATT bearer has a separate transaction model and therefore multiple ATT transactions can be outstanding at the same time, one per bearer. This can be used to allow multiple higher layer specifications to send messages concurrently.

The ATT Server stores the attributes and accepts Attribute Protocol requests, commands and confirmations from the ATT Client. The ATT Server sends responses to requests and, when configured by a higher layer, sends indications and notifications asynchronously to the ATT Client when specified events occur on the ATT Server.

6.4.2 Generic Attribute Profile

Generic Attribute Profile (GATT) is built on top of the Attribute Protocol (ATT) and establishes common operations and a framework for the data transported and stored by the Attribute Protocol. GATT defines two roles: Server and Client. A GATT Client

or Server is an ATT Client or Server respectively that conforms to the requirements in GATT. The GATT roles are not necessarily tied to specific GAP roles but may be specified by higher layer profiles. GATT and ATT are not transport specific and can be used in both BR/EDR and LE. However, GATT and ATT are mandatory to implement in LE since it is used for discovering services.

GATT also specifies the format of data contained on the GATT Server. Attributes, as transported by the Attribute Protocol, are formatted as Services and Characteristics. Services may contain a collection of characteristics. Characteristics contain a single value and any number of descriptors describing the characteristic value.

With the defined structure of services, characteristics and characteristic descriptors a GATT Client that is not specific to a profile can still traverse the GATT Server and display characteristic values to the user. The characteristic descriptors can be used to display descriptions of the characteristic values that may make the value understandable by the user.

6.5 GATT-Based Profile hierarchy

The GATT Profile specifies the structure in which profile data is exchanged. This structure defines basic elements such as services and characteristics, used in a profile.

The top level of the hierarchy is a profile. A profile is composed of one or more services necessary to fulfill a use case. A service is composed of characteristics or references to other services. Each characteristic contains a value and may contain optional information about the value. The service and characteristic and the components of the characteristic (i.e., value and descriptors) contain the profile data and are all stored in Attributes on the server.

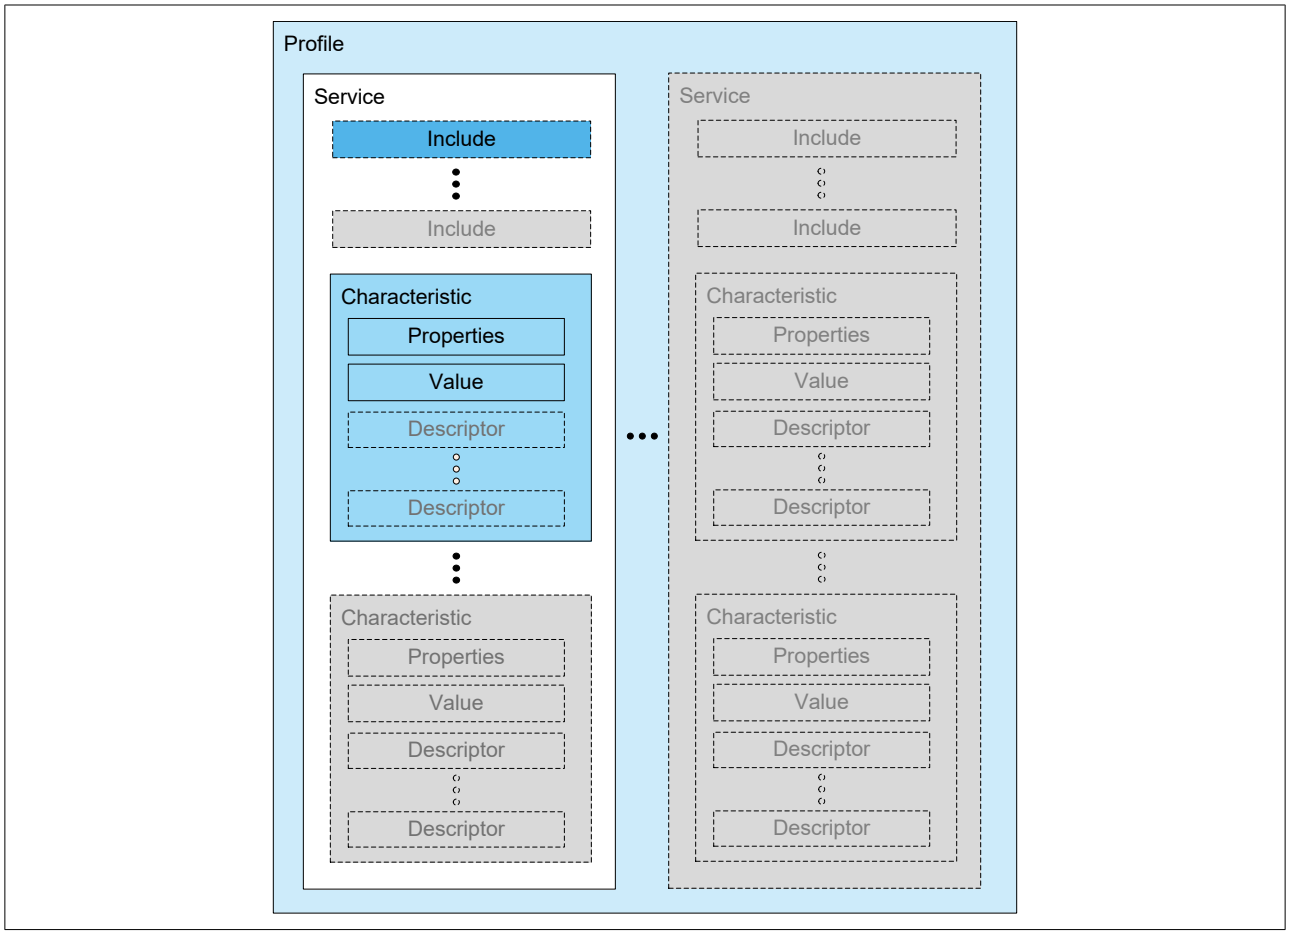

Figure 6.3: GATT-Based Profile hierarchy

6.5.1 Service

A service is a collection of data and associated behaviors to accomplish a particular function or feature of a device or portions of a device. A service may include other primary or secondary services and/or a set of characteristics that make up the service.

There are two types of services: primary and secondary. A primary service is a service that provides functionality of a device that can be used on its own. A secondary service is a service that provides additional functionality of a device in association with a primary service and is included from at least one primary service on the device.

To maintain backward compatibility with earlier clients, later revisions of a service definition can only add new included services or optional characteristics. Later revisions of a service definition are also forbidden from changing behaviors from previous revision of the service definition.

Services may be used in one or more profiles to fulfill a particular use case.

6.5.2 Included services

An included service is a method to incorporate another service definition on the server as part of the service including it. When a service includes another service, the entire included service becomes part of the new service including any nested included services and characteristics. The included service still exists as an independent service. There are no limits to the depth of nesting.

6.5.3 Characteristic

A characteristic is a value used in a service along with properties and configuration information about how the value is accessed and information about how the value is displayed or represented. A characteristic definition contains a characteristic declaration, characteristic properties, and a value. It may also contain descriptors that describe the value or permit configuration of the server with respect to the characteristic value.

6.6 [This section is no longer used]

7 COEXISTENCE AND COLLOCATION

Bluetooth devices operate in the unlicensed 2.4 GHz Industrial, Scientific and Medical (ISM) band. Many other technologies utilize the ISM band, including wireless LAN, cordless phones, and microwave ovens. The ISM band is also close enough to other frequency bands that Bluetooth devices may be an interferer of or a victim of other technologies.

Radios may be collocated or non-collocated. The term "collocated" is a loose one - in this specification, collocated radios are assumed to be in the same product (a Multi-Radio Terminal or MRT) and may have mechanisms to coordinate their activity in order to mitigate interference.

Determining the amount of expected isolation between radios is important for choosing an appropriate coexistence mechanism. With sufficient isolation, frequency division duplexing (FDD) techniques are the most efficient. With insufficient isolation or a shared antenna, time division duplexing (TDD) techniques need to be used. In many cases, a combination of FDD and TDD techniques are required to achieve acceptable levels of performance.

This specification supports a variety of features that help mitigate interference to other devices and to minimize interference from other devices. Broadly, the types of solutions fall into the following categories:

Type	Description
Frequency division	Simultaneous use of multiple radios enabled by filters and/or isolation
Time division	One radio may transmit or receive at a time through scheduling or prioritization
Time alignment	Activities of the collocated radios are aligned in the time domain to optimize performances by avoiding conflicting activities. E.g. Transmissions of multiple radios may occur simultaneously, multiple receptions may occur simultaneously, but it is not possible to transmit and receive simultaneously
Hybrid frequency and time division	Use of frequency division, time alignment, and time division techniques depending on the relative frequencies in use by the radios, filters and isolation

Table 7.1: Interference mitigation types

7.1 Core features supporting coexistence and collocation

There are features in the specification to specifically target the reduction of interference from collocated or non-collocated devices.

Feature	Version Introduced	Description
Adaptive Frequency Hopping	1.2	Allows devices to reduce the number of channels used in a piconet in order to avoid interferers
HCI Set Host Channel Classification	1.2	Allows a Host to inform the local Bluetooth Controller of the channels that are occupied by a collocated technology
Enhanced SCO (eSCO)	1.2	Added retransmissions to SCO for the purpose of combating interference
MWS Coexistence Signaling	CSA3	Provides a standardized interface between collocated radios for communicating information necessary to enable some coexistence techniques
Piconet Clock Adjust	4.1	Allows a Bluetooth device to align the piconet clock with an external technology, e.g. Long Term Evolution (LTE)
Train Nudging	4.1	Provides a mechanism to improve the success rate of page and inquiry when the slots to receive the respective responses are periodically not available
Generalized Interlaced Scanning	4.1	Provides a mechanism to improve the success rate of page scan and inquiry scan when some slots are periodically not available for scanning
Slot Availability Mask	5.0	Provides a mechanism for two Bluetooth devices to indicate to each other the availability of their time slots

Table 7.2: Interference mitigation features

7.2 Adaptive Frequency Hopping

Adaptive Frequency Hopping (AFH) allows Bluetooth devices to improve their immunity to interference from and avoid causing interference to other devices in the 2.4 GHz ISM band. The basic principle is that Bluetooth channels are classified into two categories, used and unused, where used channels are part of the hopping sequence and unused channels are replaced in the hopping sequence by used channels in a pseudo-random way. This classification mechanism allows for the Bluetooth device to use either all or fewer than the channels available. The minimum number of channels allowed by the Bluetooth specification is 20 on BR/EDR and 2 on LE.

The specification defines the aspects of AFH necessary to ensure interoperability, including the hopping kernel, Baseband behavior, Link Manager Protocol (LMP) commands, Link Layer behavior and commands, and Host Controller interface (HCI) commands and events required to change and configure hopping sequences. The Bluetooth Specification also defines a mechanism that allows for a Peripheral to report channel classification information to the Central.

Adaptive Frequency Hopping utilizes metrics obtained through many sources. These metrics are analyzed and then the resulting Channel_Map is used by the adaptive frequency hopping kernel. The metrics may come from over-the-air measurements, data supplied by the Host (e.g., via HCI commands), or reports by the Peripheral or from other hardware coexistence interfaces.

While AFH is a critical element in coexistence, it is not enough in some circumstances.

7.3 Coexistence between Bluetooth Devices and Wireless LAN Devices

Coexistence between Bluetooth and Wireless LAN has traditionally been a combination of Adaptive Frequency Hopping (AFH) and proprietary techniques to prioritize traffic between the two protocols. The specification does not specify signaling between the Bluetooth Controller and a Wireless LAN device.

7.4 Mobile Wireless Standards (MWS) coexistence

Significant interference can be present between the Bluetooth radio and a collocated MWS radio operating in frequency bands adjacent to the 2.4 GHz ISM band. This interference can prevent one radio from receiving while the other radio is transmitting.

The “Filter recommendations for Coexistence with LTE and WiMAX” whitepaper[1] describes filter specifications that, in some cases, can reduce collocated interference to an acceptable level. The specification includes complementary solutions to traditional filtering including features for Bluetooth Controllers and Hosts as well as signaling and messaging mechanisms between collocated MWS and Bluetooth radios. Figure 7.1 illustrates the general architecture model for these mechanisms. This architecture assumes separate antennae with limited isolation.

[1] https://www.bluetooth.com/develop-with-bluetooth/build/white-papers

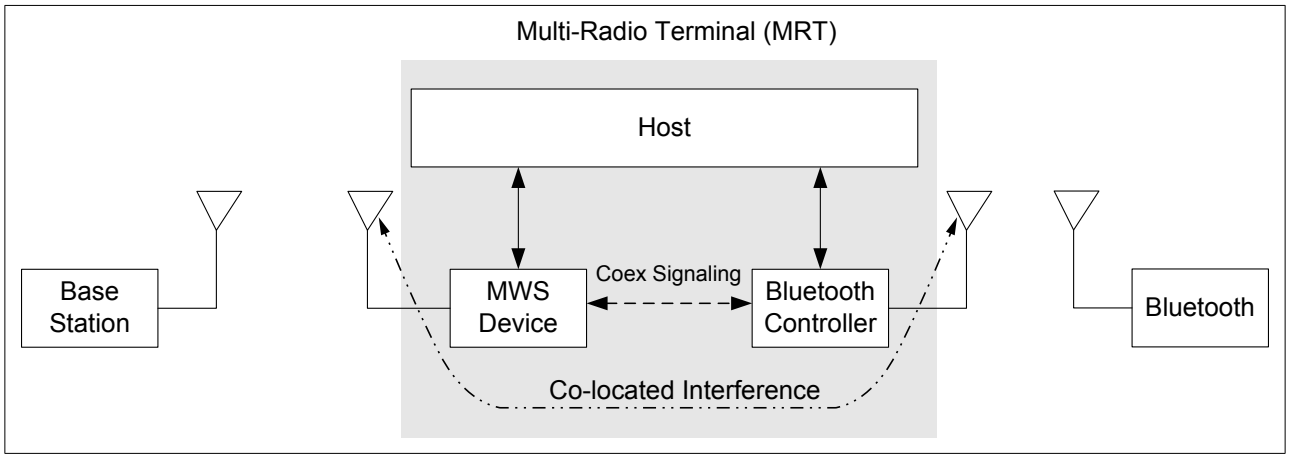

Figure 7.1: MWS coexistence architecture

Two types of solutions have been considered. In the first solution, both Bluetooth transmissions (TX) and receptions (RX) are constrained by collocated MWS activities. Solutions of this type are called Pure TDM (Time Division Multiplexed) Mode. In the second solution, only Bluetooth receptions are affected by collocated MWS transmissions and Bluetooth transmissions do not impact the operation of the collocated MWS. Solutions of this type are called Hybrid Mode and are achieved, for example, by using steep roll-off Band Select Filters (BSFs) for the ISM band in the Bluetooth transceiver. Hybrid Mode applies where the Bluetooth transmission's effect on MWS is sufficiently reduced via filtering that the Bluetooth device can transmit during the MWS downlink time. This requires a frequency guard band between the Bluetooth and MWS operational frequency ranges as well as constraints on both the Bluetooth BSF and the MWS BSF. The requirement for a time domain solution still remains, but only to protect Bluetooth reception.

These solutions are facilitated by an MWS coexistence signaling mechanism (see [Vol 7] Part A) and multiple transport layers (see [Vol 7] Part B and [Vol 7] Part C).

MWS technologies operate in licensed bands and use centralized scheduling to support Wide Area Network services. An MWS radio synchronizes both time and frequency with a network Base Station. The Base Station determines which MWS radio will transmit or receive and when. MWS radios have no control over when to transmit or receive. When Bluetooth transmissions interfere with MWS receptions in the MRT, the MWS radio can be rendered unusable if the Bluetooth radio transmits freely. Figure 7.2 shows how Bluetooth activity can interfere with every MWS reception opportunity and similarly how MWS transmissions can interfere with Bluetooth reception. In the example shown in Figure 7.2 the Bluetooth device in the MRT is operating as the Central of a piconet. Blocks marked with a "C" are single slot Central transmissions and those marked with a "P" are single slot Peripheral transmissions. The times at which reception by the MWS device may be corrupted by Bluetooth transmissions are marked with a red shade.

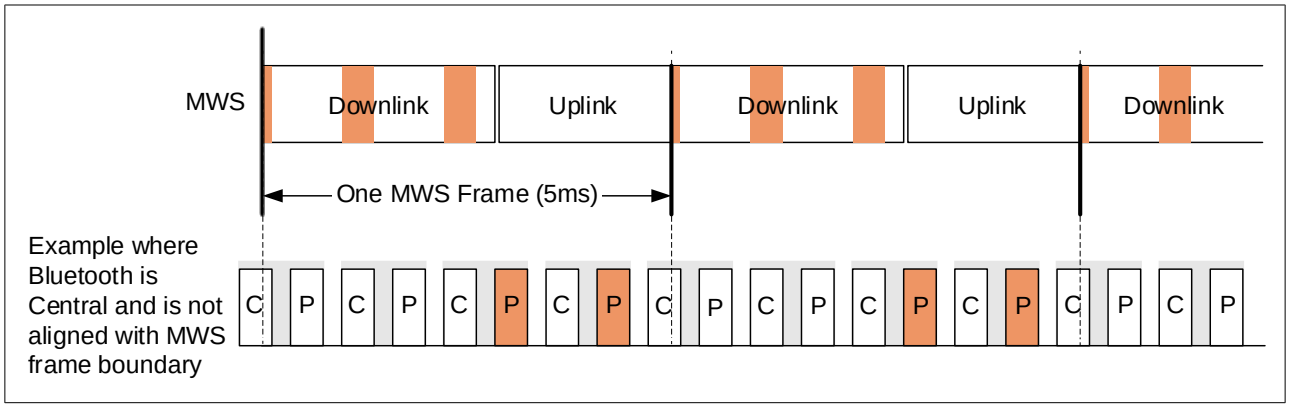

Figure 7.2: MWS receptions interfered with by uncontrolled Bluetooth transmissions

Even with the best relative timing relationship (when the Bluetooth slot boundary is aligned with the MWS frame boundary), the Bluetooth radio in the MRT suffers reduced transmission and reception opportunities due to time multiplexing with the collocated MWS radio. The Bluetooth radio only gets one transmission/reception opportunity every MWS frame, as shown in Figure 7.3.

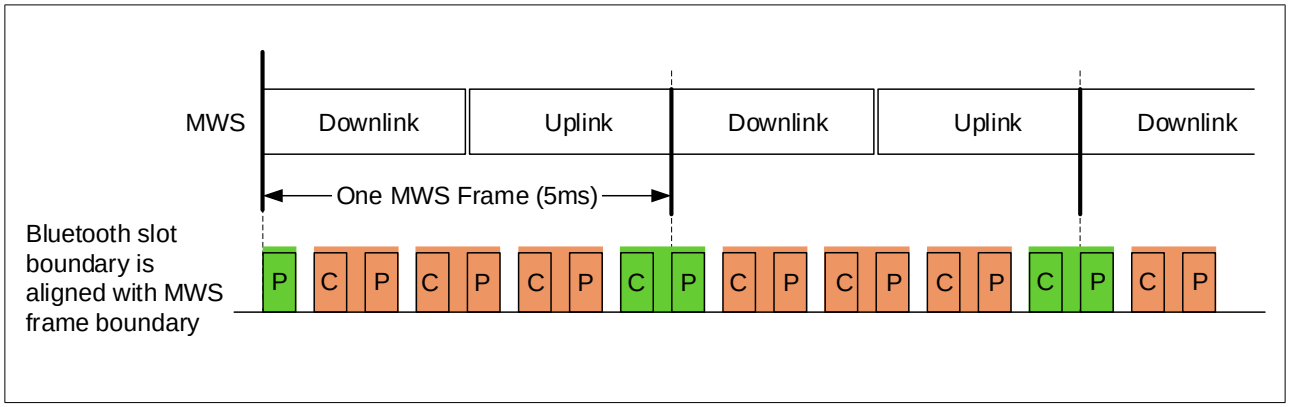

Figure 7.3: Bluetooth radio has reduced transmission/receiving opportunities

Consequently, three out of four (for 5 ms MWS frames) or seven out of eight (for 10 ms MWS frames) slot pairs of Bluetooth can be punctured by MWS activities. Furthermore, since Bluetooth inquiry and paging use a sequence of 16 channels at a time, when the Bluetooth radio in the MRT is performing inquiry or paging the channel sequence will repeat every 5 ms resulting in the same channels being repeatedly punctured by the collocated MWS activities, see Figure 7.4. As a result, there is a high probability that the remote scanning device will not be able to receive the page or inquiry IDs within the current timeout.

When the inquiry or paging channel sequence gets repeatedly punctured, Train Nudging can be used to add an additional offset to the clock bits in order to shift the channel sequence.

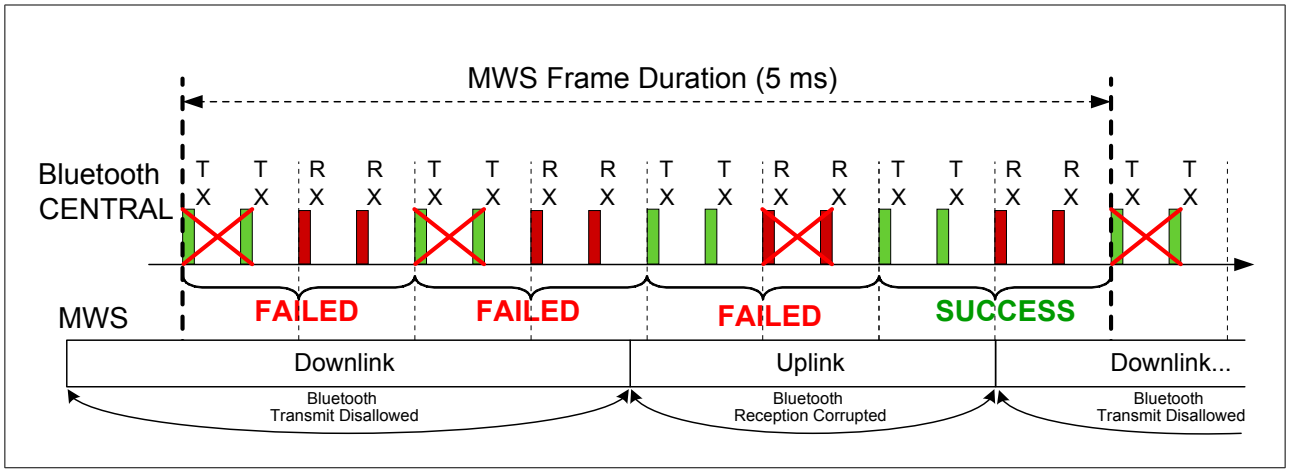

Figure 7.4: Bluetooth radio can suffer inquiry/page failures

As MWS transmissions interfere with Bluetooth receptions in the MRT, up to 50% of the transmitted IDs from the remote inquiry/page device will not be received by the Bluetooth radio in the MRT performing scanning, as shown in Figure 7.5.

Based on the pattern of slots that are not available for scanning, Generalized Interlaced Scanning can be used to tune the phase of the second scan during a back-to-back scan.

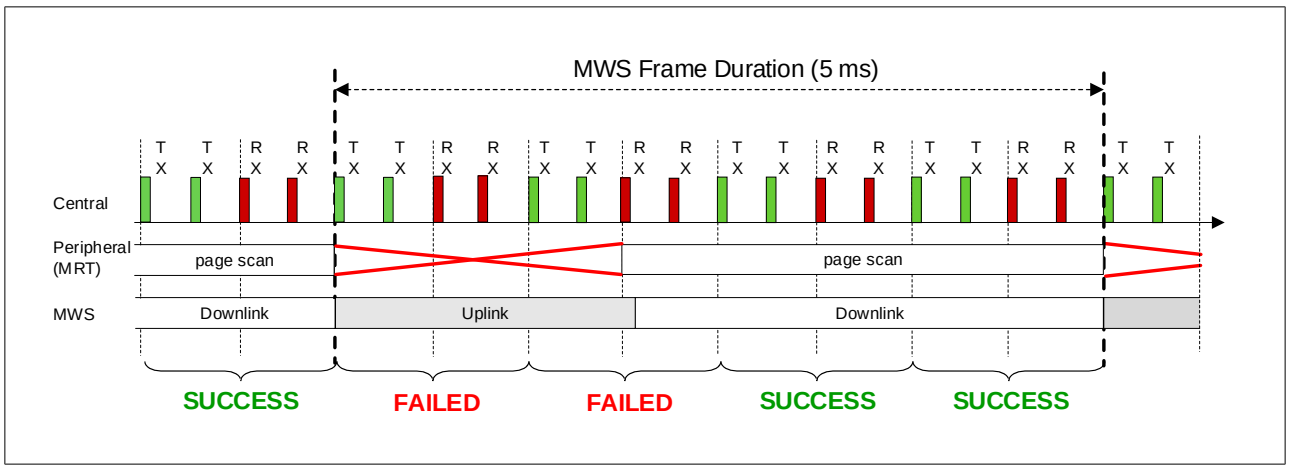

Figure 7.5: Bluetooth radio can suffer inquiry scan/page scan failures

7.5 Synchronizing Bluetooth with an external timing source

This section provides an example to illustrate the synchronization of the Bluetooth CLK with an MWS system so that the Bluetooth slots line up with the Downlink and Uplink times of the MWS system. The external frame in this example is LTE TDD Frame Configuration #1 and special subframe configuration #1; however the same mechanisms can be used for any external TDD/TDMA protocol. The example shows a time span of 10 ms.

[Vol 7] Part A defines the timing of the MWS frame as a fixed offset from the FRAME_SYNC signal in the coexistence signaling. This is shown in Figure 7.6 as FS. FS can be defined by the Host as any specific offset within the MWS frame. For a piconet Central, the most useful position for FS is the boundary between the uplink and the following downlink. This is because the Central needs to transmit in a Central slot during the uplink and then receive in the following Peripheral slot during the downlink. Putting FS at this boundary allows the Central to easily align its Bluetooth clock to put it between these slots. The situation is reversed in a Peripheral: FS is most useful on the boundary between the downlink and the following uplink.

The HCI command HCI_Set_External_Frame_Configuration ([Vol 4] Part E, Section 7.3.81) can be used to describe the MWS frame timing. This knowledge, together with FS, allows the Bluetooth Controller to align the Bluetooth clock with the MWS frame timing so as to minimize the effect of mutual interference. This is illustrated in Figure 7.6. The red ovals show slot pairs where both MWS and Bluetooth transmit and receive simultaneously and so do not interfere with each other. The MWS frame structure includes a downlink portion (“D”), an uplink portion (“U”), and a special portion (“S”) that includes a downlink and uplink portion separated by a guard period (“GP”).

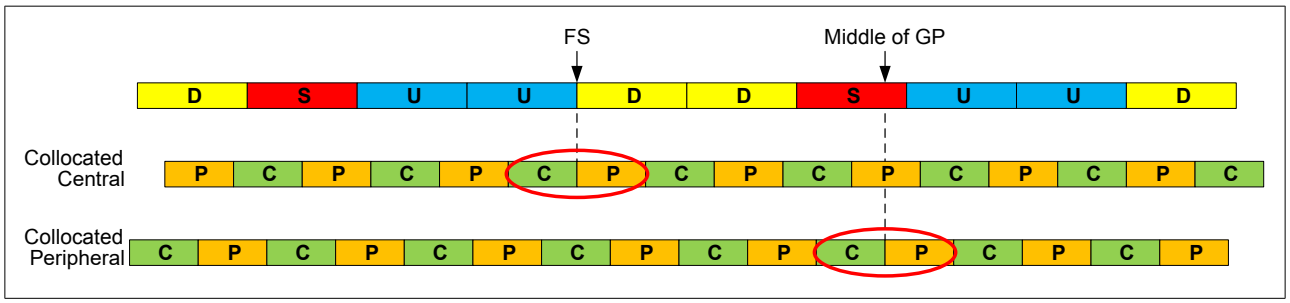

Figure 7.6: Alignment of MWS frame timing and Bluetooth clock

Note: In LTE, if the implementation does not have access to the exact LTE timing it can assume that the downlink-to-uplink boundary is the middle of the GP in a special LTE subframe.

7.6 Piconet clock adjustment

As discussed in the previous section, aligning the MWS and Bluetooth clocks correctly greatly improves throughput on both technologies. The Central has two mechanisms at its disposal to mitigate misalignments.

Coarse Clock Adjustments can be used to move the Bluetooth CLK using the LMP_CLK_ADJ PDU. The clk_adj_us parameter is used to align the slots with the MWS alignment point indicated by the FRAME_SYNC signal. The clk_adj_slots parameter can be used to move the CLK several slots forward in time. This can be useful to align e.g. eSCO. Coarse Clock Adjustment is expected to be used only rarely, for instance

at MWS connection or when the MWS frame timing changes due to roaming. Coarse Clock Adjustment can only be used when all Peripherals in the piconet support it.

The other option for the Central is to use Clock Dragging. This is a method of slowly adjusting the phase of the clock backward or forward by making the slots a few µs shorter or longer, respectively, until the desired CLK phase has been achieved. It should be noted that this is a very slow rate of adjustment, as it is designed to allow a legacy device to track the change, and therefore the requirements of [Vol 2] Part B, Section 1.1 mean that Clock Dragging must not be done at a faster rate than the maximum natural drift between devices. For this reason its main use is to facilitate small corrections over time if a misalignment with the MWS system is detected. If any device is connected that does not support Coarse Clock Adjustment, slowly moving the Peripheral using Clock Dragging is the only option.

It is recommended to let the collocated device be the Central, when possible, as it can react much faster to correct misalignments. If a Peripheral is the collocated device, doing a role switch to make it Central may be worth considering. Alternatively a Peripheral can send a Piconet Clock Adjustment Request LMP packet to the Central. The Central then has the option to perform a Coarse Clock Adjustment, Clock Dragging, or to reject the request.

7.7 Slot Availability Mask (SAM)

Slot Availability Mask (SAM) allows two Bluetooth devices to indicate to each other time slots that are available for transmission and reception. The SAM slot map specifies the availability or otherwise of Bluetooth slots. A slot could be unavailable because of external conditions (e.g., MWS coexistence) or internal conditions (e.g., scatternet commitments). SAM does not impose new mandatory rules for the scheduling of BR/EDR time slots. Instead, it merely provides information which allows Controllers to refine their scheduling of Bluetooth slots to improve performance.

SAM slot maps are calculated by the Controller itself based on its scheduling requirements. There are no HCI commands defined specifically for SAM, merely LMP sequences that enable devices to exchange maps and indicate the map in use. The HCI commands HCI_Set_External_Frame_Configuration (see [Vol 4] Part E, Section 7.3.81) and HCI_Set_MWS_PATTERN_Configuration (see [Vol 4] Part E, Section 7.3.85) and real-time signals (e.g., MWS_PATTERN_Index or FRAME_SYNC) provided by the Coexistence Logical Interface (see [Vol 7] Part A) contain information concerning the appropriate SAM_Index and SAM anchor point to use for MWS coexistence; these may therefore trigger these LMP sequences.

A Controller may choose to perform a Piconet Clock Adjustment before initiating an LMP_SAM_SWITCH sequence so as to increase the number of slot pairs available per MWS frame.

8 DIRECTION FINDING USING BLUETOOTH LOW ENERGY

An LE device can make its direction available for a peer device by transmitting direction finding enabled packets. Using direction information from several transmitters and profile-level information giving their locations, an LE radio can calculate its own position.

This feature is supported over the LE Uncoded PHYs, but not over the LE Coded PHY.

8.1 Angle of arrival (AoA) method

An LE device can make its direction available to a peer device by transmitting direction finding enabled packets using a single antenna.

The peer device, consisting of an RF switch and antenna array, switches antennae while receiving part of those packets and captures IQ samples. The IQ samples can be used to calculate the phase difference in the radio signal received using different elements of the antenna array, which in turn can be used to estimate the angle of arrival (AoA).

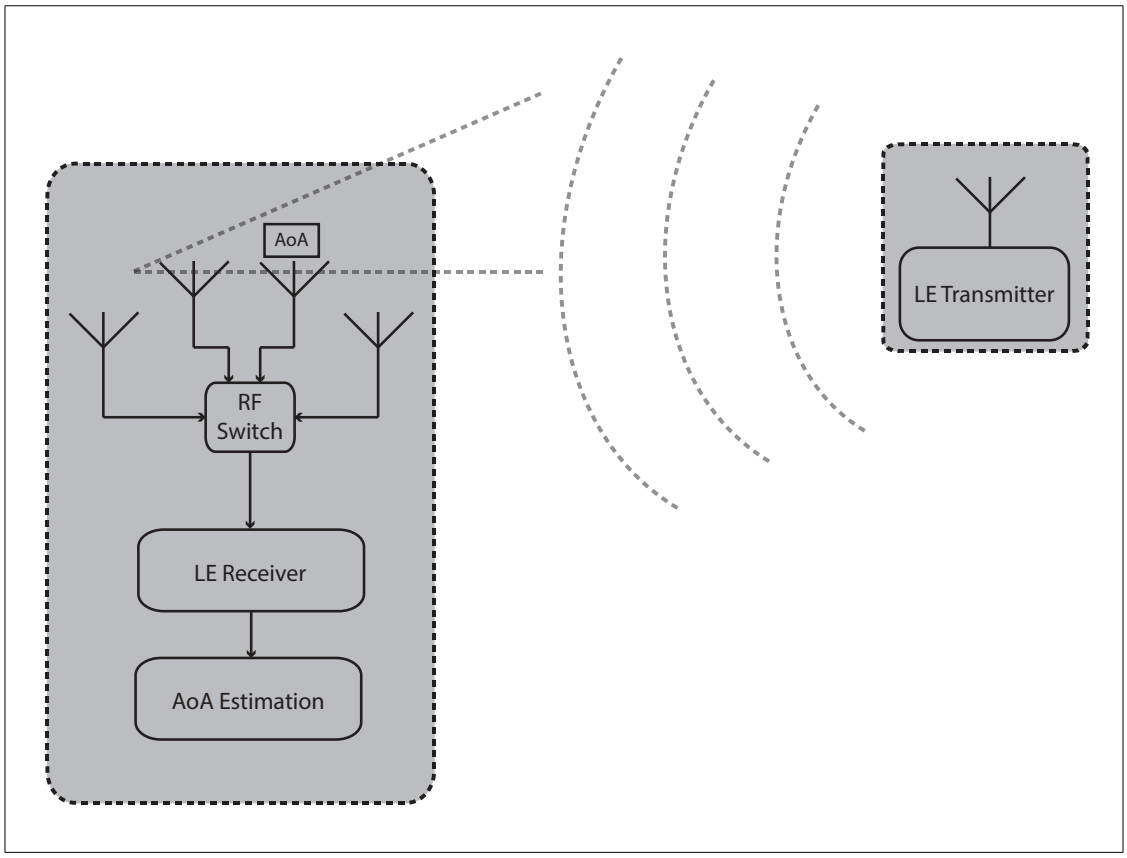

Figure 8.1: Angle of Arrival method

Consider a receiver device with an antenna array consisting of two antennae, separated by distance *d*. The transmitter device uses a single antenna to transmit a signal. As shown in Figure 8.2, a perpendicular line can be drawn from an incoming signal wave front extending to the furthest antenna (antenna 2) at the point of intersection to the closest antenna (antenna 1). The adjacent side of that right triangle represents the path difference relative to the angle of incidence of that wave front between both antennae. The phase difference, ψ, in the signal arriving at the two antennae is then

$$\psi = (2\pi d \cos(\theta)) \div \lambda$$

where λ is the wavelength of the signal and θ is the angle of arrival (measured from a line connecting the two antennae in the receiver), and so

$$\theta = \arccos((\psi\lambda) \div (2\pi d))$$

Note: The distance d is profile-level information that is used by the receiving device to calculate the angle of arrival.

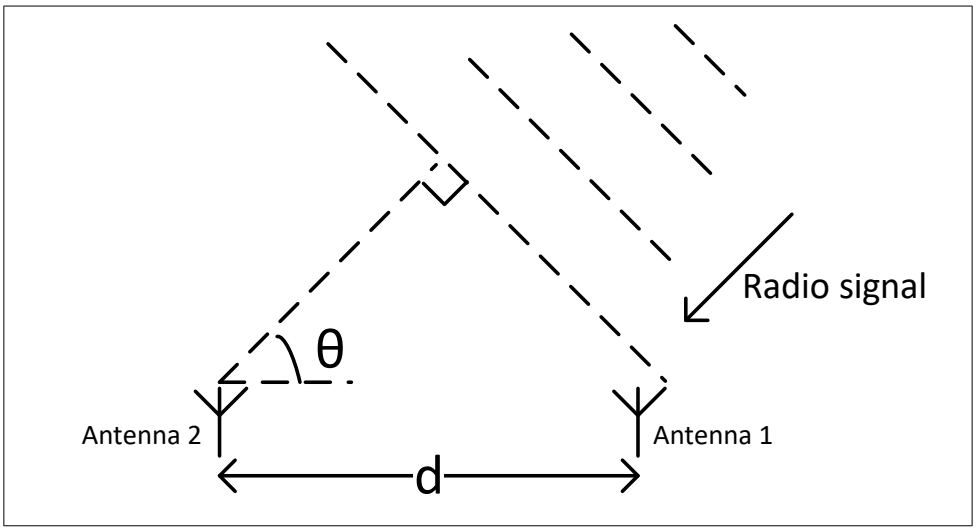

Figure 8.2: Measuring the angle of arrival

8.2 Angle of departure (AoD) method

A device consisting of an RF switch and antenna array can make its angle of departure (AoD) detectable by transmitting direction finding enabled packets, switching antennae during transmission.

The peer device receives those packets using a single antenna and captures IQ samples during part of those packets. Determination of the direction is based on the different propagation delays of the LE radio signal between the transmitting elements of the antenna array and a receiving single antenna. The propagation delays are detectable with IQ measurements. Any receiving LE radio with a single antenna that

supports the AoD feature can capture IQ samples and, with the aid of profile-level information specifying the antenna layout of the transmitter, calculate the angle of incidence of the incoming radio signal.

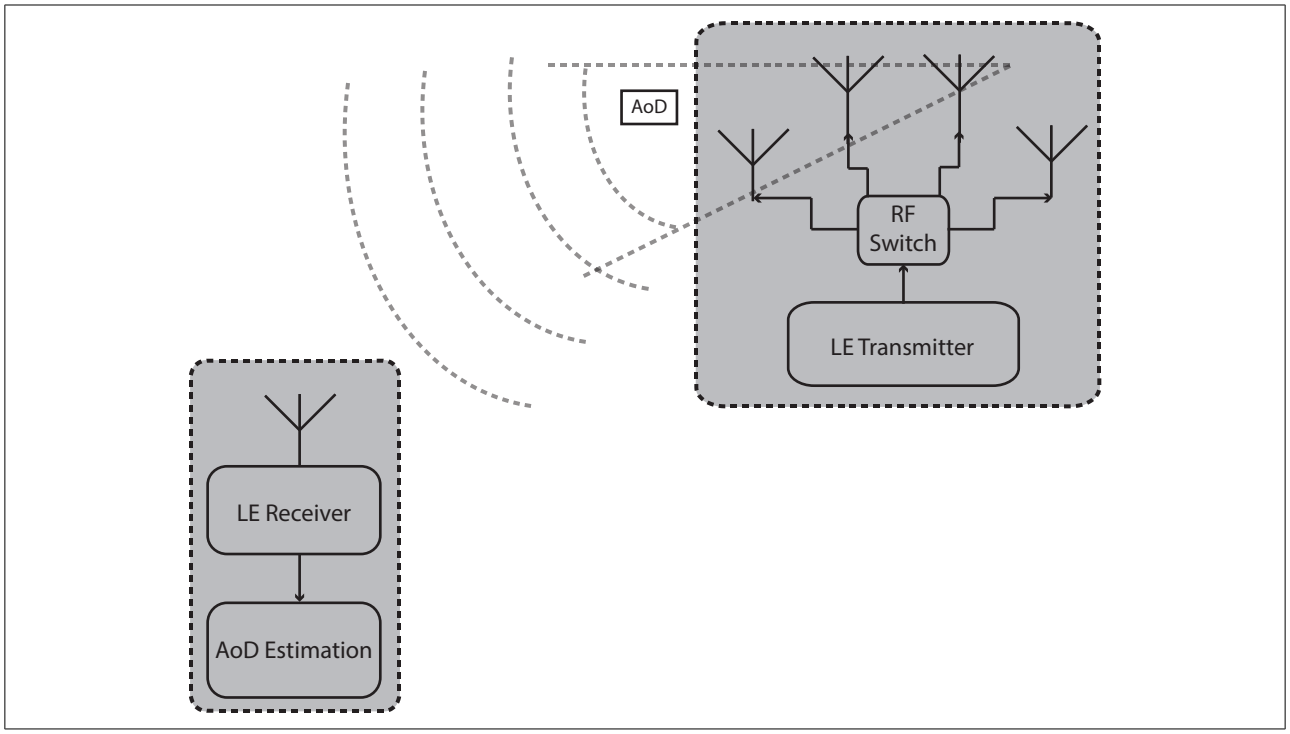

Figure 8.3: Angle of departure method

Consider a transmitter device with an antenna array consisting of two antennae, separated by distance *d*. The receiver device uses a single antenna to receive the signals. The phase difference, ψ, in the signal from antenna 1 and the signal from antenna 2 arriving at the receiver is then

$$\psi = (2\pi d \cos(\theta)) \div \lambda$$

where λ is the wavelength of the signal and θ is the angle of departure (measured from a line connecting the two antennae in the transmitter), and so

$$\theta = \arccos((\psi\lambda) \div (2\pi d))$$

Note: The distance d is profile-level information that a transmitting device exchanges with the receiving device in order for the receiving device to calculate the angle of departure.

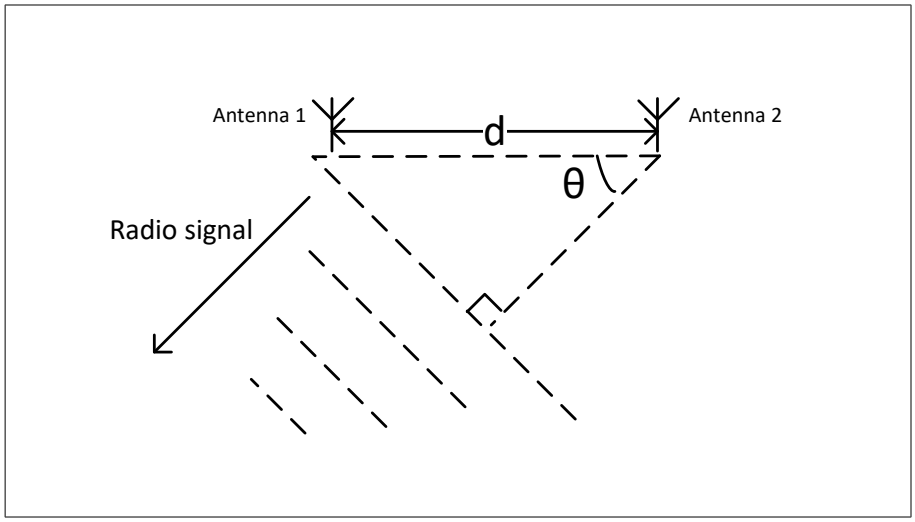

Figure 8.4: Measuring the angle of departure

9 CHANNEL SOUNDING USING BLUETOOTH LOW ENERGY

An LE device can use the Channel Sounding (CS) feature to characterize the propagation path between itself and a connected peer. The measurements obtained from a CS procedure enable a device to estimate its distance from the peer device. A device supporting the CS feature supports both round-trip time measurements and phase-based ranging measurements.

9.1 Channel Sounding procedure

The CS feature consists of a combination of Link Layer procedures and a dedicated air interface protocol that creates a tightly interlocked exchange of RF signals between two devices on multiple RF channels. This exchange is known as a CS procedure.

A CS procedure consists of CS events, subevents and steps. These define a set of time and frequency slots in which two devices exchange a combination of RF signals. The purpose of that exchange is to measure the physical characteristics of the transmission channel. These exchanges are bidirectional; both devices take turns sending and receiving RF signals.

A CS procedure is divided into one or more CS events. A CS event consists of one or more CS subevents. A CS subevent consists of two or more CS steps, each of which starts with a frequency change period called T_FCS. Time separation between CS subevents avoids continuous allocation of the RF resources of a given device and facilitates coexistence with other RF technologies. Within a CS subevent, the first CS steps are used to provide calibration information for the remaining CS steps within that CS subevent. Figure 9.1 shows the relationship between CS procedures, CS events, CS subevents, and CS steps.

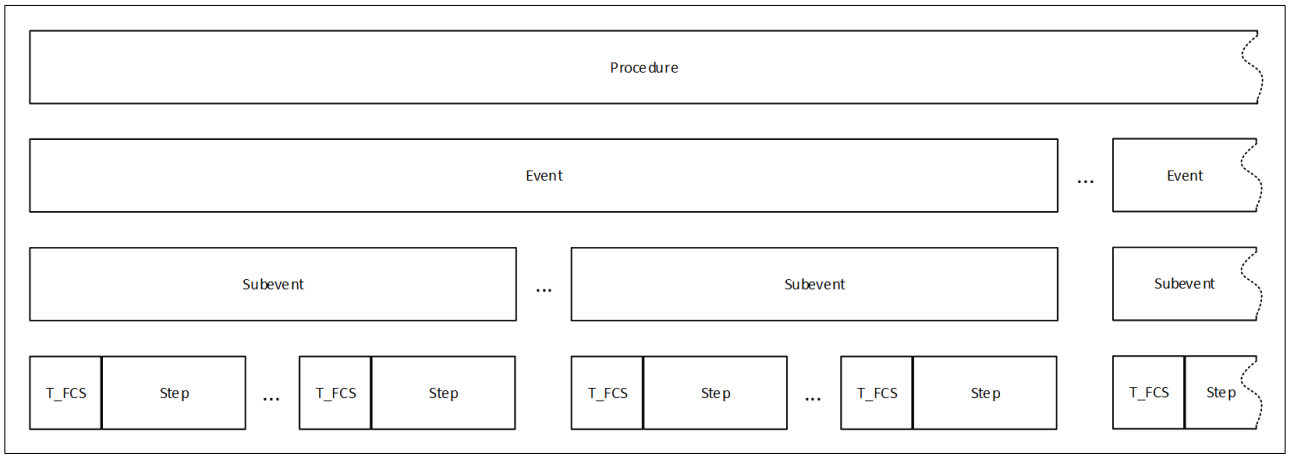

Figure 9.1: CS procedure/event/subevent/step hierarchy

Each CS subevent has a separate starting point. The Link Layer procedures that configure devices to run the CS procedure define the CS steps for these subevents, in terms of both time and frequency, relative to these starting points.

Four CS step types, known as mode-0 through mode-3, are defined. Each mode is used for a specific purpose. Mode-0 is used to calibrate one device to the other in terms of frequency and timing. Mode-1 is used to exchange a round-trip time (RTT) packet. Mode-2 is used to exchange phase-based ranging (PBR) CS tones to measure phase and amplitude of the communication channel. Mode-3 is used to exchange both RTT and phase/amplitude measurements.

After the CS procedure completes, each device retains information collected from each CS step that describes the communication channel. Mode-0 steps reflect local frequency adjustments. Mode-1 and mode-3 steps measure time of arrival and time of departure. Mode-2 and mode-3 steps measure phase and magnitude information in the form of in-phase and quadrature (IQ) measurements. The reflector communicates this information to higher layers to be sent back to the initiator.

9.2 Distance estimation based on phase and amplitude information

The Channel Sounding feature does not specify an algorithm for computing a distance estimate, but a mathematical representation is provided here.

Let $\theta_{CH}(f)$ represent the phase delay of the channel, where f is the channel frequency, and $\Delta\theta_{LO}(f)$ represents the relative difference in phase of the RF carrier between the devices.

Then the relative phases of a carrier measured at the reflector and initiator's antenna is

$$\theta_{REFL}(f) = \theta_{CH}(f) + \Delta\theta_{LO}(f) \text{ and } \theta_{INIT}(f) = \theta_{CH}(f) - \Delta\theta_{LO}(f).$$

Further, let $A_{REFL}(f)$ and $A_{INIT}(f)$ represent the amplitude of that measured carrier at the reflector and initiator's antenna. Let a phase correction term (PCT) be defined by the angle that, if added to the internal angle of the local oscillator, would result in a phase identical to that of the incoming signal. Then IQ values represented by the PCT measured at the reflector and initiator are given by

$$PCT_{REFL}(f) = A_{REFL}(f)e^{i\theta_{REFL}(f)} \text{ and } PCT_{INIT}(f) = A_{INIT}(f)e^{i\theta_{INIT}(f)}$$

Assume that the communication channel is symmetrical between the initiator and reflector. Then the measured phases are dependent on both the communication channel and the relative difference in phase of the RF carrier between the devices.

The communication channel transfer function can then be estimated from

$$H^2(f) = A_{REFL}(f)e^{i\theta_{REFL}(f)} \times A_{INIT}(f)e^{i\theta_{INIT}(f)} = A_{CH}^2(f)e^{i2\theta_{CH}(f)}$$

Assume that from $H^2(f)$ it is possible to calculate the actual channel transfer function $H(f)$. Assuming that $H(f)$ is a linear-time invariant transfer function, then an under-resolved estimate of the impulse response $h(t)$ can be calculated from the inverse Fourier transform of $H(f)$. Assuming that there is only one propagation path, then the maximum peak in the estimate of the impulse response will occur at the delay between the two devices, and assuming communication is at the speed of light, it is possible to estimate the distance.

In the case of a single propagation path, a simplification may be made. Here, the distance can also be estimated by the change in phase as a function of frequency. Assume that the distance between initiator and reflector is x. The total distance traveled by a reflected signal will then be $2x$.

The equation for wavelength is $\lambda = \frac{c}{f}$. Assume that the initial phase of the initiator is zero. If the channel is symmetrical, and if the initial phase of the reflector is zero; then the total phase change over a distance x is given by

$$\varphi_{CH}\left(f\right) = -2 \times 2\pi\frac{x}{\lambda} = -2 \times 2\pi\frac{xf}{c}$$

From this equation, the derivative of the phase as a function of frequency is a constant and is proportional to distance.

$$\frac{d\varphi_{CH}(f)}{df} = -4\pi\frac{x}{c}$$

From the channel transfer function, the phase change can be calculated as a function of frequency.

$$\varphi_{CH}(f) = angle\left(H^2(f)\right) \quad \text{(EQ 1)}$$

An estimate of the distance, x, can then be calculated as follows.

$$x = -\frac{d\varphi_{CH}(f)}{df}\frac{c}{4\pi}$$

When channel measurements are taken at frequencies separated by 1 MHz, a distance ambiguity occurs in the equation above when

$$\varphi_{CH}(f + 1\ \ MHz) - \varphi_{CH}(f) \quad \text{(EQ 2)}$$

is an integer multiple of 2π. This gives a distance ambiguity every d_{wrap} meters, as shown below

$$d_{wrap} = \frac{2\pi}{1\ \text{MHz}} \frac{3\times10^{8}\ m/s}{4\pi} = 150\ \ m$$

To support distance estimation of larger distances, round-trip timing can be used to disambiguate distance results.

9.3 Distance estimation based on RTT packets

For RTT in the CS feature, the two devices exchange packets of the format known as CS_SYNC, which is described in [Vol 6] Part H, Section 2. Time of departure (ToD) and time of arrival (ToA) times are used to estimate the time of flight (ToF), as shown in Figure 9.2.

Assuming the same time base on both devices, sufficient precision of ToD and ToA for the required distance accuracy, and line of sight conditions with no reflections, then an estimated distance, x, can be calculated as shown in the equation below, where c is the speed of light.

$$x = \frac{T_{initator} - T_{reflector}}{2} \times c$$

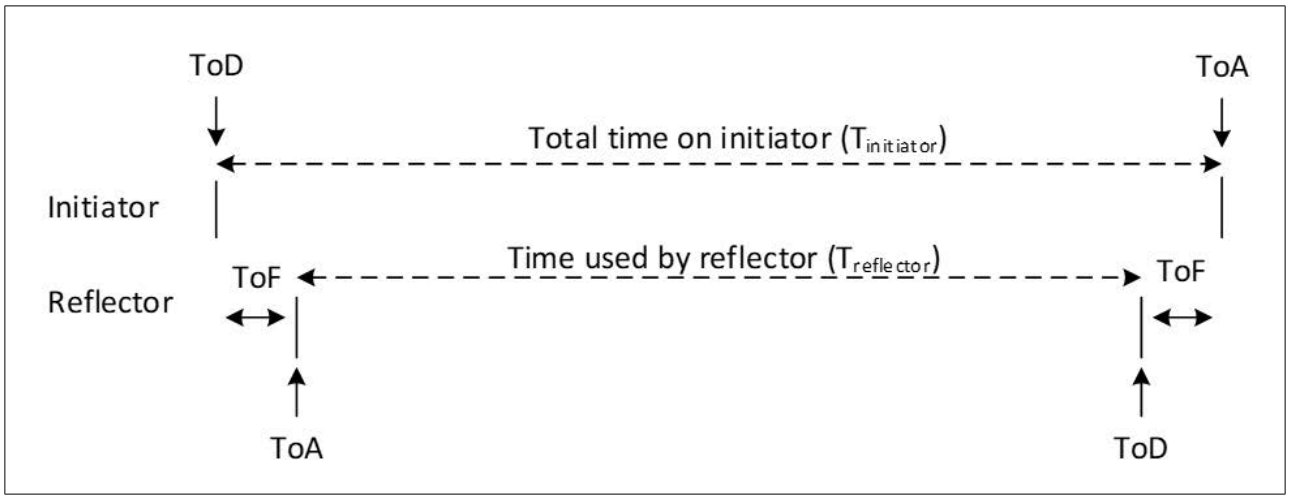

Figure 9.2: Time of arrival (ToA), time of departure (ToD), and time of flight (ToF) for RTT estimation

The accuracy of RTT ToF estimation depends on the capabilities of both devices. CS supports RTT based on timing extracted from a CS Access Address that consists of a 32-bit pseudo-noise bit sequence, and optionally based on timing extracted from a sounding sequence payload of up to 96 bits or a random sequence of up to 128 bits.

9.4 Security features

The CS feature includes security measures to reduce the probability of distance spoofing.

RTT and phase-based ranging can be employed in the same CS subevent or in the same CS step (CS step mode-3) to provide two partially independent estimates of distance.

CS step mode-1 and CS step mode-3 allow devices to potentially detect whether an attacker is present. With a random sequence, it is possible to measure how much a received GFSK modulated packet signal differs from the expected packet signal. With a sounding sequence, it is possible to detect the position of one or more marker signals.

A DRBG is employed by devices using the CS feature. The components used to generate the key material for this DRBG are exchanged between the device pair under an encrypted link and is never shared external to each device. This DRBG is used to cryptographically randomize the channel hop selection, the use of CS step modes, the modulation of tones, the transmission order in the case where multiple antenna paths are used, and the CS Access Address and payload content of CS_SYNC packets.

ACRONYMS & ABBREVIATIONS

CONTENTS

1 LIST OF ACRONYMS AND ABBREVIATIONS

Acronym or abbreviation	Writing out in full	Comments
8DPSK	8 phase Differential Phase Shift Keying	3 Mb/s modulation type used by Enhanced Data rate
AAD	Additional Authenticated Data	
ACI	Antenna Configuration Index	
ACK	Acknowledge/Acknowledgment	
ACL	Asynchronous Connection-oriented [logical transport]	Reliable or time-bounded, bi-directional, point-to-point
ACL-C	ACL Control [logical link] (LMP)	
ACL-U	ACL User [logical link] (L2CAP)	
ACO	Authenticated Ciphering Offset	
AD	Advertising Data	
Adv_idx	Advertising channel index	
ADVB	LE Advertising Broadcast	
ADVB-C	LE Advertising Broadcast Control (Logical Link)	
ADVB-U	LE Advertising Broadcast User Data (Logical Link)	
ADI	AdvDataInfo	
AES	Advanced Encryption Standard	
AES-CCM	Advanced Encryption Standard - Counter with CBC-MAC	
AFH	Adaptive Frequency Hopping	
AHS	Adapted Hop Sequence	
AoA	Angle of Arrival	
AoD	Angle of Departure	
APB	Active Peripheral Broadcast [logical transport]	Unreliable, uni-directional broadcast to any devices synchronized with the physical channel
APB-C	APB Control [logical link] (LMP)	
APB-U	APB User [logical link] (L2CAP)	
ARQ	Automatic Repeat Request	
ASK	Amplitude Shift Keying	
ATT	Attribute Protocol	

Acronym or abbreviation	Writing out in full	Comments
BB	Baseband	
BCH	Bose, Chaudhuri & Hocquenghem	Type of code The persons who discovered these codes in 1959 (H) and 1960 (B&C)
BD_ADDR	Bluetooth Device Address	
BER	Bit Error Rate	
BIG	Broadcast Isochronous Group	A group of one or more time-related Broadcast Isochronous Streams
BIS	Broadcast Isochronous Stream	Connectionless isochronous logical transport
BT	Bandwidth Time	
C	Central	
C.#	Conditional	Any number may be used. See [Vol 1] Part E, Section 2.11
CAC	Channel Access Code	
CBC-MAC	Cipher Block Chaining Message Authentication Code	
CCM	Counter with CBC-MAC	
CIG	Connected Isochronous Group	A group of one or more time-related Connected Isochronous Streams
CIS	Connected Isochronous Stream	Point-to-point isochronous logical transport
CLKN	Native Clock	
CLK	Central's Clock	
CLKE	Estimated Clock	
CODEC	COder DECoder	
COF	Ciphering Offset	
CP	CTEInfo Present	A field in the Data Channel PDU Header to indicate the presence of the CTEInfo field
CPB	Connectionless Peripheral Broadcast	The logical transport enabled by the Connectionless Peripheral Broadcast feature
CRC	Cyclic Redundancy Check	
CS	Channel Sounding	
CS Tone	Channel Sounding Tone	Unmodulated carrier associated with the phase-based ranging technique
CSA	Core Specification Addendum	(In plural Addenda)

Acronym or abbreviation	Writing out in full	Comments
CSRK	Connection Signature Resolving Key	
CTE	Constant Tone Extension	
CTEInfo	Constant Tone Extension Information	A field in the Data Channel PDU Header and the extended advertising header

Architecture, Change History,
And Conventions
Part C

CORE SPECIFICATION CHANGE HISTORY

CONTENTS

1 REMOVED FEATURES

Some features have been deemed no longer useful and have been removed. The term removed does not mean that they are no longer allowed, but that they are no longer recommended as the best way of performing a given function.

Removed features may be implemented using the latest qualifiable version (if any) of the specification that specifies the removed features.

2 CHANGES FROM V1.1 TO V1.2

2.1 New features

Several new features were introduced in the version 1.2. The major areas of improvement are:

- Architectural overview
- Faster connection
- Adaptive frequency hopping
- Extended SCO links
- Enhanced error detection and flow control
- Enhanced synchronization capability
- Enhanced flow specification

The feature descriptions are incorporated into the existing text in different core parts, described in Volumes 2 and 3.

2.2 Structure changes

Version 1.2 was significantly restructured for better consistency and readability. The most important structure changes have been performed in Baseband, LMP, HCI and L2CAP. The text in these sections has been rearranged to provide:

- Presentation of the information in a more logical progression
- Removal of redundant text and requirements
- Consolidation of Baseband-related requirements (for example, the Baseband Timers and Bluetooth Audio sections into the Baseband Specification)
- Alignment of the specification with the new architecture and terminology presented in the Architecture Overview (see [Vol 1] Part E).

In addition, new text and requirements were added for the new features as well as many changes throughout the specification to update the text to use IEEE language (see [Vol 1] Part E).

2.3 Deprecated features list

Features deprecated in version 1.2 are:

- The use of Unit Keys for security
- Optional Paging schemes
- 23 channel hopping sequence
- Page scan period mode and associated commands

2.4 Changes in wording

Two general classes of changes to the wording of the Bluetooth Specification have been done for version 1.2. They are a formalization of the language by using conventions established by the Institute of Electrical and Electronic Engineers (IEEE), and a regularization of Bluetooth wireless technology-specific terms. Many portions of the version 1.1 specification use imprecise or inaccurate terms to describe attributes of the protocol. A more accurate terminology described in Part E was introduced into the version 1.2 specification and have been applied in future versions.

2.5 Nomenclature changes

The nomenclature in Bluetooth 1.2 was also updated due to new concepts that are introduced together with the new features and the new architecture. See [Vol 1] Part A.

3 CHANGES FROM V1.2 TO V2.0 + EDR

3.1 New features

Version 2.0 + EDR introduces Enhanced Data Rate (EDR). EDR provides a set of additional packet types that use the new 2 Mb/s and 3 Mb/s modes.

In addition to EDR a set of errata provided in ESR02 has been incorporated into this version and revised to include changes caused by the addition of EDR.

These additions are incorporated into the existing text in different core parts described in Volumes 2 and 3.

3.2 Deprecated features

The only feature deprecated in version 2.0 + EDR is the Page Scan Period Mode and associated commands (based on Erratum 694 which is also included in ESR02).

4 CHANGES FROM V2.0 + EDR TO V2.1 + EDR

4.1 New features

Several new features are introduced in version 2.1 + EDR. The major areas of improvement are:

- Erroneous Data Reporting
- Encryption Pause and Resume
- Extended Inquiry Response
- Link Supervision Timeout Changed event
- Non-Automatically-Flushable Packet Boundary Flag
- Secure Simple Pairing
- Sniff Subrating
- Security Mode 4

4.2 Removed features

No features were removed in v2.1 + EDR.

5 CHANGES FROM V2.1 + EDR TO V3.0 + HS

5.1 New features

Several new features are introduced in version 3.0 + HS. The major areas of improvement are:

- AMP Manager protocol (A2MP)
- Enhancements to L2CAP including
  - Enhanced Retransmission Mode and Streaming Mode
  - Improvements to the L2CAP state machine for AMP channels
  - Fixed channel support
- Enhancements to HCI for AMP
- Enhancements to Security for AMP
- 802.11 Protocol Adaptation Layer
- Enhanced Power Control
- Unicast Connectionless Data
- HCI Read Encryption Key Size command
- Generic Test Methodology for AMP
- Enhanced USB and SDIO HCI Transports

5.2 Removed features

No features were removed in v3.0 + HS.

6 CHANGES FROM V3.0 + HS TO V4.0

6.1 New features

Several new features are introduced in version 4.0. The major areas of improvement are:

- Bluetooth Low Energy including
  - Low Energy Physical Layer
  - Low Energy Link Layer
  - Enhancements to HCI for Low Energy
  - Low Energy Direct Test Mode
  - AES Encryption
  - Enhancements to L2CAP for Low Energy
  - Enhancements to GAP for Low Energy
  - Attribute Protocol (ATT)
  - Generic Attribute profile (GATT)
  - Security Manager (SM)

6.2 Removed features

No features were removed in v4.0.

7 CHANGES FROM V4.0 TO V4.1

7.1 New features

Several new features are introduced in the version 4.1. The major areas of improvement are:

- BR/EDR Secure Connections
- Train nudging
- Generalized interlaced scan
- Low duty cycle directed advertising
- 32-bit UUID support in LE
- LE dual mode topology
- Piconet clock adjustment
- LE L2CAP connection-oriented channel support
- LE privacy v1.1
- LE Link Layer topology
- LE ping

7.1.1 Features added in CSA 4 – integrated in v4.1

- Connectionless Peripheral Broadcast
- Unencrypted unicast connectionless data support
- Fast advertising interval
- eSCO reserved slots clarification

7.1.2 Features added in CSA 3 – integrated in v4.1

- MWS coexistence HCI changes
- GAP connection parameters changes
- GAP authentication and lost bond
- Dual mode addressing
- Private address changes
- Common profile and service error code changes
- MWS coexistence signaling

- Wireless coexistence interface 1 (WCI-1) transport specification
- Wireless coexistence interface 2 (WCI-2) transport specification

7.1.3 Features added in CSA 2 – integrated in v4.1

- Limited discovery time changes
- EIR and AD data types in GAP
- Audio architecture HCI changes
- Audio architecture USB changes
- 802.11n enhancements to the 802.11 PAL

7.2 Removed features

No features were removed in v4.1.

8 CHANGES FROM V4.1 TO V4.2

8.1 New features

Several new features are introduced in version 4.2. The major areas of improvement are:

- LE Data Packet Length Extension
- LE Secure Connections
- Link Layer privacy
- Link Layer Extended Scanner Filter policies

8.2 Errata incorporated in v4.2

Table 8.1 lists the integrated ESR08 errata items and also some ESR09 items, without test impact, which were added to v4.2 prior to the ESR09 release.

	ESR08	ESR09

Table 8.1: Errata integrated in v4.2

9 CHANGES FROM V4.2 TO V5.0

9.1 New features

Several new features are introduced in version 5.0. The major areas of improvement are:

- Slot Availability Mask (SAM)
- 2 Msym/s PHY for LE
- LE Long Range
- High Duty Cycle Non-Connectable Advertising
- LE Advertising Extensions
- LE Channel Selection Algorithm #2

9.1.1 Features added in CSA5 - integrated in v5.0

- Higher Output Power

9.2 Removed features

The following features were removed in this version of the specification:

- Park State

9.3 Privacy errata

The Privacy errata shown in Table 9.1 have been resolved and integrated in this version of the specification.

Erratum	Title
5433	In Table 9.3, C1 condition should be removed
6182	Invalid behavior with resolving address list not clear in Core or Test Spec
6214	Statement mismatch between procedure description and figure
6247	Unclear when to use LE Directed Advertising Report event or LE Advertising Report event
6356	Defining scanner’s device address in “Scanner filter policy”
6391	Usage of peer address type not clear in privacy 1.2
6399	LE Enhanced Connection Complete event
6401	Central Address Resolution Char in LE Peripheral

Erratum	Title
6469	Advertiser is not required to check AdvA
6471	AdvA not well defined in SCAN_RSP pdu, when privacy 1.2 enabled
6508	HCI command name mismatch
6519	When an advertiser device (or scanning performing active scanning) using privacy and Controller based resolvable private address generation is supposed to answer to a scan request (or advertising) received?
6613	Privacy Mode not clearly defined
6629	LE Directed Advertising Report event - Order of parameters
6984	How does Adv respond to RPA in Connect Req when there's no IRK and no WL

Table 9.1: Privacy errata

Table 9.3: Errata integrated in v5.0

10 CHANGES FROM V5.0 TO V5.1

10.1 New features

Several new features are introduced in v5.1. The major areas of improvement are:

- Angle of Arrival (AoA) and Angle of Departure (AoD)
- Advertising Channel Index
- GATT Caching
- Minor Enhancements batch 1
  - HCI support for debug keys in LE Secure Connections
  - Sleep clock accuracy update mechanism
  - ADI field in scan response data
  - Interaction between QoS and Flow Specification
  - Host channel classification for secondary advertising
  - Allow the SID to appear in scan response reports
  - Specify the behavior when rules are violated
- Periodic Advertising Sync Transfer

10.1.1 Features added in CSA6 – integrated in v5.1

- Models
- Mesh-based model hierarchy

10.2 Removed features

The following features were removed in this version of the specification:

- Unit keys

10.3 Security erratum

Erratum 10734, which introduces new security requirements relating to pairing, has been resolved and integrated in this version of the specification.

10.4 Errata incorporated in v5.1

Table 10.1 lists the integrated ESR errata items.

Table 10.1: Errata integrated in v5.1

11 CHANGES FROM V5.1 TO V5.2

11.1 New features

Several new features are introduced in v5.2. The major areas of improvement are:

- LE Isochronous Channels
- Enhanced Attribute Protocol
- LE Power Control

11.2 Security erratum

Erratum 11838, which introduces new security requirements and recommendations relating to encryption key size on BR/EDR, has been resolved and integrated in this version of the specification.

11.3 Errata incorporated in v5.2

Table 11.1 lists the integrated errata items.

Table 11.1: Errata integrated in v5.2

12 CHANGES FROM V5.2 TO V5.3

12.1 New features

Several new features are introduced in v5.3. The major areas of improvement are:

- AdvDataInfo in Periodic Advertising
- Host to Controller Encryption Key Control Enhancements
- LE Enhanced Connection Update
- LE Channel Classification

12.2 Removed Features

The following features were removed in this version of the specification:

- Alternative MAC/PHY
- AMP Manager protocol (A2MP)
- L2CAP Enhancements for AMP
- 802.11 PAL
- 802.11n Enhancements to the 802.11 PAL

12.3 Errata incorporated in v5.3

V7C: Wireless Coexistence Interface 2 (WCI-2) Transport Specification	

Table 12.1: Errata integrated in v5.3

12.4 Global terminology changes

Certain terms that were identified as inappropriate have been replaced. As a consequence, some other terms have also been changed to retain consistency and some HCI command and event names had consequential changes. For a list of the original terms and names and their replacements, see the Appropriate Language Mapping Tables, https://www.bluetooth.com/language-mapping/Appropriate-Language-Mapping-Table.

These terminology changes were made under the following issues: 15328, 15334, 15336, 15338, 15342, 15343, 15344, 15345, 15346, 15347, 15348, 15349, 15350, 15351, 15352, 15353, 15354, 15355, 15356, 15357, 15358, 15359, 15360, 15361, 15362, 15363, 15389, 15529, 15531.

13 CHANGES FROM V5.3 TO V5.4

13.1 New features

Several new features are introduced in v5.4. The major areas of improvement are:

- Advertising Coding Selection
- Encrypted Advertising Data
- LE GATT Security Levels Characteristic
- Periodic Advertising with Responses

13.2 Removed features

No features were removed in v5.4.

13.3 Errata incorporated in v5.4

Table 13.1 lists the integrated errata items.

Table 13.1: Errata integrated in v5.4

14 CHANGES FROM V5.4 TO V6.0

14.1 New features

Several new features are introduced in v6.0. The major areas of improvement are:

- Channel Sounding, including Channel Sounding HCI Updates
- LL Extended Feature Set
- Decision-Based Advertising Filtering
- Enhancements for ISOAL
- Monitoring Advertisers
- Frame Space Update

14.2 Removed features

No features were removed in v6.0.

14.3 Errata incorporated in v6.0

Table 14.1 lists the integrated errata items.

V7C: WCI-2	22270

Table 14.1: Errata integrated in v6.0

15 CHANGES FROM V6.0 TO V6.1

15.1 New features

One new feature is introduced in v6.1:

- Randomized RPA Updates

15.2 Removed features

No features were removed in v6.1.

15.3 Errata incorporated in v6.1

Table 15.1 lists the integrated errata items.

[THIS PART IS NO LONGER USED]

Mixing requirements are located in [Vol 0] Part D.

Architecture, Change History,
And Conventions
Part E

GENERAL TERMINOLOGY AND INTERPRETATION

CONTENTS

1 LANGUAGE CONVENTIONS

In the development of a specification, the Bluetooth SIG has established the following conventions for use of the terms *“shall”*, *"mandatory"*, *“shall not”*, *“should”*, *“should not”*, *“may”*, *"optional"*, *“must”*, and *“can”*. In this Bluetooth specification, the terms in Table 1.1 have the specific meanings given in that table, irrespective of other meanings that exist.

shall *or* mandatory	—used to express what is required by the specification and is to be implemented exactly as written without deviation
shall not	—used to express what is forbidden by the specification
should *or* may *or* optional	—not mandatory. Used to express either: 1. what is recommended by the specification without forbidding anything ("should") 2. what is permissible within the limits of the specification ("may" or "optional")
should not	—used to indicate that something is discouraged but not forbidden by the specification
must	—used to indicate either: 1. an indisputable statement of fact that is always true regardless of the circumstances 2. an implication or natural consequence if a separately-stated requirement is followed
can	—used to express a statement of possibility or capability

Table 1.1: Language conventions terms and definitions

Where more than one item is permitted but not required, the choices to include or support those items are independent from one another unless the specification explicitly states otherwise. Each item that is implemented shall be implemented exactly as written without deviation.

1.1 [This section is no longer used]

1.3 [This section is no longer used]

1.4 [This section is no longer used]

1.5 [This section is no longer used]

1.6 [This section is no longer used]

1.7 Implementation Alternatives

When specification content indicates that there are multiple alternatives to satisfy specification requirements, if one alternative is explained or illustrated in an example it is not intended to limit other alternatives that the specification requirements permit.

1.8 Discrepancies

It is the goal of Bluetooth SIG that specifications are clear, unambiguous, and do not contain discrepancies. However, members can report any perceived discrepancy by filing an erratum and can request a test case waiver as appropriate.

1.9 Appropriate Language

Certain terms that were identified as inappropriate have been replaced. As a consequence, some other terms have also been changed to retain consistency and some HCI command and event names had consequential changes. For a list of the original terms and names and their replacements, see the Appropriate Language Mapping Tables, https://www.bluetooth.com/language-mapping/Appropriate-Language-Mapping-Table.

2 GENERAL INTERPRETATION RULES

The following rules apply throughout the specification except where explicitly overridden.

2.1 Binary and hexadecimal values

Binary numbers are normally written with a “0b” prefix, so 0b1101 is the same as the decimal number 13.

In some places a sequence of bits is written in quotation marks thus: '1010'. Such sequences are not normally intended to be interpreted as numbers. The order that the bits are to be processed will always be specified.

Hexadecimal numbers are written with a "0x" prefix, so 0x42 is the same as the decimal number 66. The letters "a" to "f" are used to represent the digits 10 to 15, so 0x1A is the same as the decimal number 26. The case of letters in a hexadecimal number is not significant.

Underscore characters may be placed between the digits of binary or hexadecimal numbers to make them easier to interpret; these underscores shall not affect the value. For example, 0b0010_1011 and 0b00101011 both equal the decimal number 43.

All numbers not written in one of the above ways are decimal.

2.2 Bit numbers and bit fields

In some cases the specification needs to refer to some of the bits of an integer value. Bits are always numbered from 0 as the least significant bit, so bit 0 of 0b1011 equals 1 while bit 2 equals 0. A single bit will be notated with a subscript, as in CLK_5.

Sometimes it is necessary to refer to a consecutive set of bits; for example, given a value CLK it may be necessary to refer to bits 2 to 4 of CLK (that is, the value equal to (CLK ÷ 4) *mod* 8. This will be notated either by a subscript with a dash or by brackets and a colon; the bit numbers will always be inclusive and the most significant bit number is given first. For example, bits 2 to 4 of CLK are written CLK_{4-2} or CLK[4:2].

2.3 Specification of bit values

Some values in the specification are divided into individual bits, each of which has a description. If explicit bit values are not given then this description represents the

meaning when the bit equals 1 and the opposite applies when the value is 0. For example, a description of:

Bit 3: use 3-slot packets

means the same as:

Bit 3 = 1: use 3-slot packets;

Bit 3 = 0: do not use 3-slot packets.

2.4 Values with restricted purposes

Where a field in a packet, PDU, or other data structure, a parameter, or another variable object is described as being split into components (e.g., when each bit of a field has a separate meaning), the rules in this section apply to each component separately.

2.4.1 Reserved for future use

Where a field in a packet, PDU, or other data structure is described as "Reserved for future use" (irrespective of whether in upper or lower case), the device creating an instance of the structure to send to another device (including messages sent between a Host and a Controller over HCI) shall set it to zero. Any device receiving or interpreting the structure shall ignore that field; in particular, it shall not reject the structure because of the value of the field.

Where a field, parameter, or other variable object can take a range of values and some values are described as "Reserved for future use", devices shall not set the object to any of those values. A device receiving an object with such a value should reject it, and any data structure containing it, as being erroneous; however, this does not apply in a context where the object is described as being ignored or if it is specified to ignore unrecognized values.

Where a field, parameter, or other variable object only has meanings specified for some values, all other values are reserved for future use.

The abbreviation "RFU" is equivalent to "Reserved for future use".

2.4.2 Previously used

The term "Previously used" (irrespective of whether in upper or lower case) indicates that a field or value was used for a removed feature (see [Vol 1] Part C, Section 1). Devices that do not implement that feature shall treat the field or value as reserved for future use.

Note: These fields and values will not be used for new features.

2.4.3 Reserved for specification development purposes

The term "Reserved for specification development purposes" (irrespective of whether in upper or lower case) indicates that a value will not appear in published specifications but may be used during specification development.

Other than during specification development, these values shall be treated as reserved for future use. Implementations shall not use these values for vendor-specific features or purposes.

2.5 Use of invalid values in checksums and other calculations

Where a field or value is used as part of a checksum, CRC, cryptographic key, or other similar calculation, and the value sent to or received from the peer is not valid (for example, it is an RFU field that has not been set to 0 by the sender), the actual value sent or received shall be used in the calculation and it shall not be replaced by a different valid value.

2.6 Assigned number requirements

The Bluetooth SIG maintains a published set of assigned numbers on the Bluetooth SIG Assigned Numbers web page. These assigned numbers are grouped in various number spaces. Numbers assigned may overlap with other assigned numbers in different number spaces, but no number within a number space is ever reused. The various number spaces are defined in the specification that defines the usage of the assigned numbers.

All assigned numbers within a given number space shall only be designated by the Bluetooth SIG and shall only be used for their intended purposes when used within a field, parameter, or other variable object defined to take on a value within that number space. All values not explicitly assigned within a given number space are Reserved for future use and subject to the requirements in Section 2.4.

All 16-bit and 32-bit UUIDs as defined in [Vol 3] Part B, Section 2.5.1, are considered assigned numbers. All other UUID values may be used in any context where a UUID is permitted provided they are generated according to the recommendations in ITU-T Rec. X.667(10/2012), alternatively known as ISO/IEC 9834.8:2014.

2.7 Responding to invalid behavior

If a device receives a packet or PDU that it supports but is not permitted in its current state, or has contents not permitted by the specification, the sending device

has exhibited invalid behavior. Unless the specification states a particular action to be taken, the receiving device should respond in one of the following ways:

- Ignore the packet or PDU.
- Attempt to recover the situation while both not violating the specification and being prepared for the sending device to be in a state where one or both devices cannot recover.
- If the packet or PDU was received from the peer device in a connection, either immediately terminate that connection or consider the connection to be lost. This may be done at any appropriate layer; e.g., following invalid behavior on an L2CAP channel, a device could choose to terminate either the channel or the underlying ACL connection.

Methods for recovering from invalid behavior include, but are not limited to:

- Sending a rejection response
- If a packet or PDU is too long, ignoring the extra contents
- If a value is out of range, using the nearest permitted value
- If a field is missing, using any default value specified

Examples of packets or PDUs not permitted in the current state include:

- A POLL packet sent by a Peripheral (see [Vol 2] Part B, Section 6.5.1.3)
- An LMP_DETACH PDU received while the device is in Hold or Sniff mode (see [Vol 2] Part C, Section 4.1.2)
- Any packet sent on the primary advertising physical channel using the LE 2M PHY or an ADV_IND PDU sent on the LE Coded PHY (see [Vol 6] Part B, Section 2.3)
- Two consecutive LL_FEATURE_REQ PDUs sent by a Central with no LL_FEATURE_RSP sent by the Peripheral between them (see [Vol 6] Part B, Section 5.1.4.1)
- A second LL_VERSION_IND PDU sent by the same device during the same connection (see [Vol 6] Part B, Section 5.1.5)
- A second ATT request or indication before the device has sent a response or confirmation in reply to the first one

Examples of packets and PDUs with contents not permitted by the specification include:

- A packet or PDU which is required to have a specific length but does not have that length
- A PDU where the value of a specific parameter or field is out of range (also see Section 2.4)

- An L2CAP C-frame sent over fixed channel CID 0x0005 that contains more than one command (see [Vol 3] Part A, Section 4) or has a length longer than that of the enclosed command packet

Note: The appropriate response to invalid behavior will depend on the specific circumstances and the choice made can affect the user experience. For example, a POLL packet sent by a Peripheral could actually be a NULL packet with the TYPE field corrupted, so it would be reasonable to ignore the POLL packet rather than terminate the connection. On the other hand, invalid behavior during a security procedure can indicate an attack by a third party and immediate disconnection may be appropriate.

Note: If the sending device supports different features or a different version of the specification, invalid behavior can occur because there are different requirements and one device has not checked for this possibility, such as by checking feature masks.

2.8 Ranges of values

Where a range is given (e.g. "the value is between 1 and 10", "in the range 7 to Nmax", or "Size: 1-31") then the range always includes both endpoints unless explicitly stated otherwise.

2.9 Type Names

The names defined in this section are used in the specification to indicate the type and representation of a value.

Values shall be stored in little-endian order. Except in arrays (see Section 2.9.2), a value of a given type shall be stored in the smallest number of octets that can contain the value; the value shall occupy the whole of each octet except the most significant bits of the last octet. All other bits in the last octet shall be reserved for future use. For example, if a value has a size of 22 bits, then it occupies 3 octets:

- The 8 least significant bits ($value_{7-0}$) are stored in the first octet.
- The next 8 bits ($value_{15-8}$) are stored in the middle octet.
- The 6 most significant bits ($value_{21-16}$) are stored in the 6 least significant bits of the last octet.
- The 2 most significant bits of the last octet are reserved for future use.

Where a value appears in an SDP service record (see [Vol 3] Part B, Section 2.2), the octets representing the value shall be reversed in order to match the big-endian order used by SDP. The order of elements of an array shall be unchanged.

2.9.1 Basic types

The names *uint#,* where # is a decimal number other than zero, indicate an unsigned integer with the specified number of bits; therefore *uint16* is an unsigned integer with 16 bits. The value shall be represented in binary, so *uint16* has the range of values 0 to 65535.

The names *sint#*, where # is a decimal number other than 0 or 1, indicate a signed integer with the specified number of bits including sign; therefore *sint12* is a signed integer with 12 bits. The value shall be represented in two's-complement binary with the sign bit as the most significant bit, so *sint12* has the range of values -2048 to +2047.

The name *boolean* indicates a single bit representing a truth value: a 0 bit represents false and a 1 bit represents true.

The names *float#,* where # is 16, 32, 64, 128, or 256, indicate a floating point number using the IEEE 754 interchange format with that number of bits.

The names *medfloat16* and *medfloat32* indicate the 16 and 32 bit floating point types defined in ISO/IEEE 11073-20601.

The names *UUID16*, *UUID32*, and *UUID128* indicate the three lengths of UUID (see [Vol 3] Part B, Section 2.5.1). The name *UUID* indicates a UUID whose length is specified separately to the value.

2.9.2 Array types

Any basic type may be converted to an array type of a specific length. The name of the array type is formed from the name of the basic type by adding the length, in brackets, after the name. For example, *sint12[3]* indicates an array of 3 values, each of type *sint12*. Empty brackets indicate that the length of the array is specified elsewhere. The original type is called the base type of the array.

If the size of the base type is 1 bit, each group of 8 consecutive elements is packed into an octet starting at the least significant bit for the first value.

If the size of the base type is 2 bits, each group of 4 consecutive elements is packed into an octet using bits 1-0 for the first value, bits 3-2 for the second value, bits 5-4 for the third value, and bits 7-6 for the fourth value.

If the size of the base type is 3 bits, each consecutive pair of elements is packed into an octet using bits 2-0 for the first value and bits 5-3 for the second value; bits 6 and 7 of each octet are reserved for future use.

If the size of the base type is 4 bits, each consecutive pair of elements is packed into an octet using bits 3-0 for the first value and bits 7-4 for the second value.

If the number of elements is not a multiple of 8, 4, or 2 as appropriate, the bits of the last octet that are not occupied by values are reserved for future use.

If the size of the base type is 5 bits or more, each element of the array occupies separate octets.

For example, the type *uint2[5]* occupies two octets, with the first value occupying bits 1-0 of the first octet, the fourth value occupying bits 7-6 of the first octet, the last value occupying bits 1-0 of the second octet, and bits 7-2 of the second octet reserved for future use. The type *sint12[3]* occupies six octets in total, two for each element.

2.9.3 Variable length types

The name *utf8s* indicates a variable length array of octets holding a string encoded using UTF-8. A specific number of octets may be indicated by appending the number in braces to the type name, so *utf8s{6}* indicates an array of 6 octets. If the actual string is shorter than the size of the array, the first unused octet shall be zero. If the number in braces is followed by the letter “z”, the remaining octets shall also be zero. For example, the string “Café” is represented in the type *utf8s{8z}* by the octet sequence 0x43, 0x61, 0x66, 0xC3, 0xA9, 0x00, 0x00, 0x00. If a specific length is not indicated, the length is specified separately to the value.

The name *utf16s* indicates a variable length array of *uint16* values holding a string encoded using UTF-16LE; the length is specified separately to the value.

The name *struct* indicates a variable length array of octets whose length and internal format are specified separately to the value.

2.10 Mathematical conventions

These conventions apply to how mathematical symbols are used in this specification, irrespective of how they are interpreted in any other context.

The operators +, −, ×, and ÷ have their usual meanings. Division is done using real numbers unless the result is being assigned to or used as an integer, in which case the quotient is rounded towards zero. The × operator is sometimes omitted if the meaning is clear. In figures these operators may appear inside square boxes.

The operator *mod* indicates the remainder from division; x *mod* y is the remainder when x is divided by y. It is only used with both operands being integers and y greater than zero. The division is rounded down so that the remainder is always non-negative; in other words, x *mod* y always equals $x - \lfloor x \div y \rfloor \times y$.

The notation “(*mod* m)” at the end of an equation indicates that the equality is tested after applying the *mod* operator on each side; in other words, “a = b (*mod* m)” is

equivalent to “a *mod* m = b *mod* m”. The three-way inequality “a ≤ b < c (*mod* m)”—with both relational operators in the same direction but each either including or excluding equality—is equivalent to “0 ≤ (b - a) *mod* m < (c - a) *mod* m”.

The operators + and – have equal precedence. The operators ×, ÷, and *mod* have equal precedence, which is higher than that of + and −. Exponentiation has higher precedence than all of these operators. Expressions involving operators of equal precedence are evaluated from left to right. Precedence can be overridden using parentheses; unless clear from the context, brackets and braces are equivalent to parentheses and are used for clarity. Exponents and subscripts are evaluated separately as if they were in parentheses; for example, x^{2-y} means x raised to the power 2 − y, not the square of x with y then subtracted.

Signed integers shall be represented as two’s complement.

Where a field, variable, parameter, or similar is specified as an integer with a specific number of bits B, then any requirement to store a value not representable in B bits shall be carried out by adding or subtracting 2^B until the value is in range. In particular, adding 1 to an unsigned variable with value $2^B - 1$ results in setting it to zero.

The relational operators <, >, ≤, ≥, =, and ≠ have lower precedence than all arithmetic operators. Multiple relational operators are logically combined; e.g., x < y ≥ z means that x is required to be less than y and that y is required to be at least as great as z.

The bitwise operators NOT, AND, OR, and XOR are applied to each bit of their operands separately; for the last three, the operands will have the same number of bits.

The symbols in Table 2.1 have the meanings given in that table.

Symbol	Meaning
$\lfloor x \rfloor$	the largest integer less than or equal to x
$\lceil x \rceil$	the smallest integer greater than or equal to x
$\lvert x \rvert$	the absolute value of x
$\sqrt{x}$	the square root of x
min (x, y)	the minimum value of x and y; there can be more than two arguments
max (x, y)	the maximum value of x and y; there can be more than two arguments
Re (z)	the real part of the complex number z
Im (z)	the imaginary part of the complex number z
exp (x)	e (the number 2.71828...) raised to the power of x
$x \pm y$	any value v such that x − y ≤ v ≤ x + y; the precedence is the same as the + operator

Symbol	Meaning
$\log_B x$	logarithm base B of x
ln x *or* ln(x)	$\log_e x$
x || y	concatenation of bit sequences
x!	the factorial of x
$\oplus$	bitwise XOR
$\subseteq$	subset of

Table 2.1: Assorted mathematical symbols

2.11 Requirement status symbols

In this document (such as in requirements tables), the following symbols are used:

- “M” for mandatory (see Section 1).
- “O” for optional (see Section 1).
- “E” for excluded. "Excluded" means not permitted in this context; cannot be supported or included for this purpose. The item can still be supported or included if allowed for some other purpose (e.g., a feature can be mandatory for one role and excluded for another; a device that supports both roles must support this feature).
- “C.#” for conditional. “Conditional” means that an item is required, optional, or prohibited based on whether one or more other items are supported or included (# represents any number). Within the definition of the condition, if those other items mean that “not permitted” applies, it has the same meaning as “E”.
- “X” for reserved for future use; excluded in this context but might change status in a future version of this document.

2.12 Table structure

A blank cell in a table indicates that there is no useful information that can be placed in this cell. Examples of this are:

- When there is no comment to make in a "comments" column
- In a column specifying properties when the relevant item is reserved for future use (and therefore does not have any properties)
- In a "units" column when the relevant item is unitless

Where an explicit absence is indicated, the cell will contain *"none"*. Examples of this are:

- In the "condition" column of the description of a finite state machine where a rule is unconditional
- In the "action" column of the description of a finite state machine where a rule has no action
- In a "restrictions" column where there are no applicable restrictions
- In an interface description where there are no parameters of a specific type

2.13 References to HCI commands and events

Outside Volume 4, references to HCI commands and events indicate a possible way of communicating between the Controller and Host and do not, of themselves, require HCI to be supported. Instead, vendor-specific communication mechanisms may be used when HCI is not used.

3 NAMING CONVENTIONS

3.1 BR/EDR

This section is not currently used.

3.2 Bluetooth Low Energy

3.2.1 Link Layer PDUs

A consistent naming scheme is used for Link Layer PDUs to make their purpose and usage clearer.

The PDU name consists of up to five components. Each component is entirely uppercase. Those components that are present are separated by a single underscore (e.g., if only three of the five components are present, there are two underscores, not four). In order, these components are:

1. Where the PDU is used (optional)
2. When the PDU is used (mandatory)
3. What the PDU does (optional but usually present)
4. Version (optional)
5. How the PDU is used (mandatory)

The first component ("where") indicates which physical channel the PDU is used on. The values currently used are shown in Table 3.1.

Value	Meaning
none	PDU is used on the primary advertising physical channel or any non-advertising physical channel
AUX	PDU is used on the secondary advertising physical channel

Table 3.1: First component (“where”) values

The second component ("when") indicates which kind of Link Layer procedure makes use of the PDU. The values currently used are shown in Table 3.2.

Value	Meaning
ADV	Normal Advertising
SYNC	Periodic Advertising
SCAN	Scanning

Value	Meaning
CONNECT	Connecting
CHAIN	Fragmented Data
LL	Control PDU on the Data logical transport
BIG	Control PDU in a Broadcast Isochronous Group on the isochronous logical transport
DATA	Reliable Data [Note 1]
CIS	Isochronous data PDU in a Connected Isochronous Stream
BIS	Isochronous data PDU in a Broadcast Isochronous Stream

Table 3.2: Second component (“when”) values

[Note 1] This name is not currently used in the specification.

The third component ("what") distinguishes different PDUs that are found in the same context. While it is normally present, it is sometimes omitted where there is a "default" or "usual" case. This component may contain more than one word separated by underlines.

For example, the different cases for legacy advertising are shown in Table 3.3.

Value	Meaning
none	Various
DIRECT	Connectable directed
NONCONN	Non-connectable and non-scannable undirected
SCAN	Scannable undirected

Table 3.3: Third component (“what”) values for legacy advertising

As another example, each Link Layer PDU has a value for this component based on the specific procedure it is used for.

The fourth component ("version") distinguishes between PDUs with the same purpose but different contents (usually because the original PDU was found to be insufficient to handle new features). The values currently used are shown in Table 3.4.

Value	Meaning
none	Original version of the PDU
EXT	Extended version of the PDU

Table 3.4: Fourth component (“version”) values

The fifth and final component ("how") indicates how the PDU fits into a procedure. The values currently used are shown in Table 3.5.

Value	Meaning
IND	An indication that doesn't expect a reply
REQ	A request that expects a response
RSP	A response to a request

Table 3.5: Fifth component ("how") values

Some examples of this convention in use, showing how the PDU name breaks up into the five components, are given in Table 3.6. A blank cell indicates that the component is omitted.

PDU name	Components				
	where	when	what	version	how
ADV_IND		ADV			IND
ADV_DIRECT_IND		ADV	DIRECT		IND
ADV_EXT_IND		ADV		EXT	IND
AUX_ADV_IND	AUX	ADV			IND
AUX_CHAIN_IND	AUX	CHAIN			IND
SCAN_REQ		SCAN			REQ
AUX_SYNC_IND	AUX	SYNC			IND
LL_PHY_UPDATE_IND		LL	PHY_UPDATE		IND
LL_LENGTH_REQ		LL	LENGTH		REQ
LL_LENGTH_RSP		LL	LENGTH		RSP
LL_REJECT_IND		LL	REJECT		IND
LL_REJECT_EXT_IND		LL	REJECT	EXT	IND
BIG_CHANNEL_MAP_IND		BIG	CHANNEL_MAP		IND

Table 3.6: Examples

Thus AUX_SYNC_IND is a PDU used for synchronous advertising on the secondary advertising physical channel that does not expect a response.

CONTROLLER ERROR CODES

CONTENTS

1 OVERVIEW OF ERROR CODES

This document lists the various possible error codes. When a command fails, or an LMP or LL message needs to indicate a failure, error codes are used to indicate the reason for the error. Error codes have a size of one octet.

1.1 Usage descriptions

The purpose of this section is to give descriptions of how the error codes should be used. It is beyond the scope of this document to give detailed descriptions of all situations where error codes can be used, especially as this is implementation dependent.

1.2 [This section is no longer used]

1.3 List of error codes

The error code of 0x00 means *Success*. The possible range of failure error codes is 0x01 to 0xFF. Section 2 provides an error code usage description for each failure error code.

Values marked as “Reserved for future use” or not listed in Table 1.1 can be used in future versions of the specification. A Host shall consider any error code that it does not explicitly understand equivalent to the error code *Unspecified Error* (0x1F).

Error Code	Name
0x00	Success
0x01	Unknown HCI Command
0x02	Unknown Connection Identifier
0x03	Hardware Failure
0x04	Page Timeout
0x05	Authentication Failure
0x06	PIN or Key Missing
0x07	Memory Capacity Exceeded
0x08	Connection Timeout
0x09	Connection Limit Exceeded
0x0A	Synchronous Connection Limit To A Device Exceeded
0x0B	Connection Already Exists
0x0C	Command Disallowed

Error Code	Name
0x0D	Rejected due to Limited Resources
0x0E	Rejected Due To Security Reasons
0x0F	Rejected due to Unacceptable BD_ADDR
0x10	Connection Accept Timeout Exceeded
0x11	Unsupported Feature or Parameter Value
0x12	Invalid HCI Command Parameters
0x13	Remote User Terminated Connection
0x14	Remote Device Terminated Connection due to Low Resources
0x15	Remote Device Terminated Connection due to Power Off
0x16	Connection Terminated By Local Host
0x17	Repeated Attempts
0x18	Pairing Not Allowed
0x19	Unknown LMP PDU
0x1A	Unsupported Remote Feature
0x1B	SCO Offset Rejected
0x1C	SCO Interval Rejected
0x1D	SCO Air Mode Rejected
0x1E	Invalid LMP Parameters / Invalid LL Parameters
0x1F	Unspecified Error
0x20	Unsupported LMP Parameter Value / Unsupported LL Parameter Value
0x21	Role Change Not Allowed
0x22	LMP Response Timeout / LL Response Timeout
0x23	LMP Error Transaction Collision / LL Procedure Collision
0x24	LMP PDU Not Allowed
0x25	Encryption Mode Not Acceptable
0x26	Link Key cannot be Changed
0x27	Requested QoS Not Supported
0x28	Instant Passed
0x29	Pairing With Unit Key Not Supported
0x2A	Different Transaction Collision
0x2B	Reserved for future use
0x2C	QoS Unacceptable Parameter
0x2D	QoS Rejected

Error Code	Name
0x2E	Channel Classification Not Supported
0x2F	Insufficient Security
0x30	Parameter Out Of Mandatory Range
0x31	Reserved for future use
0x32	Role Switch Pending
0x33	Reserved for future use
0x34	Reserved Slot Violation
0x35	Role Switch Failed
0x36	Extended Inquiry Response Too Large
0x37	Secure Simple Pairing Not Supported By Host
0x38	Host Busy - Pairing
0x39	Rejected due to No Suitable Channel Found
0x3A	Controller Busy
0x3B	Unacceptable Connection Parameters
0x3C	Advertising Timeout
0x3D	Connection Terminated due to MIC Failure
0x3E	Connection Failed to be Established / Synchronization Timeout
0x3F	*Previously used*
0x40	Coarse Clock Adjustment Rejected but Will Try to Adjust Using Clock Dragging
0x41	Type0 Submap Not Defined
0x42	Unknown Advertising Identifier
0x43	Limit Reached
0x44	Operation Cancelled by Host
0x45	Packet Too Long
0x46	Too Late
0x47	Too Early
0x48	Insufficient Channels

Table 1.1: List of possible error codes

2 ERROR CODE DESCRIPTIONS

2.1 Unknown HCI command (0x01)

The *Unknown HCI Command* error code indicates that the Controller does not understand the HCI Command packet opcode that the Host sent. The opcode given might not correspond to any of the opcodes specified in this document, or any vendor-specific opcodes, or the command may have not been implemented.

2.2 Unknown Connection Identifier (0x02)

The *Unknown Connection Identifier* error code indicates that a command was sent from the Host that should identify a connection, but that connection does not exist or does not identify the correct type of connection.

2.3 Hardware Failure (0x03)

The *Hardware Failure* error code indicates to the Host that something in the Controller has failed in a manner that cannot be described with any other error code. The meaning implied with this error code is implementation dependent.

2.4 Page Timeout (0x04)

The *Page Timeout* error code indicates that a page timed out because of the Page Timeout configuration parameter. This error code shall only be used with the HCI_Remote_Name_Request and HCI_Create_Connection commands or with equivalent mechanisms when HCI is not supported.

2.5 Authentication Failure (0x05)

The *Authentication Failure* error code indicates that pairing or authentication failed due to incorrect results in the pairing or authentication procedure. This could be due to an incorrect PIN or Link Key.

2.6 PIN or Key Missing (0x06)

The *PIN or Key Missing* error code is used when pairing failed because of a missing PIN, or authentication failed because of a missing Key.

2.7 Memory Capacity Exceeded (0x07)

The *Memory Capacity Exceeded* error code indicates to the Host that the Controller has run out of memory to store new parameters.

2.8 Connection Timeout (0x08)

The *Connection Timeout* error code indicates that either the link supervision timeout has expired for a given connection or that the synchronization timeout has expired for a given broadcast.

2.9 Connection Limit Exceeded (0x09)

The *Connection Limit Exceeded* error code indicates that an attempt to create another connection failed because the Controller is already at its limit of the number of connections it can support. The number of connections a device can support is implementation dependent.

2.10 Synchronous Connection Limit to a Device Exceeded (0x0A)

The *Synchronous Connection Limit to a Device Exceeded* error code indicates that the Controller has reached the limit to the number of synchronous connections that can be achieved to a device. The number of synchronous connections a device can support is implementation dependent.

2.11 Connection Already Exists (0x0B)

The *Connection Already Exists* error code indicates that an attempt was made to create a new Connection to a device when there is already a connection to this device and multiple connections to the same device are not permitted.

2.12 Command Disallowed (0x0C)

The *Command Disallowed* error code indicates that the command requested cannot be executed because the Controller is in a state where it cannot process this command at this time. This error shall not be used for command opcodes where the error code *Unknown HCI Command* (0x01) is valid.

2.13 Rejected due to Limited Resources (0x0D)

The *Rejected Due To Limited Resources* error code indicates that a connection or other request was rejected due to limited resources.

2.14 Rejected due to Security Reasons (0x0E)

The *Rejected Due To Security Reasons* error code indicates that a connection or other request was rejected due to security requirements not being fulfilled, like authentication or pairing.

2.15 Rejected due to Unacceptable BD_ADDR (0x0F)

The *Rejected due to Unacceptable BD_ADDR* error code indicates that a connection or other request was rejected because this device does not accept the BD_ADDR. This may be because the device will only accept connections from specific BD_ADDRs.

2.16 Connection Accept Timeout Exceeded (0x10)

The *Connection Accept Timeout Exceeded* error code indicates that the Connection Accept Timeout has been exceeded for this connection attempt.

2.17 Unsupported Feature or Parameter Value (0x11)

The *Unsupported Feature Or Parameter Value* error code indicates that a feature or parameter value in the HCI command is not supported. This error code shall not be used in an LMP PDU.

2.18 Invalid HCI Command Parameters (0x12)

The *Invalid HCI Command Parameters* error code indicates that at least one of the HCI command parameters is invalid.

This shall be used when:

- the parameter total length is invalid.
- a command parameter is an invalid type.
- a connection identifier does not match the corresponding event.
- a parameter is odd when it is required to be even.
- a parameter is outside of the specified range.
- two or more parameter values have inconsistent values.

Note: An invalid type can be, for example, when a SCO Connection_Handle is used where an ACL Connection_Handle is required.

2.19 Remote User Terminated Connection (0x13)

The *Remote User Terminated Connection* error code indicates that the user on the remote device either terminated the connection or stopped broadcasting packets.

2.20 Remote Device Terminated Connection due to Low Resources (0x14)

The *Remote Device Terminated Connection due to Low Resources* error code indicates that the remote device terminated the connection because of low resources.

2.21 Remote Device Terminated Connection due to Power Off (0x15)

The *Remote Device Terminated Connection due to Power Off* error code indicates that the remote device terminated the connection because the device is about to power off.

2.22 Connection Terminated by Local Host (0x16)

The *Connection Terminated By Local Host* error code indicates that either the local device terminated the connection, terminated synchronization with a broadcaster, or terminated broadcasting packets.

2.23 Repeated Attempts (0x17)

The *Repeated Attempts* error code indicates that the Controller is disallowing an authentication or pairing procedure because too little time has elapsed since the last authentication or pairing attempt failed.

2.24 Pairing not Allowed (0x18)

The *Pairing Not Allowed* error code indicates that the device does not allow pairing. For example, when a device only allows pairing during a certain time window after some user input allows pairing.

2.25 Unknown LMP PDU (0x19)

The *Unknown LMP PDU* error code indicates that the Controller has received an unknown LMP opcode.

2.26 Unsupported Remote Feature (0x1A)

The *Unsupported Remote Feature* error code indicates that the remote device does not support the feature associated with the issued command, LMP PDU, or Link Layer Control PDU.

2.27 SCO Offset Rejected (0x1B)

The *SCO Offset Rejected* error code indicates that the offset requested in the LMP_SCO_LINK_REQ PDU has been rejected.

2.28 SCO Interval Rejected (0x1C)

The *SCO Interval Rejected* error code indicates that the interval requested in the LMP_SCO_LINK_REQ PDU has been rejected.

2.29 SCO Air Mode Rejected (0x1D)

The *SCO Air Mode Rejected* error code indicates that the air mode requested in the LMP_SCO_LINK_REQ PDU has been rejected.

2.30 Invalid LMP Parameters / Invalid LL Parameters (0x1E)

The *Invalid LMP Parameters / Invalid LL Parameters* error code indicates that some LMP PDU / LL Control PDU parameters were invalid. This shall be used when:

- the PDU length is invalid.
- a parameter is odd when it is required to be even.
- a parameter is outside of the specified range.
- two or more parameters have inconsistent values.

2.31 Unspecified Error (0x1F)

The *Unspecified Error* error code indicates that no other error code specified is appropriate to use.

2.32 Unsupported LMP Parameter Value / Unsupported LL Parameter Value (0x20)

The *Unsupported LMP Parameter Value / Unsupported LL Parameter Value* error code indicates that an LMP PDU or an LL Control PDU contains at least one parameter value that is not supported by the Controller at this time. This is normally used after a long negotiation procedure, for example during an LMP_HOLD_REQ, LMP_SNIFF_REQ and LMP_ENCRYPTION_KEY_SIZE_REQ PDU exchanges. This may be used by the Link Layer, for example during the Connection Parameters Request Link Layer Control procedure.

2.33 Role Change not Allowed (0x21)

The *Role Change Not Allowed* error code indicates that a Controller will not allow a role change at this time.

2.34 LMP Response Timeout / LL Response Timeout (0x22)

The *LMP Response Timeout / LL Response Timeout* error code indicates that an LMP transaction failed to respond within the LMP response timeout or an LL transaction failed to respond within the LL response timeout.

2.35 LMP Error Transaction Collision / LL Procedure Collision (0x23)

The *LMP Error Transaction Collision / LL Procedure Collision* error code indicates that an LMP transaction or LL procedure has collided with the same transaction or procedure that is already in progress.

2.36 LMP PDU not Allowed (0x24)

The *LMP PDU Not Allowed* error code indicates that a Controller sent an LMP PDU with an opcode that was not allowed.

2.37 Encryption Mode not Acceptable (0x25)

The *Encryption Mode Not Acceptable* error code indicates that the requested encryption mode is not acceptable at this time.

2.38 Link Key cannot be Changed (0x26)

The *Link Key cannot be Changed* error code indicates that a link key cannot be changed because a fixed unit key is being used.

2.39 Requested QoS not Supported (0x27)

The *Requested QoS Not Supported* error code indicates that the requested Quality of Service is not supported.

2.40 Instant Passed (0x28)

The *Instant Passed* error code indicates that an LMP PDU or LL PDU that includes an instant cannot be performed because the instant when this would have occurred has passed.

2.41 Pairing with Unit Key not Supported (0x29)

The *Pairing With Unit Key Not Supported* error code indicates that it was not possible to pair as a unit key was requested and it is not supported.

2.42 Different Transaction Collision (0x2A)

The *Different Transaction Collision* error code indicates that an LMP transaction or LL Procedure was started that collides with an ongoing transaction.

2.43 QoS Unacceptable Parameter (0x2C)

The *QoS Unacceptable Parameter* error code indicates that the specified quality of service parameters could not be accepted at this time, but other parameters may be acceptable.

2.44 QoS Rejected (0x2D)

The *QoS Rejected* error code indicates that the specified quality of service parameters cannot be accepted and QoS negotiation should be terminated.

2.45 Channel Assessment Not Supported (0x2E)

The *Channel Assessment Not Supported* error code indicates that the Controller cannot perform channel assessment because it is not supported.

2.46 Insufficient Security (0x2F)

The *Insufficient Security* error code indicates that the HCI command or LMP PDU sent is only possible on an encrypted link.

2.47 Parameter Out of Mandatory Range (0x30)

The *Parameter Out Of Mandatory Range* error code indicates that a parameter value requested is outside the mandatory range of parameters for the given HCI command or LMP PDU and the recipient does not accept that value.

2.48 Role Switch Pending (0x32)

The *Role Switch Pending* error code indicates that a Role Switch is pending. This can be used when an HCI command or LMP PDU cannot be accepted because of a pending role switch. This can also be used to notify a peer device about a pending role switch.

2.49 Reserved Slot Violation (0x34)

The *Reserved Slot Violation* error code indicates that the current Synchronous negotiation was terminated with the negotiation state set to Reserved Slot Violation.

2.50 Role Switch Failed (0x35)

The *Role Switch Failed* error code indicates that a role switch was attempted but it failed and the original piconet structure is restored. The switch may have failed because the TDD switch or piconet switch failed.

2.51 Extended Inquiry Response too Large (0x36)

The *Extended Inquiry Response Too Large* error code indicates that the extended inquiry response, with the requested requirements for FEC, is too large to fit in any of the packet types supported by the Controller.

2.52 Secure Simple Pairing not Supported by Host (0x37)

The *Secure Simple Pairing Not Supported by Host* error code indicates that the IO capabilities request or response was rejected because the sending Host does not support Secure Simple Pairing even though the receiving Link Manager does.

2.53 Host Busy–Pairing (0x38)

The *Host Busy - Pairing* error code indicates that the Host is busy with another pairing operation and unable to support the requested pairing. The receiving device should retry pairing again later.

2.54 Rejected due to no Suitable Channel Found (0x39)

The *Rejected due to No Suitable Channel Found* error code indicates that the Controller could not calculate an appropriate value for the Channel selection operation.

2.55 Controller Busy (0x3A)

The *Controller Busy* error code indicates that the operation was rejected because the Controller was busy and unable to process the request.

2.56 Unacceptable Connection Parameters (0x3B)

The *Unacceptable Connection Parameters* error code indicates that the remote device either terminated the connection or rejected a request because of one or more unacceptable connection parameters.

2.57 Advertising Timeout (0x3C)[1]

The *Advertising Timeout* error code indicates that advertising for a fixed duration completed or, for directed advertising, that advertising completed without a connection being created.

2.58 Connection Terminated due to MIC Failure (0x3D)

The *Connection Terminated Due to MIC Failure* error code indicates that either the connection or the synchronization was terminated because the Message Integrity Check (MIC) failed on a received packet.

2.59 Connection Failed to be Established / Synchronization Timeout (0x3E)

The *Connection Failed to be Established / Synchronization Timeout* error code indicates that the LL initiated a connection or initiated synchronization but the connection has failed to be established or the Link Layer failed to synchronize within the specified time.

2.60 [This section is no longer used]

2.61 Coarse Clock Adjustment Rejected but Will Try to Adjust Using Clock Dragging (0x40)

The *Coarse Clock Adjustment Rejected but Will Try to Adjust Using Clock Dragging* error code indicates that the Central, at this time, is unable to make a coarse adjustment to the piconet clock, using the supplied parameters. Instead the Central will attempt to move the clock using clock dragging.

2.62 Type0 Submap not Defined (0x41)

The *Type0 Submap Not Defined* error code indicates that the LMP PDU is rejected because the Type 0 submap is not currently defined.

2.63 Unknown Advertising Identifier (0x42)

The *Unknown Advertising Identifier* error code indicates that a command was sent from the Host that should identify an Advertising or Sync handle, but the Advertising or Sync handle does not exist.

2.64 Limit Reached (0x43)

The *Limit Reached* error code indicates that number of operations requested has been reached and has indicated the completion of the activity (e.g., advertising or scanning).

2.65 Operation Cancelled by Host (0x44)

The *Operation Cancelled by Host* error code indicates a request to the Controller issued by the Host and still pending was successfully canceled.

[1]Formerly called Directed Advertising Timeout

2.66 Packet Too Long (0x45)

The *Packet Too Long* error code indicates that an attempt was made to send or receive a packet that exceeds the maximum allowed packet length.

2.67 Too Late (0x46)

The *Too Late* error code indicates that information was provided too late to the Controller.

2.68 Too Early (0x47)

The *Too Early* error code indicates that information was provided too early to the Controller.

2.69 Insufficient Channels (0x48)

The *Insufficient Channels* error code indicates that the result of the requested operation would yield too few physical channels.

Part A

RADIO SPECIFICATION

CONTENTS

1 SCOPE

Bluetooth devices operate in the unlicensed 2.4 GHz ISM (Industrial Scientific Medical) band. A frequency hop transceiver is applied to combat interference and fading.

Two modulation modes are defined. A mandatory mode, called Basic Rate, uses a shaped, binary FM modulation to minimize transceiver complexity. An optional mode, called Enhanced Data Rate, uses PSK modulation and has two variants: π/4-DQPSK and 8DPSK. The symbol rate for all modulation modes is 1 Msym/s. The gross air data rate is 1 Mb/s for Basic Rate, 2 Mb/s for Enhanced Data Rate using π/4-DQPSK and 3 Mb/s for Enhanced Data Rate using 8DPSK.

A Time Division Duplex (TDD) scheme is used in both modes. The specification defines the requirements for a Bluetooth radio for the Basic Rate and Enhanced Data Rate modes.

Requirements are defined for two reasons:

- Provide compatibility between radios used in the system
- Define the quality of the system

The Bluetooth radio shall fulfil the stated requirements under the operating conditions specified in Appendix A. The radio parameters shall be measured according to the methods described in the RF Test Specification.

The Bluetooth SIG maintains regulatory content associated with Bluetooth technology in the 2.4 GHz ISM band on its web site, at https://www.bluetooth.com/regulatory-requirements/.

1.1 Requirements

A device supporting RF shall meet the requirements of Section 3 for any packet it is able to transmit and the requirements of Section 4 for any packet it is able to receive.

The device shall be able to transmit and receive GFSK packets, according to the requirements in Section 3.1 and Section 4.1, of any length between 68 µs and 426 µs.

The device shall be able to transmit and receive any packet type it supports on all of the 79 channels specified in Section 2.

RF has the following optional features:

- π/4-DQPSK modulation
- 8DPSK modulation
- 3-slot packets
- 5-slot packets
- Power control
- Enhanced power control
- Power class 1 (see Section 5.1)

For each row of Table 1.1, if a device supports the feature named in the first column then that device shall also support the feature named in the second column.

Feature	Required feature
8DPSK modulation	π/4-DQPSK modulation
5-slot packets	3-slot packets
Enhanced power control	Power control
Power class 1	Power control

Table 1.1: Features that require other features

1.1.1 π/4-DQPSK modulation

A device that supports π/4-DQPSK modulation shall be able to transmit and receive packets using π/4-DQPSK modulation (Enhanced Data Rate 2 Mb/s packets) according to the requirements in Section 3.2 and Section 4.2 with a payload field of up to 248 symbols.

1.1.2 8DPSK modulation

A device that supports 8DPSK modulation shall be able to transmit and receive packets using 8DPSK modulation (Enhanced Data Rate 3 Mb/s packets) according to the requirements in Section 3.2 and Section 4.2 with a payload field of up to 246 symbols.

1.1.3 3-slot packets

A device that supports 3-slot packets shall be able to transmit and receive Basic Rate packets of any length between 68 µs and 1686 µs and, if supported, Enhanced Data Rate packets with a payload field of up to 1500 symbols.

1.1.4 5-slot packets

A device that supports 5-slot packets shall be able to transmit and receive Basic Rate packets of any length between 68 µs and 2916 µs and, if supported, Enhanced Data Rate packets with a payload field of up to 2748 symbols.

1.1.5 Power control

A device that supports power control shall be capable of adjusting its transmission power, shall be capable of responding to legacy power control requests (see [Vol 2] Part C, Section 4.1.3), and shall meet the requirements in Section 5.2.

1.1.6 Enhanced power control

A device that supports enhanced power control shall be capable of responding to enhanced power control requests (see [Vol 2] Part C, Section 4.1.3.1) and shall meet the requirements in Section 5.3.

2 FREQUENCY BANDS AND CHANNEL ARRANGEMENT

The Bluetooth system operates in the 2.4 GHz ISM band. This frequency band is 2400 MHz to 2483.5 MHz.

Frequency Range	RF Channels
2.400 GHz to 2.4835 GHz	f=2402+k MHz, k=0,...,78

Table 2.1: Operating frequency bands

RF channels are spaced 1 MHz and are ordered in channel number k as shown in Table 2.1.

3 TRANSMITTER CHARACTERISTICS

The requirements stated in this section are given as power levels at the antenna connector of the Bluetooth device; this is also referred to as the radiative transmit power level of the device. If the device does not have a connector, a reference antenna with 0 dBi gain is assumed. Power level values used in HCI commands, HCI events, and Link Manager Protocol (LMP) PDUs shall be assumed to be the radiative transmit power level of the device unless specified otherwise.

Due to difficulty in measurement accuracy in radiated measurements, systems with an integral antenna should provide a temporary antenna connector during RF qualification testing.

3.1 Basic Rate

3.1.1 Modulation characteristics

The Modulation is GFSK (Gaussian Frequency Shift Keying) with a bandwidth-bit period product BT=0.5. The Modulation index shall be between 0.28 and 0.35. A binary one shall be represented by a positive frequency deviation, and a binary zero shall be represented by a negative frequency deviation. The symbol timing shall be less than ±20 ppm.

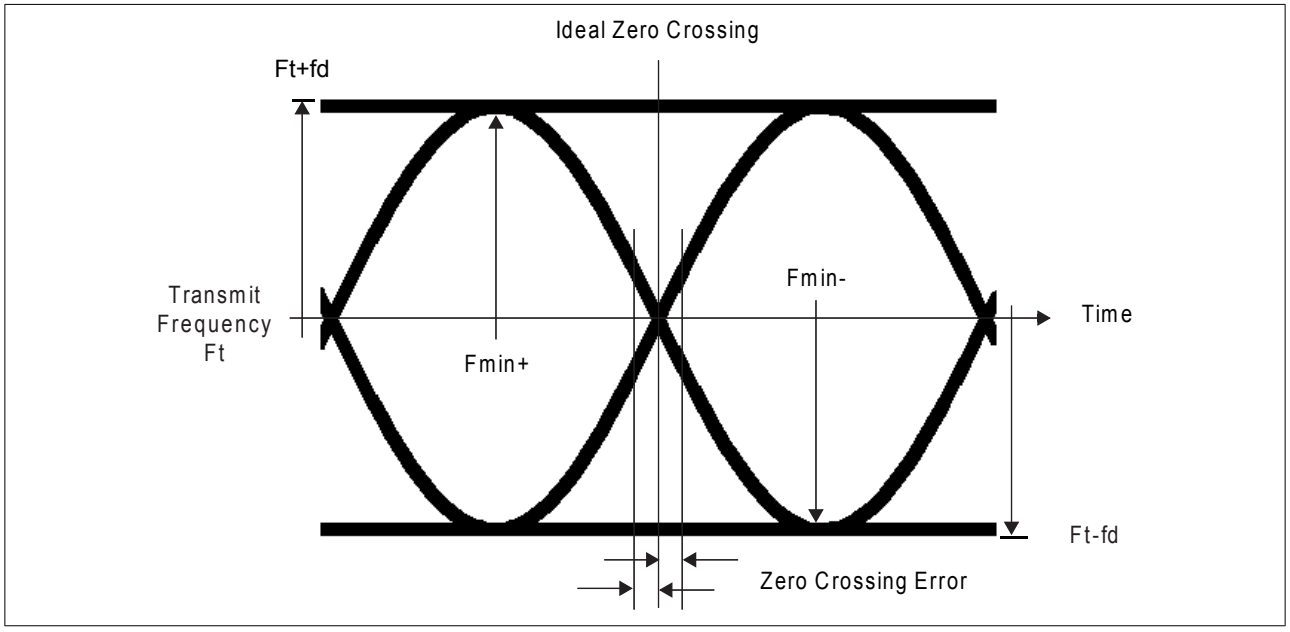

Figure 3.1: GFSK parameters definition

For each transmission, the minimum frequency deviation, Fmin = min{|Fmin+|, Fmin-}, which corresponds to 1010 sequence shall be no smaller than ±80% of the frequency

deviation (fd) with respect to the transmit frequency Ft, which corresponds to a 00001111 sequence.

In addition, the minimum frequency deviation shall never be smaller than 115 kHz. The data transmitted has a symbol rate of 1 Msym/s.

The zero crossing error is the time difference between the ideal symbol period and the measured crossing time. This shall be less than ± 1/8 of a symbol period.

See Figure 3.1 for the definitions of some symbols and terms in these requirements.

3.1.2 Spurious emissions

In-band spurious emissions shall be measured with a frequency hopping radio transmitting on one RF channel and receiving on a second RF channel; this means that the synthesizer may change RF channels between reception and transmission, but always returns to the same transmit RF channel.

3.1.2.1 In-band spurious emission

Within the ISM band the transmitter shall pass a spectrum mask, given in Table 3.1. The spectrum shall comply with the 20 dB bandwidth definition in FCC part 15.247 and shall be measured accordingly. In addition to the FCC requirement an adjacent channel power on adjacent channels with a difference in RF channel number of two or greater is defined. This adjacent channel power is defined as the sum of the measured power in a 1 MHz bandwidth. The transmitted power shall be measured in a 100 kHz bandwidth using maximum hold. The device shall transmit on RF channel M and the adjacent channel power shall be measured on RF channel number N. The transmitter shall transmit a pseudo random data pattern in the payload throughout the test.

Frequency offset	Transmit Power
± 500 kHz	-20 dBc
2 MHz (|M-N| = 2)	-20 dBm
3 MHz or greater (|M-N| ≥ 3)	-40 dBm

Table 3.1: Transmit Spectrum mask

Note: If the output power is less than 0 dBm then, wherever appropriate, the FCC's 20 dB relative requirement overrules the absolute adjacent channel power requirement stated in Table 3.1.

Exceptions are allowed in up to three bands of 1 MHz width centered on a frequency which is an integer multiple of 1 MHz. They shall comply with an absolute value of –20 dBm.

3.1.3 Radio frequency tolerance

The transmitted initial center frequency shall be within ±75 kHz from F_C. The initial frequency accuracy is defined as being the frequency accuracy before any packet information is transmitted.

The frequency drift requirement is not included in the ±75 kHz.

The limits on the transmitter center frequency drift within a packet are specified in Table 3.2. The different packets are defined in the Baseband Specification.

Duration of Packet	Frequency Drift
Max length one slot packet	±25 kHz
Max length three slot packet	±40 kHz
Max length five slot packet	±40 kHz
Maximum drift rate[1]	400 Hz/µs

Table 3.2: Maximum allowable frequency drifts in a packet

[1]The maximum drift rate is allowed anywhere in a packet.

3.2 Enhanced Data Rate

A key characteristic of the Enhanced Data Rate mode is that the modulation mode is changed within the packet. The access code and packet header, as defined in [Vol 2] Part B, Table 6.1, are transmitted with the Basic Rate 1 Mb/s GFSK modulation mode, whereas the subsequent synchronization sequence, payload, and trailer sequence are transmitted using the Enhanced Data Rate PSK modulation mode.

3.2.1 Modulation characteristics

During access code and packet header transmission the Basic Rate GFSK modulation mode shall be used. During the transmission of the synchronization sequence, payload, and trailer sequence a PSK type of modulation with a data rate of 2 Mb/s or optionally 3 Mb/s shall be used. The following subsections specify the PSK modulation for this transmission.

3.2.1.1 Modulation method overview

The PSK modulation format defined for the 2 Mb/s transmission shall be π/4 rotated differential encoded quaternary phase shift keying (π/4-DQPSK).

The PSK modulation format defined for the 3 Mb/s transmission shall be differential encoded 8-ary phase shift keying (8DPSK).

The modulation shall employ square-root raised cosine pulse shaping to generate the equivalent lowpass information-bearing signal v(t). The output of the transmitter shall be a bandpass signal that can be represented as

$$S(t) = Re\left[v(t)e^{j2\pi F_c t}\right] \quad \text{(EQ 1)}$$

with F_c denoting the carrier frequency.

3.2.1.2 Differential phase encoding

For the M-ary modulation, the binary data stream $\{b_n\}$, n=1,2,3, ...N, shall be mapped onto a corresponding sequence {Sk}, k=1,2, ...N÷$\log_2$(M) of complex valued signal points. M=4 applies for 2 Mb/s and M=8 applies for 3 Mb/s. Gray coding shall be applied as shown in Table 3.3 and Table 3.4. In the event that the length of the binary data stream N is not an integer multiple of $\log_2$(M), the last symbol of the sequence $\{S_k\}$ shall be formed by appending data zeros to the appropriate length. The signal points S_k shall be defined by:

$$S_k = S_{k-1}e^{j\varphi_k} \qquad k = 1, 2, \ ..N \div log_2(M) \quad \text{(EQ 2)}$$

$$S_0 = e^{j\phi} \qquad \text{with } \phi \in [0, 2\pi) \quad \text{(EQ 3)}$$

The relationship between the binary input b_k and the phase ϕ_k shall be as defined in Table 3.3 for the 2 Mb/s transmission and in Table 3.4 for the 3 Mb/s transmission.

b_{2k-1}	b_{2k}	φ_k
0	0	π/4
0	1	3π/4
1	1	-3π/4
1	0	-π/4

Table 3.3: π/4-DQPSK mapping

b_{3k-2}	b_{3k-1}	3k	φ_k
0	0	0	0
0	0	1	π/4
0	1	1	π/2
0	1	0	3π/4
1	1	0	π
1	1	1	-3π/4
1	0	1	-π/2
1	0	0	-π/4

Table 3.4: 8DPSK mapping

3.2.1.3 Pulse shaping

The lowpass equivalent information-bearing signal v(t) shall be generated according to

$$v(t) = \sum_k S_k p\left(t - kT\right) \quad \text{(EQ 4)}$$

in which the symbol period T shall be 1 µs.

The frequency spectrum P(f), which corresponds to the square-root raised cosine pulse p(t) of the pulse shaping filter is:

$$|P(f)| = \begin{cases} 1 & \text{when} \quad 0 \le |f| \le \frac{1-\beta}{2T} \\ \sqrt{\frac{1}{2}\left(1 - \sin\left(\frac{\pi(2|f|T-1)}{2\beta}\right)\right)} & \text{when} \quad \frac{1-\beta}{2T} \le |f| \le \frac{1+\beta}{2T} \\ 0 & \text{elsewhere} \end{cases} \quad \text{(EQ 5)}$$

The roll off factor β shall be 0.4.

3.2.1.4 Modulation accuracy

The measurement of modulation accuracy utilizes differential error vector magnitude (DEVM) with tracking of the carrier frequency drift. The definition of DEVM and the derivation of the RMS and peak measures of DEVM are given in Appendix C.

The DEVM shall be measured over the synchronization sequence and payload portions of the packet, but not the trailer symbols. For each modulation method and each measurement carrier frequency, the DEVM measurement is made over a total of 200 non-overlapping blocks, where each block contains 50 symbols.

The transmitted packets shall be the longest supported packet type for each modulation method, as defined in [Vol 2] Part B, Table 6.8 and [Vol 2] Part B, Table 6.9.

The DEVM is measured using a square-root raised cosine filter, with a roll-off of 0.4 and a 3 dB bandwidth of ±500 kHz.

3.2.1.4.1 RMS DEVM

The RMS DEVM for any of the measured blocks shall not exceed 0.20 for π/4-DQPSK and 0.13 for 8DPSK.

3.2.1.4.2 99% DEVM

The 99% DEVM (defined as the DEVM value for which 99% of measured symbols have a lower DEVM) shall not exceed 0.30 for π/4-DQPSK and 0.20 for 8DPSK.

3.2.1.4.3 Peak DEVM

The Peak DEVM shall not exceed 0.35 for π/4-DQPSK and 0.25 for 8DPSK.

3.2.2 Spurious emissions

In-band spurious emissions shall be measured with a frequency hopping radio transmitting on one RF channel and receiving on a second RF channel; this means that the synthesizer may change RF channels between reception and transmission, but always returns to the same transmit RF channel.

3.2.2.1 In-band spurious emission

Within the ISM band the power spectral density of the transmitter shall comply with the following requirements when sending pseudo random data. All power measurements shall use a 100 kHz bandwidth with maximum hold. The power measurements between 1 MHz and 1.5 MHz from the carrier shall be at least 26 dB below the maximum power measurement up to 500 kHz from the carrier. The adjacent channel power for channels at least 2 MHz from the carrier is defined as the sum of the power measurements over a 1 MHz channel and shall not exceed -20 dBm for the second adjacent channels and -40 dBm for the third and subsequent adjacent channels. These requirements shall apply to the transmitted signal from the start of the guard time to the end of the power down ramp. The spectral mask is illustrated in Figure 3.2.

Exceptions are allowed in up to 3 bands of 1 MHz width centered on a frequency which is an integer multiple of 1 MHz. They shall comply with an absolute value of –20 dBm.

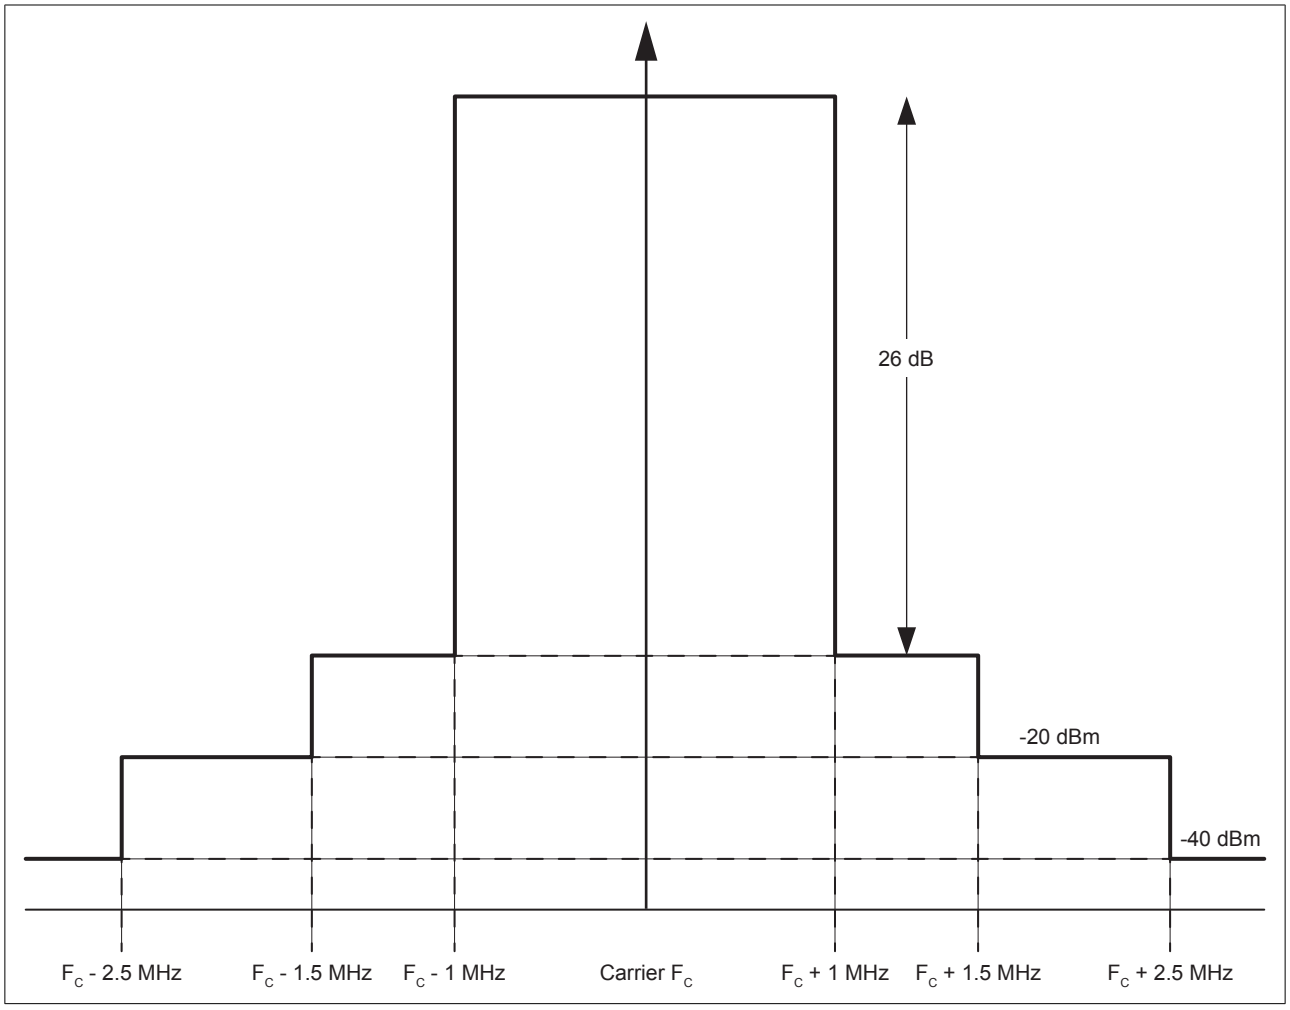

Figure 3.2: Transmitter spectrum mask

3.2.3 Radio frequency tolerance

The same carrier frequencies F_c as used for Basic Rate transmissions shall be used for the Enhanced Data Rate transmissions. The transmitted initial center frequency accuracy shall be within ±75 kHz from F_c. The maximum excursion from F_c (frequency offset plus drift) shall not exceed ±75 kHz.

The initial frequency accuracy is defined as being the frequency accuracy before any information is transmitted.

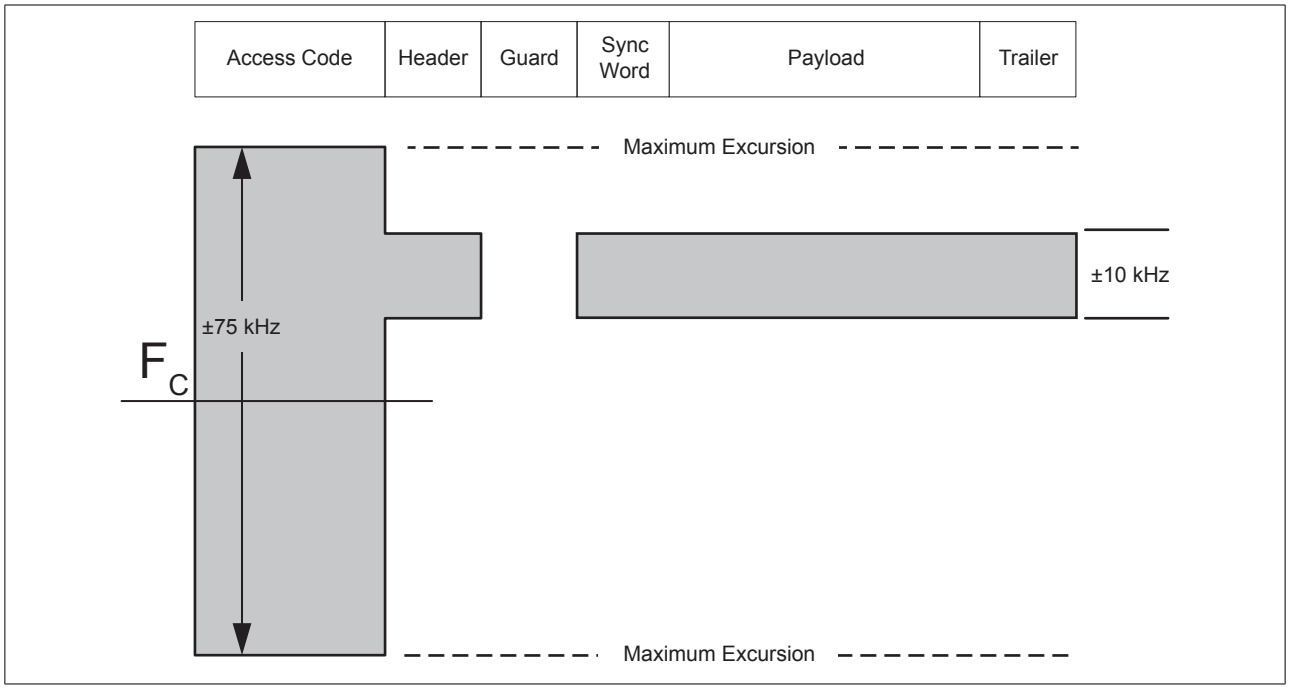

Figure 3.3: Carrier frequency mask

The requirements on accuracy and stability are illustrated by Figure 3.3 for the Enhanced Data Rate packet format defined in Definition: Baseband Specification . The higher frequency accuracy requirement shall start at the first symbol of the header. The maximum drift over the header, synchronization sequence and payload shall be ±10 kHz.

3.2.4 Relative transmit power

The requirement on the relative power of the GFSK and DPSK portions of the Enhanced Data Rate packet is defined as follows. The average power level during the transmission of access code and header is denoted as P_{GFSK} and the average power level during the transmission of the synchronization sequence and the payload is denoted as P_{DPSK}. The following inequalities shall be satisfied independently for each Enhanced Data Rate packet transmitted:

$(P_{GFSK} - 4\ dB) < P_{DPSK} < (P_{GFSK} + 1\ dB)$

4 RECEIVER CHARACTERISTICS

The receiver characteristics shall be measured using loopback as defined in [Vol 3] Part D, Section 1.

The reference sensitivity level referred to in this section is -70 dBm.

4.1 Basic Rate

4.1.1 Actual sensitivity level

The actual sensitivity level is defined as the input level for which a raw bit error rate (BER) of 0.1% is met. The receiver sensitivity shall be below or equal to –70 dBm when receiving signals specified in Section 3.1.

4.1.2 Interference performance

The interference performance on Co-channel and adjacent 1 MHz and 2 MHz shall be measured with the wanted signal 10 dB over the reference sensitivity level. For interference performance on all other RF channels the wanted signal shall be 3 dB over the reference sensitivity level. If the frequency of an interfering signal is outside of the band 2400 MHz to 2483.5 MHz, the out-of-band blocking specification (see Section 4.1.3) shall apply. The interfering signal shall be Bluetooth-modulated (see Section 4.1.7). The BER shall be ≤0.1% for all the signal-to-interference ratios listed in Table 4.1:

Frequency of Interference	Ratio
Co-Channel interference, $C/I_{co\text{-}channel}$	11 dB
Adjacent (1 MHz) interference[1], $C/I_{1\ MHz}$	0 dB
Adjacent (2 MHz) interference[1], $C/I_{2\ MHz}$	-30 dB
Adjacent (≥3 MHz) interference[1], $C/I_{\geq 3\ MHz}$	-40 dB
Image frequency Interference[1,2,3], C/I_{Image}	-9 dB
Adjacent (1 MHz) interference to in-band image frequency[1], $C/I_{Image \pm 1MHz}$	-20 dB

Table 4.1: Interference performance

[1]If two adjacent channel specifications from Table 4.1 are applicable to the same channel, the more relaxed specification applies.

[2]In-band image frequency

[3]If the image frequency ≠ n MHz, then the image reference frequency is defined as the closest n MHz frequency for integer n.

These specifications are only to be tested at nominal temperature conditions with a device receiving on one RF channel and transmitting on a second RF channel;

this means that the synthesizer may change RF channels between reception and transmission, but always returns to the same receive RF channel.

RF channels where the requirements are not met are called spurious response RF channels. Five spurious response RF channels are allowed at RF channels with a distance of ≥2 MHz from the wanted signal. On these spurious response RF channels a relaxed interference requirement C/I = -17 dB shall be met.

4.1.3 Out-of-band blocking

The out-of-band suppression (or rejection) shall be measured with the wanted signal 3 dB over the reference sensitivity level. The interfering signal shall be a continuous wave signal. The BER shall be ≤0.1%. The out-of-band blocking shall fulfil the following requirements:

Interfering Signal Frequency	Interfering Signal Power Level
30 MHz to 2000 MHz	-10 dBm
2000 MHz to 2399 MHz	-27 dBm
2484 MHz to 3000 MHz	-27 dBm
3000 MHz to 12.75 GHz	-10 dBm

Table 4.2: Out-of-band suppression (or rejection) requirements

24 exceptions are permitted which are dependent upon the given RF channel and are centered at a frequency which is an integer multiple of 1 MHz. For at least 19 of these spurious response frequencies, a reduced interference level of at least -50 dBm is allowed in order to achieve the required BER = 0.1% performance, whereas for a maximum of 5 of the spurious frequencies the interference level may be assumed arbitrarily lower.

4.1.4 Intermodulation characteristics

The reference sensitivity performance, BER = 0.1%, shall be met under the following conditions:

- The wanted signal shall be at frequency f_0 with a power level 6 dB over the reference sensitivity level.
- A static sine wave signal shall be at a frequency f_1 with a power level of –39 dBm.
- A Bluetooth modulated signal (see Section 4.1.7) shall be at f_2 with a power level of -39 dBm.

Frequencies f_0, f_1 and f_2 shall be chosen such that $f_0=2f_1-f_2$ and $|f_2-f_1|=n$ MHz, where n can be 3, 4, or 5. The system shall fulfill at least one of the three alternatives (n=3, 4, or 5).

4.1.5 Maximum usable level

The maximum usable input level that the receiver operates at shall be greater than -20 dBm. The BER shall be less than or equal to 0.1% at –20 dBm input power.

4.1.6 Received Signal Strength Indication

If a device supports Received Signal Strength Indication (RSSI) the accuracy shall be ±6 dB. If the device is aware that the RSSI varies across frequencies, then it should update the RSSI value of a packet depending on the frequency that the packet was received on before using the value, e.g., before reporting it to the Host.

4.1.7 Reference signal definition

A Bluetooth modulated interfering signal shall be defined as:

Modulation = GFSK
Modulation index = 0.32±1%
BT= 0.5±1%
Bit Rate = 1 Mb/s ±1 ppm
Modulating Data for wanted signal = PRBS9
Modulating Data for interfering signal = PRBS15
Frequency accuracy better than ±1 ppm.

4.2 Enhanced Data Rate

4.2.1 Actual sensitivity level

The actual sensitivity level shall be defined as the input level for which a raw bit error rate (BER) of 0.01% is met. The requirement for a Bluetooth π/4-DQPSK and 8DPSK Enhanced Data Rate receiver shall be an actual sensitivity level of –70 dBm or better. The receiver shall achieve the –70 dBm sensitivity level when receiving signals specified in Section 3.2.

4.2.2 BER floor performance

The receiver shall achieve a BER less than 0.001% at 10 dB above the reference sensitivity level.

4.2.3 Interference performance

The interference performance for co-channel and adjacent 1 MHz and 2 MHz channels shall be measured with the wanted signal 10 dB above the reference sensitivity level. On all other frequencies the wanted signal shall be 3 dB above the reference sensitivity level. The requirements in this section shall only apply if the frequency of the interferer is inside of the band 2400 MHz to 2483.5 MHz.

The interfering signal for co-channel interference shall be similarly modulated as the desired signal. The interfering signal for other channels shall be equivalent to a nominal Bluetooth Basic Rate GFSK transmitter. The interfering signal shall carry random data.

A BER of 0.1% or better shall be achieved for the signal to interference ratios defined in Table 4.3.

Frequency of Interference	π/4-DQPSK Ratio	8DPSK Ratio
Co-Channel interference, $C/I_{co\text{-}channel}$	13 dB	21 dB
Adjacent (1 MHz) interference[1], $C/I_{1\ MHz}$	0 dB	5 dB
Adjacent (2 MHz) interference[1], $C/I_{2\ MHz}$	-30 dB	-25 dB
Adjacent (≥3 MHz) interference[1]	-40 dB	-33 dB
Image frequency interference[1,2,3], C/I_{Image}	-7 dB	0 dB
Adjacent (1 MHz) interference to in-band image frequency[1,2,3], $C/I_{Image\ \pm 1\ MHz}$	-20 dB	-13 dB

Table 4.3: Interference performance

[1]If two adjacent channel specifications from Table 4.3 are applicable to the same channel, the more relaxed specification applies.

[2]In-band image frequency.

[3]If the image frequency is not equal to n MHz, then the image reference frequency is defined as the closest n MHz frequency for integer n.

These specifications are only to be tested at nominal temperature conditions with a receiver hopping on one frequency; this means that the synthesizer may change frequency between receive slot and transmit slot, but always returns to the same receive frequency.

Frequencies where the requirements are not met are called spurious response frequencies. Five spurious response frequencies are allowed at frequencies with a distance of ≥2 MHz from the wanted signal. On these spurious response frequencies a relaxed interference requirement C/I = -15 dB for π/4-DQPSK and C/I = -10 dB for 8DPSK shall be met.

4.2.4 Maximum usable level

The maximum usable input level that the receiver operates at shall be greater than -20 dBm. The BER shall be less than or equal to 0.1% at -20 dBm input power.

4.2.5 Out-of-band and intermodulation characteristics

The Basic Rate out-of-band blocking and intermodulation requirements also apply to Enhanced Data Rate since they result in adequate performance. No additional requirements apply to Enhanced Data Rate.

4.2.6 Reference signal definition

A 2 Mb/s Bluetooth signal used as "wanted" or "interfering signal" is defined as:

Modulation = π/4-DQPSK
Symbol Rate = 1 Msym/s ± 1 ppm
Frequency accuracy better than ±1 ppm
Modulating Data for wanted signal = PRBS9
Modulating Data for interfering signal = PRBS15
RMS Differential Error Vector Magnitude < 5%
Average power over the GFSK and DPSK portions of the packet shall be equal to within ±1 dB

A 3 Mb/s Bluetooth signal used as "wanted" or "interfering signal" is defined as:

Modulation = 8DPSK
Symbol Rate = 1 Msym/s ± 1 ppm
Frequency accuracy better than ±1 ppm
Modulating Data for wanted signal = PRBS9
Modulating Data for interfering signal = PRBS15
RMS Differential Error Vector Magnitude < 5%
Average power over the GFSK and DPSK portions of the packet shall be equal to within ±1 dB

5 POWER MANAGEMENT

5.1 Power classes

Bluetooth devices are classified into three power classes based on their output power capabilities level at the maximum power setting (P_{max}) the device supports, as defined in Table 5.1.

Power Class	Requirements
1	100 mW (20 dBm) ≥ P_{max} > 2.5 mW (4 dBm)
2	2.5 mW (4 dBm) ≥ P_{max} > 1 mW (0 dBm)
3	1 mW (0 dBm) ≥ P_{max}

Table 5.1: Power classes

A class 1 device shall be able to adjust its transmit power down to 4 dBm or less.

If a class 1 device is paging or inquiring very close to another device, the input power can be larger than the requirement in Section 4.1.5. This can cause the receiving device to fail to respond. It may therefore be useful to page at class 2 or 3 power in addition to paging at power class 1.

If the receiving device in a connection does not support the necessary messaging for sending power control messages (see [Vol 2] Part C, Section 4.1.3), then the output power of the transmitting device shall not exceed the maximum output power of power class 2.

5.2 Power control

A device that supports power control shall have a set of transmission power levels; the difference in power level between adjacent levels forms a “power step”. The power steps shall form a monotonic sequence, with a maximum step size of 8 dB and a minimum step size of 2 dB. The power level at the lowest power step should be less than -30 dBm.

The transmit power level difference between the packet headers of all supported packet types at any given power step shall not exceed 10 dB.

A device that supports power control shall control the output power in a physical link in response to LMP commands received from a peer device that is capable of sending such requests (see [Vol 2] Part C, Section 4.1.3).

Using high transmit power in use cases where short ranges could be encountered can cause the receiver on the remote device to be saturated and result in link failure. Power

control requests can be used to adjust a connected remote device's transmit power level based on the receiver's signal level.

A power class 1 device can use power control to limit the transmitted power of a remote device to no more than +4 dBm. A power class 2 or class 3 device can use power control to optimize the power consumption and reduce the overall interference level for all devices that use the same spectrum that Bluetooth devices use.

5.3 Enhanced power control

When communicating with a device that does not support enhanced power control, a device that supports enhanced power control shall have an equal number of power steps for each supported modulation scheme so that all supported modulation modes shall reach their respective maximum (or minimum) levels at the same time. The power levels may vary per modulation mode.

Appendix A Test conditions

A.1 Nominal test conditions

A.1.1 Nominal temperature

The nominal temperature conditions for tests shall be +15 to +35 °C. When it is impractical to carry out the test under this condition a note to this effect, stating the ambient temperature, shall be recorded. The actual value during the test shall be recorded in the test report.

A.1.2 Nominal power source

The normal test voltage for the equipment shall be the nominal voltage for which the equipment was designed.

A.2 [This section is no longer used]

Appendix B [This Appendix is no longer used]

Appendix C Modulation accuracy definition

C.1 Enhanced Data Rate modulation accuracy

The Enhanced Data Rate modulation accuracy is defined by the differential error vector, being the difference between the vectors representing consecutive symbols of the transmitted signal, after passing the signal through a specified measurement filter, sampling it at the symbol rate with an optimum sampling phase and compensating it for carrier frequency error and for the ideal carrier phase changes. The magnitude of the normalized differential error vector is called the Differential Error Vector Magnitude (DEVM). The objective of the DEVM is to estimate the modulation errors that would be perceived by a differential receiver.

In an ideal transmitter, the input bit sequence $\{b_j\}$ is mapped onto a complex valued symbol sequence $\{S_k\}$. Subsequently, this symbol sequence is transformed into a baseband signal S(t) by means of a pulse-shaping filter.

In an actual transmitter implementation, the bit sequence $\{b_j\}$ generates a baseband equivalent transmitted signal Y(t). This signal Y(t) contains, besides the desired component S(t), multiple distortion components. This is illustrated in Figure C.1 (in Figure C.1 and Figure C.2 a circle with an X indicates a mixer).

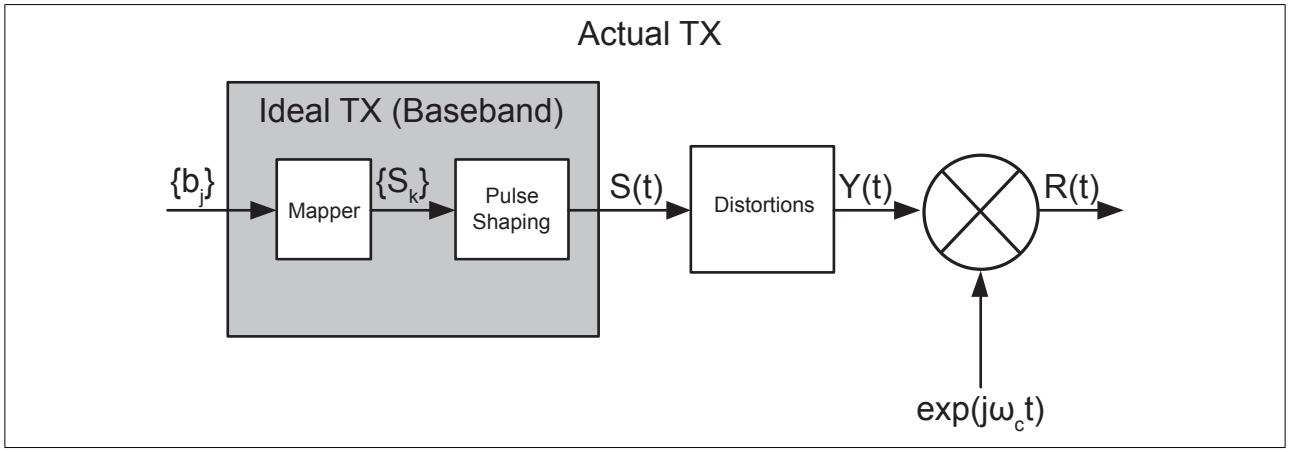

Figure C.1: TX model

Let Z(t) be the output of the measurement filter after first compensating the received signal for the initial center frequency error, ω_i, of the received packet, i.e. the output after down conversion and filtering the transmit signal R(t) (see Figure C.2).The measurement filter is defined by a square-root raised cosine shaping filter with a roll-off factor equal to 0.4 and 3 dB bandwidth of ±500 kHz.

Let $\{Z_k(\varepsilon)\}$ be the sequence of samples obtained by sampling the signal Z(t) with a sampling period equal to the symbol period T and a sampling phase equal to ε such that $Z_k(\varepsilon)=Z((k+\varepsilon)T)$.

This sequence $\{Z_k(\varepsilon)\}$ would coincide with the symbol sequence $\{S_k\}$ if no distortion is present and the correct timing phase ε is chosen.

To reflect the behavior of a typical differential receiver, the sample sequence $\{Z_k(\varepsilon)\}$ should be compensated for carrier frequency drift. Therefore, the sequence $\{Z_k(\varepsilon)\}$ is multiplied by a factor W^{-k} in which $W = e^{j\omega T}$ accounts for the frequency offset ω. A constant value of ω is used for each DEVM block of N = 50 symbols, but ω may vary between DEVM blocks (the values of ω can be used to measure carrier frequency drift).

In addition, $\{Z_k(\varepsilon)\}$ is compensated for the ideal phase changes between symbols by multiplying it with the complex conjugate of the symbol sequence $\{S_k\}$. However, it is not necessary to compensate $\{Z_k(\varepsilon)\}$ for initial carrier phase or output power of the transmitter.

Let $\{Q_k(\varepsilon,\omega)\}$ denote the compensated sequence $\{Z_k(\varepsilon)\}$, where the ideal phase changes have been removed and ε and ω are chosen optimally to minimize the DEVM, (i.e. remove time and frequency uncertainty). For a transmitter with no distortions other than a constant frequency error, $\{Q_k(\varepsilon,\omega)\}$ is a complex constant that depends on the initial carrier phase and the output power of the transmitter.

The differential error sequence $\{E_k(\varepsilon,\omega)\}$ is defined as the difference between $\{Q_k(\varepsilon,\omega)\}$ and $\{Q_{k-1}(\varepsilon,\omega)\}$. This reflects the modulation errors that would be perceived by a differential receiver. For a transmitter with no distortions other than a constant frequency error, $\{E_k(\varepsilon,\omega)\}$ is zero.

The definitions of the DEVM measures are based upon this differential error sequence $\{E_k(\varepsilon,\omega)\}$. The generation of the error sequence is depicted in Figure C.2 (the circle with the + indicates a direct summation function; the input with the "−" is negated before being summed).

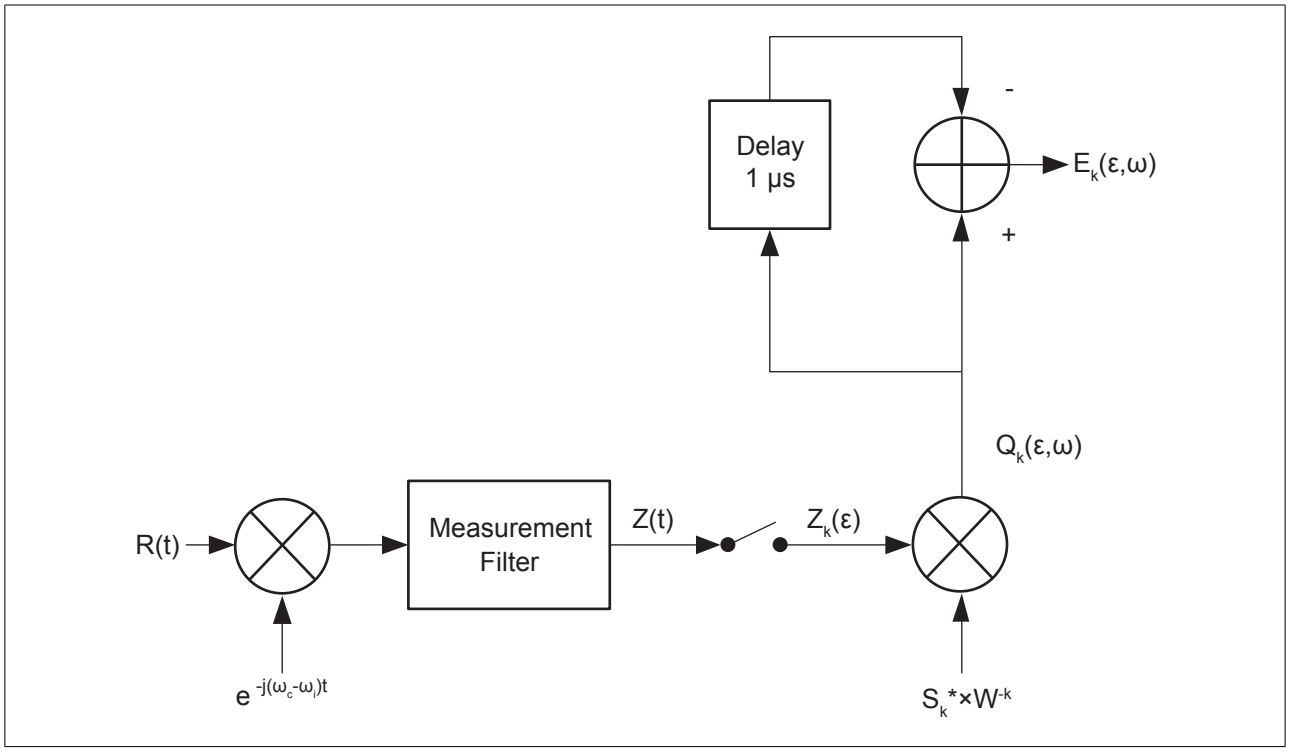

Figure C.2: Error sequence generation

C.1.1 RMS DEVM

The root mean squared DEVM (RMS DEVM) computed over N = 50 symbols is defined as:

$$RMS\ \ DEVM = \min_{\varepsilon,\omega}\left\{\sqrt{\frac{\sum_{k=1}^{N}|E_k(\varepsilon,\omega)|^2}{\sum_{k=1}^{N}|Q_k(\varepsilon,\omega)|^2}}\right\} \quad \text{(EQ 6)}$$

As can be seen from the expression above, the RMS DEVM is the square-root of the normalized power of the error.

C.1.2 Peak DEVM

The DEVM at symbol k is defined as:

$$DEVM\,(k) = \sqrt{\frac{|E_k(\varepsilon_0,\omega_0)|^2}{\sum_{j=1}^{N}|\ Q_j(\varepsilon_0,\omega_0)|^2/N}} \quad \text{(EQ 7)}$$

where ε_0 and ω_0 are the values for ε and ω used to calculate the RMS DEVM.

The peak DEVM is defined as:

$$Peak\ DEVM = \max_{k}\{\mathrm{DEVM}\,(k)\} \quad \text{(EQ 8)}$$

BR/EDR Controller
Part B

BASEBAND SPECIFICATION

This Part describes the specification of the Bluetooth Link Controller which carries out the Baseband protocols and other low-level link routines.

CONTENTS

1 GENERAL DESCRIPTION

This part specifies the normal operation of a Bluetooth Baseband.

The Bluetooth system provides a point-to-point connection or a point-to-multipoint connection, see (a) and (b) in Figure 1.1. In a point-to-point connection the physical channel is shared between two Bluetooth devices. In a point-to-multipoint connection, the physical channel is shared among several Bluetooth devices. Two or more devices sharing the same physical channel form a *piconet*. One Bluetooth device acts as the Central of the piconet, whereas the other device(s) act as Peripheral(s). Up to seven Peripherals can be active in the piconet. The channel access is controlled by the Central. An unlimited number of Peripherals can receive data on the physical channel carrying the Connectionless Peripheral Broadcast physical link.

Piconets that have common devices are called a *scatternet,* see (c) in Figure 1.1. Each piconet only has a single Central, however, Peripherals can participate in different piconets on a time-division multiplex basis. In addition, a Central in one piconet can be a Peripheral in other piconets. Piconets shall not be frequency synchronized and each piconet has its own hopping sequence.

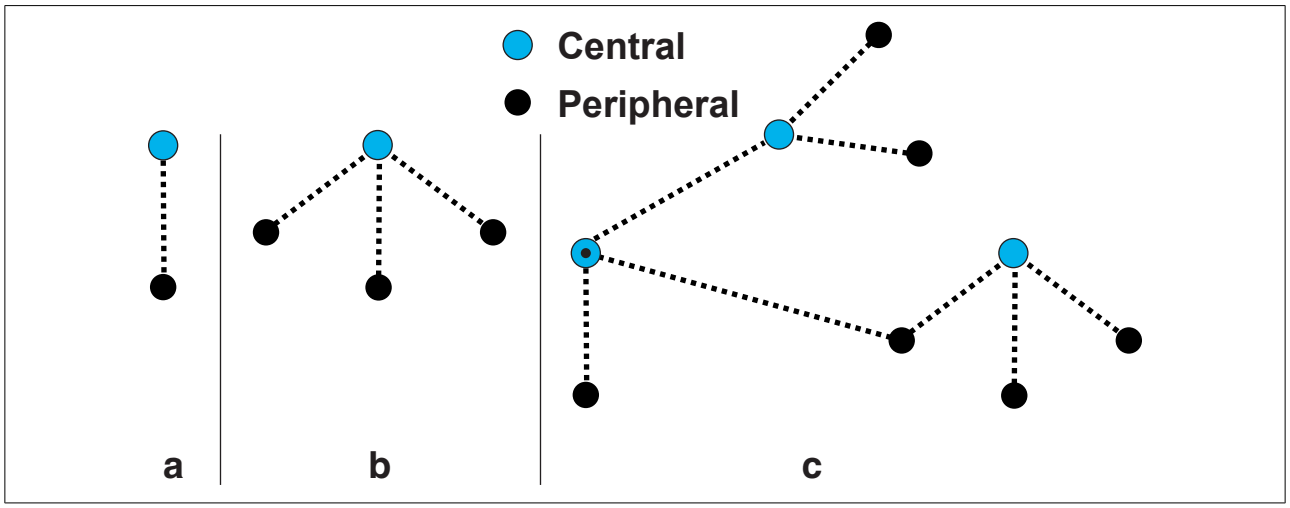

Figure 1.1: Piconets with a single Peripheral operation (a), a multi-Peripheral operation (b) and a scatternet operation (c)

Data is transmitted over the air in packets. Two modes are defined: a mandatory mode called Basic Rate and an optional mode called Enhanced Data Rate. The symbol rate for all modulation modes is 1 Msym/s. The gross air data rate is 1 Mb/s for Basic Rate. Enhanced Data Rate has a primary modulation mode that provides a gross air data rate of 2 Mb/s, and a secondary modulation mode that provides a gross air data rate of 3 Mb/s.

The general Basic Rate packet format is shown in Figure 1.2. Each packet consists of 3 entities: the access code, the header, and the payload.

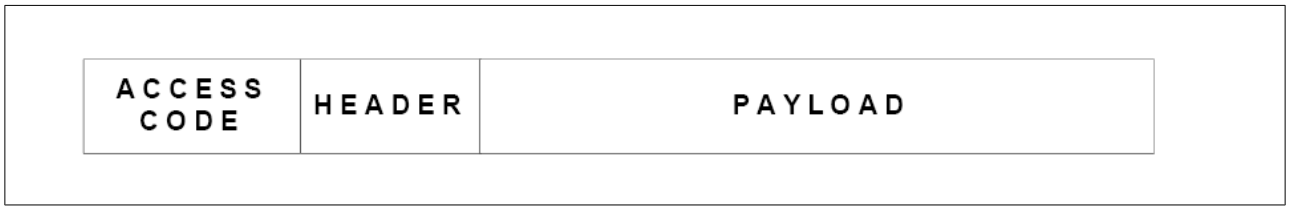

Figure 1.2: Standard Basic Rate packet format

The general Enhanced Data Rate packet format is shown in Figure 1.3. Each packet consists of 6 entities: the access code, the header, the guard period, the synchronization sequence, the Enhanced Data Rate payload and the trailer. The access code and header use the same modulation mode as for Basic Rate packets while the synchronization sequence, the Enhanced Data Rate payload and the trailer use the Enhanced Data Rate modulation mode. The guard time allows for the transition between the modulation modes.

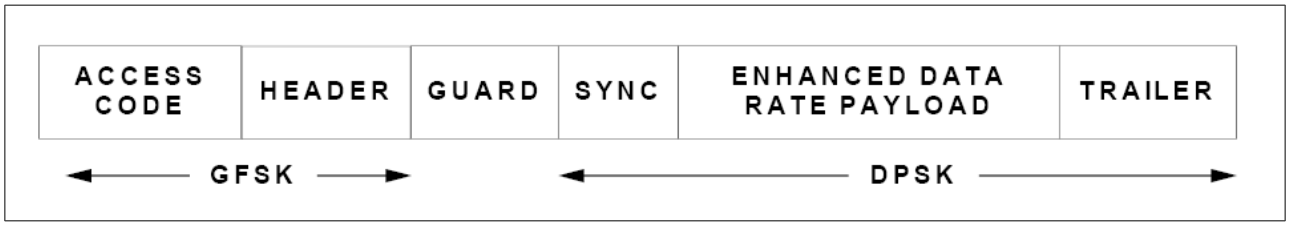

Figure 1.3: Standard Enhanced Data Rate packet format

1.1 Bluetooth clock

Every Bluetooth device shall have a native clock that shall be derived from a free running reference clock. Offsets may be added to the reference clock to synchronize the native clock with other non-Bluetooth systems. For synchronization with other Bluetooth devices, offsets are used that, when added to the native clock, provide temporary Bluetooth clocks that are mutually synchronized. It should be noted that the Bluetooth clock has no relation to the time of day; it may therefore be initialized to any value. The clock has a cycle of about a day. If the clock is implemented with a counter, a 28-bit counter is required that shall wrap around at 2^{28} -1. The least significant bit (LSB) shall tick in units of 312.5 µs (i.e. half a time slot), giving a clock rate of 3.2 kHz.

The clock determines critical periods and triggers the events in the device. Four periods are important in the Bluetooth system: 312.5 µs, 625 µs, 1.25 ms, and 1.28 s; these periods correspond to the timer bits CLK_0, CLK_1, CLK_2, and CLK_{12}, respectively, see Figure 1.4.

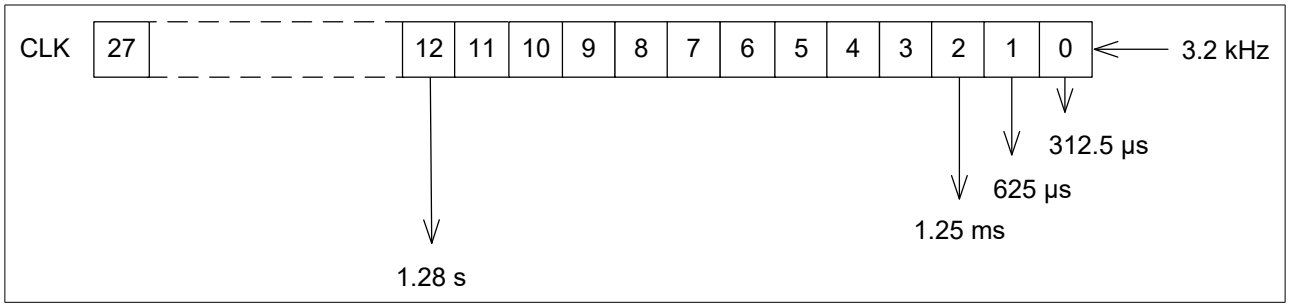

Figure 1.4: Bluetooth clock

In the different modes and states a device can reside in, the clock has different appearances:

- CLKR reference clock
- CLKN native clock
- CLKE estimated clock
- CLK Central's clock

CLKR is the reference clock driven by the free running system clock. CLKN may be offset from the reference clock by a timing offset. In Standby state and in Hold, Sniff, and Connectionless Peripheral Broadcast modes the reference clock shall have a worst case accuracy of ±250 ppm. In all other circumstances, it shall have a worst case accuracy of ±20 ppm; this accuracy shall also be used by the piconet Central while performing Piconet Clock Adjustment (see Section 8.6.10).

See Section 2.2.4 for the definition of CLK and Section 2.4.1 for the definition of CLKE.

The Central may adjust its native clock during the existence of the piconet within certain limits (see Section 8.6.10.3). The Central may also perform a coarse adjustment of the native clock by using the LMP_CLK_ADJ sequence.

1.2 Bluetooth Device addressing

Each Bluetooth device shall be allocated a unique 48-bit Bluetooth Device Address (BD_ADDR). The address shall be a 48-bit extended unique identifier (EUI-48) created in accordance with section 8.2 ("Universal addresses") of the IEEE 802-2014 standard (http://standards.ieee.org/findstds/standard/802-2014.html).

Creation of a valid EUI-48 requires one of the following MAC Address Block types to be obtained from the IEEE Registration Authority:

- MAC Address Block Large (MA-L)
- MAC Address Block Medium (MA-M)
- MAC Address Block Small (MA-S)

See http://standards.ieee.org/develop/regauth/index.html for information on obtaining one of these MAC Address Blocks. See also the IEEE's guidelines for use of these addresses (https://standards.ieee.org/develop/regauth/tut/eui.pdf).

Figure 1.5 illustrates how the LAP, UAP, and NAP map to the EUI-48. The bit pattern in Figure 1.5 is an example BD_ADDR.

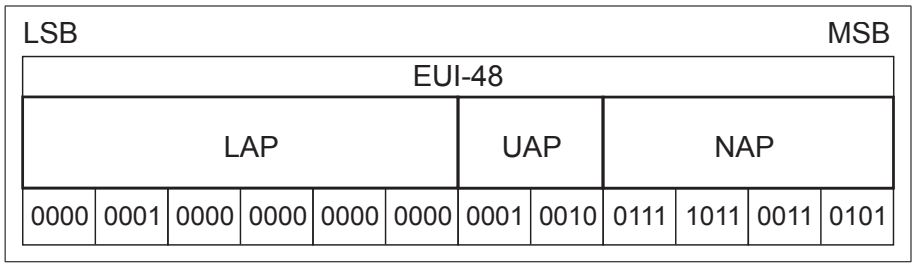

Figure 1.5: Format of BD_ADDR

The BD_ADDR may take any values except those that would have any of the 64 reserved LAP values for general and dedicated inquiries (see Section 1.2.1).

1.2.1 Reserved addresses

A block of 64 contiguous LAPs is reserved for inquiry operations; one LAP common to all devices is reserved for general inquiry, the remaining 63 LAPs are reserved for dedicated inquiry of specific classes of devices (see Assigned Numbers). The same LAP values are used regardless of the contents of UAP and NAP. Consequently, none of these LAPs can be part of a user BD_ADDR.

The reserved LAP addresses are 0x9E8B00 to 0x9E8B3F. The general inquiry LAP is 0x9E8B33. All addresses have the LSB at the rightmost position, hexadecimal notation. The default check initialization (DCI) is used as the UAP whenever one of the reserved LAP addresses is used. The DCI is defined to be 0x00 (hexadecimal).

1.3 Access codes

In the Bluetooth system all transmissions over the physical channel begin with an access code. Three different access codes are defined, see also Section 6.3.1:

- device access code (DAC)
- channel access code (CAC)
- inquiry access code (IAC)

All access codes are derived from the LAP of a device address or an inquiry address. The device access code is used during Page, Page Scan, Central Page Response, and Peripheral Page Response substates and shall be derived from the paged device's BD_ADDR. The channel access code is used in the Connection state, Synchronization Train substate, and Synchronization Scan substate, and forms the beginning of all packets exchanged on the piconet physical channel. The channel access code shall be derived from the LAP of the Central's BD_ADDR. Finally, the inquiry access code shall be used in the Inquiry substate. There is one general IAC (GIAC) for general inquiry operations and there are 63 dedicated IACs (DIACs) for dedicated inquiry operations.

The access code also indicates to the receiver the arrival of a packet. It is used for timing synchronization and offset compensation. The receiver correlates against the entire synchronization word in the access code, providing very robust signaling.

2 PHYSICAL CHANNELS

The lowest architectural layer in the Bluetooth system is the physical channel. A number of types of physical channels are defined. All Bluetooth physical channels are characterized by the combination of a basic pseudo-random frequency hopping sequence (which, for physical links on the adapted piconet physical channel, is then modified by the *AFH_channel_map* (defined in [Vol 2] Part C, Section 5.2) for that link), the specific slot timing of the transmissions, the access code and packet header encoding. These aspects, together with the range of the transmitters, define the signature of the physical channel. For the basic and adapted piconet physical channels frequency hopping is used to change frequency periodically to reduce the effects of interference.

Two devices that wish to communicate use a shared physical channel for this communication. To achieve this, their transceivers must be tuned to the same RF frequency at the same time, and they must be within a nominal range of each other.

Given that the number of RF carriers is limited and that many Bluetooth devices could be operating independently within the same spatial and temporal area there is a strong likelihood of two independent Bluetooth devices having their transceivers tuned to the same RF carrier, resulting in a physical channel collision. To mitigate the unwanted effects of this collision each transmission on a physical channel starts with an access code that is used as a correlation code by devices tuned to the physical channel. This channel access code is a property of the physical channel. The access code is always present at the start of every transmitted packet.

Several Bluetooth physical channels are defined. Each is optimized and used for a different purpose. Two of these physical channels (the basic piconet channel and adapted piconet channel) are used for communication between connected devices and are associated with a specific piconet. Other physical channels are used for discovering (the inquiry scan channel) and connecting (the page scan channel) Bluetooth devices. The synchronization scan physical channel is used by devices to obtain timing and frequency information about the Connectionless Peripheral Broadcast physical link or to recover the current piconet clock.

A Bluetooth device can only use one of these physical channels at any given time. In order to support multiple concurrent operations the device uses time-division multiplexing between the channels. In this way a Bluetooth device can appear to operate simultaneously in several piconets, as well as being discoverable and connectable.

Whenever a Bluetooth device is synchronized to the timing, frequency and access code of a physical channel it is said to be 'connected' to this channel (whether or not it is

actively involved in communications over the channel.) At a minimum, a device need only be capable of connection to one physical channel at a time, however, advanced devices may be capable of connecting simultaneously to more than one physical channel, but the specification does not assume that this is possible.

2.1 Physical channel definition

Physical channels, apart from the synchronization scan physical channel (which uses a set of fixed RF channels), are defined by a basic pseudo-random RF channel hopping sequence, the packet (slot) timing, and an access code. The hopping sequences are determined by the UAP and LAP of a Bluetooth Device Address, the selected basic hopping sequence, and – for the adapted piconet physical channel – the *AFH_channel_map* being used on a physical link. The phase in the hopping sequence is determined by the Bluetooth clock. All physical channels are subdivided into time slots. Within the physical channel, each reception or transmission event is associated with a time slot or time slots. For each reception or transmission event an RF channel is selected by the hop selection kernel (see Section 2.6).The maximum hop rate is 1600 hops per second in the Connection state, the Synchronization Train substate, and the Synchronization Scan substate and the maximum is 3200 hops per second in the Inquiry and Page substates.

The following physical channels are defined:

- basic piconet physical channel
- adapted piconet physical channel
- page scan physical channel
- inquiry scan physical channel
- synchronization scan physical channel

2.2 Basic piconet physical channel

During the Connection state the basic piconet physical channel is used by default. The adapted piconet physical channel may also be used. The adapted piconet physical channel is identical to the basic piconet physical channel except for the differences listed in Section 2.3.

2.2.1 Central and Peripheral roles

The basic piconet physical channel is defined by the Central of the piconet. The Central controls the traffic on the piconet physical channel by a polling scheme (see Section 8.5).

By definition, the device that initiates a connection by paging is the Central. Once a piconet has been established, the Central and Peripheral may exchange roles. This is described in Section 8.6.5.

2.2.2 Hopping characteristics

The basic piconet physical channel is characterized by a pseudo-random hopping through all 79 RF channels. The frequency hopping in the piconet physical channel is determined by the Bluetooth clock and BD_ADDR of the Central. When the piconet is established, the Central's clock is communicated to the Peripherals. Each Peripheral shall add an offset to its native clock to synchronize with the Central's clock. Since the clocks are independent, the offsets must be updated regularly. All devices participating in the piconet are time-synchronized and hop-synchronized to the channel.

The basic piconet physical channel uses the basic channel hopping sequence and is described in Section 2.6.

2.2.3 Time slots

The basic piconet physical channel is divided into time slots, each 625 µs in length. The time slots are numbered according to the most significant 27 bits of the Bluetooth clock CLK_{27-1} of the piconet Central. The slot numbering ranges from 0 to 2^{27}-1 and is cyclic with a cycle length of 2^{27}. The time slot number is denoted as k.

A TDD scheme is used where Central and Peripheral alternately transmit, see Figure 2.1. The packet start shall be aligned with the slot start. Packets may extend over up to five time slots.

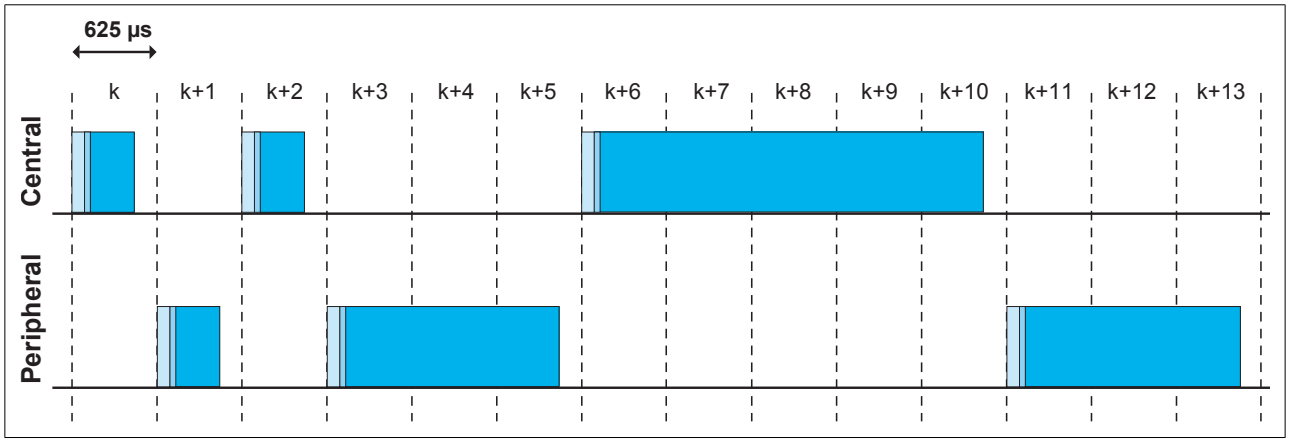

Figure 2.1: Multi-slot packets

The term *slot pairs* is used to indicate two adjacent time slots starting with a Central-to-Peripheral transmission slot.

2.2.4 Piconet clocks

CLK is the clock of the Central of the piconet. It shall be used for all timing and scheduling activities in the piconet. All devices shall use the CLK to schedule their transmission and reception. The CLK shall be derived from the reference clock CLKR (see Section 1.1) by adding a time_base_offset and a peripheral_clock_offset, see Figure 2.2. The time_base_offset is a value that devices may use to store a locally generated offset to CLKN caused by alignment to an external time base. The peripheral_clock_offset shall be zero for the Central since CLK is identical to its own native clock CLKN. Each Peripheral shall add an appropriate peripheral_clock_offset to its CLKN such that the CLK corresponds to the CLKN of the Central. Although all CLKNs in the devices run at the same nominal rate, mutual drift causes inaccuracies in CLK. Therefore, the peripheral_clock_offset in the Peripherals must be regularly updated such that CLK is approximately CLKN of the Central.

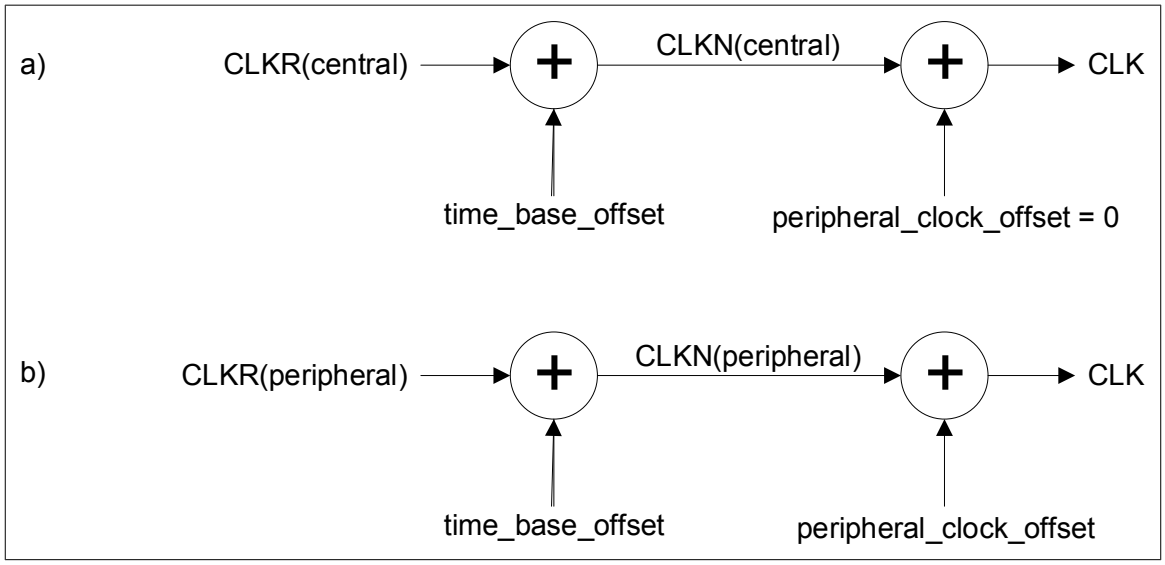

Figure 2.2: Derivation of CLK in Central (a) and in Peripheral (b)

Changes in time_base_offset are only made by the Central of a piconet; a device acting only as a Peripheral has no need to distinguish CLKR and CLKN in normal operation. In a scatternet situation, a Controller may be changing both time_base_offset to align its CLKN with an external clock, either collocated or at the request of a Peripheral, and peripheral_clock_offset to maintain synchronization with a different piconet clock. In some cases, it is not possible to determine how much of an observed offset is caused by external frame timing alignment (time_base_offset) and how much is caused by the offset between Central and Peripheral (peripheral_clock_offset).

2.2.5 Transmit/receive timing

The Central transmission shall always start at even numbered time slots (CLK_1=0) and the Peripheral transmission shall always start at odd numbered time slots (CLK_1=1).

Due to packet types that cover more than a single slot, Central transmission may continue in odd numbered slots and Peripheral transmission may continue in even numbered slots, see Figure 2.1.

All timing diagrams shown in Section 2 are based on the signals as present at the antenna. The term “exact” when used to describe timing refers to an ideal transmission or reception and neglects timing jitter and clock frequency imperfections.

The average timing of packet transmission shall not drift faster than 20 ppm relative to the ideal slot timing of 625 µs. The instantaneous timing shall not deviate more than 1 µs from the average timing. Thus, the absolute packet transmission timing t_k of slot boundary k shall fulfill the equation:

$$t_k = \left(\sum_{i=1}^{k} (1 + d_i) T_N \right) + j_k + \text{ offset}, \qquad \text{(EQ 1)}$$

where T_N is the nominal slot length (625 µs), j_k denotes jitter ($|j_k| \leq 1$ µs) at the start of slot k, and, d_k, denotes the drift ($|d_k| \leq 20$ ppm) within slot k. The jitter and drift can vary arbitrarily within the given limits for every slot, while *offset* is an arbitrary but fixed constant. For Hold and Sniff modes the drift and jitter parameters specified in Link Manager Protocol [Vol 2] Part C, Section 4.3.1 apply.

2.2.5.1 Piconet physical channel timing

In the figures, only single-slot packets are shown as an example.

The Central TX/RX timing is shown in Figure 2.3. In Figure 2.3 and Figure 2.4 the channel hopping frequencies are indicated by *f(k)* where k is the time slot number. After transmission, a return packet is expected N × 625 µs after the start of the TX packet where N is an odd, integer larger than 0. N depends on the type of the transmitted packet.

To allow for some time slipping, an uncertainty window is defined around the exact receive timing. During normal operation, the window length shall be 20 µs, which allows the RX packet to arrive up to 10 µs too early or 10 µs too late. It is recommended that Peripherals implement variable sized windows or time tracking to accommodate a Central's absence of more than 250 ms.

During the beginning of the RX cycle, the access correlator shall search for the correct channel access code over the uncertainty window. If an event trigger does not occur the receiver may go to sleep until the next RX event. If in the course of the search, it becomes apparent that the correlation output will never exceed the final threshold, the receiver may go to sleep earlier. If a trigger event occurs, the receiver shall remain open to receive the rest of the packet unless the packet is for another device, a non-recoverable header error is detected, or a non-recoverable payload error is detected.

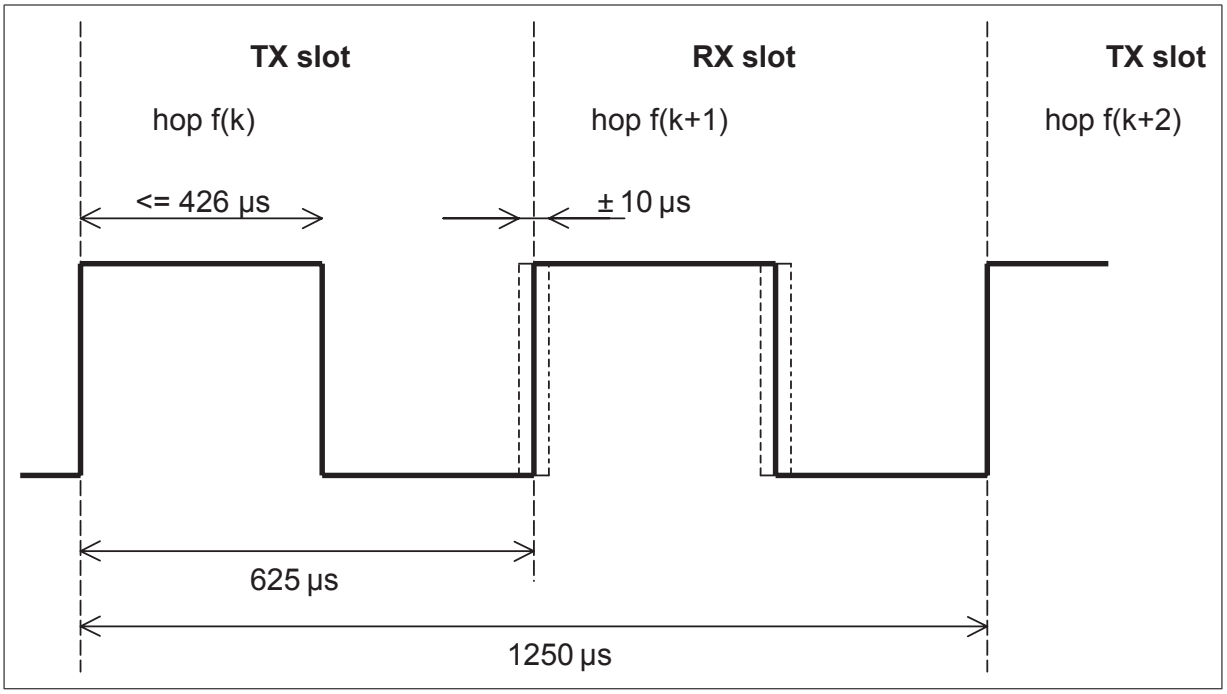

Figure 2.3: RX/TX cycle of Central transceiver in normal mode for single-slot packets

Each Central transmission shall be derived from bit 2 of the Central's native Bluetooth clock, thus the current transmission will be scheduled M × 1250 µs after the start of the previous Central TX burst where M depends on the transmitted and received packet type and is an even, integer larger than 0. The Central TX timing shall be derived from the Central's native Bluetooth clock, and thus it will not be affected by time drifts in the Peripheral(s).

Peripherals maintain an estimate of the Central's native clock by adding a timing offset to the Peripheral's native clock (see Section 2.2.4). This offset shall be updated each time a packet is received from the Central. By comparing the exact RX timing of the received packet with the estimated RX timing, Peripherals shall correct the offset for any timing misalignments. Since only the channel access code is required to synchronize the Peripheral, Peripheral RX timing can be corrected with any packet sent in the Central-to-Peripheral transmission slot.

The Peripheral's TX/RX timing is shown in Figure 2.4. The Peripheral's transmission shall be scheduled N × 625 µs after the start of the Peripheral's RX packet where N is an odd, positive integer larger than 0. If the Peripheral's RX timing drifts, so will its TX timing. During periods when a Peripheral is in the Active mode (see Section 8.6) and is prevented from receiving valid channel access codes from the Central due to local RF interference, Peripheral activity in a different piconet, or any other reason, the Peripheral may increase its receive uncertainty window and/or use predicted timing drift to increase the probability of receiving the Central's bursts when reception resumes.

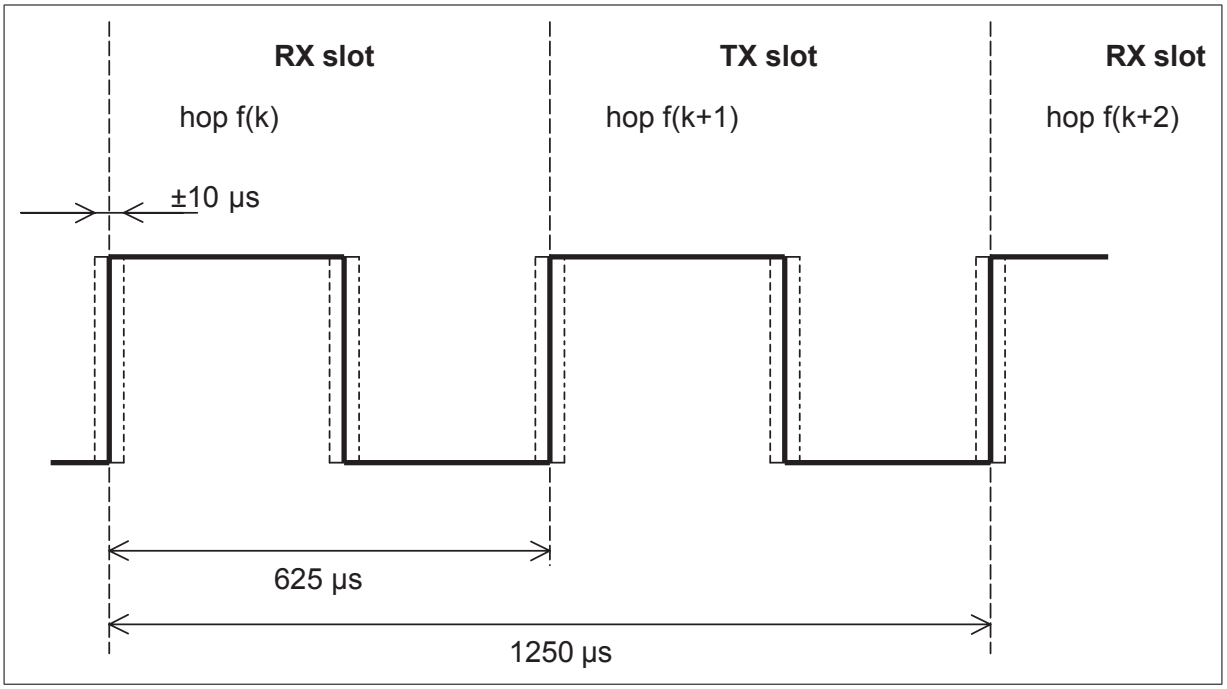

Figure 2.4: RX/TX cycle of Peripheral transceiver in normal mode for single-slot packets

2.2.5.2 Piconet physical channel re-synchronization

In the piconet physical channel, a Peripheral can lose synchronization if it does not receive a packet from the Central at least every 200 ms (or less if the low power clock is used). The Central may fail to transmit to the Peripheral due to the Central being busy with other tasks such as maintaining connections to other devices in Sniff or Hold modes, due to SCO, eSCO, or Connectionless Peripheral Broadcast activity, due to the Central being involved in a scatternet, or due to interference. When re-synchronizing to the piconet physical channel a Peripheral shall listen for the Central before it may send information (except for a Connectionless Peripheral Broadcast Receiver device which shall listen for the Transmitter but does not send information). In this case, the length of the synchronization search window in the Peripheral may be increased from 20 µs to a larger value X µs as illustrated in Figure 2.5. Only RX hop frequencies are used: the hop frequency used in the Central-to-Peripheral (RX) slot shall also be used in the uncertainty window, even when it is extended into the preceding time interval normally used for the Peripheral-to-Central (TX) slot.

If the length of search window, X, exceeds 1250 µs, consecutive windows shall avoid overlapping search windows. Consecutive windows should instead be centered at *f(k), f(k+4),... f(k+4i)* (where 'i' is an integer), which gives a maximum value X=2500 µs, or even at *f(k), f(k+6),...f(k+6i)* which gives a maximum value X=3750 µs. The RX hop frequencies used shall correspond to the Central-to-Peripheral transmission slots.

It is recommended that single slot packets are transmitted by the Central during Peripheral re-synchronization.

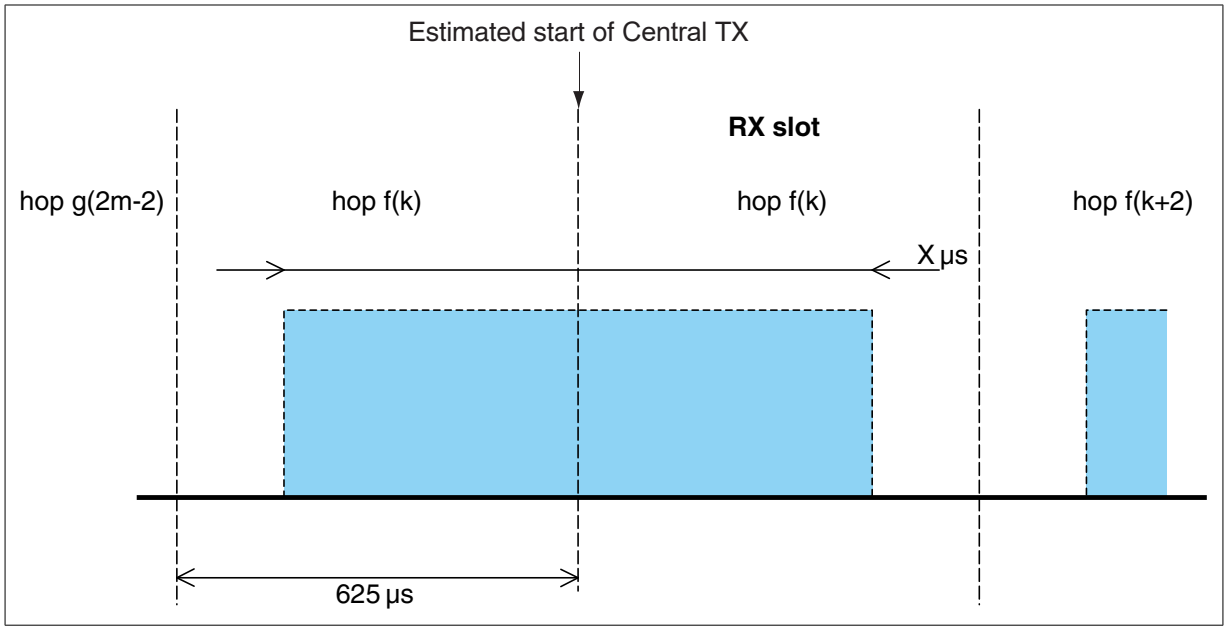

Figure 2.5: RX timing of Peripheral returning from Hold mode

2.3 Adapted piconet physical channel

For devices that enter Connectionless Peripheral Broadcast mode, the device that transmits Connectionless Peripheral Broadcast packets is the Central of the piconet and any device that receives Connectionless Peripheral Broadcast packets is a Peripheral of the piconet.

2.3.1 Hopping characteristics

Each physical link on the adapted piconet physical channel shall use at least N_{min} RF channels (where N_{min} is 20).

The adapted piconet physical channel uses the adapted channel hopping sequence described in Section 2.6.

Adapted piconet physical channels can be used for connected devices that have adaptive frequency hopping (AFH) enabled. There are two distinctions between basic and adapted piconet physical channels. The first is the same channel mechanism that makes the Peripheral frequency the same as the preceding Central transmission. The second aspect is that the adapted piconet physical channel may be based on less than the full 79 frequencies of the basic piconet physical channel. Each physical link on an adapted piconet physical channel may use a different set of frequencies.

2.4 Page scan physical channel

Although Central and Peripheral roles are not defined prior to a connection, the term *Central* is used for the paging device (that becomes a Central in the Connection state)

and *Peripheral* is used for the page scanning device (that becomes a Peripheral in the Connection state).

2.4.1 Clock estimate for paging

A paging device uses an estimate of the native clock of the page scanning device, CLKE; i.e. an offset shall be added to the CLKN of the pager to approximate the CLKN of the recipient, see Figure 2.6. CLKE shall be derived from the native CLKN by adding an offset. By using the CLKN of the recipient, the pager might be able to speed up the connection establishment.

Note: CLKR is never used for deriving CLKE or for any other control of the hopping kernel.

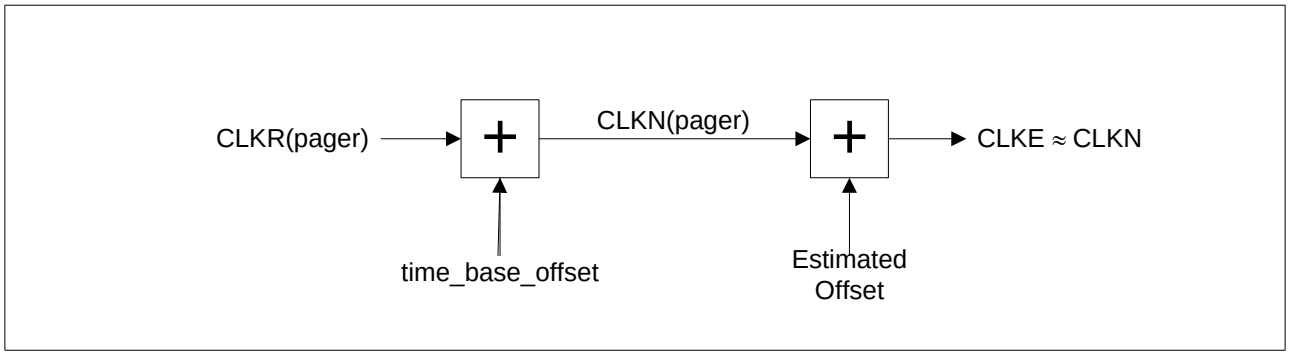

Figure 2.6: Derivation of CLKE

2.4.2 Hopping characteristics

The page scan physical channel follows a slower hopping pattern than the basic piconet physical channel and is a short pseudo-random hopping sequence through the RF channels. The timing of the page scan channel shall be determined by the native Bluetooth clock of the scanning device. The frequency hopping sequence is determined by the Bluetooth address of the scanning device.

The page scan physical channel uses the page, Central page response, Peripheral page response, and page scan hopping sequences specified in Section 2.6.

2.4.3 Paging procedure timing

During the paging procedure, the Central shall transmit paging messages (see Table 8.3) corresponding to the Peripheral to be connected. Since the paging message is a very short packet, the hop rate is 3200 hops per second. In a single TX slot interval, the paging device shall transmit on two different hop frequencies. In Figure 2.7 to Figure 2.11, *f(k)* is used for the frequencies of the page hopping sequence and *f'(k)* denotes the corresponding page response sequence frequencies. The first transmission starts where $CLK_0 = 0$ and the second transmission starts where $CLK_0 = 1$.

In a single RX slot interval, the paging device shall listen for the Peripheral page response message on two different hop frequencies. Similar to transmission, the nominal reception starts where CLK_0 = 0 and the second reception nominally starts where CLK_0 = 1; see Figure 2.7. During the TX slot, the paging device shall send the paging message at the TX hop frequencies *f(k)* and *f(k+1)*. In the RX slot, it shall listen for a response on the corresponding RX hop frequencies *f'(k)* and *f'(k+1)*. The listening periods shall be exactly timed 625 µs after the corresponding paging packets, and shall include a ±10 µs uncertainty window.

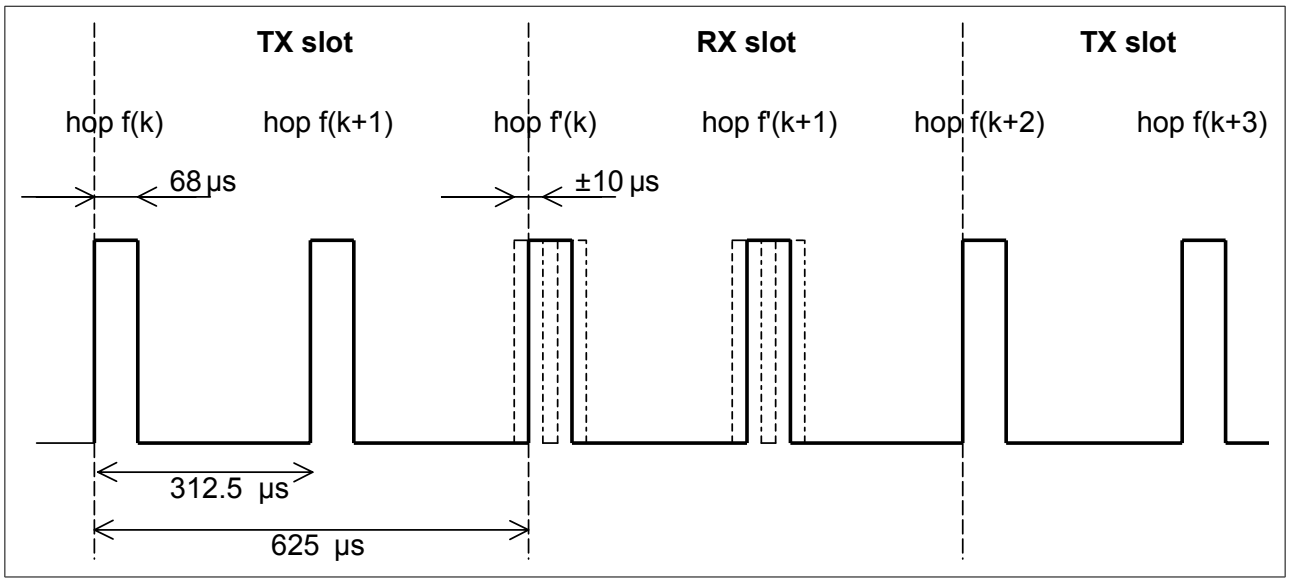

Figure 2.7: RX/TX cycle of transceiver in Page mode

2.4.4 Page response timing

At connection setup a Central page response packet is transmitted from the Central to the Peripheral (see Table 8.3). This packet establishes the timing and frequency synchronization. After the Peripheral has received the page message, it shall return a response message that consists of the Peripheral page response packet and shall follow 625 µs after the receipt of the page message. The Central shall send the Central page response packet in the TX slot following the RX slot in which it received the Peripheral's response, according to the RX/TX timing of the Central. The time difference between the Peripheral page response and Central page response message will depend on the timing of the page message the Peripheral received. In Figure 2.8, the Peripheral receives the paging message sent **first** in the Central-to-Peripheral slot. It then responds with a first Peripheral page response packet in the first half of the Peripheral-to-Central slot. The timing of the Central page response packet is based on the timing of the page message sent first in the preceding Central-to-Peripheral slot: there is an exact 1250 µs delay between the first page message and the Central page response packet. The packet is sent at the hop frequency *f(k+1)* which is the hop frequency following the hop frequency *f(k)* the page message was received in.

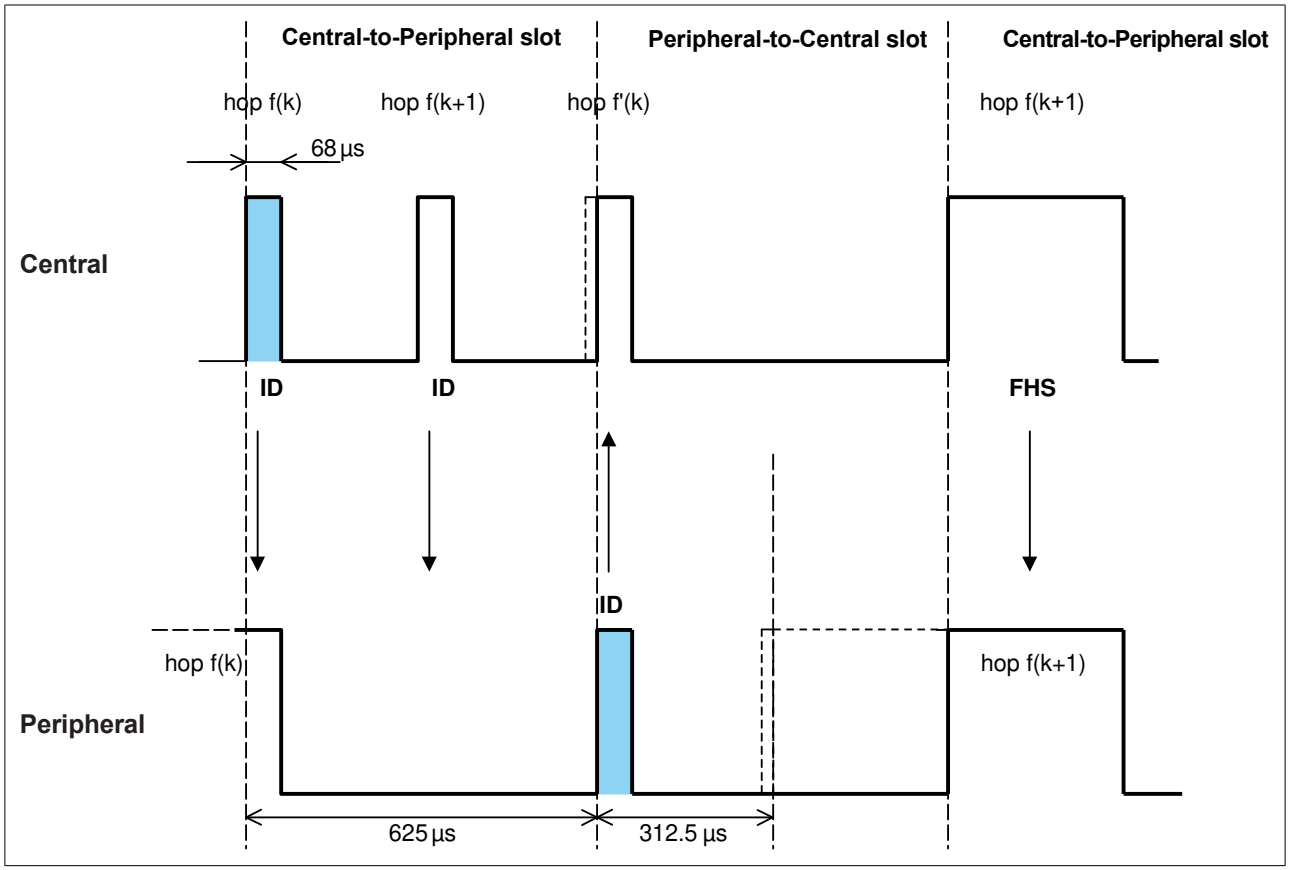

Figure 2.8: Timing of page response packets on successful page in first half slot

In Figure 2.9, the Peripheral receives the paging message sent **second** in the Central-to-Peripheral slot. It then responds with a Peripheral page response packet in the second half of the Peripheral-to-Central slot exactly 625 µs after the receipt of the page message. The timing of the Central page response packet is still based on the timing of the page message sent **first** in the preceding Central-to-Peripheral slot: there is an exact 1250 µs delay between the **first** page message and the Central page response packet. The packet is sent at the hop frequency $f(k+2)$ which is the hop frequency following the hop frequency $f(k+1)$ the page message was received in.

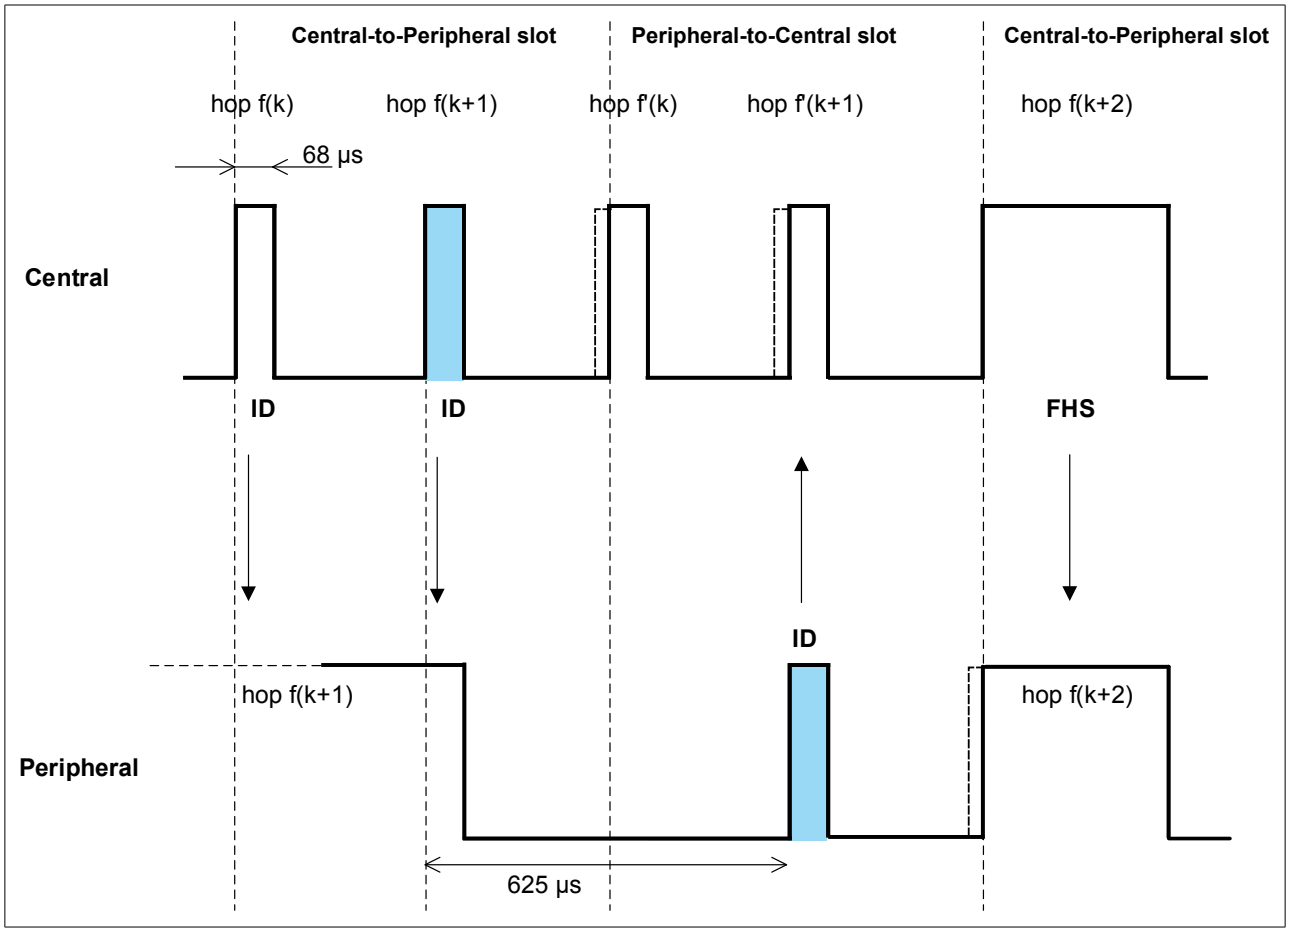

Figure 2.9: Timing of page response packets on successful page in second half slot

The Peripheral shall adjust its RX/TX timing according to the reception of the Central page response packet (and not according to the reception of the page message). That is, the second Peripheral page response message that acknowledges the reception of the Central page response packet shall be transmitted 625 µs after the start of the Central page response packet.

2.5 Inquiry scan physical channel

Although Central and Peripheral roles are not defined prior to a connection, the term *Central* is used for the inquiring device and *Peripheral* is used for the inquiry scanning device.

2.5.1 Clock for inquiry

The clock used for inquiry and inquiry scan shall be the device's native clock.

2.5.2 Hopping characteristics

The inquiry scan channel follows a slower hopping pattern than the piconet physical channel and is a short pseudo-random hopping sequence through the RF channels. The timing of the inquiry scan channel is determined by the native Bluetooth clock of the scanning device while the frequency hopping sequence is determined by the general inquiry access code.

The inquiry scan physical channel uses the inquiry, inquiry response, and inquiry scan hopping sequences described in Section 2.6.

2.5.3 Inquiry procedure timing

During the inquiry procedure, the Central shall transmit inquiry messages with the general or dedicated inquiry access code. The timing for inquiry is the same as for paging (see Section 2.4.3).

2.5.4 Inquiry response timing

An inquiry response packet is transmitted from the Peripheral to the Central after the Peripheral has received an inquiry message (see Table 8.5). This packet contains information necessary for the inquiring Central to page the Peripheral (see definition of the FHS packet in Section 6.5.1.4) and follows 625 µs after the receipt of the inquiry message. If the Peripheral transmits an extended inquiry response packet, it shall be transmitted 1250 µs after the start of the inquiry response packet.

In Figure 2.10 and Figure 2.11, *f(k)* is used for the frequencies of the inquiry hopping sequence and f'(k) denotes the corresponding inquiry response sequence frequency. The inquiry response packet and the extended inquiry response packet are received by the Central at the hop frequency *f'(k)* when the inquiry message received by the Peripheral was first in the Central-to-Peripheral slot.

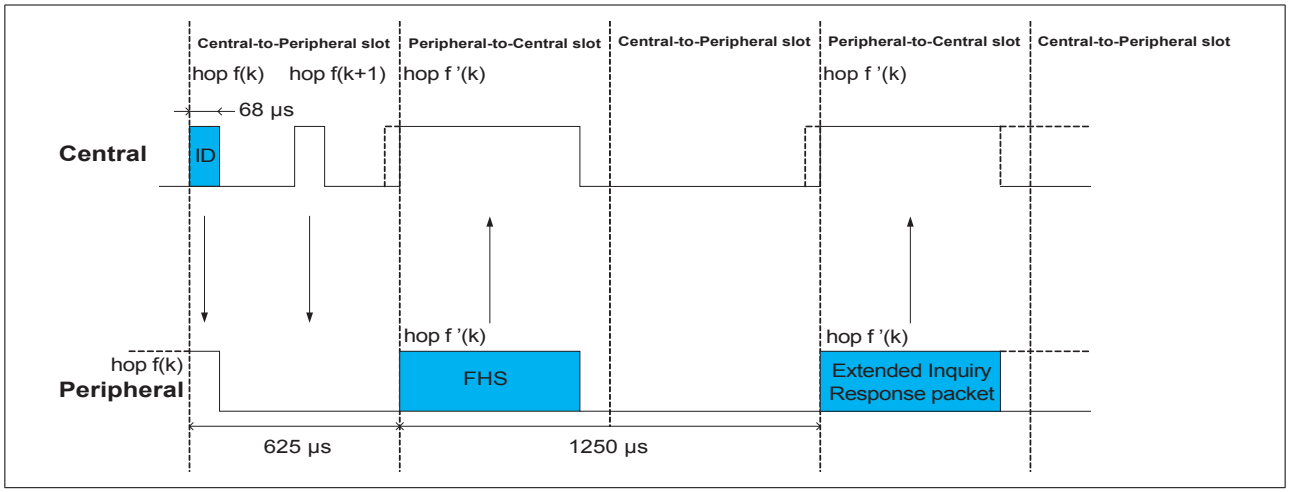

Figure 2.10: Timing of inquiry response packets on successful inquiry in first half slot

When the inquiry message received by the Peripheral was the second in the Central-to-Peripheral slot the inquiry response packet and the extended inquiry response packet are received by the Central at the hop frequency *f'(k+1)*.

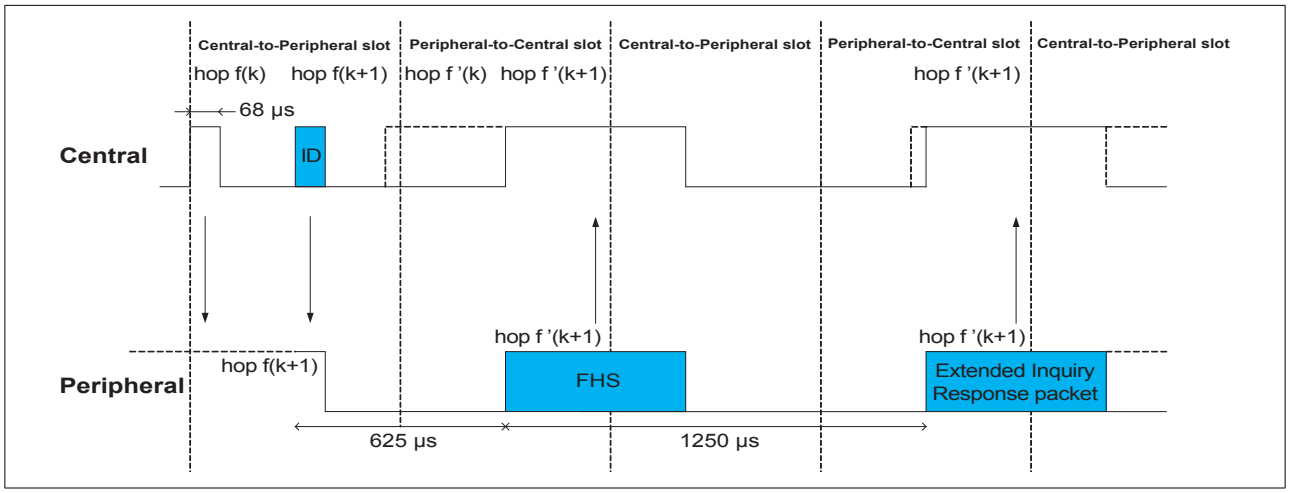

Figure 2.11: Timing of inquiry response packets on successful inquiry in second half slot

2.6 Hop selection

Bluetooth devices shall use the hopping kernel as defined in the following sections.

In total, six types of hopping sequence are defined – five for the basic hop system and one for an adapted set of hop locations used by adaptive frequency hopping (AFH). These sequences are:

- A page hopping sequence with 32 wake-up frequencies distributed equally over the 79 MHz, with a period length of 32.

- A page response hopping sequence covering 32 response frequencies that are in a one-to-one correspondence to the current page hopping sequence. The Central and Peripheral use different rules to obtain the same sequence.
- An inquiry hopping sequence with 32 wake-up frequencies distributed equally over the 79 MHz, with a period length of 32.
- An inquiry response hopping sequence covering 32 response frequencies that are in a one-to-one correspondence to the current inquiry hopping sequence.
- A basic channel hopping sequence which has a very long period length, which does not show repetitive patterns over a short time interval, and which distributes the hop frequencies equally over the 79 MHz during a short time interval.
- An adapted channel hopping sequence derived from the basic channel hopping sequence which uses the same channel mechanism and may use fewer than 79 frequencies. The adapted channel hopping sequence is only used in place of the basic channel hopping sequence. All other hopping sequences are not affected by hop sequence adaptation.

In addition, a set of synchronization train RF channels with 3 fixed frequencies is defined.

2.6.1 General selection scheme

The selection scheme consists of two parts:

- selecting a sequence;
- mapping this sequence onto the hop frequencies.

The general block diagram of the hop selection scheme is shown in Figure 2.12. The mapping from the input to a particular RF channel index is performed in the selection box.

The inputs to the selection box are the selected clock, frozen clock, N, k_{offset}, interlace_offset, address, sequence selection and AFH_channel_map. The source of the clock input depends on the hopping sequence selected. Additionally, each hopping sequence uses different bits of the clock (see Table 2.2). N, interlace_offset, and k_{offset} are defined in Section 2.6.4.

The *sequence selection* input can be set to the following values:

- page scan
- inquiry scan
- page

- inquiry
- Central page response
- Peripheral page response
- inquiry response
- basic channel
- adapted channel

The address input consists of 28 bits as specified in Table 2.3 (see Section 2.6.4). The hopping sequence is selected by the sequence selection input to the selection box.

When the adapted channel hopping sequence is selected, the *AFH_channel_map* is an additional input to the selection box. The *AFH_channel_map* indicates which channels shall be *used* and which shall be *unused*. These terms are defined in Section 2.6.3.

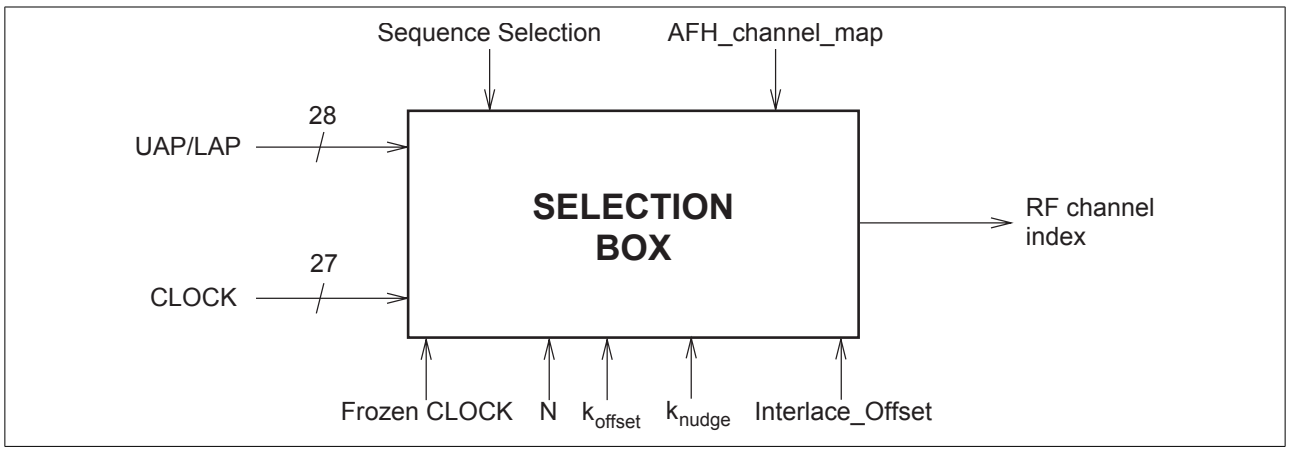

Figure 2.12: General block diagram of hop selection scheme

The output, *RF channel index*, constitutes a pseudo-random sequence. The RF channel index is mapped to RF channel frequencies using the equation in [Vol 2] Part A, Table 2.1.

The selection scheme chooses a segment of 32 hop frequencies spanning about 64 MHz and visits these hops in a pseudo-random order. Next, a different 32-hop segment is chosen, etc. In the page, Central page response, Peripheral page response, page scan, inquiry, inquiry response and inquiry scan hopping sequences, the same 32-hop segment is used all the time (the segment is selected by the address; different devices will have different paging segments). When the basic channel hopping sequence is selected, the output constitutes a pseudo-random sequence that slides through the 79 hops. The principle is depicted in Figure 2.13.

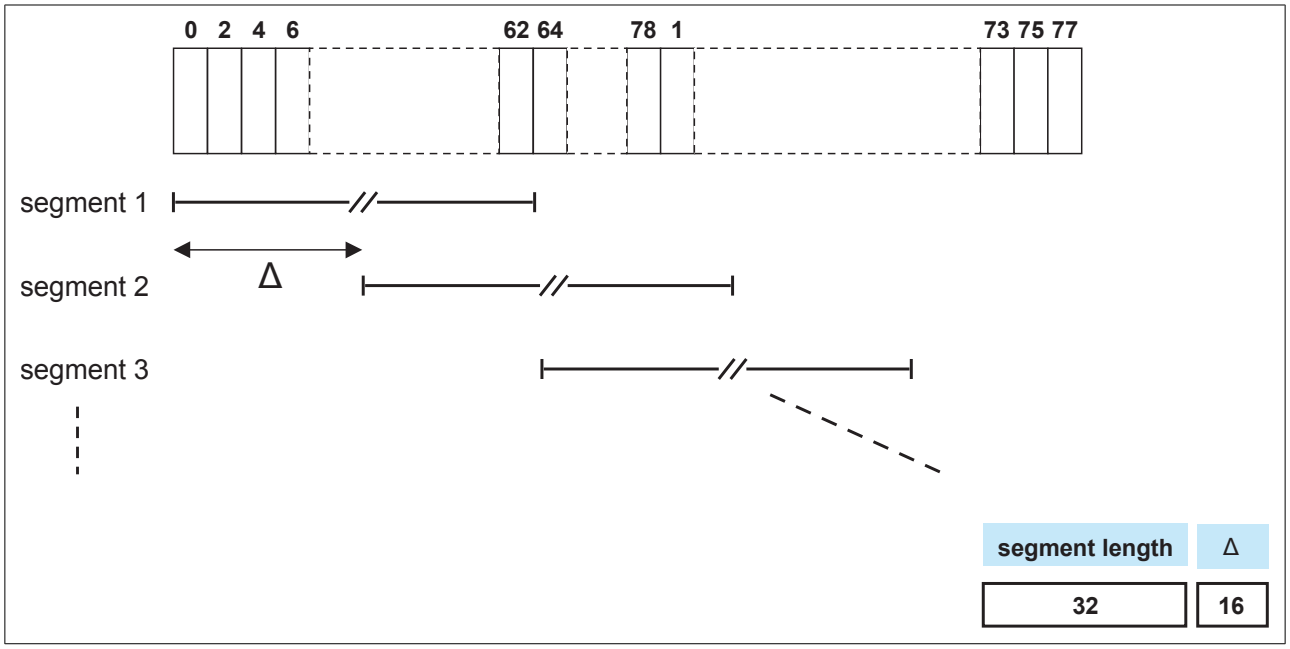

Figure 2.13: Hop selection scheme in Connection state

The RF frequency shall remain fixed for the duration of the packet. The RF frequency for the packet shall be derived from the Bluetooth clock value in the first slot of the packet. The RF frequency in the first slot after a multi-slot packet shall use the frequency as determined by the Bluetooth clock value for that slot. Figure 2.14 illustrates the hop definition on single- and multi-slot packets.

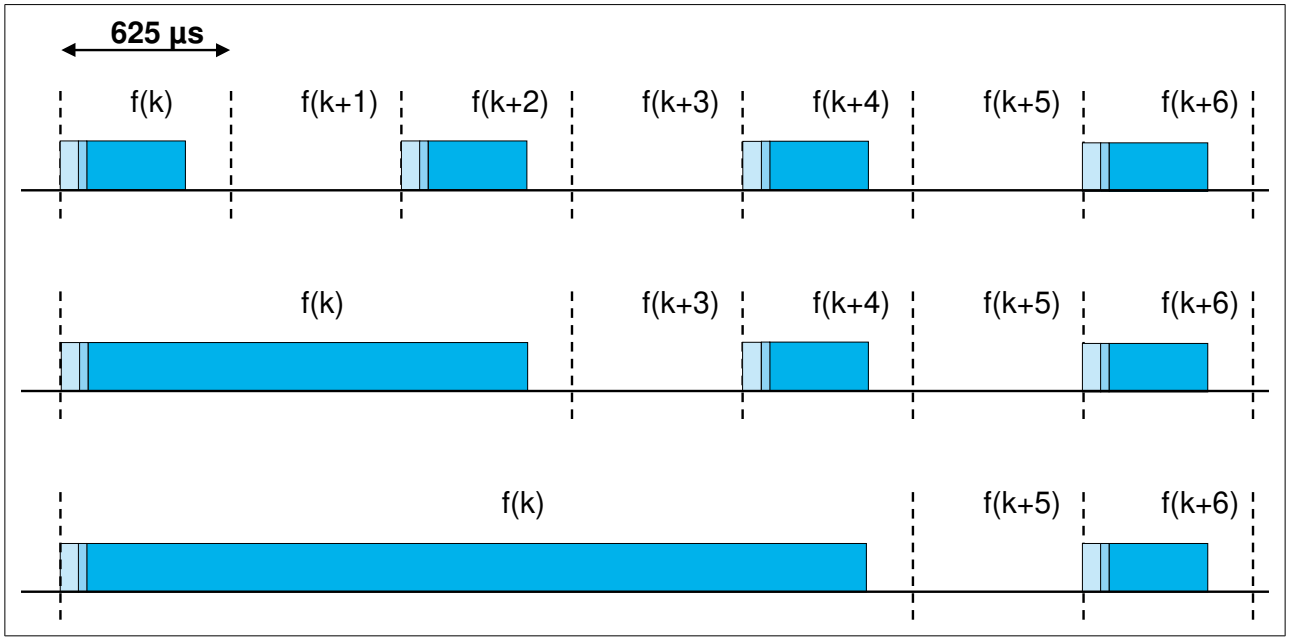

Figure 2.14: Single- and multi-slot packets

When the adapted channel hopping sequence is used, the pseudo-random sequence contains only frequencies that are in the RF channel set defined by the *AFH_channel_map* input. The adapted sequence has similar statistical properties to the non-adapted hop sequence. In addition, the Peripheral responds with its packet on the same RF channel that was used by the Central to address that Peripheral (or would have been in the case of a synchronous reserved slot without a validly received Central-to-Peripheral transmission). This is called the *same channel mechanism* of AFH. Thus, the RF channel used for the Central to Peripheral packet is also used for the immediately following Peripheral to Central packet. An example of the same channel mechanism is illustrated in Figure 2.15. The same channel mechanism shall be used whenever the adapted channel hopping sequence is selected.

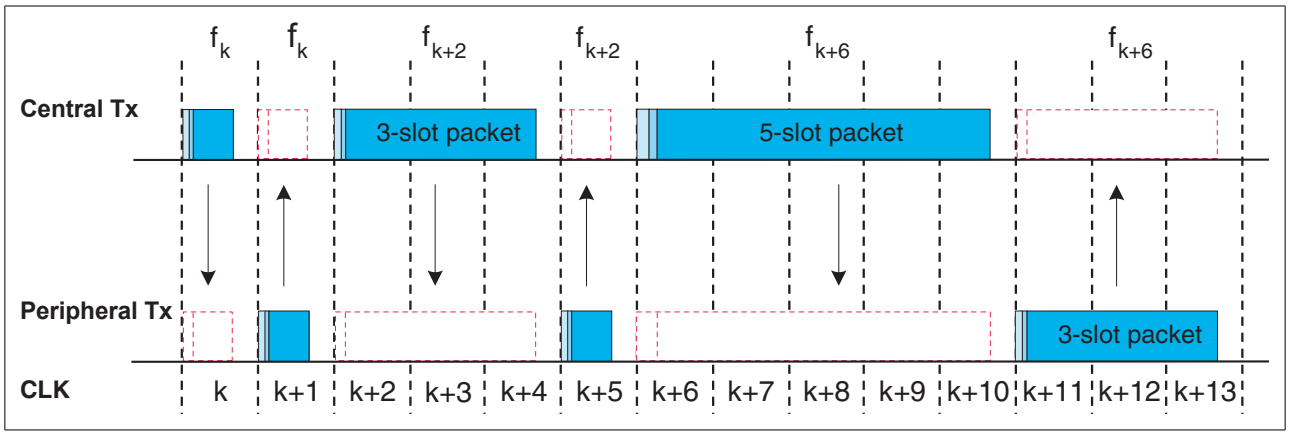

Figure 2.15: Example of the same channel mechanism

2.6.2 Selection kernel

The basic hop selection kernel shall be as shown in Figure 2.16 and is used for the page, page response, inquiry, inquiry response and basic channel hopping selection kernels. In these substates the AFH_channel_map input is unused. The adapted channel hopping selection kernel is described in Section 2.6.3. The X input determines the phase in the 32-hop segment, whereas Y1 and Y2 selects between Central-to-Peripheral and Peripheral-to-Central. The inputs A to D determine the ordering within the segment, the inputs E and F determine the mapping onto the hop frequencies. The kernel addresses a register containing the RF channel indices. This list is ordered so that first all even RF channel indices are listed and then all odd hop frequencies. In this way, a 32-hop segment spans about 64 MHz.

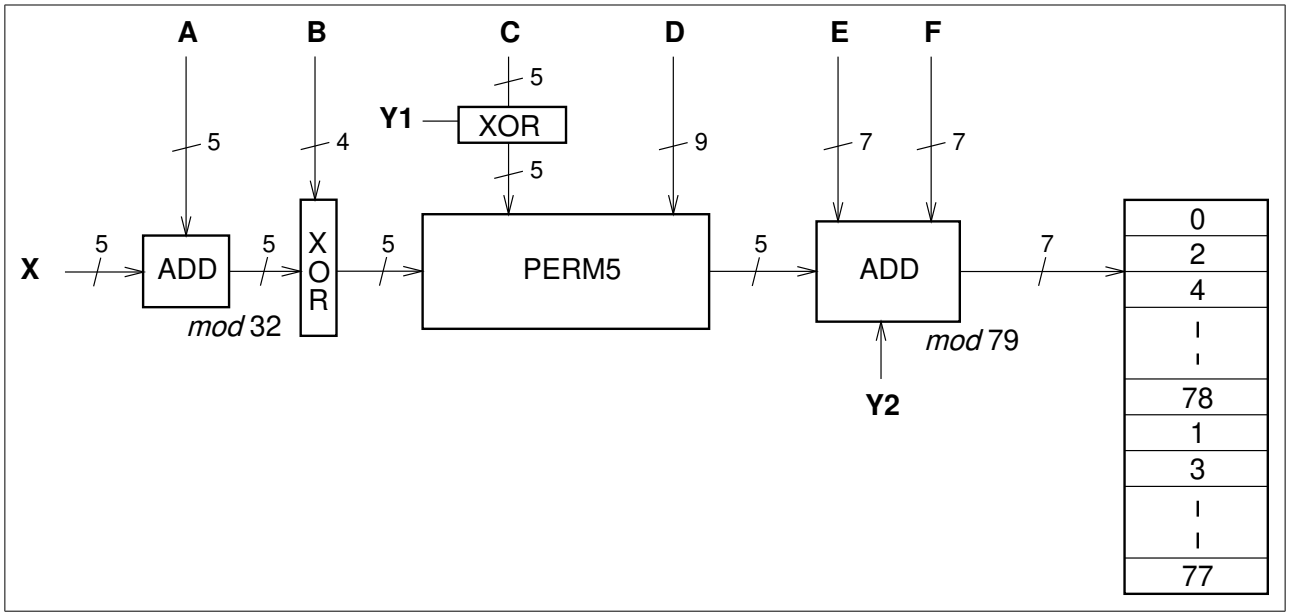

Figure 2.16: Block diagram of the basic hop selection kernel for the hop system

The selection procedure consists of an addition, an XOR operation, a permutation operation, an addition, and finally a register selection. In Section 2.6.2 and Table 2.2, the notation A_i is used for bit i of the BD_ADDR.

2.6.2.1 First addition operation

The first addition operation only adds a constant to the phase and applies a *mod* 32 operation. For the page hopping sequence, the first addition is redundant since it only changes the phase within the segment. However, when different segments are concatenated (as in the basic channel hopping sequence), the first addition operation will have an impact on the resulting sequence.

2.6.2.2 XOR operation

In the XOR operation, the four LSBs of the output of the first addition (designated Z′ here) are XORed with the address bits $A_{22\text{-}19}$, while the Z'_4 bit is left unaltered. The operation is illustrated in Figure 2.17.

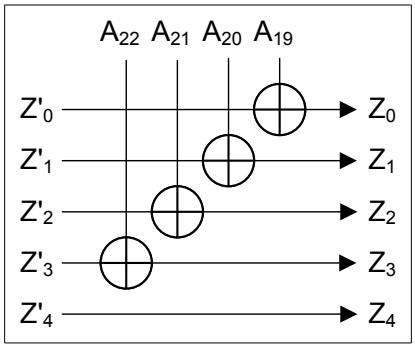

Figure 2.17: XOR operation for the hop system

2.6.2.3 Permutation operation

The permutation operation involves the switching from 5 inputs to 5 outputs for the hop system, controlled by the control word. The permutation or switching box shall be as shown in Figure 2.18. It consists of 7 stages of butterfly operations. The control of the butterflies by the control signals P is shown in Table 2.1. $P_{0\text{-}8}$ corresponds to $D_{0\text{-}8}$, and, P_{i+9} corresponds to $C_i \oplus Y1$ for $i = 0 \ldots 4$ in Figure 2.16.

Control signal	Butterfly
P_0	$\{Z_0,Z_1\}$
P_1	$\{Z_2,Z_3\}$
P_2	$\{Z_1,Z_2\}$
P_3	$\{Z_3,Z_4\}$
P_4	$\{Z_0,Z_4\}$
P_5	$\{Z_1,Z_3\}$
P_6	$\{Z_0,Z_2\}$

Control signal	Butterfly
P_7	$\{Z_3,Z_4\}$
P_8	$\{Z_1,Z_4\}$
P_9	$\{Z_0,Z_3\}$
P_{10}	$\{Z_2,Z_4\}$
P_{11}	$\{Z_1,Z_3\}$
P_{12}	$\{Z_0,Z_3\}$
P_{13}	$\{Z_1,Z_2\}$

Table 2.1: Control of the butterflies for the hop system

The Z input is the output of the XOR operation as described in the previous section. The butterfly operation can be implemented with multiplexers as depicted in Figure 2.19.

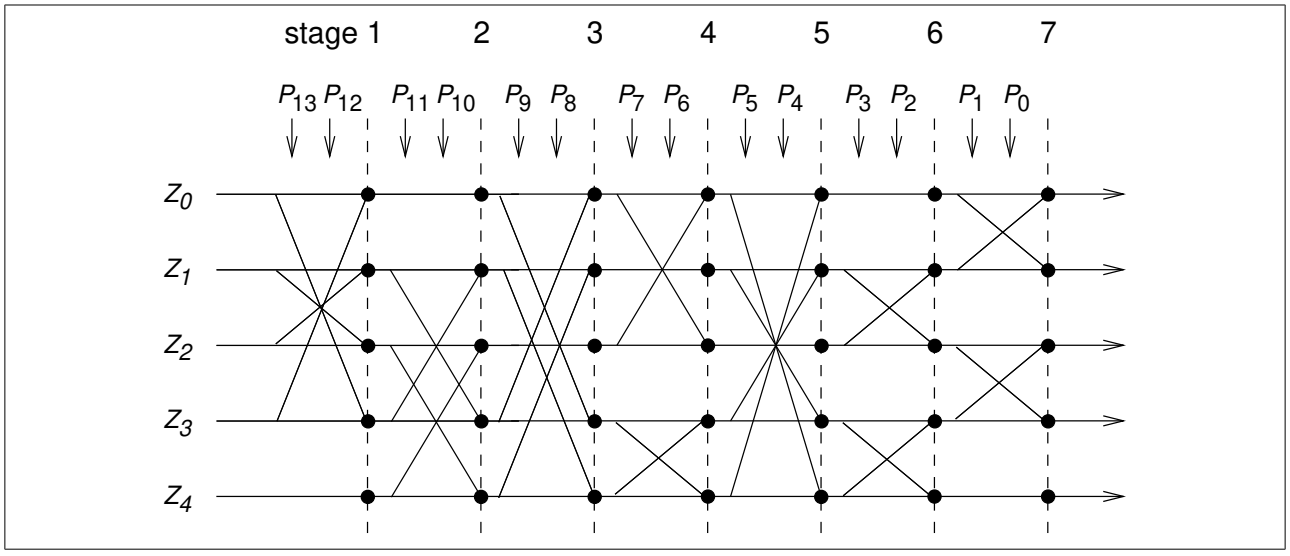

Figure 2.18: Permutation operation for the hop system

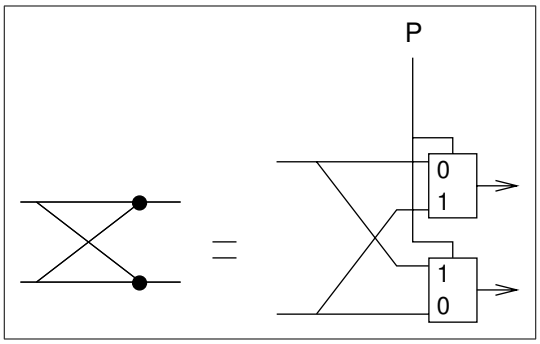

Figure 2.19: Butterfly implementation

2.6.2.4 Second addition operation

The addition operation selects the hop frequencies to be used by the current segment and also switches between Central-to-Peripheral and Peripheral-to-Central. It adds the output of the current permutation (which selects a channel within the segment), a constant, the clock bit selecting Central or Peripheral slots, and a value used to switch each segment to a new set of channels in Connection state. The addition is applied *mod* 79.

2.6.2.5 Register bank

The output of the adder addresses a bank of 79 registers. The registers are loaded with the synthesizer code words corresponding to the hop frequencies 0 to 78.

The upper half of the bank contains the even hop frequencies, whereas the lower half of the bank contains the odd hop frequencies.

2.6.3 Adapted hop selection kernel

The adapted hop selection kernel is based on the basic hop selection kernel defined in the preceding sections.

The inputs to the adapted hop selection kernel are the same as for the basic hop system kernel except that the input *AFH_channel_map* (defined in Link Manager Protocol [Vol 2] Part C, Section 5.2) is used. The *AFH_channel_map* indicates which RF channels shall be *used* and which shall be *unused*. When hop sequence adaptation is enabled, the number of *used* RF channels may be reduced from 79 to some smaller value N. All devices shall be capable of operating on an adapted hop sequence (AHS) with $N_{min} \leq N \leq 79$, with any combination of *used* RF channels within the *AFH_channel_map* that meets this constraint. N_{min} is defined in Section 2.3.1.

Adaptation of the hopping sequence is achieved through two additions to the basic channel hopping sequence according to Figure 2.16:

- *Unused* RF channels are re-mapped uniformly onto *used* RF channels. That is, if the hop selection kernel of the basic system generates an *unused* RF channel, an alternative RF channel out of the set of *used* RF channels is selected pseudo-randomly.
- The *used* RF channel generated for the Central-to-Peripheral packet is also used for the immediately following Peripheral-to-Central packet (see Section 2.6.1).

2.6.3.1 Channel re-mapping function

When the adapted hop selection kernel is selected, the basic hop selection kernel according to Figure 2.16 is initially used to determine an RF channel. If this RF channel is *unused* according to the *AFH_channel_map*, the *unused* RF channel is re-mapped by the re-mapping function to one of the *used* RF channels. If the RF channel determined by the basic hop selection kernel is already in the set of *used* RF channels, no adjustment is made. The hop sequence of the (non-adapted) basic hop equals the sequence of the adapted selection kernel on all locations where *used* RF channels are generated by the basic hop. This property facilitates all Peripherals remaining synchronized even if they are not all using the same hopping sequence.

A block diagram of the re-mapping mechanism is shown in Figure 2.20. The re-mapping function is a post-processing step to the selection kernel from Figure 2.16, denoted as ‘Hop selection of the basic hop’. The output f_k of the basic hop selection kernel is an RF channel number that ranges between 0 and 78. This RF channel will either be in the set of *used* RF channels or in the set of *unused* RF channels.

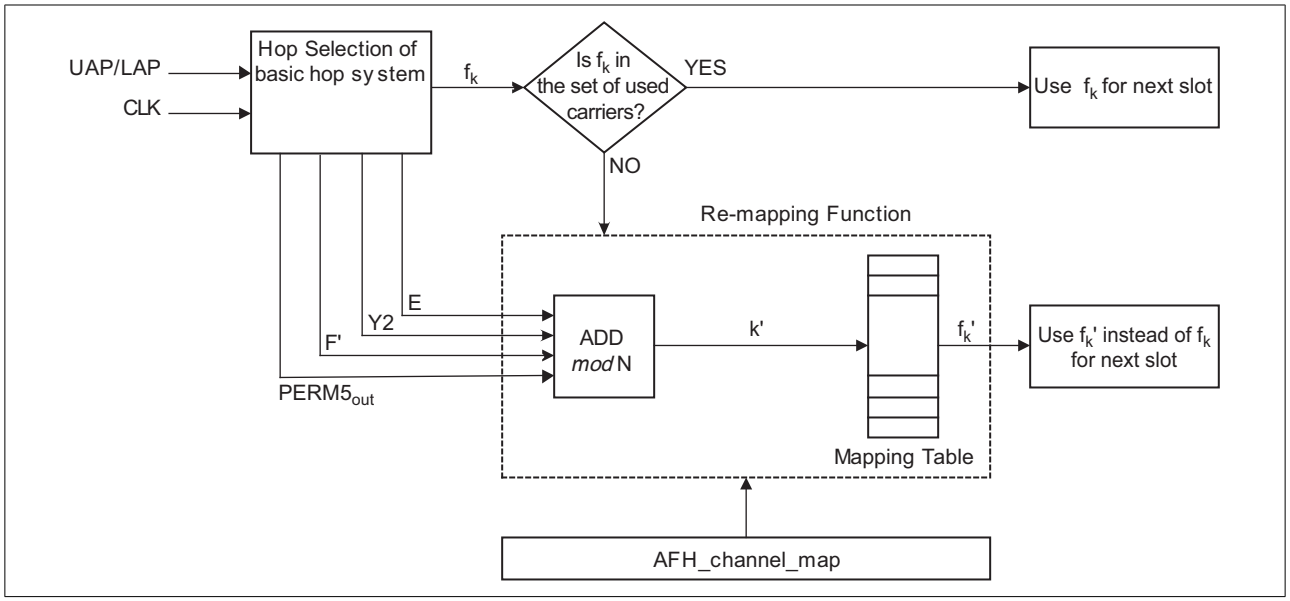

Figure 2.20: Block diagram of adaptive hop selection mechanism

When an unused RF channel is generated by the basic hop selection mechanism, it is re-mapped to the set of *used* RF channels as follows. A new index *k'* ∈ {0, 1,..., *N*-1} is calculated using some of the parameters from the basic hop selection kernel:

$$k' = (PERM5_{out} + E + F' + Y2) \bmod N$$

where *F'* is defined in Table 2.2. The index *k'* is then used to select the re-mapped channel from a mapping table that contains all of the even *used* RF channels in ascending order followed by all the odd *used* RF channels in ascending order (i.e., the mapping table of Figure 2.16 with all the *unused* RF channels removed).

2.6.4 Control word

The control word of the kernel is controlled by the overall control signals X, Y1, Y2, A to F, and F' as illustrated in Figure 2.16 and Figure 2.20. During paging and inquiry, the inputs A to E use the address values as given in the corresponding columns of Table 2.2. In addition, the inputs X, Y1 and Y2 are used. The F and F' inputs are unused. The clock bits $CLK_{6\text{-}2}$ (i.e., input X) specify the phase within the length 32 sequence. CLK_1 (i.e., inputs Y1 and Y2) is used to select between TX and RX. The address inputs determine the sequence order within segments. The final mapping onto the hop frequencies is determined by the register contents.

During the Connection state (see Section 8.5), the inputs A, C and D shall be derived from the address bits being bit-wise XORed with the clock bits as shown in the "Connection state" column of Table 2.2 (the two most significant bits, MSBs, are XORed together, the two second MSBs are XORed together, etc.).

	(a) Page scan **(b) Generalized Interlaced Page Scan** **(c) Inquiry scan** **(d) Generalized Interlaced Inquiry Scan**	**(e) Page** **(f) Inquiry**	**(g) Central page response** **(h) Peripheral page response** **(k) Inquiry response**	**Connection state**
X	(a) $CLKN_{16-12}$ (b) ($CLKN_{16-12}$ + interlace offset) *mod* 32 (c) Xir_{4-0} (d) (Xir_{4-0} + interlace offset) *mod* 32	(e) Xp_{4-0} (f) Xi_{4-0}	(g) $Xprc_{4-0}$ (h) $Xprp_{4-0}$ (k) Xir_{4-0}	CLK_{6-2}
Y1	0	(e) $CLKE_1$ (f) $CLKN_1$	(g) $CLKE_1$ (h) $CLKN_1$ (k) 1	CLK_1
Y2	32 × Y1			
A	A_{27-23}			$A_{27-23} \oplus CLK_{25-21}$
B	A_{22-19}			
C	$A_{8,6,4,2,0}$			$A_{8,6,4,2,0} \oplus CLK_{20-16}$
D	A_{18-10}			$A_{18-10} \oplus CLK_{15-7}$
E	$A_{13,11,9,7,5,3,1}$			
F	0			16 × CLK_{27-7} *mod* 79
F’	n/a			16 × CLK_{27-7} *mod N*

Table 2.2: Control for hop system

The five X input bits vary depending on the current state of the device. In the Page Scan and Inquiry Scan substates, the native clock (CLKN) shall be used. In Connection state the Central's clock (CLK) shall be used as input. The situation is somewhat more complicated for the other states.

The address bits A_0 to A_{27} depend on the sequence selection input as specified in Table 2.3.

Sequence	**$A_{23–0}$**	**$A_{27–24}$**
Page scan Page Central page response Peripheral page response	LAP of the device being paged	$UAP_{3–0}$ of the device being paged
Inquiry scan Inquiry Inquiry response	GIAC (0x9E8B33)	DCI (0x00)

Sequence	$A_{23–0}$	$A_{27–24}$
Basic channel Adapted channel	LAP of the Central	$UAP_{3–0}$ of the Central

Table 2.3: Address bits for each sequence selection input

2.6.4.1 Page scan and inquiry scan hopping sequences

For the transmitted access code and in the receiver correlator, the appropriate GIAC or DIAC shall be used. The application decides which inquiry access code to use depending on the purpose of the inquiry.

2.6.4.2 Page hopping sequence

When the sequence selection input is set to page, the paging device shall start using the **A**-train, i.e., $(f(k-8), \ldots, f(k), \ldots, f(k+7))$, where *f*(*k*) is the source's estimate of the current receiver frequency in the paged device. The index *k* is a function of all the inputs in Figure 2.16. There are 32 possible paging frequencies within each 1.28 second interval. Half of these frequencies belong to the **A**-train, the rest (i.e., $(f(k+8), \ldots, f(k+15), f(k-16), \ldots, f(k-9))$) belong to the **B**-train. In order to achieve the -8 offset of the **A**-train, a constant of 24 shall be added to the clock bits (which is equivalent to -8 due to the *mod* 32 operation). The **B**-train is obtained by setting the offset to 8. In the case where slots to receive the first Peripheral response are periodically not available, an additional offset (k_{nudge}) is added to the clock bits in order to shift the train by an integer multiple of 1.25 ms duration. A cyclic shift of the order within the trains is also necessary in order to avoid a possible repetitive mismatch between the paging and scanning devices. Thus,

$$Xp = \left[\mathrm{CLKE}_{16-12} + k_{offset} + k_{nudge} + (\mathrm{CLKE}_{4-2,0} - \mathrm{CLKE}_{16-12} + 32) \ \ mod\ 16\right] \ \ mod\ 32, \quad \text{(EQ 2)}$$

where

$$k_{offset} = \begin{cases} 24 & \text{A-train,} \\ 8 & \text{B-train.} \end{cases} \quad \text{(EQ 3)}$$

$$k_{nudge} = \begin{cases} 0 & \text{During } 1^{st} \ \ 2\times N_{\mathrm{page}} \ \ repetitions \\ \text{Even} & \text{During all other repetitions.} \end{cases} \quad \text{(EQ 4)}$$

Alternatively, each switch between the **A-** and **B-**trains may be accomplished by adding 16 to the current value of k_{offset} (originally initialized with 24).

2.6.4.3 Peripheral page response hopping sequence

When the sequence selection input is set to *Peripheral page response,* in order to eliminate the possibility of losing the link due to discrepancies of the native clock CLKN

and the Central's clock estimate CLKE, the five bits $CLKN_{16\text{-}12}$ shall be frozen at their current value. The value shall be frozen at the content it has in the slot where the recipient's access code is detected. The native clock shall *not* be stopped; it is merely the values of the bits used for creating the X-input that are kept fixed for a while. A frozen value is denoted by an asterisk (*) in the discussion below.

For each response slot the paged device shall use an X-input value one larger (*mod* 32) than in the preceding response slot. However, the first response shall be made with the X-input kept at the same value as it was when the access code was recognized. Let *N* be a counter starting at zero. Then, the X-input in the (*N* + 1) -th response slot (the first response slot being the one immediately following the page slot now responding to) of the Peripheral Page Response substate is:

$$Xprp = [\mathrm{CLKN}^*_{16-12} + N] \ \ mod\ 32, \qquad \text{(EQ 5)}$$

The counter *N* shall be set to zero in the slot where the Peripheral acknowledges the page (see Figure 8.3 and Figure 8.4). Then, the value of *N* shall be increased by one each time $CLKN_1$ is set to zero, which corresponds to the start of a Central TX slot. The X-input shall be constructed this way until the first **FHS** packet is received *and* the immediately following response packet has been transmitted. After this the Peripheral shall enter the Connection state using the parameters received in the **FHS** packet.

2.6.4.4 Central page response hopping sequence

When the sequence selection input is set to *Central page response*, the Central shall freeze its estimate of the Peripheral's clock to the value that triggered a response from the paged device. It is equivalent to using the values of the clock estimate when receiving the Peripheral's response (since only $CLKE_1$ will differ from the corresponding page transmission). Thus, the values are frozen when the Peripheral's **ID** packet is received. In addition to the clock bits used, the current values of k_{offset} and k_{nudge} shall also be frozen. The Central shall adjust its X-input in the same way the paged device does, i.e., by incrementing this value by one for each time $CLKE_1$ is set to zero. The first increment shall be done before sending the **FHS** packet to the paged device. Let *N* be a counter starting at one. The rule for forming the X-input is:

$$\begin{aligned} Xprc = [&\mathrm{CLKE}^*_{16-12} + \mathrm{k}^*_{offset} + \mathrm{k}^*_{nudge} + \\ &(\mathrm{CLKE}^*_{4-2,0} - \mathrm{CLKE}^*_{16-12}) \ \ mod\ 16 + N] \ \ mod\ 32, \end{aligned} \qquad \text{(EQ 6)}$$

The value of *N* shall be increased each time $CLKE_1$ is set to zero, which corresponds to the start of a Central TX slot.

2.6.4.5 Inquiry hopping sequence

When the sequence selection input is set to *inquiry*, the X-input is similar to that used in the page hopping sequence. Since no particular device is addressed, the native clock

CLKN of the inquirer shall be used. Moreover, which of the two train offsets to start with is of no real concern in this state. Consequently,

$$Xi = [\mathrm{CLKN}_{16-12} + \mathrm{k}_{offset} + \mathrm{k}_{nudge} + (\mathrm{CLKN}_{4-2,0} - \mathrm{CLKN}_{16-12}) \ mod\ 16] \ \ mod\ 32 \quad \text{(EQ 7)}$$

where k_{offset} and k_{nudge} are defined by (EQ 3) and (EQ 4).

The initial choice of k_{offset} is arbitrary.

2.6.4.6 Inquiry response hopping sequence

The inquiry response hopping sequence is similar to the Peripheral page response hopping sequence with respect to the X-input. The clock input shall not be frozen, thus the following equation applies:

$$Xir = [\mathrm{CLKN}_{16-12} + N] \ \ mod\ \ 32, \quad \text{(EQ 8)}$$

Furthermore, the counter *N* is increased not on CLKE_1 basis, but rather after each **FHS** packet has been transmitted in response to the inquiry. There is no restriction on the initial value of *N* as it is independent of the corresponding value in the inquiring unit.

The X_{ir} value used for the extended inquiry response packet shall be the same X_{ir} value as calculated for the immediately preceding FHS packet.

2.6.4.7 Basic and adapted channel hopping sequence

In the basic and adapted channel hopping sequences, the clock bits to use in the basic or adapted hopping sequence generation shall always be derived from the Central's clock, CLK.

2.6.4.8 Synchronization train RF channels

The synchronization train and synchronization scan use RF channels from the set of three fixed RF channels with indices 0, 24, and 78.

2.7 Synchronization scan physical channel

The synchronization scan physical channel enables devices to receive synchronization train packets.

2.7.1 Hopping characteristics

When a device enters the Synchronization Scan substate, it shall scan the synchronization train RF channels using the timing defined in Section 2.7.3. Each individual scan window shall use a different RF channel than the previous two scan windows.

The synchronization scan physical channel shall use all of the synchronization train RF channels defined in Section 2.6.4.8.

2.7.2 Synchronization Train procedure timing

The Central shall use the synchronization train procedure only when Connectionless Peripheral Broadcast mode is enabled or during the Coarse Clock Adjustment Recovery Mode (Section 8.6.10.2); these can happen concurrently. During the synchronization train procedure, the Central shall attempt to transmit synchronization train packets on all of the RF channels specified in Section 2.6.4.8. The transmission of synchronization train packets on each RF channel is independent of the transmission on other RF channels. For each RF channel, the Central shall:

1. Establish synchronization train events that are separated by $T_{Sync\_Train\_Interval}$ slots. During Coarse Clock Adjustment Recovery Mode the value of $T_{Sync\_Train\_Interval}$ shall be 32. At all other times, it shall be the value selected by the Controller from a range provided by the Host ([Vol 4] Part E, Section 7.3.90).
2. Attempt to send a synchronization train packet between each pair of synchronization train events.
3. In the absence of scheduling conflicts, delay the start of the synchronization train packet transmission by $T_{Sync\_Train\_Delay}$ slots from the synchronization train event, where $T_{Sync\_Train\_Delay}$ is a (pseudo-)random number between 0 and $T_{Sync\_Train\_Delay\_Max}$. Each value of $T_{Sync\_Train\_Delay}$ shall be an even integer. $T_{Sync\_Train\_Delay\_Max}$ shall equal 4 slots during Coarse Clock Adjustment Recovery Mode and 16 slots at all other times. Each synchronization packet transmission shall start at the beginning of a time slot where CLK[1:0]=0b00.
4. If the transmission of the synchronization train packet conflicts with the timing of higher priority packets, the actual delay may be adjusted to avoid the conflict. The actual delay should stay within the range 0 to $T_{Sync\_Train\_Delay\_Max}$ and shall not be greater than or equal to $T_{Sync\_Train\_Interval}$. If it is not possible to transmit the complete packet before the next synchronization train event, it shall not be transmitted.

   Increasing the delay beyond the recommended range (0 to $T_{Sync\_Train\_Delay\_Max}$) increases the chance that the scanning device will miss the packet.
5. There shall be no more than one synchronization train packet transmitted between any two consecutive synchronization train events.
6. The actual delays used shall not all be the same for any three consecutive synchronization train packets (though any two may be).

Note: Subject to the above requirements, synchronization train events on different RF channels may be managed separately or may be co-ordinated using the same value of $T_{Sync\_Train\_Delay}$.

Figure 2.21 shows the timing relationship of consecutive synchronization train packets on a single RF channel.

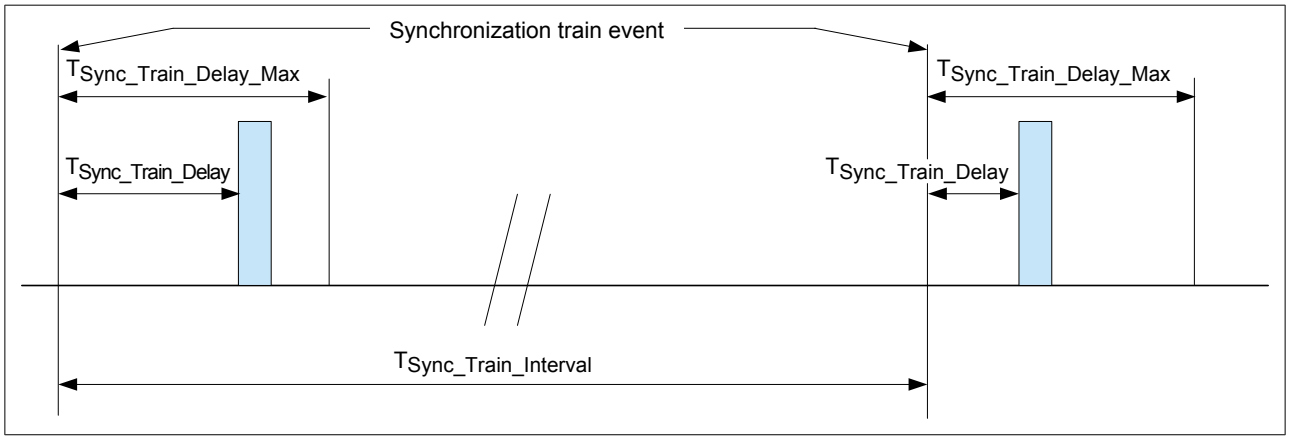

Figure 2.21: Synchronization train packet timing on a single channel

2.7.3 Synchronization Scan procedure timing

During the Synchronization Scan procedure, a device performs synchronization scans on the synchronization train RF channels. During each scan window, the device listens for the duration of $T_{Sync\_Scan\_Window}$. The RF channel for each scan window shall be selected as specified in Section 2.7.1. Each scan window should be continuous and not interrupted by other activities. The interval between the start of consecutive scan windows shall be equal to $T_{Sync\_Scan\_Interval}$. The values for $T_{Sync\_Scan\_Window}$ and $T_{Sync\_Scan\_Interval}$ shall be chosen as follows:

- During Connectionless Peripheral Broadcast, refer to [Vol 4] Part E, Section 7.1.52.
- During Coarse Clock Adjustment Recovery Mode, the values chosen are implementation specific.

This timing relationship is shown in Figure 2.22.

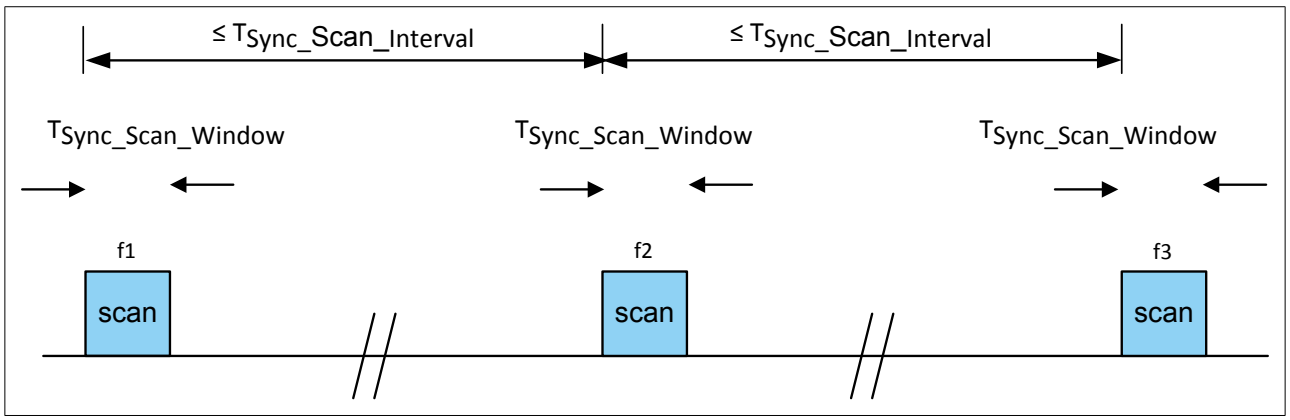

Figure 2.22: Synchronization scan timing

3 PHYSICAL LINKS

A physical link represents a Baseband connection between devices. A physical link is always associated with exactly one physical channel. Physical links have common properties that apply to all logical transports on the physical link.

Other than the Connectionless Peripheral Broadcast physical link, common properties of physical links are:

- Power control (see [Vol 2] Part C, Section 4.1.3)
- Link supervision (see Section 3.1 and [Vol 2] Part C, Section 4.1.6)
- Encryption (see [Vol 2] Part H, Section 4 and [Vol 2] Part C, Section 4.2.5)
- Channel quality-driven data rate change (see [Vol 2] Part C, Section 4.1.7)
- Multi-slot packet control (see [Vol 2] Part C, Section 4.1.10)

and for physical links on the adapted piconet physical channel:

- AFH channel map (see Section 2.3 and [Vol 2] Part C, Section 4.1.4)

The Connectionless Peripheral Broadcast physical link is associated with the BR/EDR adapted piconet physical channel, a single logical transport (the CPB logical transport), and does not support the Link Manager protocol. For information on link supervision on Connectionless Peripheral Broadcast physical links, see Section 3.2. Multi-slot packets on Connectionless Peripheral Broadcast physical links are controlled by the Host and specified at the profile level.

3.1 Link supervision for active physical links

A connection can break down due to various reasons such as a device moving out of range, encountering severe interference or a power failure condition. Since this can happen without any prior warning, it is important to monitor the link on both the Central and the Peripheral side to avoid possible collisions when the logical transport address (see Section 4.2) is reassigned to another Peripheral.

To be able to detect link loss, both the Central and the Peripheral shall use a link supervision timer, $T_{supervision}$. Upon reception of a valid packet header with one of the Peripheral's addresses (see Section 4.2) on the physical link, the timer shall be reset. If at any time in Connection state, the timer reaches the *supervisionTO* value, the connection shall be considered disconnected. The same link supervision timer shall be used for SCO, eSCO, and ACL logical transports.

The timeout period, *supervisionTO*, is negotiated by the Link Manager. Its value shall be chosen so that the supervision timeout will be longer than hold and sniff periods.

3.2 Link supervision for Connectionless Peripheral Broadcast physical links

For Connectionless Peripheral Broadcast physical links, only the Receiver side monitors the link. To detect link loss, the Receiver shall use a link supervision timer, $T_{CPB\_Supervision}$. Each Connectionless Peripheral Broadcast Receiver shall reset the timer upon reception of a Connectionless Peripheral Broadcast packet with a valid packet header. If at any time in Connectionless Peripheral Broadcast mode of the Connection state, the timer reaches the *CPB_supervisionTO* value, the connection shall be considered disconnected.

For each Receiver, the timeout period, *CPB_supervisionTO*, can be provided by the Host (see Section B.1.7).

3.3 Authenticated payload timeout for active links

For active physical links, when encryption is enabled and AES-CCM is used, a device monitors the time between receiving packets from the remote device containing a MIC. To ensure the integrity of the link, an Authenticated Payload timer, $T_{Authenticated\_Payload}$, is used. Each device shall reset the timer upon reception of a packet with a valid MIC. The timer shall not be reset upon the reception of a retransmitted packet. If at any time in the Connection state, the timer reaches the *authenticatedPayloadTO* value, the Host shall be notified. The timeout period, *authenticatedPayloadTO*, shall be provided by the Host.

The device shall reset the timer each time after the Host is notified. The Controller shall reset the timer when the Host writes the *authenticatedPayloadTO* value.

4 LOGICAL TRANSPORTS

4.1 General

Between Central and Peripheral(s), different types of logical transports may be established. Five logical transports have been defined:

- Synchronous Connection-Oriented (SCO) logical transport
- Extended Synchronous Connection-Oriented (eSCO) logical transport
- Asynchronous Connection-Oriented (ACL) logical transport
- Active Peripheral Broadcast (APB) logical transport
- Connectionless Peripheral Broadcast (CPB) logical transport.

The synchronous logical transports are point-to-point logical transports between a Central and a single Peripheral in the piconet. The synchronous logical transports typically support time-bounded information like voice or general synchronous data. The Central maintains the synchronous logical transports by using reserved slots at regular intervals. In addition to the reserved slots the eSCO logical transport may have a retransmission window after the reserved slots.

The ACL logical transport is also a point-to-point logical transport between the Central and a Peripheral. In the slots not reserved for synchronous logical transport(s), the Central can establish an ACL logical transport on a per-slot basis to any Peripheral, including the Peripheral(s) already engaged in a synchronous logical transport.

The APB logical transport is used by a Central to communicate with active Peripherals.

The CPB logical transport is used by a Central to send profile broadcast data to zero or more Peripherals.

4.2 Logical transport address (LT_ADDR)

Each Peripheral active in a piconet is assigned a primary 3-bit logical transport address (LT_ADDR). The all-zero LT_ADDR is reserved for APB broadcast messages. The CPB logical transport uses a single non-zero LT_ADDR. The Central does not have an LT_ADDR. A Central's timing relative to the Peripherals' distinguishes it from the Peripherals. A secondary LT_ADDR is assigned to the Peripheral for each eSCO logical transport in use in the piconet. The secondary LT_ADDR shall not be 0. Only eSCO traffic (i.e. NULL, POLL, and one of the EV packet types as negotiated at eSCO logical transport setup) may be sent on these LT_ADDRs. ACL traffic (including LMP) shall always be sent on the primary LT_ADDR. A Peripheral shall only accept packets with

matching primary or secondary LT_ADDR and broadcast packets. The LT_ADDR is carried in the packet header (see Section 6.4). The LT_ADDR shall only be valid for as long as a Peripheral is connected. As soon as it is disconnected, the Peripheral shall lose all of its LT_ADDRs.

The primary LT_ADDR shall be assigned by the Central to the Peripheral when the Peripheral is activated. This is either at connection establishment or role switch, when the primary LT_ADDR is carried in the **FHS** payload.

At any given time an LT_ADDR (other than the special case of the all-zero LT_ADDR) is either unused or is used for exactly one of the three purposes of the primary address for a Peripheral, a secondary address for eSCO traffic, or for a CPB logical transport. Therefore allocating a secondary LT_ADDR for an eSCO logical transport, or reserving an LT_ADDR for the CPB logical transport, reduces the maximum number of active Peripherals possible in the piconet.

4.3 Synchronous logical transports

The first type of synchronous logical transport, the SCO logical transport, is a symmetric, point-to-point transport between the Central and a specific Peripheral. The SCO logical transport reserves slots and can therefore be considered as a circuit-switched connection between the Central and the Peripheral. The Central may support up to three SCO links to the same Peripheral or to different Peripherals. A Peripheral may support up to three SCO links from the same Central, or two SCO links if the links originate from different Centrals. SCO packets are never retransmitted.

The second type of synchronous logical transport, the eSCO logical transport, is a point-to-point logical transport between the Central and a specific Peripheral. eSCO logical transports may be symmetric or asymmetric. Similar to SCO, eSCO reserves slots and can therefore be considered a circuit-switched connection between the Central and the Peripheral. In addition to the reserved slots, eSCO supports a retransmission window immediately following the reserved slots. Together, the reserved slots and the retransmission window form the complete eSCO window.

4.4 Asynchronous logical transport

In the slots not reserved for synchronous logical transports, the Central may exchange packets with any Peripheral on a per-slot basis. The ACL logical transport provides a packet-switched connection between the Central and all active Peripherals participating in the piconet. Both asynchronous and isochronous services are supported. Only a single ACL logical transport shall exist between any two devices. For most ACL packets, packet retransmission is applied to assure data integrity.

ACL packets not addressed to a specific Peripheral (LT_ADDR=0) are considered as broadcast packets and should be received by every Peripheral except Peripherals with

only a CPB logical transport. If there is no data to be sent on the ACL logical transport and no polling is required, no transmission is required.

4.5 Transmit/receive routines

This section describes the way to use the packets as defined in Section 6 in order to support the traffic on the ACL, SCO and eSCO logical transports. Both single-Peripheral and multi-Peripheral configurations are considered. In addition, the use of buffers for the TX and RX routines are described.

4.5.1 TX routine

The TX routine is carried out separately for each asynchronous and synchronous logical transport. Figure 4.1 shows the asynchronous and synchronous buffers as used in the TX routine. In this figure, only a single TX asynchronous buffer and a single TX synchronous buffer are shown. In the Central, there is a separate TX asynchronous buffer for each Peripheral. In addition there can be one or more TX synchronous buffers for each synchronous Peripheral (different SCO or eSCO logical transports could either reuse the same TX synchronous buffer, or each have their own TX synchronous buffer). Each TX buffer consists of two FIFO registers: one **current** register which can be accessed and read by the Link Controller in order to compose the packets, and one **next** register that can be accessed by the Baseband Resource Manager to load new information. The positions of the switches S1 and S2 determine which register is current and which register is next; the switches are controlled by the Link Controller. The switches at the input and the output of the FIFO registers can never be connected to the same register simultaneously.

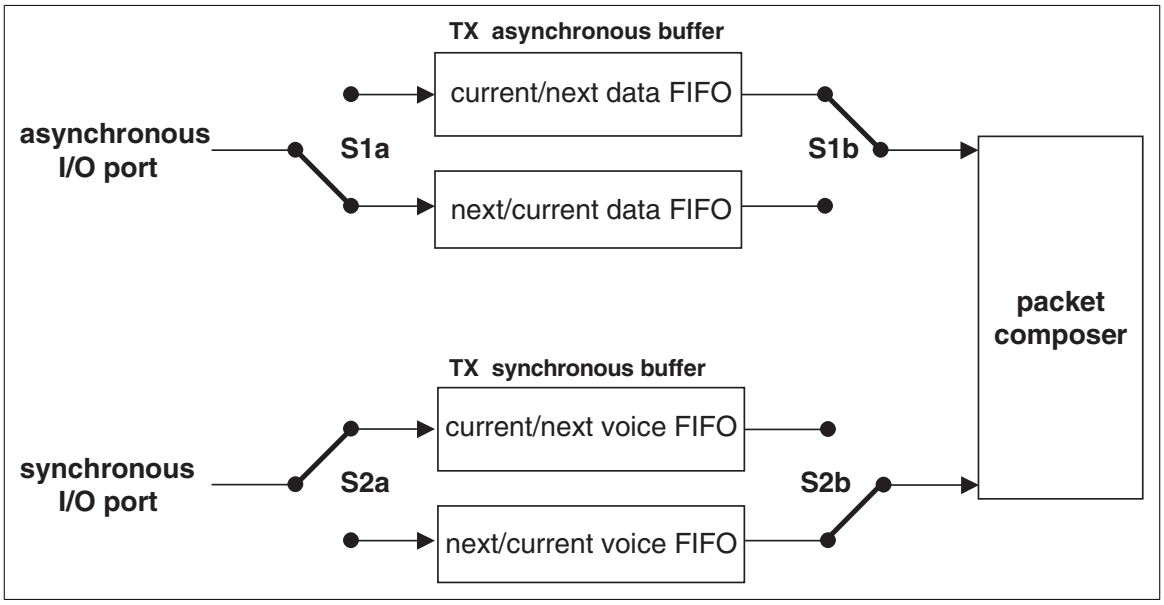

Figure 4.1: Functional diagram of TX buffering

Of the packets common to the ACL and SCO logical transports (**NULL**, **POLL and DM1**), only the **DM1** packet carries a payload that is exchanged between the Link Controller and the Link Manager; this packet makes use of the asynchronous buffer. All ACL packets make use of the asynchronous buffer. All SCO and eSCO packets make use of the synchronous buffer except for the **DV** packet where the synchronous data part is handled by the synchronous buffer and the data part is handled by the asynchronous buffer. In the next sections, the operation for ACL traffic, SCO traffic, eSCO traffic, and combined data-voice traffic on the SCO logical transport are described.

4.5.1.1 ACL traffic

In the case of asynchronous data only the TX ACL buffer in Figure 4.1 has to be considered. In this case, only packet types **DM** or **DH** are used, and these can have different lengths. The length is indicated in the payload header. The selection of **DM** or **DH** packets should depend on the quality of the link. See [Vol 2] Part C, Section 4.1.7.

The default packet type in pure data traffic is **NULL** (see Section 6.5.1.2). This means that, if there is no data to be sent (the data traffic is asynchronous, and therefore pauses occur in which no data is available) or no Peripherals need to be polled, **NULL** packets are sent instead – in order to send link control information to the other device (e.g. ACK/STOP information for received data). When no link control information is available (either no need to acknowledge and/or no need to stop the RX flow) no packet is sent at all.

The TX routine works as follows. The Baseband Resource Manager loads new data information in the register to which the switch S1a points. Next, it gives a command to the Link Controller, which forces the switch S1 to change (both S1a and S1b switch synchronously). When the payload needs to be sent, the packet composer reads the current register and, depending on the packet type, builds a payload which is appended to the channel access code and the header and is subsequently transmitted. In the response packet (which arrives in the following RX slot if it concerned a Central transmission, or may be postponed until some later RX slot if it concerned a Peripheral transmission), the result of the transmission is reported back. In case of an ACK, the switch S1 changes position; if a NAK (explicit or implicit) is received instead, the switch S1 will not change position. In that case, the same payload is retransmitted at the next TX occasion.

As long as the Baseband Resource Manager keeps loading the registers with new information, the Link Controller will automatically transmit the payload; in addition, retransmissions are performed automatically in case of errors. The Link Controller will send **NULL** or nothing when no new data is loaded. If no new data has been loaded in the **next** register, during the last transmission, the packet composer will be pointing to an empty register after the last transmission has been acknowledged and the **next**

register becomes the **current** register. If new data is loaded in the **next** register, a Flush command is required to switch the S1 switch to the proper register. As long as the Baseband Resource Manager keeps loading the data and type registers before each TX slot, the data is automatically processed by the Link Controller since the S1 switch is controlled by the ACK information received in response. However, if the traffic from the Baseband Resource Manager is interrupted once and a default packet is sent instead, a Flush command is necessary to continue the flow in the Link Controller.

The Flush command may also be used in case of time-bounded (isochronous) data. In case of a bad link, many retransmissions are necessary. In certain applications, the data is time-bounded: if a payload is retransmitted all the time because of link errors, it may become outdated, and the system might decide to continue with more recent data instead and skip the payload that does not come through. This is accomplished by the Flush command as well. With the **flush**, the switch S1 is forced to change and the Link Controller is forced to consider the next data payload and overrules the ACK control. Any ACL type of packet can be used to send data or link control information to any other ACL Peripheral.

4.5.1.2 SCO traffic

On the SCO logical transport only **HV** and **DV** packet types are used, See Section 6.5.2. The synchronous port may continuously load the **next** register in the synchronous buffer. The S2 switches are changed according to the T_{sco} interval. This T_{sco} interval is negotiated between the Central and the Peripheral at the time the SCO logical transport is established.

For each new SCO slot, the packet composer reads the **current** register after which the S2 switch is changed. If the SCO slot has to be used to send control information with high priority concerning a control packet between the Central and the SCO Peripheral, or a control packet between the Central and any other Peripheral, the packet composer will discard the SCO information and use the control information instead. This control information shall be sent in a DM1 packet. Data or link control information may also be exchanged between the Central and the SCO Peripheral by using the **DV** or **DM1** packets.

4.5.1.3 Mixed data/voice traffic

In Section 6.5.2, a **DV** packet has been defined that can support both data and voice simultaneously on a single SCO logical transport. When the TYPE is **DV**, the Link Controller reads the data register to fill the data field and the voice register to fill the voice field. Thereafter, the switch S2 is changed. However, the position of S1 depends on the result of the transmission as on the ACL logical transport: only if an ACK has been received will the S1 switch change its position. In each **DV** packet, the voice information is new, but the data information might be retransmitted if the previous transmission failed. If there is no data to be sent, the SCO logical transport will

automatically change from **DV** packet type to the current **HV** packet type used before the mixed data/voice transmission.

A Flush command is necessary when the data stream has been interrupted and new data has arrived.

Combined data-voice transmission can also be accomplished by using a separate ACL logical transport in addition to the SCO logical transport(s) if channel capacity permits this.

4.5.1.4 eSCO traffic

On the eSCO logical transport only **EV**, **POLL** and **NULL** packet types are used, see Section 6.5.3. The synchronous port may continuously load the next register in the synchronous buffer. The S2 switches are changed according to the T_{eSCO} interval. This T_{eSCO} interval is negotiated between the Central and the Peripheral at the time the eSCO logical transport is established.

For each new eSCO slot, the packet composer reads the current register after which the S2 switch is changed. If the eSCO slot has to be used to send control information with high priority concerning a control packet between the Central and the eSCO Peripheral, or an ACL packet between the Central and any other Peripheral, the packet composer will discard the eSCO information and use the control information instead. Control information to the eSCO Peripheral is sent in a DM1 packet on the primary LT_ADDR.

4.5.1.5 Default packet types

On the ACL links, the default type is always **NULL** both for the Central and the Peripheral. This means that if no user information needs to be sent, either a **NULL** packet is sent if there is **ACK** or **STOP** information, or no packet is sent at all. The **NULL** packet can be used by the Central to allocate the next Peripheral-to-Central slot to a certain Peripheral (namely the one addressed). However, the Peripheral is not forced to respond to the **NULL** packet from the Central. If the Central requires a response, it sends a **POLL** packet.

The SCO and eSCO packet types are negotiated at the LM level when the SCO or eSCO logical transport is established. The agreed packet type is also the default packet type for the reserved SCO or eSCO slots.

4.5.2 RX routine

The RX routine is carried out separately for the ACL logical transport and the synchronous logical transports. However, in contrast to the Central TX asynchronous buffer, a single RX buffer is shared among all Peripherals. For the synchronous buffer, how the different synchronous logical transports are distinguished depends on whether

extra synchronous buffers are required or not. Figure 4.2 shows the asynchronous and synchronous buffers as used in the RX routine. The RX asynchronous buffer consists of two FIFO registers: one register that can be accessed and loaded by the Link Controller with the payload of the latest RX packet, and one register that can be accessed by the Baseband Resource Manager to read the previous payload. The RX synchronous buffer also consists of two FIFO registers: one register which is filled with newly arrived voice information, and one register which can be read by the voice processing unit.

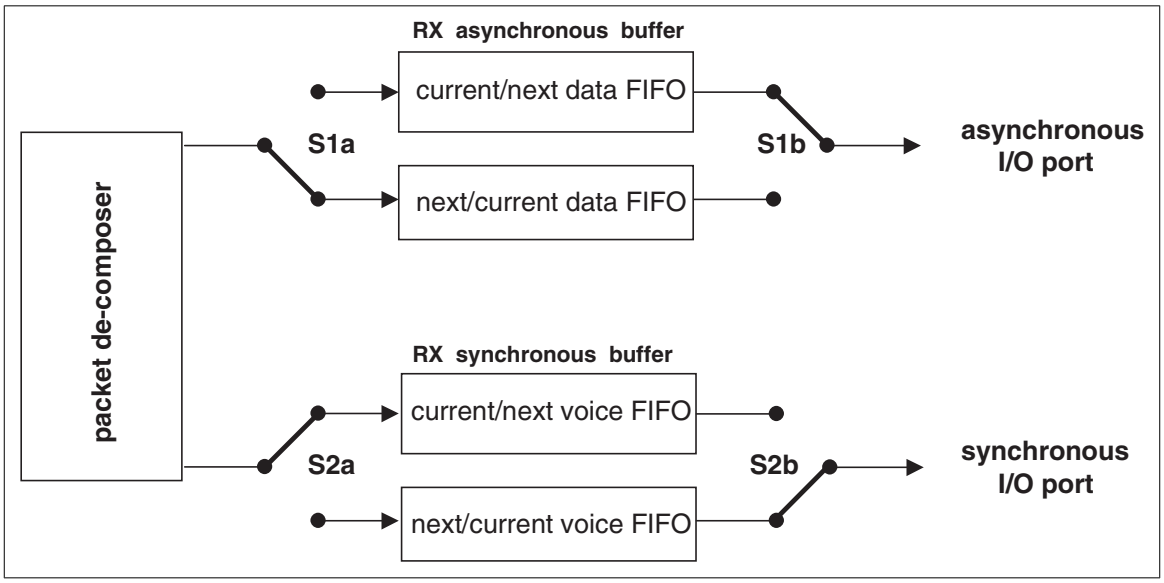

Figure 4.2: Functional diagram of RX buffering

Since the TYPE indication in the header (see Section 6.4.2) of the received packet indicates whether the payload contains data and/or voice, the packet de-composer can automatically direct the traffic to the proper buffers. The switch S1 changes every time the Baseband Resource Manager reads the old register. If the next payload arrives before the RX register is emptied, a STOP indication is included in the packet header of the next TX packet that is returned. The STOP indication is removed again as soon as the RX register is emptied. The SEQN field is checked before a new ACL payload is stored into the asynchronous register (flush indication in LLID and broadcast messages influence the interpretation of the SEQN field see Section 7.6).

The S2 switch is changed every T_{SCO} or T_{eSCO} for SCO and eSCO respectively. If, due to errors in the header, no new synchronous payload arrives, the switch still changes. The synchronous data processing unit then processes the synchronous data to account for the missing parts.

4.5.3 Flow control

Since the RX ACL buffer can be full while a new payload arrives, flow control is required. The header field FLOW in the return TX packet may use STOP or GO in order to control the transmission of new data.

4.5.3.1 Destination control

As long as data cannot be received, a STOP indication shall be transmitted which is automatically inserted by the Link Controller into the header of the return packet. STOP shall be returned as long as the RX ACL buffer is not emptied by the Baseband Resource Manager. When new data can be accepted again, the GO indication shall be returned. GO shall be the default value. All packet types not including data can still be received. Voice communication for example is not affected by the flow control. Although a device can-not receive new information, it may still continue to transmit information: the flow control shall be separate for each direction.

4.5.3.2 Source control

On the reception of a STOP signal, the Link Controller shall automatically switch to the default packet type. The ACL packet transmitted just before the reception of the STOP indication shall be kept until a GO signal is received. It may be retransmitted as soon as a GO indication is received. Only default packets shall be sent as long as the STOP indication is received. When no packet is received, GO shall be assumed implicitly. The default packets contain link control information (in the header) for the receive direction (which may still be open) and may contain synchronous data (**HV** or **EV** packets). When a GO indication is received, the Link Controller may resume transmitting the data that is present in the TX ACL buffers.

In a multi-Peripheral configuration, only the transmission to the Peripheral that issued the STOP signal shall be stalled. This means that the Central shall only stop transmission from the TX ACL buffer corresponding to the Peripheral that momentarily cannot accept data.

4.6 Active Peripheral broadcast transport

The Active Peripheral Broadcast logical transport is used to transport L2CAP user traffic and certain LMP traffic to all devices in the piconet that are currently connected to the piconet physical channel that is used by the APB. There is no acknowledgment protocol and the traffic is uni-directional from the piconet Central to the Peripherals.

The APB logical transport is unreliable. To improve reliability somewhat each packet is transmitted a number of times. An identical sequence number is used to assist with filtering retransmissions at the Peripheral.

The APB logical transport is identified by the reserved, all-zero, LT_ADDR. Packets on the APB logical transport may be sent by the Central at any time.

4.7 [This section is no longer used]

4.8 Connectionless Peripheral Broadcast logical transport

The CPB logical transport is used to transport profile broadcast data from a Transmitter (Central) to multiple Receivers (Peripherals). There is no acknowledgment scheme and the traffic is unidirectional.

Note: The CPB logical transport is not used for L2CAP connection-oriented channels, L2CAP control signaling, or LMP control signaling.

The CPB logical transport is unreliable. To improve reliability each packet payload may be transmitted a number of times.

5 LOGICAL LINKS

The following logical links are defined:

- Link Control (LC)
- ACL Control (ACL-C and APB-C)
- User Asynchronous/Isochronous (ACL-U and APB-U)
- User Synchronous (SCO-S)
- User Extended Synchronous (eSCO-S)
- Profile Broadcast Data (PBD)

The control logical link LC is used at the link control level. The ACL-C and APB-C logical links are used at the link manager level. The ACL-U and APB-U logical links are used to carry either asynchronous or isochronous user information. The SCO-S, and eSCO-S logical links are used to carry synchronous user information. The PBD logical link is used to carry profile broadcast data. The LC logical link is carried in the packet header, all other logical links are carried in the packet payload. The ACL-C, ACL-U, APB-C, and APB-U logical links are indicated in the logical link ID, LLID, field in the payload header. The SCO-S and eSCO-S logical links are carried by the synchronous logical transports only; the ACL-U link is normally carried by the ACL logical transport; however, it may also be carried by the data in the DV packet on the SCO logical transport. The ACL-C link may be carried either by the SCO or the ACL logical transport. The APB-C and APB-U links are carried by the APB logical transport. The PBD logical link is carried by the CPB logical transport.

5.1 Link Control logical link (LC)

The LC control logical link shall be mapped onto the packet header. This logical link carries low level link control information like ARQ, flow control, and payload characterization. The LC logical link is carried in every packet except in the **ID** packet which does not have a packet header.

5.2 ACL Control logical links (ACL-C and APB-C)

The ACL-C and APB-C logical links shall carry control information exchanged between the link managers of the Central and the Peripheral(s). The ACL-C logical link shall use DM1 or DV packets. DV packets shall only be used on the ACL-C link if the ACL-C message is less than or equal to 9 bytes and an HV1 synchronous logical transport is in use. The APB-C logical link shall use DM1 packets. The ACL-C and APB-C logical links are indicated by the LLID code 0b11 in the payload header.

5.3 User asynchronous/isochronous logical links (ACL-U and APB-U)

The ACL-U and APB-U logical links shall carry L2CAP asynchronous and isochronous user data. These messages may be transmitted in one or more Baseband packets. For fragmented messages, the start packet shall use an LLID code of 0b10 in the payload header. Remaining continuation packets shall use LLID code 0b01. If there is no fragmentation, all packets shall use the LLID start code 0b10.

For each logical link, the Controller shall transmit data over the air in the same order that it is received from the Host. The boundaries between packets over the air for a specific L2CAP PDU may be different from the boundaries in the data provided by the Host. Each new L2CAP PDU shall start a new packet over the air. (See [Vol 3] Part A, Section 7.2.1 for related requirements in L2CAP.)

For each logical link, the Controller shall transmit the data received over the air to the Host (whether over HCI or otherwise) in the same order that it was received. The boundaries in the data sent to the Host for a specific L2CAP PDU may be different from the boundaries between packets received over the air. The Controller shall retain boundaries between L2CAP PDUs. Data from different logical links may be interleaved. (See [Vol 3] Part A, Section 7.2.2 for related requirements in L2CAP.)

5.3.1 Pausing the ACL-U logical link

When paused by the LM, the Link Controller transmits the current packet with ACL-U information, if any, until an ACK is received. While the ACL-U logical link is paused, the Link Controller shall not transmit any (more) packets with ACL-U logical link information.

When the ACL-U logical link is resumed by the LM, the Link Controller may resume transmitting packets with ACL-U information.

5.4 User synchronous data logical link (SCO-S)

The SCO-S logical link carries transparent synchronous user data. This logical link is carried over the synchronous logical transport SCO.

5.5 User extended synchronous data logical link (eSCO-S)

The eSCO-S logical link also carries transparent synchronous user data. This logical link is carried over the extended synchronous logical transport eSCO.

5.6 Logical link priorities

The ACL-C logical link shall have a higher priority than the ACL-U logical link when scheduling traffic on the shared ACL logical transport, except in the case when

retransmissions of unacknowledged ACL packets shall be given priority over traffic on the ACL-C logical link. The APB-C logical link shall have a higher priority than the APB-U logical link when scheduling traffic on the shared APB logical transport. The ACL-C logical link should also have priority over traffic on the SCO-S and eSCO-S logical links but opportunities for interleaving the logical links should be taken. The ACL-C, SCO-S, and eSCO-S logical links should have priority over traffic on the PBD logical link.

5.7 Profile broadcast data logical link

The PBD logical link carries profile broadcast data. Messages shall not be fragmented and shall always use LLID start code 0b10.

6 PACKETS

Bluetooth devices shall use the packets as defined in the following sections.

6.1 General format

6.1.1 Basic Rate

The general packet format of Basic Rate packets is shown in Figure 6.1. Each packet consists of 3 entities: the access code, the header, and the payload. In the figure, the number of bits per entity is indicated.

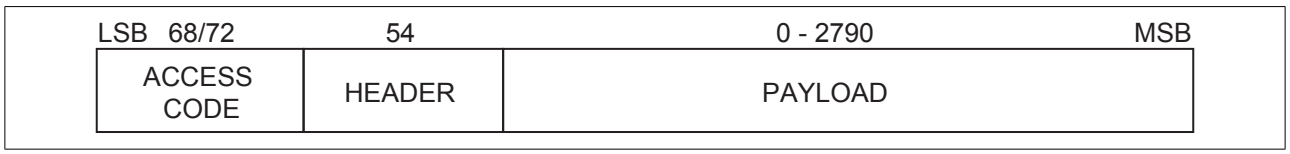

Figure 6.1: General Basic Rate packet format

The access code is 72 or 68 bits and the header is 54 bits. The payload ranges from zero to a maximum of 2790 bits. Different packet types have been defined. A packet may consist of:

- the shortened access code only (see Section 6.5.1.1)
- the access code and the packet header
- the access code, the packet header and the payload.

6.1.2 Enhanced Data Rate

The general format of Enhanced Data Rate packets is shown in Figure 6.2. The access code and packet header are identical in format and modulation to Basic Rate packets. Enhanced Data Rate packets have a guard time and synchronization sequence following the packet header. Following the payload are two trailer symbols. The guard time, synchronization sequence and trailer are defined in Section 6.6.

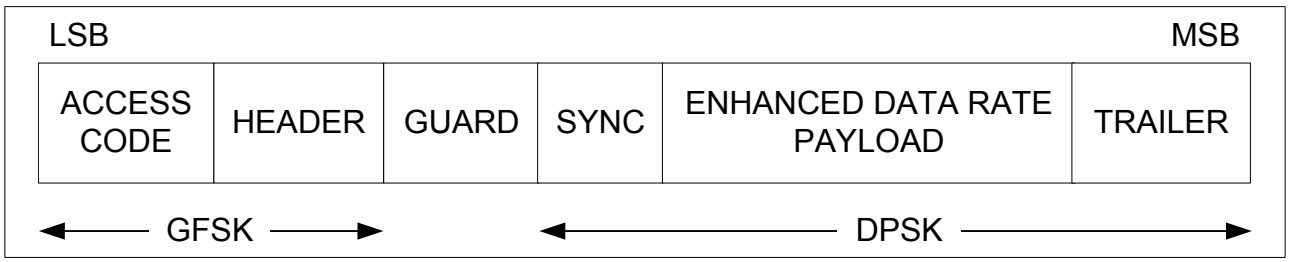

Figure 6.2: General Enhanced Data Rate packet format

6.2 Bit ordering

The bit ordering when defining packets and messages in the *Baseband Specification*, follows the little-endian format. The following rules apply:

- The *least significant bit* (LSB) corresponds to b_0;
- The LSB is the first bit sent over the air;
- In illustrations, the LSB is shown on the left side;

Furthermore, data fields generated internally at Baseband level, such as the packet header fields and payload header length, shall be transmitted with the LSB first. For instance, a 3-bit parameter X=3 is sent as:

$b_0 b_1 b_2 = 110$

over the air where 1 is sent first and 0 is sent last.

6.3 Access code

Every packet starts with an access code. If a packet header follows, the access code is 72 bits long, otherwise the access code is 68 bits long and is known as a shortened access code. The shortened access code does not contain a trailer. This access code is used for synchronization, DC offset compensation and identification. The access code identifies all packets exchanged on a physical channel: all packets sent in the same physical channel are preceded by the same access code. In the receiver of the device, a sliding correlator correlates against the access code and triggers when a threshold is exceeded. This trigger signal is used to determine the receive timing.

The shortened access code is used in paging and inquiry. In this case, the access code itself is used as a signaling message and neither a header nor a payload is present.

The access code consists of a preamble, a sync word, and possibly a trailer, see Figure 6.3. For details see Section 6.3.1.

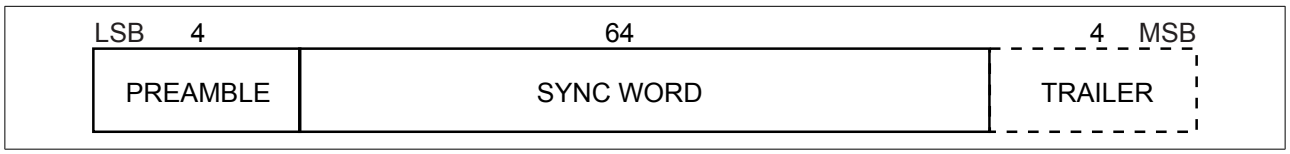

Figure 6.3: Access code format

6.3.1 Access code types

The different access code types use different Lower Address Parts (LAPs) to construct the sync word. The LAP field of the BD_ADDR is explained in Section 1.2. A summary of the different access code types is in Table 6.1.

Code type	LAP	Code length	Comments
CAC	Central	72	See also Section 1.3
DAC	Paged device	68/72[1]	
GIAC	Reserved	68/72[1]	
DIAC	Dedicated	68/72[1]	

Table 6.1: Summary of access code types

[1]length 72 is only used in combination with FHS packets

The CAC consists of a **preamble**, **sync word**, and **trailer** and its total length is 72 bits. When used as self-contained messages without a header, the DAC and IAC do not include the trailer bits and are of length 68 bits.

6.3.2 Preamble

The preamble is a fixed zero-one pattern of 4 symbols used to facilitate DC compensation. The sequence is either '1010' or '0101' (in transmission order), depending on whether the LSB of the following sync word is 1 or 0, respectively. The preamble is shown in Figure 6.4.

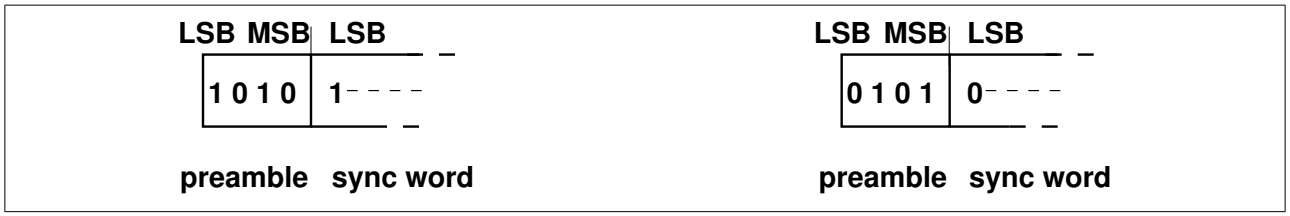

Figure 6.4: Preamble

6.3.3 Sync word

The sync word is a 64-bit code word derived from a 24 bit address (LAP); for the CAC the Central's LAP is used; for the GIAC and the DIAC, reserved, dedicated LAPs are used; for the DAC, the Peripheral LAP is used. The construction results in a large Hamming distance between sync words based on different LAPs. In addition, the good auto correlation properties of the sync word improve timing acquisition.

6.3.3.1 Synchronization word definition

The sync words are based on a (64,30) expurgated block code with an overlay (bit-wise XOR) of a 64 bit full length pseudo-random noise (PN) sequence. The expurgated code results in a large Hamming distance (d_{min} = 14) between sync words based on different

addresses. The PN sequence improves the auto correlation properties of the access code. The following steps describe how the sync word shall be generated:

1. Generate information sequence;
2. XOR this with the “information covering” part of the PN overlay sequence;
3. Generate the codeword;
4. XOR the codeword with all 64 bits of the PN overlay sequence;

The information sequence is generated by appending 6 bits to the 24 bit LAP (step 1). The appended bits are '001101' (in transmission order) if the MSB of the LAP equals 0. If the MSB of the LAP is 1 the appended bits are '110010'. The LAP MSB together with the appended bits constitute a length-seven Barker sequence. The purpose of including a Barker sequence is to further improve the auto correlation properties. In step 2 the information is pre-scrambled by XORing it with the bits $p_{34\ldots}p_{63}$ of the PN sequence (defined in Section 6.3.3.2). After generating the codeword (step 3), the complete PN sequence is XORed to the codeword (step 4). This step de-scrambles the information part of the codeword. At the same time the parity bits of the codeword are scrambled. Consequently, the original LAP and Barker sequence are ensured a role as a part of the access code sync word, and the cyclic properties of the underlying code is removed. The principle is depicted in Figure 6.5.

In the following discussion, binary sequences will be denoted by their corresponding D-transform (in which D^i represents a delay of i time units). Let $p'(D) = p'_0 + p'_1 D + \ldots + p'_{62} D^{62}$ be the 63 bit PN sequence, where p'_0 is the first bit (LSB) leaving the PRNG (see Figure 6.6), and, p'_{62} is the last bit (MSB). To obtain 64 bits, an extra zero is appended at the *end* of this sequence (thus, $p'(D)$ is unchanged). For notational convenience, the reciprocal of this extended polynomial, $p(D) = D^{63} p'(1/D)$, will be used in the following discussion. This is the sequence $p'(D)$ in reverse order. We denote the 24 bit lower address part (LAP) of the Bluetooth Device Address by $a(D) = a_0 + a_1 D + \ldots + a_{23} D^{23}$ (a_0 is the LSB of the Bluetooth Device Address).

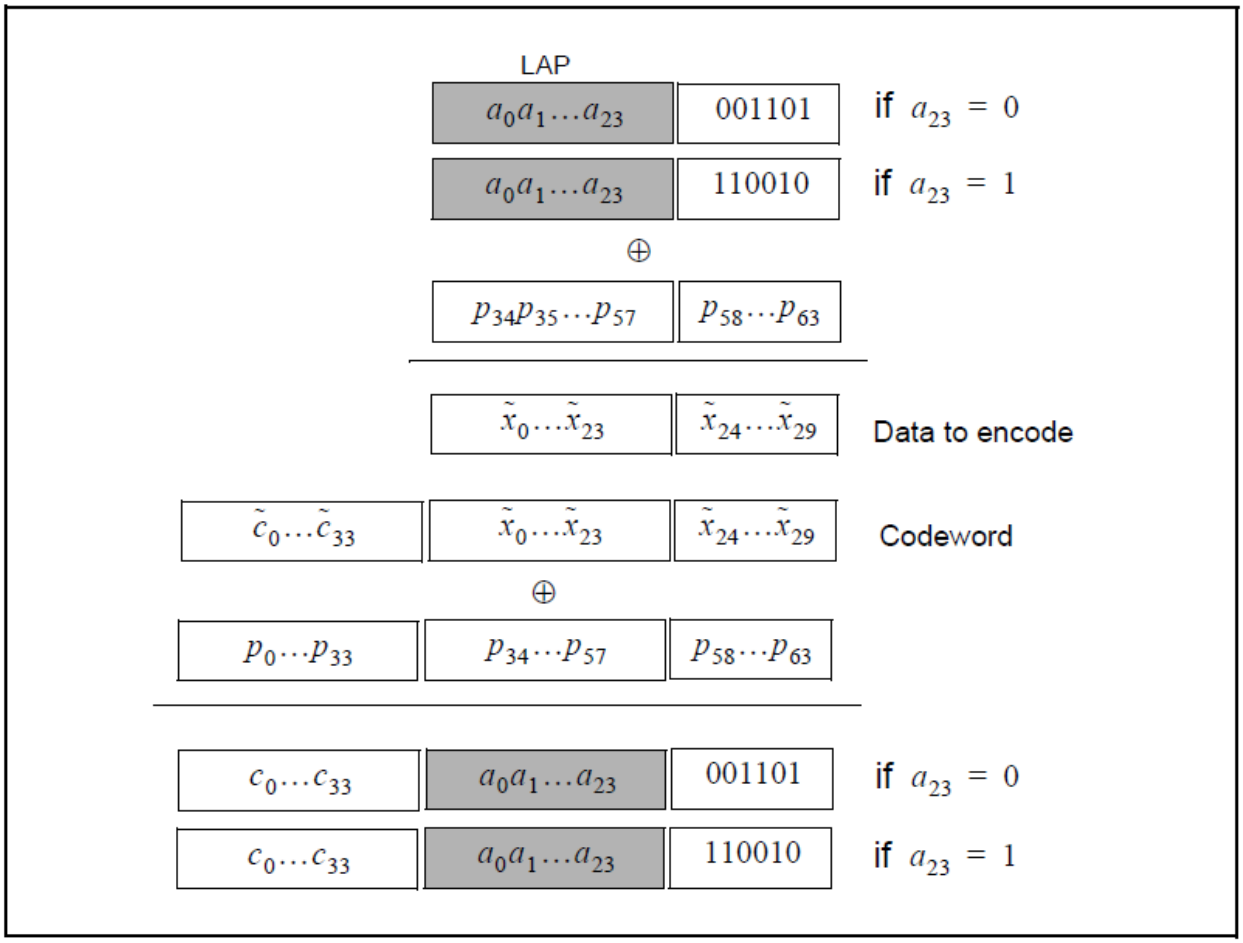

Figure 6.5: Construction of the sync word

The (64,30) block code generator polynomial is denoted $g(D) = (1 + D)g'(D)$, where $g'(D)$ is the generator polynomial 0x37CD0EB67 of a primitive binary (63,30) BCH code. Thus, *g(D)* is

$$g(D) = 0\text{x}585713\text{DA9}, \quad \text{(EQ 9)}$$

where the left-most bit corresponds to the high-order (g_{34}) coefficient. The DC-free four bit sequences '0101' and '1010' (in transmission order) can be written

$$\begin{cases} F_0(D) = D + D^3, \\ F_1(D) = 1 + D^2, \end{cases} \quad \text{(EQ 10)}$$

respectively. Furthermore,

$$\begin{cases} B_0(D) = D^2 + D^3 + D^5, \\ B_1(D) = 1 + D + D^4, \end{cases} \quad \text{(EQ 11)}$$

which are used to create the length seven Barker sequences. Then, the access code shall be generated by the following procedure:

1. Format the 30 information bits to encode:

$$x(D) = a(D) + D^{24}B_{a_{23}}(D).$$

2. Add the information covering part of the PN overlay sequence:

$$\tilde{x}(D) = x(D) + p_{34} + p_{35}D + \ldots + p_{63}D^{29}.$$

3. Generate parity bits of the (64,30) expurgated block code:[1]

$$\tilde{c}(D) = D^{34}\tilde{x}(D) \ \ mod \ \ g(D).$$

4. Create the codeword:

$$\tilde{s}(D) = D^{34}\tilde{x}(D) + \tilde{c}(D).$$

5. Add the PN sequence:

$$s(D) = \tilde{s}(D) + p(D).$$

6. Append the (DC-free) preamble and trailer:

$$y(D) = F_{c_0}(D) + D^4 s(D) + D^{68}F_{a_{23}}(D).$$

6.3.3.2 Pseudo-random noise sequence generation

To generate the PN sequence the primitive polynomial *h(D)* = 1 + *D* + D^3 + D^4 + D^6 shall be used. The LFSR and its starting state are shown in Figure 6.6. The PN sequence generated (including the extra terminating zero) becomes 0x83848D96BBCC54FC. The LFSR output starts with the left-most bit of this PN sequence. This corresponds to $p'(D)$ of the previous section. Thus, using the reciprocal $p'(D)$ as overlay gives the 64 bit sequence:

$$p = '3F2A33DD69B121C1' \qquad \text{(EQ 12)}$$

(in transmission order) where the left-most bit is p_0 = 0 (there are two initial zeros in the binary representation of the hexadecimal digit 3), and p_{63} = 1 is the right-most bit.

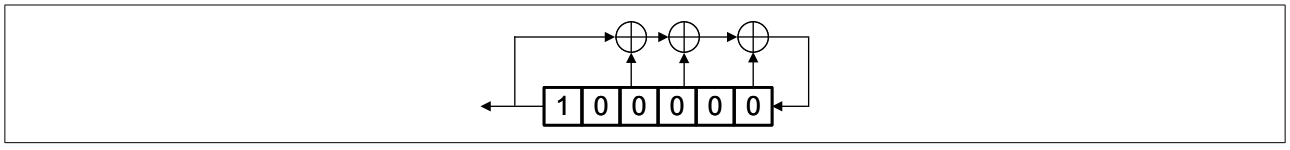

Figure 6.6: LFSR and the starting state to generate $p'(D)$

[1] *x*(*D*) *mod y*(*D*) denotes the remainder when *x*(*D*) is divided by *y*(*D*).

6.3.4 Trailer

The trailer is appended to the sync word as soon as the packet header follows the access code. This is typically the case with the CAC, but the trailer is also used in the DAC and IAC when these codes are used in FHS packets exchanged during page response and inquiry response.

The trailer is a fixed zero-one pattern of four symbols. The trailer together with the three MSBs of the syncword form a 7-bit pattern of alternating ones and zeroes which can be used for extended DC compensation. The trailer sequence is either ‘1010’ or ‘0101’ (in transmission order) depending on whether the MSB of the sync word is 0 or 1, respectively. The choice of trailer is illustrated in Figure 6.7.

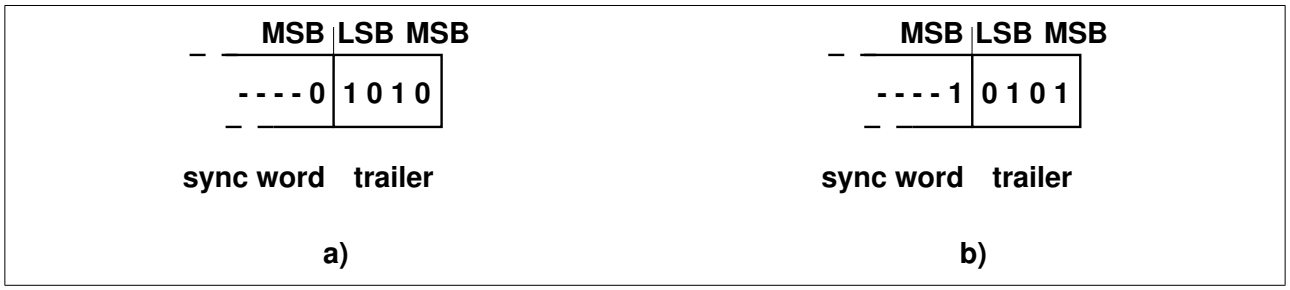

Figure 6.7: Trailer in CAC when MSB of sync word is 0 (a), and when MSB of sync word is 1 (b)

6.4 Packet header

The header contains link control (LC) information and consists of 6 fields:

- LT_ADDR: 3-bit logical transport address
- TYPE: 4-bit type code
- FLOW: 1-bit flow control
- ARQN: 1-bit acknowledge indication
- SEQN: 1-bit sequence number
- HEC: 8-bit header error check

The total header, including the HEC, consists of 18 bits, see Figure 6.8, and is encoded with a rate 1/3 FEC (not shown but described in Section 7.4) resulting in a 54-bit header. The LT_ADDR and TYPE fields shall be sent LSB first.

Figure 6.8: Header format

6.4.1 LT_ADDR

The 3-bit LT_ADDR field contains the logical transport address for the packet (see Section 4.2). This field indicates the destination Peripheral (or Peripherals in the case of a broadcast) for a packet in a Central-to-Peripheral transmission slot and indicates the source Peripheral for a Peripheral-to-Central transmission slot.

6.4.2 TYPE

Sixteen different types of packets can be distinguished. The 4-bit TYPE code specifies which packet type is used. The interpretation of the TYPE code depends on the logical transport address in the packet. First, it shall be determined whether the packet is sent on a SCO logical transport, an eSCO logical transport, an ACL logical transport, or a CPB logical transport. Second, it shall be determined whether Enhanced Data Rate has been enabled for the logical transport (ACL or eSCO) indicated by LT_ADDR. It can then be determined which type of SCO packet, eSCO packet, or ACL packet has been received. The TYPE code determines how many slots the current packet will occupy (see the slot occupancy column in Table 6.2). This allows the non-addressed receivers to refrain from listening to the channel for the duration of the remaining slots. In Section 6.5, each packet type is described in more detail.

6.4.3 FLOW

The FLOW bit is used for flow control of packets over the ACL logical transport. When the RX buffer for the ACL logical transport in the recipient is full, a STOP indication (FLOW=0) shall be returned to stop the other device from transmitting data temporarily. The STOP signal only affects ACL packets. Packets including only link control information (POLL and NULL packets), SCO packets or eSCO packets can still be received. When the RX buffer can accept data, a GO indication (FLOW=1) shall be returned. When no packet is received, or the received header is in error, a GO shall be assumed implicitly. In this case, the Peripheral can receive a new packet with CRC although its RX buffer is still not emptied. The Peripheral shall then return a NAK in response to this packet even if the packet passed the CRC check.

The FLOW bit is not used on the eSCO logical transport and shall be set to one on transmission and ignored upon receipt. The FLOW bit is reserved for future use on the CPB logical transport.

6.4.4 ARQN

The 1-bit acknowledgment indication ARQN is used to inform the source of a successful transfer of payload data with CRC, and can be positive acknowledge ACK or negative acknowledge NAK. See Section 7.6 for initialization and usage of this bit.

The ARQN bit is reserved for future use on the CPB logical transport.

6.4.5 SEQN

The SEQN bit provides a sequential numbering scheme to order the data packet stream. See Section 7.6.2 for initialization and usage of the SEQN bit. For Active Peripheral Broadcast packets, a modified sequencing method is used, see Section 7.6.5.

The SEQN bit is reserved for future use on the CPB logical transport.

6.4.6 HEC

Each header has a header-error-check to check the header integrity. The HEC is an 8-bit word (generation of the HEC is specified in Section 7.1.1). Before generating the HEC, the HEC generator is initialized with an 8-bit value. For FHS packets sent in Central Page Response substate, the Peripheral upper address part (UAP) shall be used. For FHS packets and extended inquiry response packets sent in Inquiry Response substate, the default check initialization (DCI, see Section 1.2.1) shall be used. In all other cases, the UAP of the Central shall be used.

After the initialization, a HEC shall be calculated for the 10 header bits. Before checking the HEC, the receiver shall initialize the HEC check circuitry with the proper 8-bit UAP (or DCI). If the HEC does not check, the entire packet shall be discarded. More information can be found in Section 7.1.

6.5 Packet types

The packets used on the piconet are related to the logical transports on which they are used. Four logical transports with distinct packet types are defined (see Section 4):

- SCO logical transport
- eSCO logical transport
- ACL logical transport
- CPB logical transport.

To indicate the different packets on a logical transport, the 4-bit TYPE code is used. The packet types are divided into four segments. The first segment is reserved for control packets. All control packets occupy a single time slot. The second segment is reserved for packets occupying a single time slot. The third segment is reserved for packets occupying three time slots. The fourth segment is reserved for packets occupying five time slots. The slot occupancy is reflected in the segmentation and can directly be derived from the type code. Table 6.2 summarizes the packets defined for the SCO, eSCO, ACL, and CPB logical transport types; a dash means the value is reserved for future use.

All packet types with a payload shall use GFSK modulation unless specified otherwise in the following sections.

ACL logical transports Enhanced Data Rate packet types are explicitly selected via LMP using the *packet_type_table* (ptt) parameter. eSCO Enhanced Data Rate packet types are selected when the eSCO logical transport is established. Enhanced Data Rate packet types for the CPB logical transport are selected when the CPB logical transport is established.

Segment	TYPE code $b_3b_2b_1b_0$	Slot occu-pancy	SCO logical transport (1 Mb/s)	eSCO logical transport (1 Mb/s)	eSCO logical transport (2-3 Mb/s)	ACL logical transport (1 Mb/s) ptt=0	ACL logical transport (2-3 Mb/s) ptt=1	CPB logical transport (1 Mb/s)	CPB logical transport (2-3 Mb/s)
1	0000	1	NULL	NULL	NULL	NULL	NULL	NULL	NULL
	0001	1	POLL	POLL	POLL	POLL	POLL	—	—
	0010	1	FHS	—	—	FHS	FHS	—	—
	0011	1	DM1	—	—	DM1	DM1	DM1	DM1

Table 6.2: Packets defined for synchronous, asynchronous, and CPB logical transport types

6.5.1 Common packet types

There are five common kinds of packets. In addition to the types listed in segment 1 of Table 6.2, the ID packet is also a common packet type but is not listed in segment 1 because it does not have a packet header.

6.5.1.1 ID packet

The identity or ID packet consists of the device access code (DAC) or inquiry access code (IAC). It has a fixed length of 68 bits. It is a very robust packet since the receiver uses a bit correlator to match the received packet to the known bit sequence of the ID packet.

The ID packet shall only be used where explicitly stated in paging (see Section 8.3), inquiry (see Section 8.4), and role switch (see Section 8.6.5). It shall not be used where any other packet type is permitted.

6.5.1.2 NULL packet

The NULL packet has no payload and consists of the channel access code and packet header only. Its total (fixed) length is 126 bits. The NULL packet may be used to return link information to the source regarding the success of the previous transmission (ARQN), or the status of the RX buffer (FLOW). The NULL packet does not require acknowledgment.

6.5.1.3 POLL packet

The POLL packet is very similar to the NULL packet. It does not have a payload. In contrast to the NULL packet, it requires a confirmation from the recipient. It is not a part of the ARQ scheme. The POLL packet does not affect the ARQN and SEQN fields. Upon reception of a POLL packet the Peripheral shall respond with a packet even when the Peripheral does not have any information to send unless the Peripheral has scatternet commitments in that timeslot. This return packet is an implicit acknowledgment of the POLL packet. This packet can be used by the Central in a piconet to poll the Peripherals. Peripherals shall not transmit the POLL packet. POLL packets shall not be sent on a Connectionless Peripheral Broadcast logical transport.

6.5.1.4 FHS packet

The FHS packet is a special control packet containing, among other things, the Bluetooth Device Address and the clock of the sender. The payload contains 144 information bits plus a 16-bit CRC code. The payload is coded with a rate 2/3 FEC with a gross payload length of 240 bits.

Figure 6.9 illustrates the format and contents of the FHS payload. The FHS packet is used in Central page response, inquiry response and in role switch.

The FHS packet is not encrypted. No payload header or MIC is present.

The FHS packet contains real-time clock information. This clock information shall be updated before each retransmission. The retransmission of the FHS payload is different than retransmissions of ordinary data payloads where the same payload is used for each retransmission. The FHS packet is used for frequency hop synchronization before the piconet channel has been established, or when an existing piconet changes to a new piconet. However, the FHS packet is not used by Connectionless Peripheral Broadcast Receivers for frequency hop synchronization with Connectionless Peripheral Broadcast Transmitters.

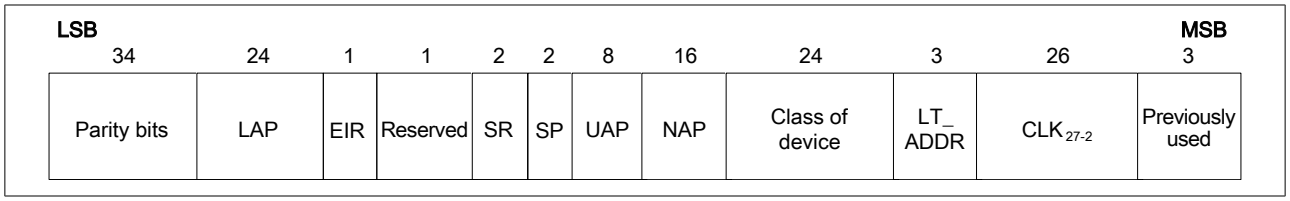

Figure 6.9: Format of the FHS payload

Each field is described in more detail below:

Parity bits	This 34-bit field contains the parity bits that form the first part of the sync word of the access code of the device that sends the FHS packet. These bits are derived from the LAP as described in Section 1.2.
LAP	This 24-bit field shall contain the lower address part of the device that sends the FHS packet.
EIR	This bit shall indicate that an extended inquiry response packet may follow. See Section 8.4.3.
Reserved	This 1-bit field is reserved for future use.
SR	This 2-bit field is the page scan repetition mode field and indicates the interval between two consecutive page scan windows, see also Table 6.4 and Table 8.1
SP	This 2-bit field shall be set to 0b10.
UAP	This 8-bit field shall contain the upper address part of the device that sends the FHS packet.
NAP	This 16-bit field shall contain the non-significant address part of the device that sends the FHS packet (see also Section 1.2 for LAP, UAP, and NAP).
Class of Device	This 24-bit field shall contain the Class of Device of the device that sends the FHS packet. The field is defined in Assigned Numbers.

LT_ADDR	This 3-bit field shall contain the logical transport address the recipient shall use if the FHS packet is used at connection setup or role switch. A Peripheral responding to a Central or a device responding to an inquiry request message shall include an all-zero LT_ADDR field if it sends the FHS packet.
CLK_{27-2}	This 26-bit field shall contain the value of the native clock of the device that sends the FHS packet, sampled at the beginning of the transmission of the access code of this FHS packet. This clock value has a resolution of 1.25 ms (two-slot interval). For each new transmission, this field is updated so that it accurately reflects the real-time clock value.

Table 6.3: Description of the FHS payload

The device sending the FHS shall set the SR bits according to Table 6.4.

SR bit format b_1b_0	SR (page scan repetition) mode
00	R0
01	R1
10	R2
11	Reserved for future use

Table 6.4: Contents of SR field

The LAP, UAP, and NAP together form the 48-bit Bluetooth Device Address of the device that sends the FHS packet. Using the parity bits and the LAP, the recipient can directly construct the channel access code of the sender of the FHS packet.

When initializing the HEC and CRC for the FHS packet of inquiry response, the UAP shall be the DCI.

6.5.1.5 DM1 packet

DM1 is part of segment 1 in order to support control messages in any logical transport that allows the DM1 packet (see Table 6.2). However, it may also carry regular user data. Since the DM1 packet can be regarded as an ACL packet, it will be discussed in Section 6.5.4.

6.5.2 SCO packets

HV and DV packets are used on the synchronous SCO logical transport. The HV packets do not include a MIC or CRC and shall not be retransmitted. DV packets include a CRC on the data section, but not on the synchronous data section. DV packets do not include a MIC. The data section of DV packets shall be retransmitted. SCO packets may be routed to the synchronous I/O port. Four packets are allowed on the SCO logical transport: HV1, HV2, HV3 and DV. These packets are typically used for 64 kb/s speech transmission but may be used for transparent synchronous data.

SCO packets shall only be encrypted with E0 when E0 is enabled. SCO packets shall not be sent when AES-CCM Encryption is enabled.

6.5.2.1 HV1 packet

The **HV1** packet has 10 information bytes. The bytes are protected with a rate 1/3 FEC. No MIC is present. No CRC is present. The payload length is fixed at 240 bits. There is no payload header present.

6.5.2.2 HV2 packet

The **HV2** packet has 20 information bytes. The bytes are protected with a rate 2/3 FEC. No MIC is present. No CRC is present. The payload length is fixed at 240 bits. There is no payload header present.

6.5.2.3 HV3 packet

The **HV3** packet has 30 information bytes. The bytes are not protected by FEC. No MIC is present. No CRC is present. The payload length is fixed at 240 bits. There is no payload header present.

6.5.2.4 DV packet

The DV packet is a combined data - voice packet. The DV packet shall only be used in place of an HV1 packet. The payload is divided into a voice field of 80 bits and a data field containing up to 150 bits, see Figure 6.10. The voice field is not protected by FEC. The data field has between 1 and 10 information bytes (including the 1-byte payload header) plus a 16-bit CRC code. No MIC is present. The data field (including the CRC) is encoded with a rate 2/3 FEC. Since the **DV** packet has to be sent at regular intervals due to its synchronous contents, it is listed under the SCO packet types. The voice and data fields shall be treated separately. The voice field shall be handled in the same way as normal SCO data and shall never be retransmitted; that is, the voice field is always new. The data field is checked for errors and shall be retransmitted if necessary. When the asynchronous data field in the DV packet has not been acknowledged before the SCO logical transport is terminated, the asynchronous data field shall be retransmitted in a DM1 packet.

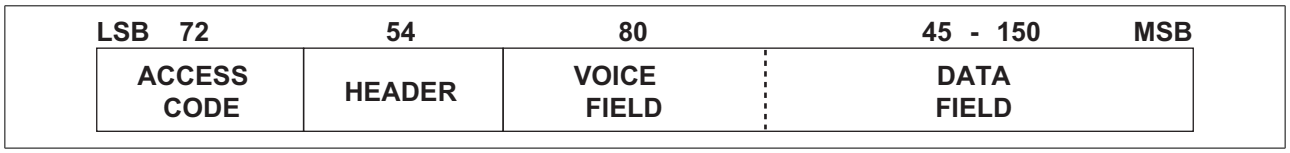

Figure 6.10: DV packet format

6.5.3 eSCO packets

EV packets are used on the synchronous eSCO logical transport. The packets include a CRC and retransmission may be applied if no acknowledgment of proper reception

is received within the retransmission window. No MIC is present. eSCO packets may be routed to the synchronous I/O port. Three eSCO packet types (EV3, EV4, EV5) are defined for Basic Rate operation and four additional eSCO packet types (2-EV3, 3-EV3, 2-EV5, 3-EV5) for Enhanced Data Rate operation. The eSCO packets may be used for 64 kb/s speech transmission as well as transparent data at 64 kb/s and other rates.

6.5.3.1 EV3 packet

The **EV3** packet has between 1 and 30 information bytes plus a 16-bit CRC code. No MIC is present. The bytes are not protected by FEC. The EV3 packet may cover up to a single time slot. There is no payload header present. The payload length is set during the LMP eSCO setup and remains fixed until the link is removed or re-negotiated.

6.5.3.2 EV4 packet

The **EV4** packet has between 1 and 120 information bytes plus a 16-bit CRC code. No MIC is present. The EV4 packet may cover to up three time slots. The information plus CRC bits are coded with a rate 2/3 FEC. There is no payload header present. The payload length is set during the LMP eSCO setup and remains fixed until the link is removed or re-negotiated.

6.5.3.3 EV5 packet

The **EV5** packet has between 1 and 180 information bytes plus a 16-bit CRC code. No MIC is present. The bytes are not protected by FEC. The EV5 packet may cover up to three time slots. There is no payload header present. The payload length is set during the LMP eSCO setup and remains fixed until the link is removed or re-negotiated.

6.5.3.4 2-EV3 packet

The **2-EV3** packet is similar to the EV3 packet except that the payload is modulated using π/4-DQPSK. It has between 1 and 60 information bytes plus a 16-bit CRC code. No MIC is present. The bytes are not protected by FEC. The 2-EV3 packet covers a single time slot. There is no payload header present. The payload length is set during the LMP eSCO setup and remains fixed until the link is removed or re-negotiated.

6.5.3.5 2-EV5 packet

The **2-EV5** packet is similar to the EV5 packet except that the payload is modulated using π/4-DQPSK. It has between 1 and 360 information bytes plus a 16-bit CRC code. No MIC is present. The bytes are not protected by FEC. The 2-EV5 packet may cover up to three time slots. There is no payload header present. The payload length is set during the LMP eSCO setup and remains fixed until the link is removed or re-negotiated.

6.5.3.6 3-EV3 packet

The **3-EV3** packet is similar to the EV3 packet except that the payload is modulated using 8DPSK. It has between 1 and 90 information bytes plus a 16-bit CRC code. No MIC is present. The bytes are not protected by FEC. The 3-EV3 packet covers a single time slot. There is no payload header present. The payload length is set during the LMP eSCO setup and remains fixed until the link is removed or re-negotiated.

6.5.3.7 3-EV5 packet

The **3-EV5** packet is similar to the EV5 packet except that the payload is modulated using 8DPSK. It has between 1 and 540 information bytes plus a 16-bit CRC code. No MIC is present. The bytes are not protected by FEC. The 3-EV5 packet may cover up to three time slots. There is no payload header present. The payload length is set during the LMP eSCO setup and remains fixed until the link is removed or re-negotiated.

6.5.4 ACL packets

ACL packets are used on the asynchronous logical transport and the CPB logical transport. The information carried may be user data for either logical transport or control data for the asynchronous logical transport.

Six packet types are defined for Basic Rate operation: DM1, DH1, DM3, DH3, DM5, and DH5. Six additional packets are defined for Enhanced Data Rate operation: 2-DH1, 3-DH1, 2-DH3, 3-DH3, 2-DH5 and 3-DH5. The AUX1 packet is also defined for test purposes.

The length indicator in the payload header specifies the number of user bytes (excluding payload header, MIC and the CRC code).

6.5.4.1 DM1 packet

The DM1 packet carries data information only. The payload has between 1 and 18 information bytes (including the 1-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The DM1 packet occupies a single time slot. The information bits, MIC bits (when present), plus CRC bits are coded with a rate 2/3 FEC. The payload header in the DM1 packet is 1 byte long, see Figure 6.12.

6.5.4.2 DH1 packet

This packet is similar to the DM1 packet, except that the information in the payload is not FEC encoded. As a result, the DH1 packet has between 1 and 28 information bytes (including the 1-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The DH1 packet occupies a single time slot.

6.5.4.3 DM3 packet

The DM3 packet may occupy up to three time slots. The payload has between 2 and 123 information bytes (including the 2-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The information bits, MIC bits (when present), plus CRC bits are coded with a rate 2/3 FEC. The payload header in the DM3 packet is 2 bytes long, see Figure 6.13.

6.5.4.4 DH3 packet

This packet is similar to the DM3 packet, except that the information in the payload is not FEC encoded. As a result, the DH3 packet has between 2 and 185 information bytes (including the 2-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The DH3 packet may occupy up to three time slots.

6.5.4.5 DM5 packet

The DM5 packet may occupy up to five time slots. The payload has between 2 and 226 information bytes (including the 2-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The payload header in the DM5 packet is 2 bytes long. The information bits, MIC bits (when present), plus CRC bits are coded with a rate 2/3 FEC.

6.5.4.6 DH5 packet

This packet is similar to the DM5 packet, except that the information in the payload is not FEC encoded. As a result, the DH5 packet has between 2 and 341 information bytes (including the 2-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The DH5 packet may occupy up to five time slots.

6.5.4.7 AUX1 packet

This packet resembles a DH1 packet but has no MIC or CRC code. The AUX1 packet has between 1 and 30 information bytes (including the 1-byte payload header). The AUX1 packet occupies a single time slot. The AUX1 packet shall only be used in test mode (see [Vol 3] Part D). The Link Controller shall discard any AUX1 packet received in any other circumstances.

6.5.4.8 2-DH1 packet

This packet is similar to the DH1 packet except that the payload is modulated using π/4-DQPSK. The 2-DH1 packet has between 2 and 56 information bytes (including the 2-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled.The 2-DH1 packet occupies a single time slot.

6.5.4.9 2-DH3 packet

This packet is similar to the DH3 packet except that the payload is modulated using π/4-DQPSK. The 2-DH3 packet has between 2 and 369 information bytes (including the 2-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The 2-DH3 packet may occupy up to three time slots.

6.5.4.10 2-DH5 packet

This packet is similar to the DH5 packet except that the payload is modulated using π/4-DQPSK. The 2-DH5 packet has between 2 and 681 information bytes (including the 2-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The 2-DH5 packet may occupy up to five time slots.

6.5.4.11 3-DH1 packet

This packet is similar to the DH1 packet except that the payload is modulated using 8DPSK. The 3-DH1 packet has between 2 and 85 information bytes (including the 2-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The 3-DH1 packet occupies a single time slot.

6.5.4.12 3-DH3 packet

This packet is similar to the DH3 packet except that the payload is modulated using 8DPSK. The 3-DH3 packet has between 2 and 554 information bytes (including the 2-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The 3-DH3 packet may occupy up to three time slots.

6.5.4.13 3-DH5 packet

This packet is similar to the DH5 packet except that the payload is modulated using 8DPSK. The 3-DH5 packet has between 2 and 1023 information bytes (including the 2-byte payload header) plus a 16-bit CRC code. A 32-bit MIC is present only when encryption with AES-CCM is enabled. The 3-DH5 packet may occupy up to five time slots.

6.6 Payload format

In the payload, two fields are distinguished: the synchronous data field and the asynchronous data field. The ACL packets only have the asynchronous data field and the SCO and eSCO packets only have the synchronous data field – with the exception of the DV packets which have both.

6.6.1 Synchronous data field

In SCO, which is only supported in Basic Rate mode, the synchronous data field has a fixed length and consists only of the synchronous data body portion. No payload header is present.

In Basic Rate eSCO, the synchronous data field consists of two segments: a synchronous data body and a CRC code. No payload header is present.

In Enhanced Data Rate eSCO, the synchronous data field consists of five segments: a guard time, a synchronization sequence, a synchronous data body, a CRC code and a trailer. No payload header is present.

1. **Enhanced Data Rate guard time**

   For Enhanced Data Rate packets the guard time is defined as the period starting at the end of the last GFSK symbol of the header and ending at the start of the reference symbol of the synchronization sequence. The length of the guard time shall be between 4.75 µs and 5.25 µs.

2. **Enhanced Data Rate synchronization sequence**

   For Enhanced Data Rate packets the symbol timing at the start of the synchronization sequence shall be within ±¼ µs of the symbol timing of the last GFSK symbol of the packet header. The length of the synchronization sequence is 11 µs (11 DPSK symbols) and consists of a reference symbol (with arbitrary phase) followed by ten DPSK symbols.

   The phase changes between the DPSK symbols (shown in Figure 6.11) shall be

$$\{\varphi_1, \varphi_2, \varphi_3, \varphi_4, \varphi_5, \varphi_6, \varphi_7, \varphi_8, \varphi_9, \varphi_{10}\} = \{3\pi/4, -3\pi/4, 3\pi/4, -3\pi/4, 3\pi/4, -3\pi/4, -3\pi/4, 3\pi/4, 3\pi/4, 3\pi/4\} \quad \text{(EQ 13)}$$

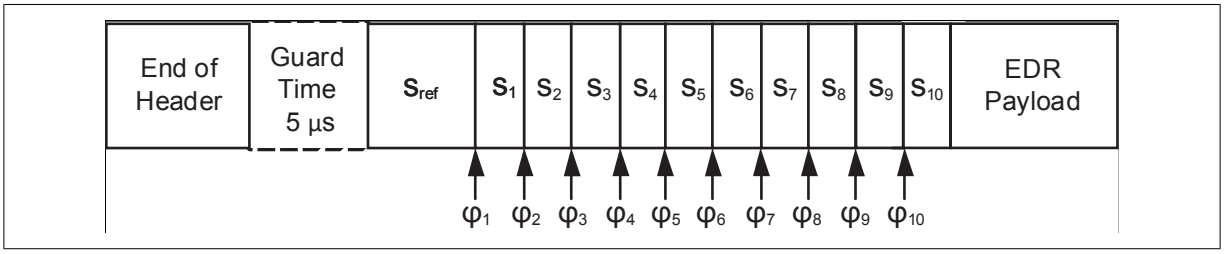

Figure 6.11: Synchronization sequence

Sref is the reference symbol. φ_1 is the phase change between the reference symbol and the first DPSK symbol S_1. φ_k is the phase change between the k-1th symbol S_{k-1} and the kth symbol S_k

Note: The synchronization sequence may be generated using the modulator by pre-pending the data with bits that generate the synchronization sequence.

For π/4-DQPSK, the bit sequence used to generate the synchronization sequence is 0,1,1,1,0,1,1,1,0,1,1,1,1,1,0,1,0,1,0,1.

For 8DPSK, the bit sequence used to generate the synchronization sequence is 0,1,0,1,1,1,0,1,0,1,1,1,0,1,0,1,1,1,1,1,1,1,0,1,0,0,1,0,0,1,0.

3. **Synchronous data body**

   For HV and DV packets, the synchronous data body length is fixed. For EV packets, the synchronous data body length is negotiated during the LMP eSCO setup. Once negotiated, the synchronous data body length remains constant unless re-negotiated. The synchronous data body length may be different for each direction of the eSCO logical transport.

4. **CRC code**

   The 16-bit CRC in the payload is generated as specified in Section 7.1. The 8-bit UAP of the Central is used to initialize the CRC generator.

   Only the Synchronous data body segment is used to generate the CRC code.

5. **Enhanced Data Rate trailer**

   For Enhanced Data Rate packets, two trailer symbols shall be added to the end of the payload. The trailer bits shall be all zero, i.e. {00, 00} for the π/4-DQPSK and {000, 000} for the 8DPSK.

6.6.2 Asynchronous data field

Basic rate ACL packets have an asynchronous data field consisting of two, three or four segments: a payload header, a payload body, possibly a MIC, and possibly a CRC code.

Enhanced Data Rate ACL packets have an asynchronous data field consisting of six or seven segments: a guard time, a synchronization sequence, a payload header, a payload body, possibly a MIC, a CRC and a trailer.

1. **Enhanced Data Rate guard time**

   This is the same as defined for the Synchronous data field in Section 6.6.1.

2. **Enhanced Data Rate synchronization sequence**

   This is the same as defined for the Synchronous data field in Section 6.6.1.

3. **Payload header**

   The payload header is one or two bytes long. Basic rate packets in segments one and two have a 1-byte payload header; Basic Rate packets in segments three

and four and all Enhanced Data Rate packets have a 2-byte payload header. The payload header specifies the logical link (2-bit LLID indication), controls the flow on the logical channels (1-bit FLOW indication), and has a payload length indicator (5 bits and 10 bits for 1-byte and 2-byte payload headers, respectively). In the case of a 2-byte payload header, the length indicator is extended by five bits into the next byte. The remaining three bits of the second byte are reserved for future use. The formats of the 1-byte and 2-byte payload headers are shown in Figure 6.12 and Figure 6.13.

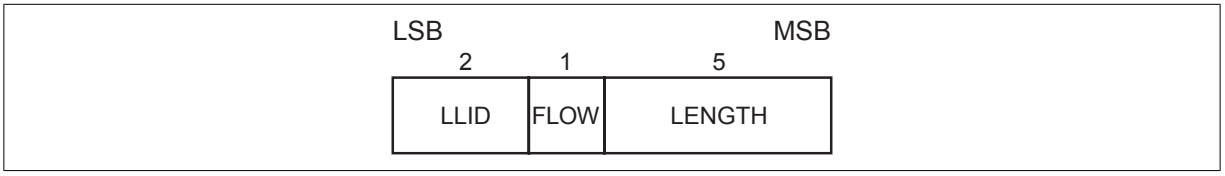

Figure 6.12: Payload header format for Basic Rate single-slot ACL packets

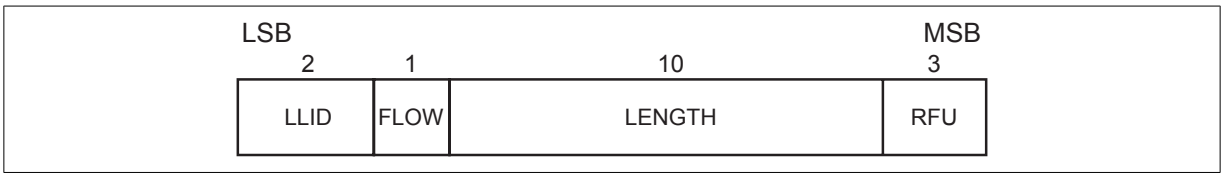

Figure 6.13: Payload header format for multi-slot ACL packets and all EDR ACL packets

The LLID field shall be transmitted first, the length field last. In Table 6.5, more details about the contents of the LLID field are listed.

LLID	Logical Link	Information
0b00		Reserved for future use
0b01	ACL-U and APB-U	Continuation fragment of an L2CAP message
0b10	ACL-U and APB-U	Start of an L2CAP message or no fragmentation
	PBD	Profile broadcast data, no fragmentation
0b11	ACL-C and APB-C	LMP message

Table 6.5: Logical Link LLID field contents

An L2CAP message may be fragmented into several packets. Code 0b10 shall be used for an ACL-U or APB-U packet carrying the first fragment of such a message; code 0b01 shall be used for continuing fragments. The first fragment of an L2CAP message sent over HCI is identified by having a Packet_Boundary_Flag value of 0b00 or 0b10 both of which are mapped to LLID code 0b10. If there is no fragmentation, code 0b10 shall be used for every packet. ACL packets used over the PBD logical link do not use fragmentation. For ACL packets used over the

PBD logical link, LLID code 0b10 shall be used by the transmitter. Any ACL packet used over the PBD logical link with LLID not equal to 0b10 shall be ignored by the receiver. Code 0b11 shall be used for LMP messages. Code 0b00 is reserved for future use.

The flow indicator in the payload is used to control the flow at the L2CAP level. It is used to control the flow per logical link. FLOW=1 means flow-on (GO) and FLOW=0 means flow-off (STOP). After a new connection has been established the flow indicator shall be set to GO. When a device receives a payload header with the flow bit set to STOP, it shall stop the transmission of ACL-U packets before an additional amount of payload data is sent. This amount is defined as the flow control lag, expressed as a number of bytes. The shorter the flow control lag, the less buffering the other device must dedicate to this function. The flow control lag shall not exceed 1792 bytes (7 × 256 bytes). In order to allow devices to optimize the selection of packet length and buffer space, the flow control lag of a given implementation shall be provided in the LMP_FEATURES_RES message.

If a packet containing the payload flow bit of STOP is received, with a valid packet header but bad payload, the payload flow control bit shall be ignored. The Baseband acknowledgment contained in the packet header will be received and a further ACL packet may be transmitted. Each occurrence of this situation allows a further ACL packet to be sent in spite of the flow control request being sent via the payload header flow control bit. It is recommended that devices that use the payload header flow bit should ensure that no further ACL packets are sent until the payload flow bit has been correctly received. This can be accomplished by simultaneously turning on the flow bit in the packet header and keeping it on until an ACK is received back (ARQN=1). This will typically be only one round trip time.

The Baseband Resource Manager is responsible for setting and processing the flow bit in the payload header. Real-time flow control shall be carried out at the packet level by the Link Controller via the flow bit in the packet header (see Section 6.4.3). With the payload flow bit, traffic from the remote end can be controlled. It is allowed to generate and send an ACL packet with payload length zero irrespective of flow status. L2CAP start-fragment and continue-fragment indications (LLID=10 and LLID=01) also retain their meaning when the payload length is equal to zero (i.e. an empty start-fragment shall not be sent in the middle of an on-going ACL-U or APB-U packet transmission). It is always allowed to send an ACL packet with length=0 and LLID=01. The payload flow bit has its own meaning for each logical link, see Table 6.6. On the ACL-C, APB-C, and APB-U logical links, no flow control is applied and the payload FLOW bit shall always be set to one. On the PBD logical link, no flow control is applied and the payload FLOW bit shall always be set to zero.

LLID code b_1b_0	Logical Link	Usage and semantics of the ACL payload header FLOW bit
00		Reserved for future use.
01	ACL-U	Flow control of the ACL-U channel (L2CAP messages).
	APB-U	Always set FLOW=1 on transmission and ignore the bit on reception.
	PBD	Reserved for future use.
10	ACL-U	Flow control of the ACL-U channel (L2CAP messages).
	APB-U	Always set FLOW=1 on transmission and ignore the bit on reception.
	PBD	Always set FLOW=0 on transmission and ignore the bit on reception.
11	ACL-C and APB-C	Always set FLOW=1 on transmission and ignore the bit on reception.

Table 6.6: Use of payload header flow bit on the Logical Links

The length indicator shall be set to the number of bytes (i.e. 8-bit words) in the payload excluding the payload header, MIC, and the CRC code; i.e. the payload body only. With reference to Figure 6.12 and Figure 6.13, the MSB of the length field in a 1-byte header is the last (right-most) bit in the payload header; the MSB of the length field in a 2-byte header is the fourth bit to the left from the right-most end of the second byte in the payload header.

4. **Payload body**

   The payload body includes the user information and determines the effective user throughput. The length of the payload body is indicated in the length field of the payload header.

5. **Message Integrity Check**

   The 32-bit Message Integrity Check (MIC) in the payload is generated as specified in [Vol 2] Part H, Section 9.2.

6. **CRC code generation**

   The 16-bit cyclic redundancy check code in the payload is generated as specified in Section 7.1. Before determining the CRC code, an 8-bit value is used to initialize the CRC generator. For the CRC code in the FHS packets sent in Central Page Response substate, the UAP of the Peripheral is used. For the FHS packet and the extended inquiry response packet sent in Inquiry Response substate, the DCI (see Section 1.2.1) is used. For all other packets, the UAP of the Central is used.

   Only the Payload header, Payload body, and MIC segments (if present) are used to generate the CRC code.

7. **Enhanced Data Rate trailer**

   This is the same as defined for the Synchronous data field in Section 6.6.1.

6.7 Packet summary

A summary of the packets and their characteristics is shown in Table 6.7, Table 6.8, and Table 6.9. The payload represents the packet payload excluding FEC, CRC, and payload header.

Type	Payload (bytes)	FEC	MIC	CRC	Symmetric Max. Rate	Asymmetric Max. Rate
ID	N/A	N/A	N/A	N/A	N/A	N/A
NULL	N/A	N/A	N/A	N/A	N/A	N/A
POLL	N/A	N/A	N/A	N/A	N/A	N/A
FHS	18	2/3	N/A	Yes	N/A	N/A

Table 6.7: Link control packets

Type	Payload Header (bytes)	User Payload (bytes)	FEC	MIC	CRC	Symmetric Max. Rate (kb/s)	Asymmetric Max. Rate (kb/s)	
							Forward	Reverse
DM1	1	0-17	2/3	C.1	Yes	108.8	108.8	108.8

Table 6.9: Synchronous packets

[1]Items followed by ‘D’ relate to data field only.

7 BIT STREAM PROCESSING

Bluetooth devices shall use the bit stream processing schemes as defined in the following sections.

Before the payload is sent over the air interface, several bit manipulations are performed in the transmitter to increase reliability and security. An HEC is added to the packet header, the header bits are scrambled with a whitening word, and FEC coding is applied. In the receiver, the inverse processes are carried out. Figure 7.1 shows the processes carried out for the packet header both at the transmit and the receive side. All header bit processes are mandatory except that whitening and de-whitening shall not be performed on synchronization train packets. In Figure 7.1 processes not performed on all packet types are indicated by dashed blocks.

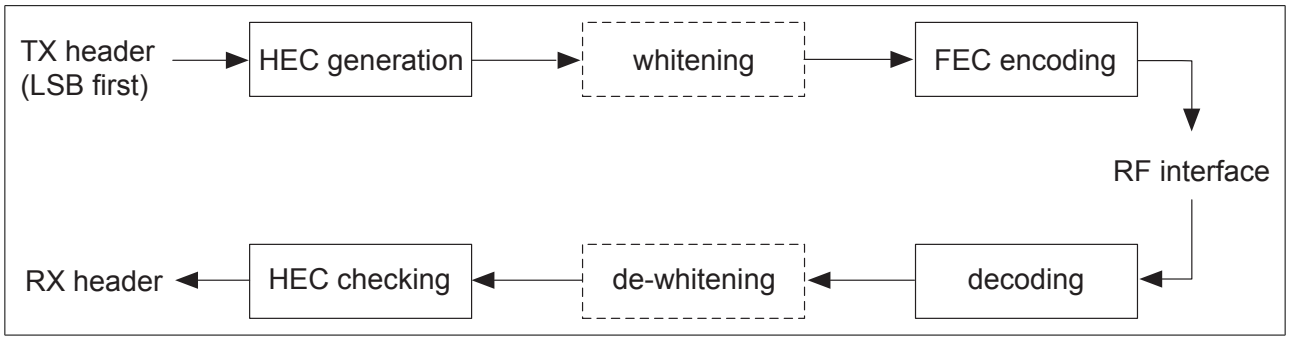

Figure 7.1: Header bit processes

Figure 7.2 shows the processes that may be carried out on the payload. In addition to the processes defined for the packet header, encryption can be applied on the payload. Whitening and de-whitening, as explained in Section 7.2, are mandatory for every payload except synchronization train payloads, where they are forbidden.All other processes are optional and depend on the packet type (see Section 6.6) and whether encryption is enabled. In Figure 7.2, optional processes are indicated by dashed blocks. When E0 encryption is used, the entire payload shall be encrypted. When AES-CCM encryption is used, only the payload body and MIC shall be encrypted; the payload header and CRC shall not be encrypted..

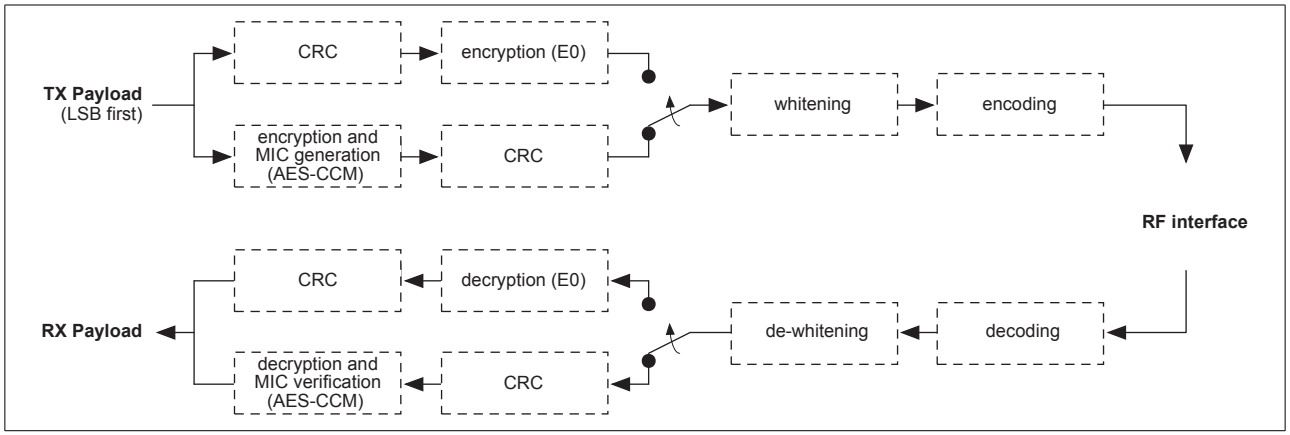

Figure 7.2: Payload bit processes

7.1 Error checking

The packet can be checked for errors or wrong delivery using the channel access code, the HEC in the header, and the CRC in the payload. At packet reception, the access code is checked first. Since the 64-bit sync word in the channel access code is derived from the 24-bit Central's LAP, this checks if the LAP is correct, and prevents the receiver from accepting a packet of another piconet (provided the LAP field of the Central's BD_ADDR is different).

The HEC and CRC computations are initialized as follows:

- In the Inquiry Response substate, the DCI value shall be used for the FHS and Extended Inquiry Response packet.
- In the Central Page Response substate, the UAP of the Peripheral shall be used in the FHS packet.
- In the Connection state, the UAP of the Central shall be used. Even though the access code may be the same for two piconets the different UAP values will typically cause the HEC and CRC to fail.
- During Role Switch starting from the TDD switch, the UAP of the new Peripheral shall be used for the FHS packet.

The generation and check of the HEC and CRC are summarized in Figure 7.5 and Figure 7.8. Before calculating the HEC or CRC, the shift registers in the HEC/CRC generators shall be initialized with the 8-bit UAP (or DCI) value. Then the header and payload information shall be shifted into the HEC and CRC generators, respectively (with the LSB first).

A packet has a valid header if the access code is correct for the piconet and the HEC has the correct value, irrespective of the values of the other header fields.

7.1.1 HEC generation

The HEC generating LFSR is depicted in Figure 7.3. The generator polynomial is $g(D) = (D + 1)(D^7 + D^4 + D^3 + D^2 + 1) = D^8 + D^7 + D^5 + D^2 + D + 1$. Initially this circuit shall be pre-loaded with the 8-bit UAP such that the LSB of the UAP (denoted UAP_0) goes to the left-most shift register element, and, UAP_7 goes to the right-most element. The initial state of the HEC LFSR is depicted in Figure 7.4. Then the data shall be shifted in with the switch S set in position 1. When the last data bit has been clocked into the LFSR, the switch S shall be set in position 2, and, the HEC can be read out from the register. The LFSR bits shall be read out from right to left (i.e., the bit in position 7 is the first to be transmitted, followed by the bit in position 6, etc.).

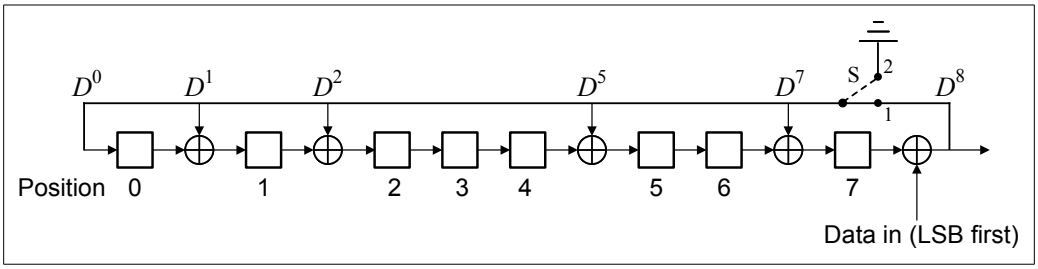

Figure 7.3: LFSR circuit generating the HEC

Position:	0	1	2	3	4	5	6	7
LFSR:	UAP 0	UAP 1	UAP 2	UAP 3	UAP 4	UAP 5	UAP 6	UAP 7

Figure 7.4: Initial state of the HEC generating circuit

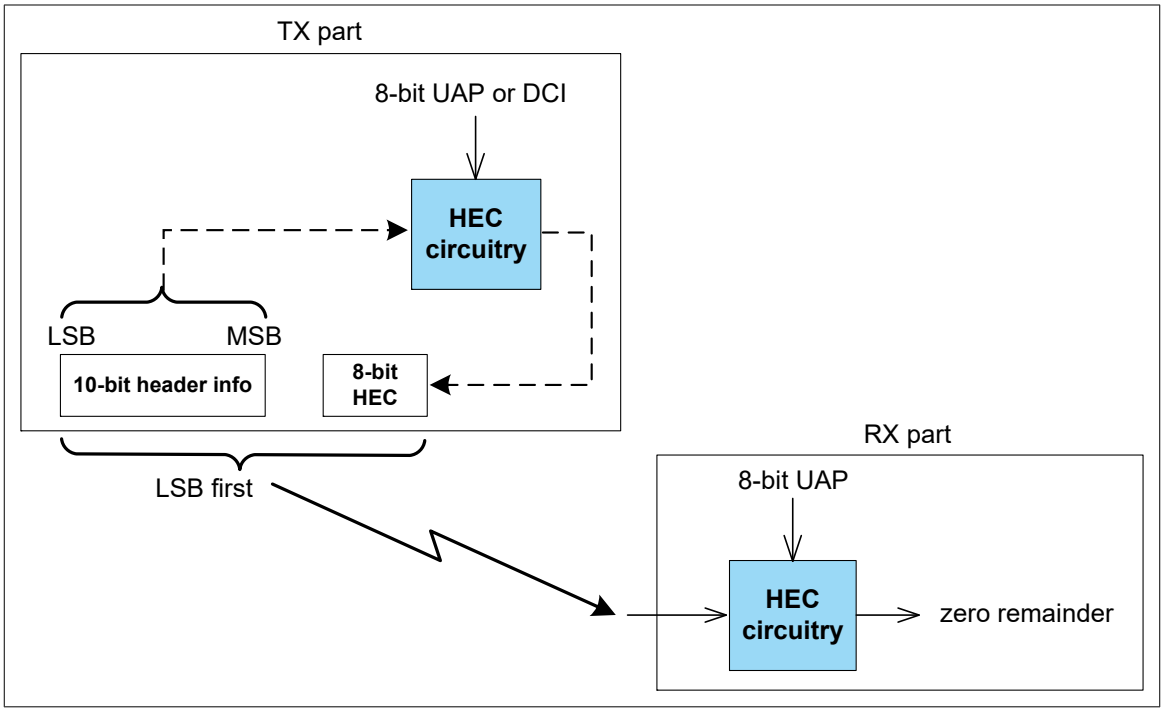

Figure 7.5: HEC generation and checking

7.1.2 CRC generation

The 16 bit LFSR for the CRC is constructed similarly to the HEC using the CRC-CCITT generator polynomial $g(D) = D^{16} + D^{12} + D^5 + 1$ (i.e., 0x11021) (see Figure 7.6). For this case, the 8 left-most bits shall be initially loaded with the 8-bit UAP (UAP_0 to the left and UAP_7 to the right) while the 8 right-most bits shall be reset to zero. The initial state of the 16 bit LFSR is specified in Figure 7.7. The switch S shall be set in position 1 while the data is shifted in. After the last bit has entered the LFSR, the switch shall be set in position 2, and, the register's contents shall be transmitted, from right to left (i.e., starting with position 15, then position 14, etc.).

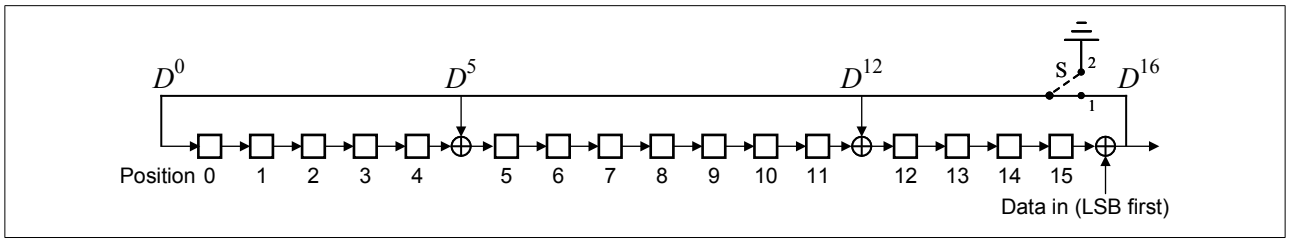

Figure 7.6: The LFSR circuit generating the CRC

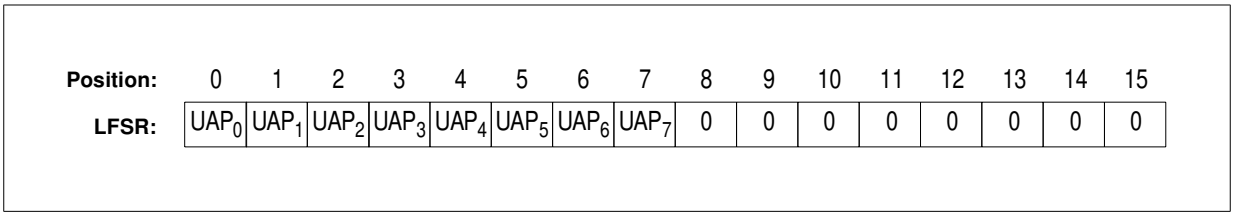

Figure 7.7: Initial state of the CRC generating circuit

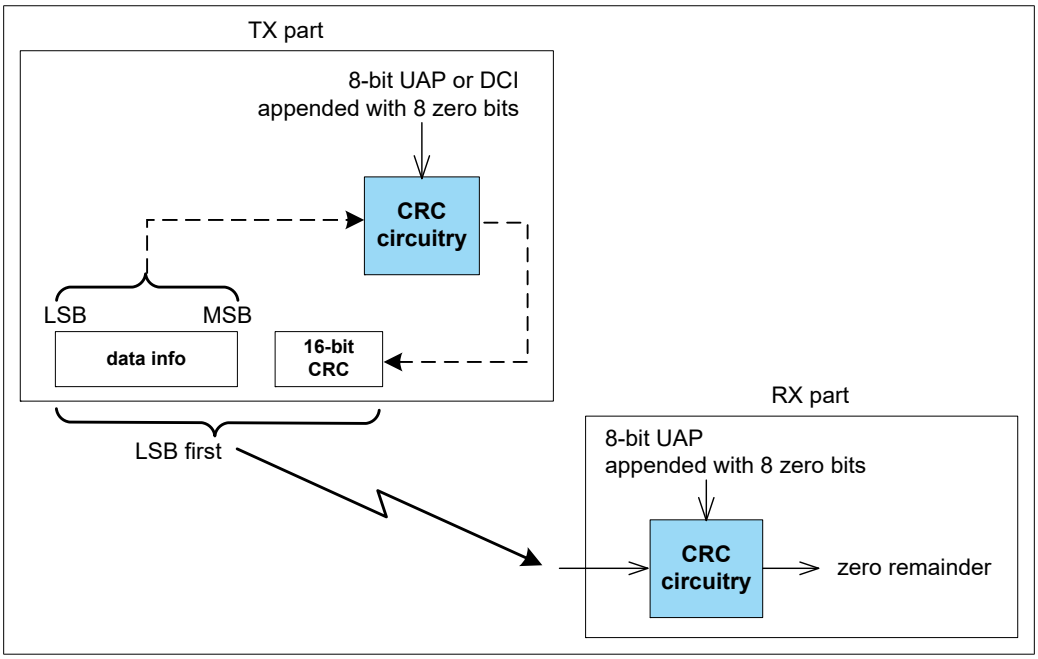

Figure 7.8: CRC generation and checking

7.2 Data whitening

Before transmission of all packets both the header and the payload shall be scrambled with a data whitening word in order to randomize the data from highly redundant patterns and to minimize DC bias in the packet. The scrambling shall be performed prior to the FEC encoding. As an exception, Synchronization train packets shall not be scrambled with a data whitening word.

At the receiver, the received data of scrambled packets shall be descrambled using the same whitening word generated in the recipient. The descrambling shall be performed after FEC decoding.

The whitening word is generated with the polynomial $g(D) = D^7 + D^4 + 1$ (i.e., 0x91) and shall be subsequently XORed with the header and the payload. The whitening word is generated with the linear feedback shift register shown in Figure 7.9. Before each transmission, the shift register shall be initialized with a portion of the Central's clock, CLK_{6-1}, extended with an MSB of value one. This initialization shall be carried out with

CLK_1 written to position 0, CLK_2 written to position 1, etc. Exceptions are the FHS packet sent during inquiry response or Central page response, and the extended inquiry response packet sent during inquiry response, where initialization of the whitening register shall be carried out differently. Instead of the Central's clock, the X-input used in the inquiry or page response (depending on current state) routine shall be used, see Table 2.2. The 5-bit value shall be extended with two MSBs of value 1. During register initialization, the LSB of X (i.e., X_0) shall be written to position 0, X_1 shall be written to position 1, etc.

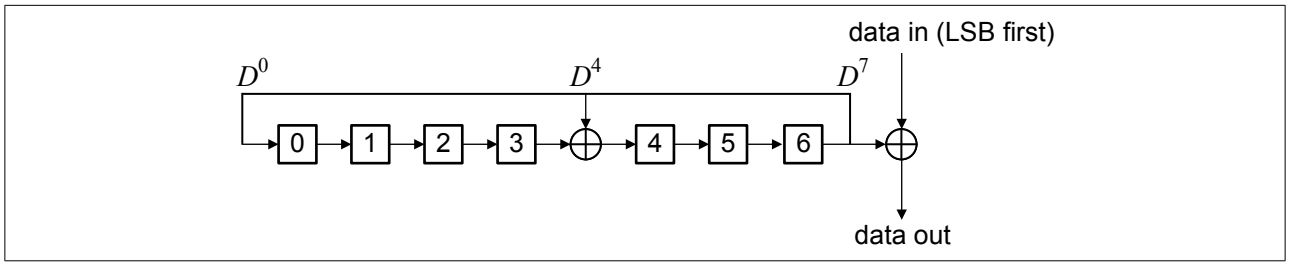

Figure 7.9: Data whitening LFSR

After initialization, the packet header and the payload (including the CRC) are whitened. The payload whitening shall continue from the state the whitening LFSR had at the end of HEC. There shall be no re-initialization of the shift register between packet header and payload. The first bit of the “data in” sequence shall be the LSB of the packet header.

For Enhanced Data Rate packets, whitening shall not be applied to the guard, synchronization and trailer portions of the Enhanced Data Rate packets. During the periods where whitening is not applied the LFSR shall be paused.

7.3 Error correction

There are three error correction schemes defined for Bluetooth:

- 1/3 rate FEC
- 2/3 rate FEC
- ARQ scheme for the data

The purpose of the FEC scheme on the data payload is to reduce the number of retransmissions. However, in a reasonably error-free environment, FEC gives unnecessary overhead that reduces the throughput. Therefore, the packet definitions given in Section 6 have been kept flexible to use FEC in the payload or not, resulting in the **DM** and **DH** packets for the ACL logical transport, **HV** packets for the SCO logical transport, and **EV** packets for the eSCO logical transport. The packet header is always protected by a 1/3 rate FEC since it contains valuable link information and is designed to withstand more bit errors.

Correction measures to mask errors in the voice decoder are not included in this section. This matter is discussed in Section 9.3.

7.4 FEC code: rate 1/3

A simple 3-times repetition FEC code is used for the header. The repetition code is implemented by repeating each bit three times, see the illustration in Figure 7.10. The 3-times repetition code is used for the entire header, as well as for the synchronous data field in the **HV1** packet.

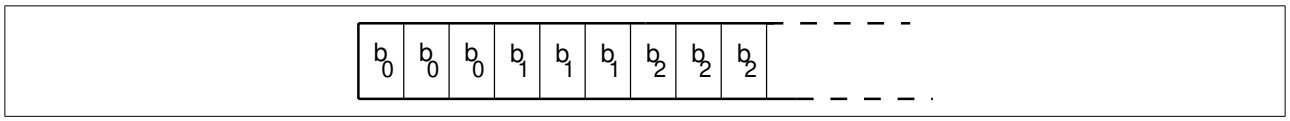

Figure 7.10: Bit-repetition encoding scheme

7.5 FEC code: rate 2/3

The other FEC scheme is a (15,10) shortened Hamming code. The generator polynomial is $g(D) = (D + 1)(D^4 + D + 1)$. This corresponds to 0x35. The LFSR generating this code is depicted in Figure 7.11. Initially all register elements are set to zero. The 10 information bits are sequentially fed into the LFSR with the switches S1 and S2 set in position 1. Then, after the final input bit, the switches S1 and S2 are set in position 2, and the five parity bits are shifted out. The parity bits are appended to the information bits. Subsequently, each block of 10 information bits is encoded into a 15 bit codeword. This code can correct all single errors and detect all double errors in each codeword. This 2/3 rate FEC is used in the **DM** packets, in the data field of the **DV** packet, in the **FHS** packet, in the **HV2** packet, and in the **EV4** packet. Since the encoder operates with information segments of length 10, tail bits with value zero shall be appended after the CRC bits to bring the total number of bits equal to a multiple of 10. The number of tail bits to append shall be the least possible that achieves this (i.e., in the interval 0...9). These tail bits are not included in the payload length indicator for ACL packets or in the payload length field of the eSCO setup LMP command.

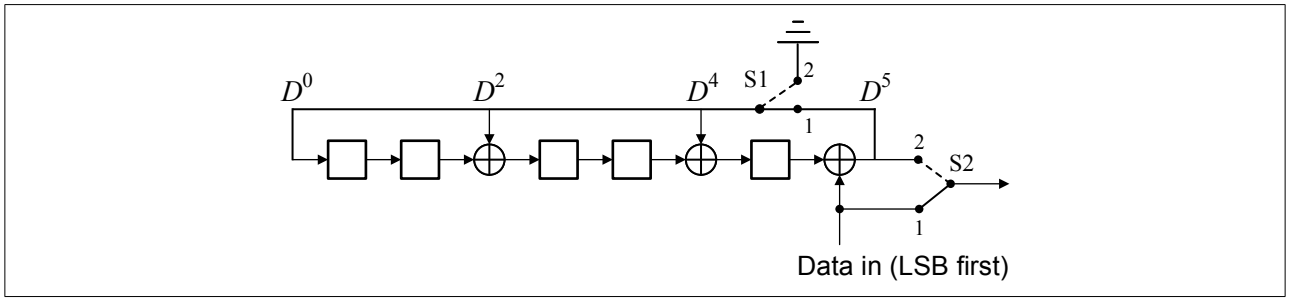

Figure 7.11: LFSR generating the (15,10) shortened Hamming code

7.6 ARQ scheme

With an automatic repeat request scheme, DM packets, DH packets, the data field of DV packets, and EV packets shall be transmitted until acknowledgment of a successful reception is returned by the destination (or timeout is exceeded). The acknowledgment information shall be included in the header of the return packet. The ARQ scheme is only used on the payload in the packet and only on packets that have a CRC. The packet header and the synchronous data payload of HV and DV packets are not protected by the ARQ scheme.

7.6.1 Unnumbered ARQ

Bluetooth uses a fast, unnumbered acknowledgment scheme. An ACK (ARQN=1) or a NAK (ARQN=0) is returned in response to the receipt of a previously received packet. The Peripheral shall respond in the Peripheral-to-Central slot directly following the Central-to-Peripheral slot unless the Peripheral has scatternet commitments in that timeslot; the Central shall respond at the next event addressing the same Peripheral (the Central may have addressed other Peripherals between the last received packet from the considered Peripheral and the Central's response to this packet). A packet reception is successful if the HEC passes and, when present, the MIC and CRC pass.

In the first POLL packet at the start of a new connection (as a result of a page, page scan, or role switch) the Central shall initialize the ARQN bit to NAK. The response packet sent by the Peripheral shall also have the ARQN bit set to NAK. The subsequent packets shall use the following rules. The initial value of the Central's eSCO ARQN at link set-up shall be NAK.

The ARQN bit shall only be affected by data packets containing CRC and empty slots. As shown in Figure 7.12, Figure 7.13, and Figure 7.14, upon successful reception of a CRC packet, the ARQN bit shall be set to ACK. If, in any receive slot in the Peripheral, or, in a receive slot in the Central following transmission of a packet, one of these events applies:

1. no access code is detected
2. the HEC fails
3. the CRC fails
4. the MIC fails.

then the ARQN bit shall be set to NAK except in the conditions below:

- In eSCO the ARQN bit may be set to ACK even when the CRC on an EV packet has failed thus enabling delivery of erroneous packets.
- For ACL packets, if a CRC packet with a correct header has the same SEQN as the previously received CRC packet, the ARQN bit shall be set to ACK and the payload shall be ignored without checking the CRC.

Packets that have correct HEC but that are addressed to other Peripherals, or packets other than DH, DM, DV or EV packets, shall not affect the ARQN bit, except as noted in Section 7.6.2.2. In these cases the ARQN bit shall be left as it was prior to reception of the packet. For eSCO packets, the SEQN shall not be used when determining the ARQN. If an eSCO packet has been received successfully within the eSCO window subsequent receptions within the eSCO window shall be ignored. At the end of the eSCO window, the Central's ARQN shall be retained for the first Central-to-Peripheral transmission in the next eSCO window.

The ARQN bit in the FHS packet is not meaningful. Contents of the ARQN bit in the FHS packet shall not be checked.

The ARQN bit in the extended inquiry response packet is reserved for future use.

Broadcast packets shall be checked on errors using the CRC, but no ARQ scheme shall be applied. Broadcast packets shall never be acknowledged.

In Figure 7.12, TX refers to the next transmission that the device makes, which might not be in the next slot. NO TX indicates that the device is not allowed to transmit in the next slot.

In Figure 7.14, "Packet OK" means that the packet has an allowed TYPE for the connection and the CRC is valid.

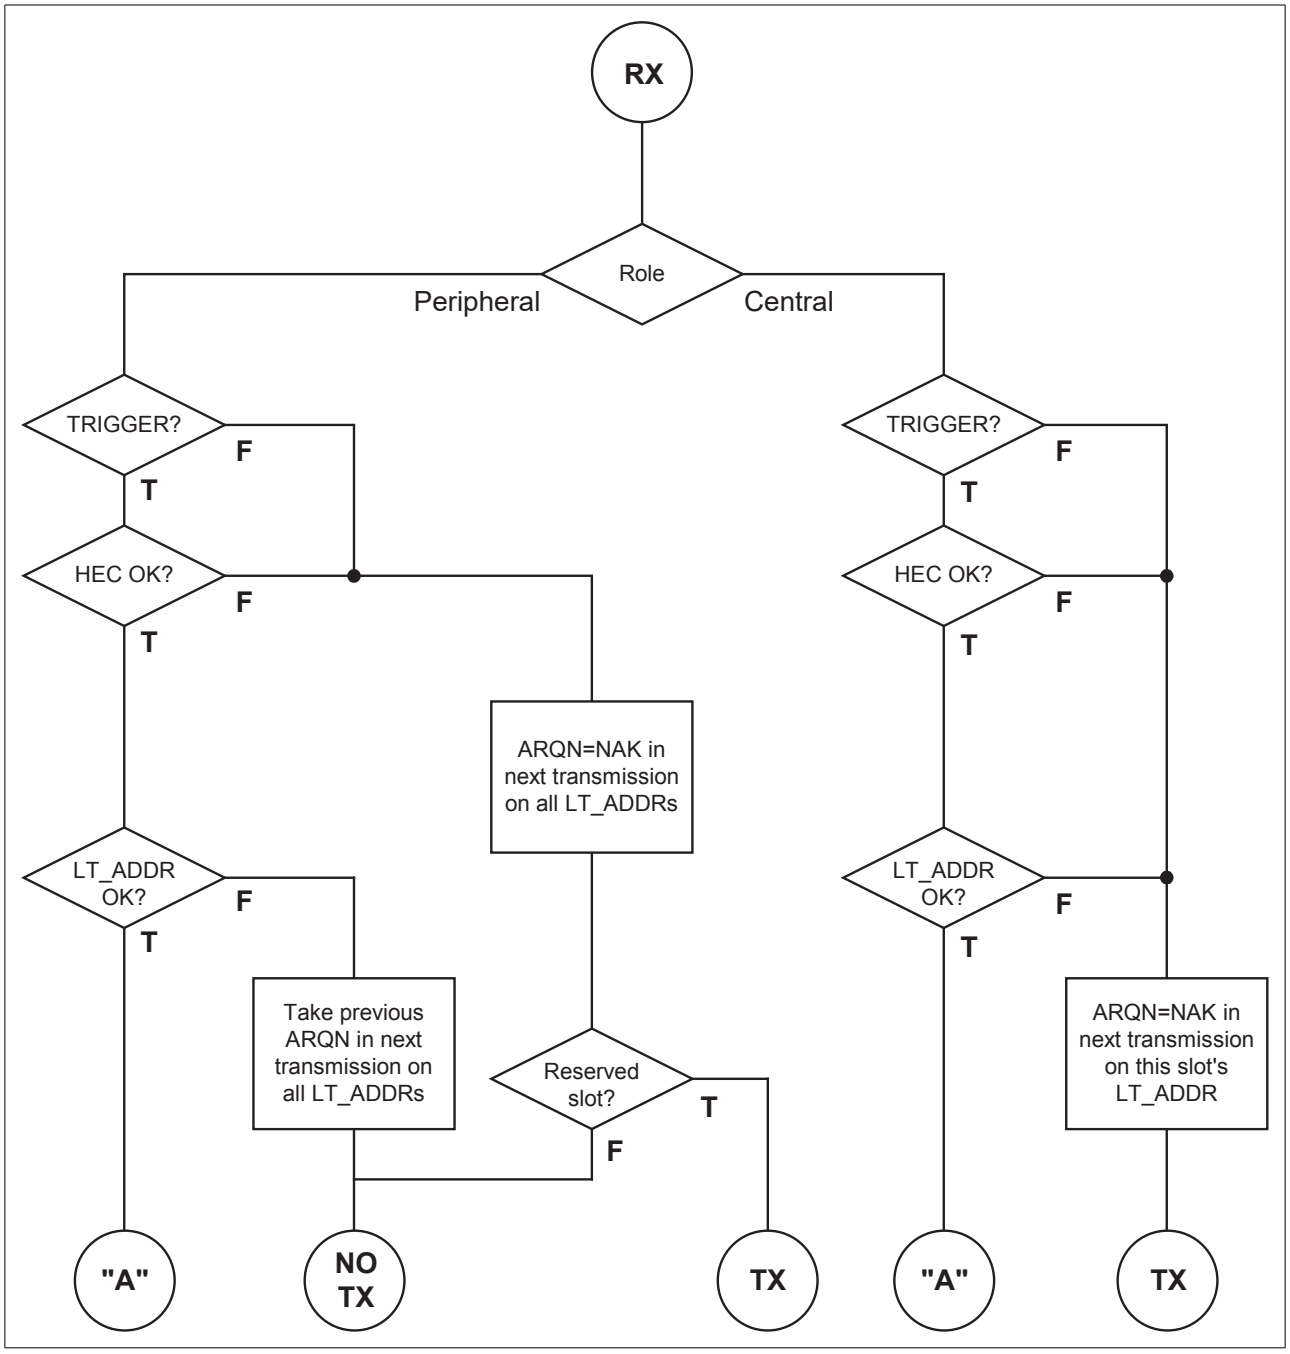

Figure 7.12: Stage 1 of the receive protocol for determining the ARQN bit

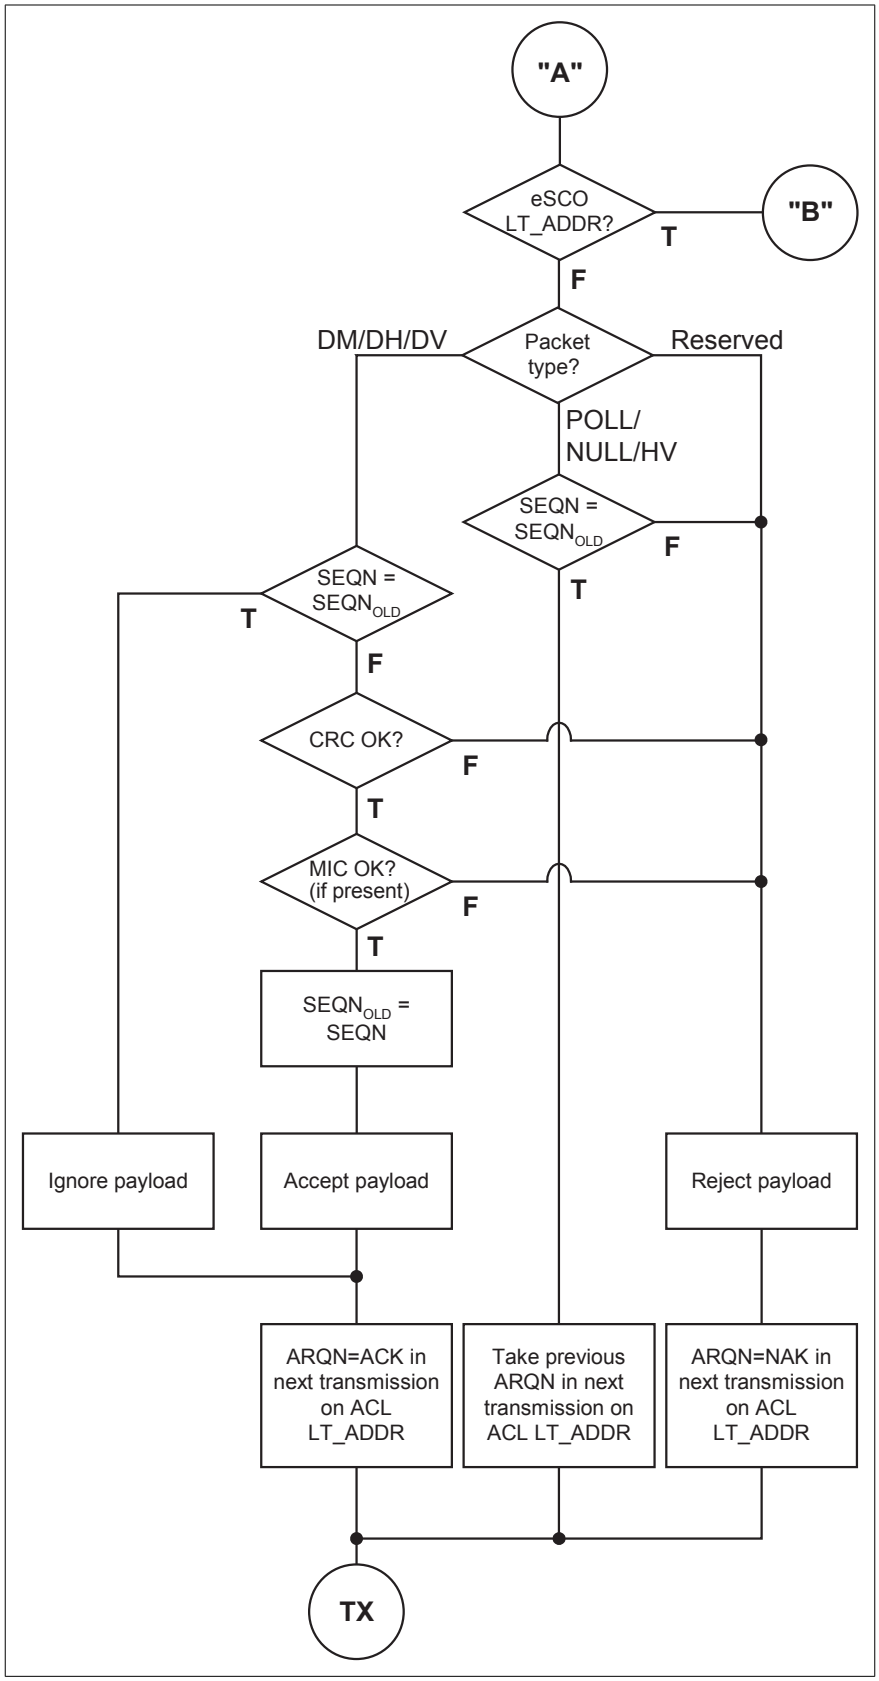

Figure 7.13: Stage 2 (ACL) of the receive protocol for determining the ARQN bit

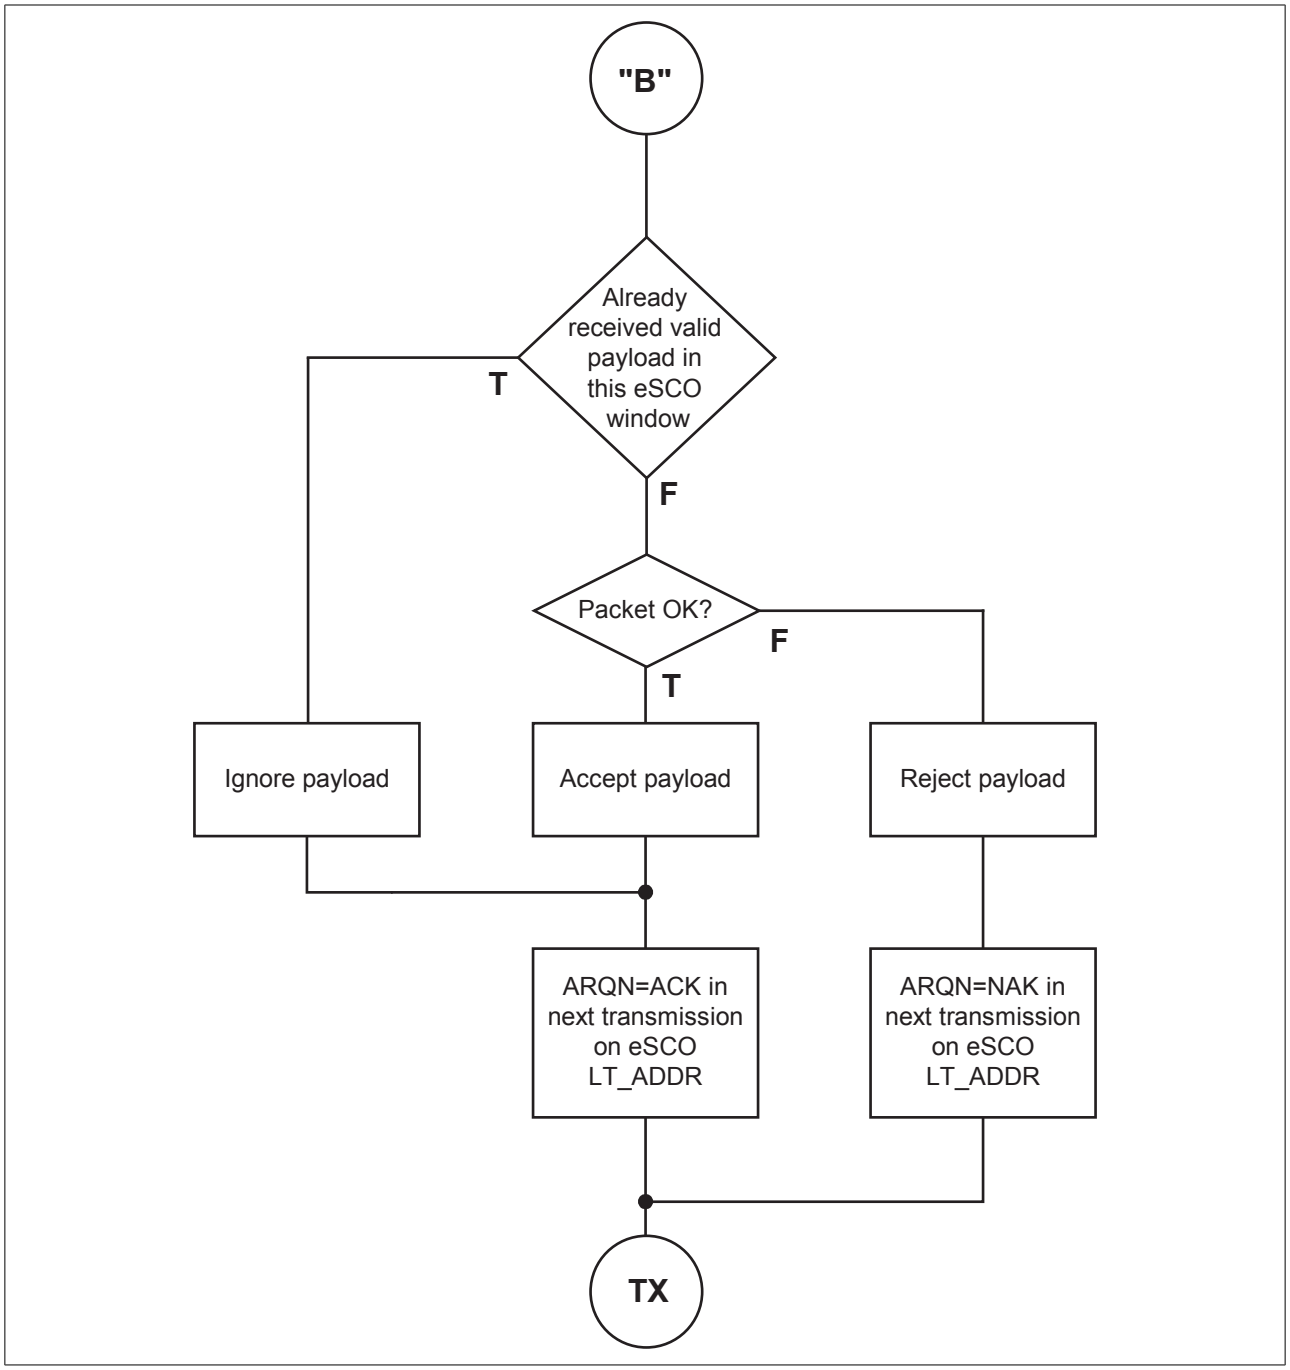

Figure 7.14: Stage 2 (eSCO) of the receive protocol for determining the ARQN bit

7.6.2 Retransmit filtering

The data payload shall be transmitted until a positive acknowledgment is received or a timeout is exceeded. A retransmission shall be carried out either because the packet transmission itself failed, or because the acknowledgment transmitted in the return packet failed (which has a lower failure probability since the header is more heavily coded). In the latter case, the destination keeps receiving the same payload over and

over again. In order to filter out the retransmissions in the destination, the SEQN bit is present in the header. Normally, this bit is alternated for every new CRC data payload transmission. In case of a retransmission, this bit shall not be changed so the destination can compare the SEQN bit with the previous SEQN value. If different, a new data payload has arrived; otherwise it is the same data payload and may be ignored. Only new data payloads shall be transferred to the Baseband Resource Manager.

Note: CRC data payloads can be carried only by **DM**, **DH**, **DV** or **EV** packets.

7.6.2.1 Initialization of SEQN at start of new connection

The SEQN bit of the first CRC data packet at the start of a connection (as a result of page, page scan, or role switch) on both the Central and the Peripheral sides shall be set to 1. The subsequent packets shall use the rules in the following sections.

7.6.2.2 ACL and SCO retransmit filtering

The SEQN bit shall only be affected by the CRC data packets as shown in Figure 7.15. It shall be inverted every time a new CRC data packet is sent. The CRC data packet shall be retransmitted with the same SEQN number until an ACK is received or the packet is flushed. When an ACK is received, a new payload may be sent and on that transmission the SEQN bit shall be inverted. If a device decides to flush (see Section 7.6.3), and it has not received an acknowledgment for the current packet, it shall replace the current packet with an ACL-U continuation packet with the same sequence number as the current packet and length zero. If it replaces the current packet in this way it shall not move on to transmit the next packet until it has received an ACK.

If the Peripheral receives a packet other than DH, DM, DV or EV with the SEQN bit inverted from that in the last header successfully received on the same LT_ADDR, it shall set the ARQN bit to NAK until a DH, DM, DV or EV packet is successfully received.

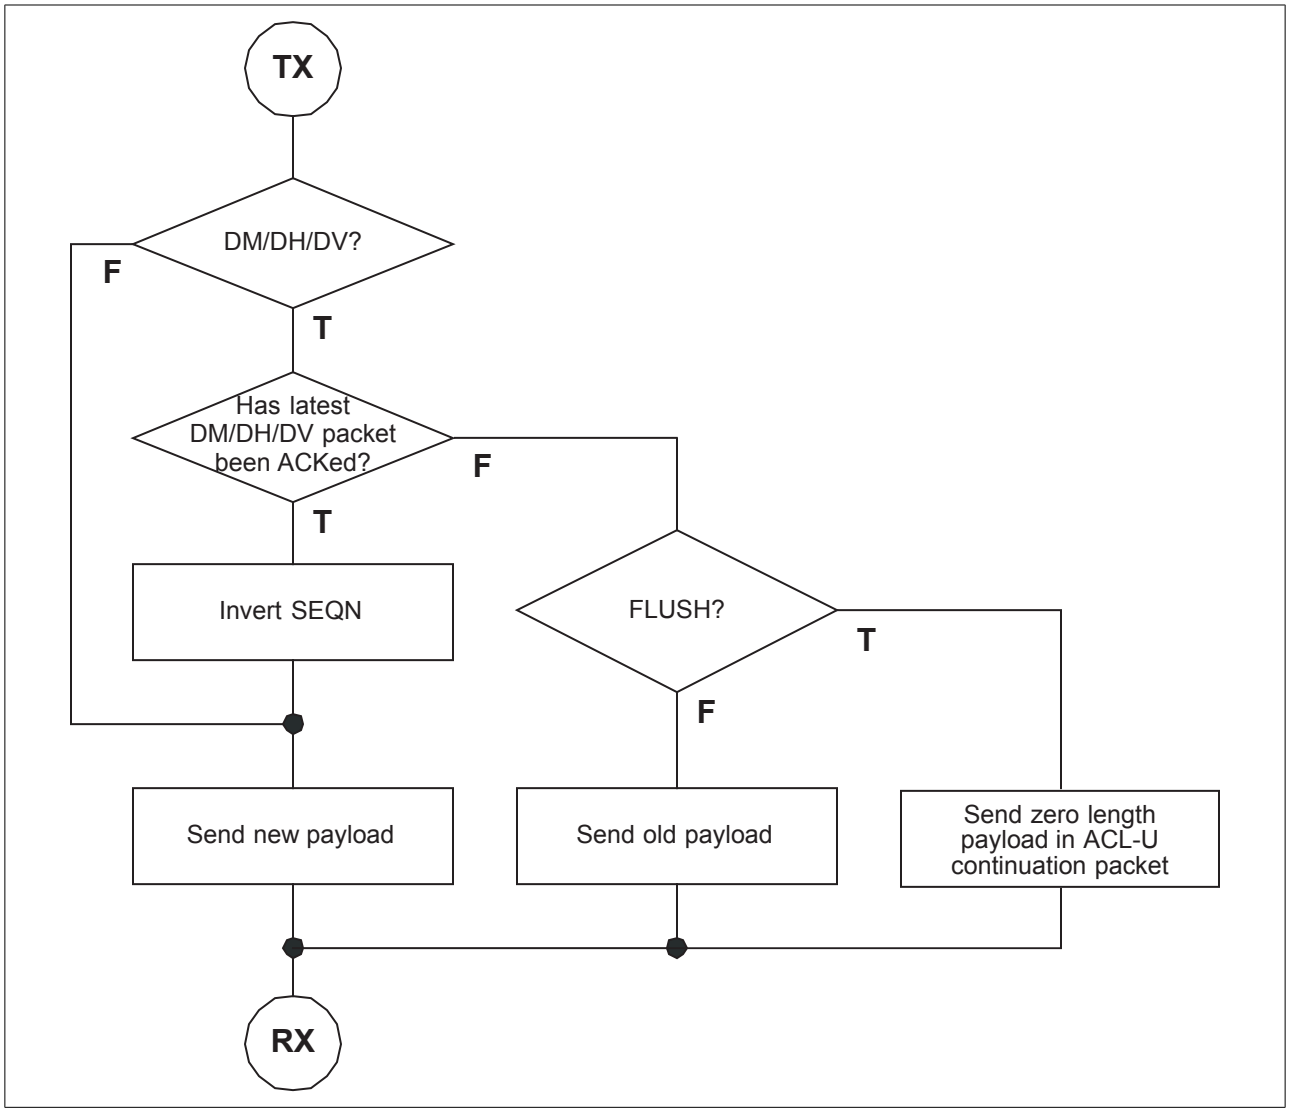

Figure 7.15: Transmit filtering for packets with CRC

7.6.2.3 eSCO retransmit filtering

In eSCO, the SEQN bit shall be toggled every eSCO window. The value shall be constant for the duration of the eSCO window. The initial value of SEQN shall be zero.

For a given eSCO window the SEQN value shall be constant.

7.6.2.4 FHS retransmit filtering

The SEQN bit in the FHS packet is not meaningful. This bit may be set to any value. Contents of the SEQN bit in the FHS packet shall not be checked.

7.6.2.5 Extended inquiry response retransmit filtering

The SEQN bit in the extended inquiry response packet is reserved for future use.

7.6.2.6 Packets without CRC retransmit filtering

During transmission of packets without a CRC the SEQN bit shall remain the same as it was in the previous packet.

7.6.3 Flushing payloads

On ACL logical transports, the ARQ scheme can cause variable delay in the traffic flow since retransmissions are inserted to assure error-free data transfer. For certain communication links, only a limited amount of delay is allowed: retransmissions are allowed up to a certain limit at which the current payload shall be ignored. This data transfer is indicated as **isochronous traffic**. This means that the retransmit process must be overruled in order to continue with the next data payload. Aborting the retransmit scheme is accomplished by *flushing* the old data and forcing the Link Controller to take the next data instead.

Flushing results in loss of remaining portions of an L2CAP message. Therefore, the packet following the flush shall have a start packet indication of LLID = 10 in the payload header for the next L2CAP message. This informs the destination of the flush (see Section 6.6). Flushing will not necessarily result in a change in the SEQN bit value, see the previous section.

The Flush Timeout defines a maximum period after which all segments of the ACL-U packet with a Packet_Boundary_Flag value of 10 are flushed from the Controller buffer. The Flush Timeout shall start when the First segment of the ACL-U packet is stored in the Controller buffer. If the First segment of an ACL-U packet has a Packet_Boundary_Flag value of 00, it is non-automatically-flushable and shall not cause the Flush Timeout to start. After the Flush timeout has expired the Link Controller may continue transmissions according to the procedure described in Section 7.6.2.2, however the Baseband Resource Manager shall not continue the transmission of the ACL-U packet to the Link Controller. If the Baseband Resource Manager has further segments of the packet queued for transmission to the Link Controller it shall delete the remaining segments of the ACL-U packet from the queue. In case the complete ACL-U packet was not stored in the Controller buffer yet, any Continuation segments, received for the ACL logical transport, shall be flushed, until a First segment is received. When the complete ACL-U packet has been flushed, the Link Manager shall continue transmission of the next ACL-U packet for the ACL logical transport. The default Flush Timeout shall be infinite, i.e. re-transmissions are carried out until physical link loss occurs. This is also referred to as a 'reliable channel.' All devices shall support the default Flush Timeout. Reliable data shall be sent over a channel with a finite flush timeout by marking reliable packets as non-automatically-flushable.

On eSCO logical transports, packets shall be automatically flushed at the end of the eSCO window.

Connectionless Peripheral Broadcast packets are transmitted at each scheduled Connectionless Peripheral Broadcast Instant. If no new data is available, the Connectionless Peripheral Broadcast Transmitter shall transmit a packet with the last available data in the payload.

7.6.4 Multi-Peripheral considerations

In a piconet with multiple logical transports, the Central shall carry out the ARQ protocol independently on each logical transport.

7.6.5 Active Peripheral Broadcast packets

APB broadcast packets are packets transmitted by the Central to all the Peripherals simultaneously (see Section 8.6.4) If multiple hop sequences are being used each transmission may only be received by some of the Peripherals. In this case the Central shall repeat the transmission on each hop sequence. An APB broadcast packet shall be indicated by the all-zero LT_ADDR.

Note: The FHS packet and the extended inquiry response packet are the only packets which may have an all-zero LT_ADDR but are not broadcast packets.

Broadcast packets shall not be acknowledged (at least not at the LC level), hence each broadcast packet is transmitted at least a fixed number of times. An APB broadcast packet should be transmitted N_{BC} times before the next broadcast packet of the same broadcast message is transmitted, see Figure 7.16. Optionally, an APB broadcast packet may be transmitted N_{BC} + 1 times, so N_{BC}=1 means that each broadcast packet should be sent only once but may be sent twice. However, time-critical broadcast information may abort the ongoing broadcast train. In addition, an LMP packet sent on the APB-C logical link is always a complete message for these purposes and is always sent exactly once; the LMP specification may provide requirements for whether and when to send another message with the same or related contents.

If multiple hop sequences are being used then the Central may transmit on the different hop sequences in any order, providing that transmission of a new broadcast packet shall not be started until all transmissions of any previous broadcast packet have completed on all hop sequences. The transmission of a single broadcast packet may be interleaved among the hop sequences to minimize the total time to broadcast a packet. The Central has the option of transmitting only N_{BC} times on channels common to all hop sequences.

APB broadcast packets with a CRC shall have their own sequence number. The SEQN of the first broadcast packet with a CRC shall be set to SEQN = 1 by the Central and shall be inverted for each new broadcast packet with CRC thereafter. APB broadcast packets without a CRC have no influence on the sequence number. The Peripheral shall accept the SEQN of the first broadcast packet it receives in a connection and

shall check for change in SEQN for subsequent broadcast packets. Since there is no acknowledgment of broadcast messages and there is no end packet indication, it is important to receive the start packets correctly. To ensure this, repetitions of the broadcast packets that are L2CAP start packets and LMP packets shall not be filtered out. These packets shall be indicated by LLID=1X in the payload header as explained in Table 6.5. Only repetitions of the L2CAP continuation packets shall be filtered out.

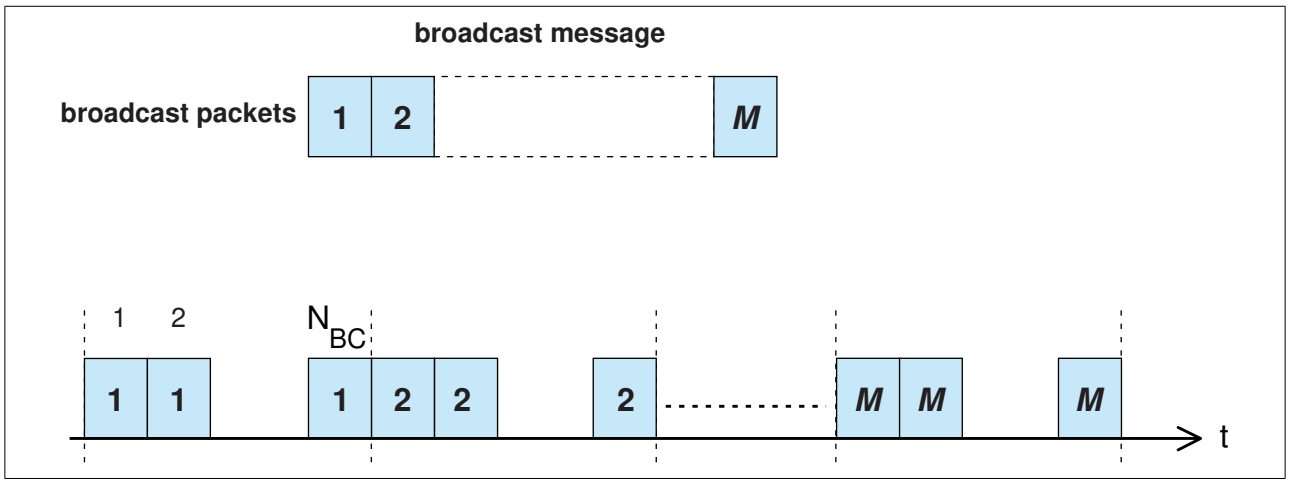

Figure 7.16: Broadcast repetition scheme

7.7 Erroneous synchronous data reporting

Erroneous data reporting may be enabled for synchronous links. When enabled, synchronous data shall be processed as follows:

- If, during an (e)SCO interval, an eSCO packet was received with valid HEC, an allowed TYPE for the connection, and valid CRC, or a SCO packet was received with valid HEC, the received payload data shall be sent to the upper-edge of the Controller with a "good data" indication.
- If, during an eSCO interval, eSCO packets with valid HEC were received, but none of them had an allowed TYPE for the connection and a valid CRC, the best known data available (e.g., data derived from the received data or the actual payload data that was received with a CRC error) shall be sent to the upper-edge of the Controller with a "data with possible errors" indication.
- If, during an (e)SCO interval, no SCO or eSCO packet with valid HEC has been received, a "lost data" indication shall be sent to the upper-edge of the Controller.

7.8 Message Integrity Check

When encryption with AES-CCM is enabled, a Message Integrity Check (MIC) is added to the payload before the CRC for packets that are defined to include the MIC. The MIC is sent Most Significant Octet (MSO) first.

8 LINK CONTROLLER OPERATION

This section describes how a piconet is established and how devices can be added to and released from the piconet. Several states of operation of the devices are defined to support these functions. In addition, the operation of several piconets with one or more common members, the scatternet, is discussed.

8.1 Overview of states

Figure 8.1 shows a state diagram illustrating the different states used in the Link Controller. There are two major states: Standby and Connection; in addition, there are nine substates, Page, Page Scan, Inquiry, Inquiry Scan, Synchronization Train, Synchronization Scan, Central Page Response, Peripheral Page Response, and Inquiry Response (the Central Page Response, Peripheral Page Response, and Inquiry Response substates are not shown in the simplified figure below). The substates are interim states that are used to establish connections and enable device discovery. To move from one state or substate to another, either commands from the link manager are used, or internal signals in the Link Controller are used (such as the trigger signal from the correlator and the timeout signals).

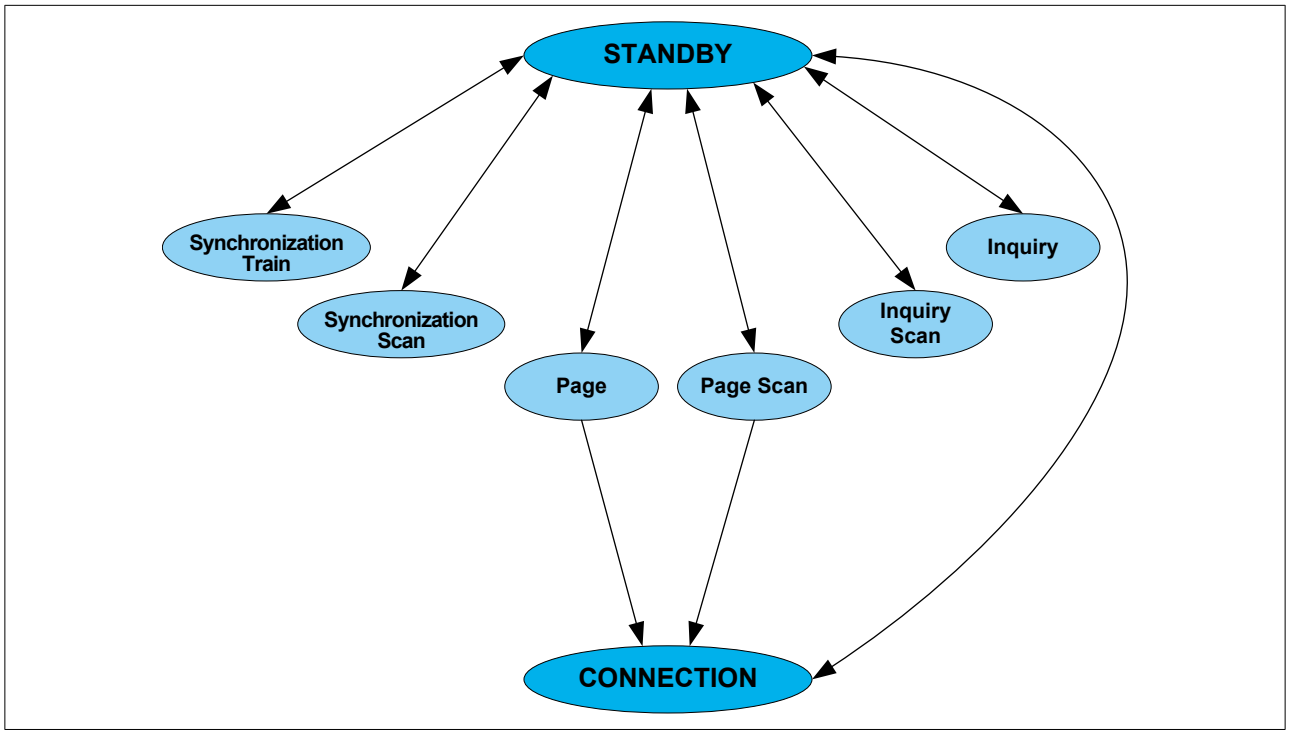

Figure 8.1: State diagram of Link Controller

8.2 Standby state

The Standby state is the default state in the device. In this state, the device may be in a low-power mode. Only the native clock is running with a worst case accuracy of ±250 ppm.

The Controller may leave the Standby state to scan for page or inquiry messages, or to page or inquiry itself.

8.3 Connection establishment substates

In order to establish new connections the paging procedure or the synchronization scan procedure is used. Only the Bluetooth Device Address is required to set up a connection using the paging procedure. Knowledge about the clock, obtained from the inquiry procedure (see Section 8.4) or from a previous connection with this device, and the page scanning mode of the other device will accelerate the paging procedure. A device that establishes a connection using a page procedure will automatically become the Central of the connection. A device that establishes a connection using a synchronization scan procedure does so in two steps. First, from within the Synchronization Scan substate, the BR/EDR Controller follows the synchronization scan procedure to collect clock, packet timing, and AFH channel map information from the Central and then transitions to the Standby state. Second, as commanded by the Host, the BR/EDR Controller transitions from the Standby state to the Connectionless Peripheral Broadcast mode of the Connection state.

The truncated page procedure is a modification of the paging procedure and is used to deliberately generate a page response timeout on the Peripheral.

8.3.1 Page Scan substate

In the Page Scan substate, a device may be configured to use either the standard or generalized interlaced scanning procedure. During a standard scan, a device listens for the duration of the scan window $T_{w\_page\_scan}$ (11.25 ms default, see [Vol 4] Part E, Section 7.3.20), while the generalized interlaced scan is performed as two back to back scans of $T_{w\_page\_scan}$. If the scan interval is not at least twice the scan window, then generalized interlaced scan shall not be used. During each scan window, the device shall listen at a single hop frequency, its correlator matched to its device access code (DAC). The scan window shall be long enough to completely scan 16 page frequencies.

When a device enters the Page Scan substate, it shall select the scan frequency according to the page hopping sequence determined by the device's Bluetooth Device Address, see Section 2.6.4.1. The phase in the sequence shall be determined by $CLKN_{16\text{-}12}$ of the device's native clock; that is, every 1.28 s a different frequency is selected.

In the case of a standard scan, if the correlator exceeds the trigger threshold during the page scan, the device shall enter the Peripheral Page Response substate described in Section 8.3.3.1. The scanning device may also use generalized interlaced scan. In this case, if the correlator does not exceed the trigger threshold during the first scan it shall scan a second time using the phase in the sequence determined by [$CLKN_{16-12}$ + interlace_offset] *mod* 32. If on this second scan the correlator exceeds the trigger threshold the device shall enter the Peripheral Page Response substate using [$CLKN_{16-12}$ + interlace_offset] *mod* 32 as the frozen CLKN* in the calculation for Xprp (see Section 2.6.4.3 for details). If the correlator does not exceed the trigger threshold during a scan in normal mode or during the second scan in interlaced scan mode it shall return to either the Standby or Connection state.

The interlace_offset value ranges from 0 to 31. The value 16 should be used unless the pattern of slots that are not available for scanning implies a different value should be used.

The Page Scan substate can be entered from the Standby state or the Connection state. In the Standby state, no connection has been established and the device can use all the capacity to carry out the page scan. Before entering the Page Scan substate from the Connection state, the device should reserve as much capacity as possible for scanning. If desired, the device may place ACL connections in Hold mode (see Section 8.8) or Sniff mode (see Section 8.7). Synchronous connections should not be interrupted by the page scan, although eSCO retransmissions should be paused during the scan. The page scan may be interrupted by the reserved synchronous slots which should have higher priority than the page scan. SCO packets should be used requiring the least amount of capacity (**HV3** packets). The scan window shall be increased to minimize the setup delay. If one SCO logical transport is present using **HV3** packets and T_{SCO}=6 slots or one eSCO logical transport is present using **EV3** packets and T_{eSCO}=6 slots, a total scan window $T_{w\_page\_scan}$ of at least 36 slots (22.5 ms) is recommended; if two SCO links are present using **HV3** packets and T_{SCO}=6 slots or two eSCO links are present using **EV3** packets and T_{eSCO}=6 slots, a total scan window of at least 54 slots (33.75 ms) is recommended.

The scan interval T_{page_scan} is defined as the interval between the beginnings of two consecutive page scans. A distinction is made between the case where the scan interval is equal to the scan window $T_{w\_page\_scan}$ (continuous scan), the scan interval is maximal 1.28 s, or the scan interval is maximal 2.56 s. These three cases shall determine the behavior of the paging device; that is, whether the paging device shall use R0, R1 or R2, see also Section 8.3.2. Table 8.1 illustrates the relationship between T_{page_scan} and modes R0, R1 and R2. Although scanning in the R0 mode is continuous, the scanning may be interrupted for example by reserved synchronous slots. The scan interval information (also known as the page scan repetition mode) is included in the SR field in the FHS packet.

SR mode	T_{page_scan}
R0	≤ 1.28 s and = $T_{w\_page\_scan}$
R1	≤ 1.28 s
R2	≤ 2.56 s

Table 8.1: Relationship between scan interval and page scan repetition modes R0, R1, and R2

8.3.2 Page substate

The Page substate is used by the Central (source) to activate and connect to a Peripheral (destination) in the Page Scan substate. The Central tries to coincide with the Peripheral's scan activity by repeatedly transmitting the paging message consisting of the Peripheral's device access code (DAC) in different hop channels. Since the Bluetooth clocks of the Central and the Peripheral are not synchronized, the Central does not know exactly when the Peripheral wakes up and on which hop frequency. Therefore, it transmits a train of identical page messages at different hop frequencies and listens in between the transmit intervals until it receives a response from the Peripheral.

The page procedure in the Central consists of a number of steps. First, the Host communicates the BD_ADDR of the Peripheral to the Controller. This BD_ADDR shall be used by the Central to determine the page hopping sequence; see Section 2.6.4.2. If the BD_ADDR of the Peripheral is identical to the BD_ADDR of the Central, then the Central's Controller shall reject the page procedure. For the phase in the sequence, the Central shall use an estimate of the Peripheral's clock. For example, this estimate can be derived from timing information that was exchanged during the last encounter with this particular device (which could have acted as a Central at that time), or from an inquiry procedure. With this estimate CLKE of the Peripheral's Bluetooth clock, the Central can predict on which hop channel the Peripheral starts page scanning.

The estimate of the Bluetooth clock in the Peripheral can be completely wrong. Although the Central and the Peripheral use the same hopping sequence, they use different phases in the sequence and might never select the same frequency. To compensate for the clock drifts, the Central shall send its page message during a short time interval on a number of wake-up frequencies. It shall transmit also on hop frequencies just before and after the current, predicted hop frequency. During each TX slot, the Central shall sequentially transmit on two different hop frequencies. In the following RX slot, the receiver shall listen sequentially to two corresponding RX hops for an ID packet. The RX hops shall be selected according to the page response hopping sequence. The page response hopping sequence is strictly related to the page hopping sequence: for each page hop there is a corresponding page response hop. The RX/TX timing in the Page substate is described in Section 2.2.5, see also Figure 2.7. In the next TX slot, the Central shall transmit on two hop frequencies different from the former ones.

Note: The hop rate is increased to 3200 hops per second.

With the increased hopping rate as described above, the transmitter can cover 16 different hop frequencies in 16 slots or 10 ms. The page hopping sequence is divided over two paging trains **A** and **B** of 16 frequencies. Train **A** includes the 16 hop frequencies surrounding the current, predicted hop frequency *f(k)*, where k is determined by the clock estimate $CLKE_{16-12}$. The first train consists of hops

f(k-8), f(k-7),...,f(k),...,f(k+7)

When the difference between the Bluetooth clocks of the Central and the Peripheral is between -8x1.28 s and +7x1.28 s, one of the frequencies used by the Central will be the hop frequency the Peripheral will listen to. Since the Central does not know when the Peripheral will enter the Page Scan substate, the Central has to repeat this train **A** N_{page} times or until a response is obtained, whichever is shorter. If the Peripheral scan interval corresponds to R1, the repetition number is at least 128; if the Peripheral scan interval corresponds to R2 or if the Central has not previously read the Peripheral's SR (page scan repetition) mode, the repetition number is at least 256. If the Central has not previously read the Peripheral's SR mode it shall use N_{page} >= 256.

Note: $CLKE_{16-12}$ changes every 1.28 s; therefore, every 1.28 s, the trains will include different frequencies of the page hopping set.

When the difference between the Bluetooth clocks of the Central and the Peripheral is less than -8x1.28 s or larger than +7x1.28 s, the remaining 16 hops are used to form the new 10 ms train **B.** The second train consists of hops

f(k-16), f(k-15),...,f(k-9),f(k+8)...,f(k+15)

Train **B** shall be repeated for N_{page} times. If no response is obtained, k_{nudge} may be updated in the case where slots to receive are periodically not available and train **A** shall be tried again N_{page} times. Alternate use of train **A** and train **B** and updates of k_{nudge} shall be continued until a response is received or the timeout *pageTO* + *extended_pageTO* is exceeded. If a response is returned by the Peripheral, the Central enters the Central Page Response substate.

The Page substate may be entered from the Standby state or the Connection state. In the Standby state, no connection has been established and the device can use all the capacity to carry out the page. Before entering the Page substate from the Connection state, the device should free as much capacity as possible for paging. To ensure this, it is recommended that the ACL connections are put on hold. However, the synchronous connections shall not be disturbed by the page. This means that the page will be interrupted by the reserved SCO and eSCO slots which have higher priority than the page. In order to obtain as much capacity for paging, it is recommended to use the SCO packets which use the least amount of capacity (**HV3** packets). If SCO or eSCO

links are present, the repetition number N_{page} of a single train shall be increased, see Table 8.2. Here it has been assumed that the **HV3** packet are used with an interval T_{SCO}=6 slots or **EV3** packets are used with an interval of T_{eSCO}=6 slots, which would correspond to a 64 kb/s synchronous link.

SR mode	no synchronous link	one synchronous link (HV3)	two synchronous links (HV3)
R0	N_{page}≥1	N_{page}≥2	N_{page}≥3
R1	N_{page}≥128	N_{page}≥256	N_{page}≥384
R2	N_{page}≥256	N_{page}≥512	N_{page}≥768

Table 8.2: Relationship between train repetition and paging modes R0, R1 and R2 when synchronous links are present

The construction of the page train shall be independent of the presence of synchronous links; that is, synchronous packets are sent on the reserved slots but shall not affect the hop frequencies used in the unreserved slots, see Figure 8.2.

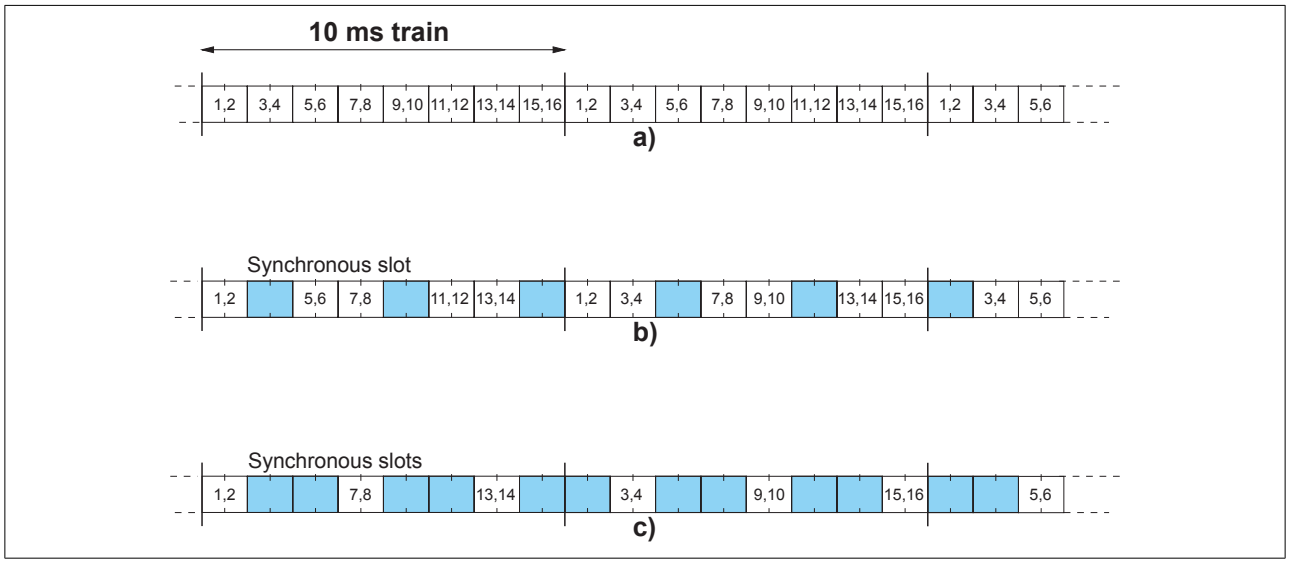

Figure 8.2: Conventional page (a), page while one synchronous link present (b), page while two synchronous links present (c)

8.3.3 Page response substates

When a page message is successfully received by the Peripheral, there is a coarse frequency hopping synchronization between the Central and the Peripheral. Both the Central and the Peripheral enter a response substate to exchange vital information to continue the connection setup. It is important for the piconet connection that both devices shall use the same channel access code, use the same channel hopping sequence, and their clocks are synchronized. These parameters shall be derived from the Central. The device that initializes the connection (starts paging) is defined as

the Central (which is thus only valid during the time the piconet exists). The channel access code and channel hopping sequence shall be derived from the Bluetooth Device Address (BD_ADDR) of the Central. The timing shall be determined by the Central's clock. An offset shall be added to the Peripheral's native clock to temporarily synchronize the Peripheral's clock to the Central's clock. At start-up, the Central's parameters are transmitted from the Central to the Peripheral. The messaging between the Central and the Peripheral at start-up is specified in this section.

If Central and Peripheral are already connected (irrespective of roles) then the Peripheral shall either ignore the page or shall immediately close the existing connection without sending any further packets relating to that connection and then continue with the page response procedure.

If the BD_ADDR of the Central is identical to the BD_ADDR of the Peripheral, then the Peripheral's Controller shall ignore the page and end the page response procedure.

The initial messaging between Central and Peripheral is shown in Table 8.3 and in Figure 8.3 and Figure 8.4. In those two figures frequencies f (k), f(k+1), etc. are the frequencies of the page hopping sequence determined by the Peripheral's BD_ADDR. The frequencies f'(k), f'(k+1), etc. are the corresponding page_response frequencies (Peripheral-to-Central). The frequencies g(m) belong to the basic channel hopping sequence.

Step	Message	Packet Type	Direction	Hopping Sequence	Access Code and Clock
1	Page	ID	Central to Peripheral	Page	Peripheral
2	First Peripheral page response	ID	Peripheral to Central	Page response	Peripheral
3	Central page re-sponse	FHS	Central to Peripheral	Page	Peripheral
4	Second Peripheral page response	ID	Peripheral to Central	Page response	Peripheral
5	1st packet Central	POLL	Central to Peripheral	Channel	Central
6	1st packet Peripheral	NULL/DM 1/DH1	Peripheral to Central	Channel	Central

Table 8.3: Initial messaging during start-up

In step 1 (see Table 8.3), the Central is in Page substate and the Peripheral in the Page Scan substate. Assume in this step that the page message sent by the Central reaches the Peripheral. On receiving the page message, the Peripheral enters the Peripheral Page Response substate in step 2. The Central waits for a reply from the Peripheral and when this arrives in step 2, it shall enter the Central Page Response substate in step 3.

Note: During the initial message exchange, all parameters are derived from the Peripheral's device address, and that only the page hopping and page response hopping sequences are used (are also derived from the Peripheral's device address). When the Central and Peripheral enter the response states, their clock input to the page and page response hop selection is frozen as is described in Section 2.6.4.3.

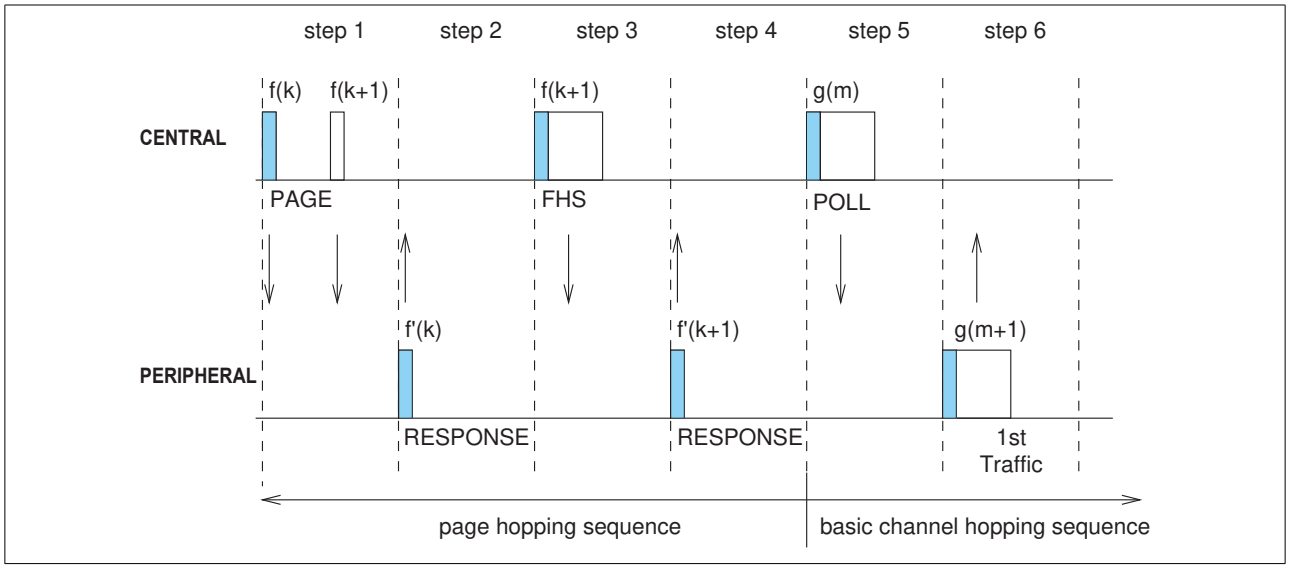

Figure 8.3: Messaging at initial connection when Peripheral responds to first page message

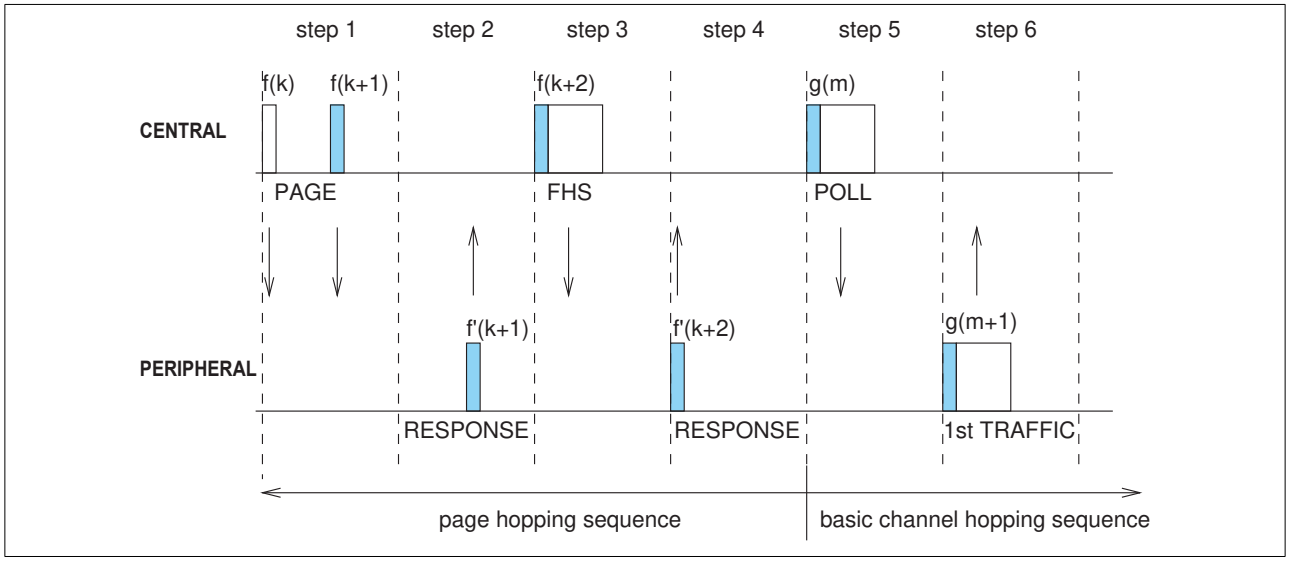

Figure 8.4: Messaging at initial connection when Peripheral responds to second page message

In the case of the truncated page procedure, the messaging stops after step 2 in the sequence shown in Table 8.3. This procedure is illustrated in Figure 8.5 and Figure 8.6.

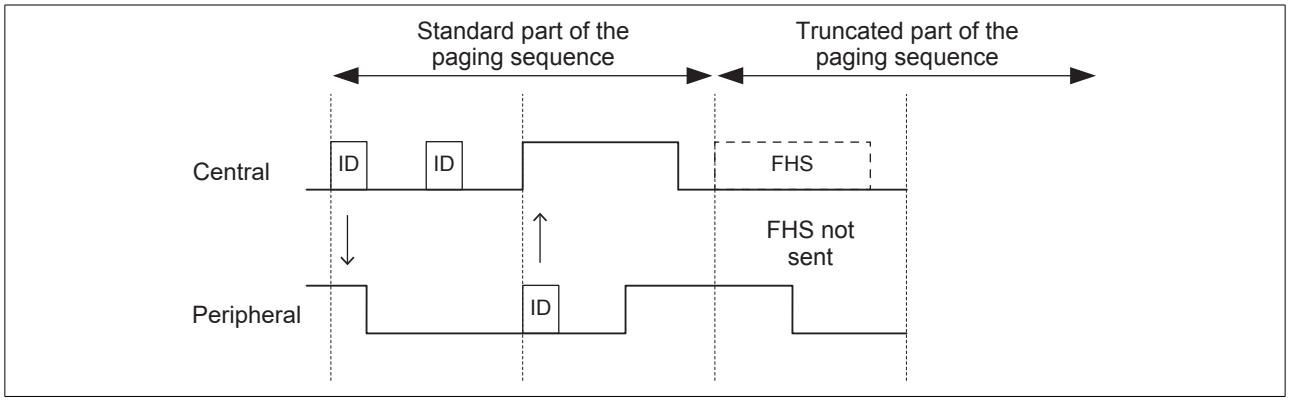

Figure 8.5: First half slot truncated page

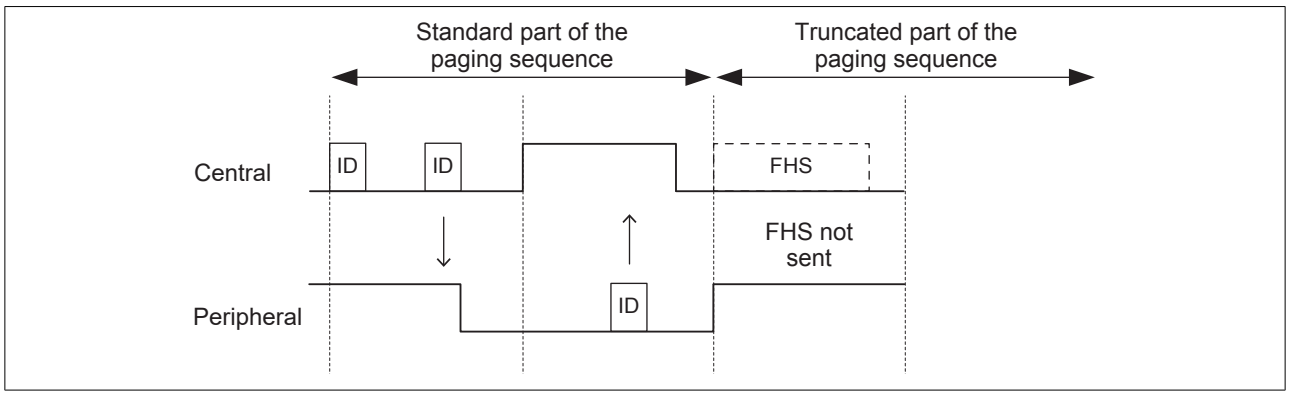

Figure 8.6: Second half slot truncated page

8.3.3.1 Peripheral Page Response substate

After having received the page message in step 1, the Peripheral shall transmit a Peripheral page response message (the Peripheral's device access code) in step 2. This response message shall be the Peripheral's device access code. The Peripheral shall transmit this response 625 µs after the beginning of the received page message and at the response hop frequency that corresponds to the hop frequency in which the page message was received. The Peripheral's transmission is therefore time aligned to the Central's transmission. During initial messaging, the Peripheral shall still use the page response hopping sequence to return information to the Central. The clock input $CLKN_{16\text{-}12}$ shall be frozen at the value it had at the time the page message was received.

After having sent the response message, the Peripheral's receiver shall be activated 312.5 µs after the start of the response message and shall await the arrival of an **FHS** packet.

Note: An **FHS** packet can arrive 312.5 µs after the arrival of the page message as shown in Figure 8.4, and not after 625 µs as is usually the case in the piconet physical channel RX/TX timing (more details about the timing can be found in Section 2.4.4).

If the setup fails before the Connection state has been reached, the following procedure shall be carried out. The Peripheral shall listen as long as no **FHS** packet is received until *pagerespTO* is exceeded. Every 1.25 ms, however, it shall select the next Central-to-Peripheral hop frequency according to the page hop sequence. If nothing is received after *pagerespTO*, the Peripheral shall return back to the Page Scan substate for one scan period. Length of the scan period depends on the synchronous reserved slots present. If no page message is received during this additional scan period, the Peripheral shall resume scanning at its regular scan interval and return to the state it was in prior to the first page scan state.

If an **FHS** packet is received by the Peripheral in the Peripheral Page Response substate, the Peripheral shall return a Peripheral page response message in step 4 to acknowledge reception of the **FHS** packet. This response shall use the page response hopping sequence. The transmission of the Peripheral page response packet is based on the reception of the **FHS** packet. Then the Peripheral shall change to the Central's channel access code and clock as received from the **FHS** packet. Only the 26 MSBs of the Central's clock are transferred: the timing shall be such that CLK_1 and CLK_0 are both zero at the time the **FHS** packet was received as the Central transmits in even slots only. The offset between the Central's clock and the Peripheral's clock shall be determined from the Central's clock in the **FHS** packet and reported to the Peripheral's Baseband Resource Manager.

Finally, the Peripheral enters the Connection state in step 5. From then on, the Peripheral shall use the Central's clock and the Central's BD_ADDR to determine the basic channel hopping sequence and the channel access code. The Peripheral shall use the LT_ADDR in the **FHS** payload as the primary LT_ADDR in the Connection state. The connection mode shall start with a POLL packet transmitted by the Central. The Peripheral may respond with a NULL, DM1, or DH1 packet. If the POLL packet is not received by the Peripheral, or the response packet is not received by the Central, within *newconnectionTO* number of slots after FHS packet acknowledgment, the Central and the Peripheral shall return to Page and Page Scan substates, respectively. See Section 8.5.

8.3.3.2 Central Page Response substate

When the Central has received a Peripheral page response message in step 2, and the Central is not executing the truncated page procedure, it shall enter the Central Response substate. It shall freeze the current clock input to the page hop selection scheme. The Central shall then transmit an **FHS** packet in step 3 containing the Central's real-time Bluetooth clock, the Central's BD_ADDR, the BCH parity bits, and the Class of Device. The **FHS** packet contains all information to construct the channel access code without requiring a mathematical derivation from the Central's Bluetooth Device Address. The LT_ADDR field in the packet header of FHS packets in the Central Page Response substate shall be set to all-zeros. The **FHS** packet shall be

transmitted at the beginning of the Central-to-Peripheral slot following the slot in which the Peripheral responded. The FHS packet shall carry the all-zero LT_ADDR. The TX timing of the **FHS** is not based on the reception of the response packet from the Peripheral. The **FHS** packet may therefore be sent 312.5 µs after the reception of the response packet like shown in Figure 8.4 and not 625 µs after the received packet as is usual in the piconet physical channel RX/TX timing, see also Section 2.4.4.

After the Central has sent its **FHS** packet, it shall wait for a second Peripheral page response message in step 4 acknowledging the reception of the **FHS** packet. This response shall be the Peripheral's device access code. If no response is received, the Central shall retransmit the **FHS** packet with an updated clock and still using the Peripheral's parameters. It shall retransmit the FHS packet with the clock updated each time until a second Peripheral page response message is received, or the timeout of *pagerespTO* is exceeded. In the latter case, the Central shall return to the Page substate and send an error message to the Baseband Resource Manager. During the retransmissions of the **FHS** packet, the Central shall use the page hopping sequence.

If the Peripheral's response is received, the Central shall change to using the Central's parameters, so it shall use the channel access code and the Central's clock. The lower clock bits CLK_0 and CLK_1 shall be reset to zero at the start of the **FHS** packet transmission and are not included in the **FHS** packet. Finally, the Central enters the Connection state in step 5. The Central BD_ADDR shall be used to change to a new hopping sequence, the *basic channel hopping sequence*. The basic channel hopping sequence uses all 79 hop channels in a pseudo-random fashion, see also Section 2.6.4.7. The Central shall now send its first traffic packet in a hop determined with the new (Central) parameters. This first packet shall be a POLL packet. See Section 8.5. This packet shall be sent within *newconnectionTO* number of slots after reception of the FHS packet acknowledgment. The Peripheral may respond with a NULL, DM1, or DH1 packet. If the POLL packet is not received by the Peripheral or the POLL packet response is not received by the Central within *newconnectionTO* number of slots, the Central and the Peripheral shall return to Page and Page Scan substates, respectively.

8.4 Device discovery substates

In order to discover other devices a device shall enter Inquiry substate. In this substate, it shall repeatedly transmit the inquiry message (ID packet, see Section 6.5.1.1) at different hop frequencies. The inquiry hop sequence is derived from the LAP of the GIAC. Thus, even when DIACs are used, the applied hopping sequence is generated from the GIAC LAP. A device that allows itself to be discovered, shall regularly enter the Inquiry Scan substate to respond to inquiry messages. The following sections describe the message exchange and contention resolution during inquiry response. The inquiry response is optional: a device is not forced to respond to an inquiry message.

During the Inquiry substate, the discovering device collects the Bluetooth Device Addresses and clocks of all devices that respond to the inquiry message. In addition, the discovering device also collects extended information (e.g. local name and supported services) from devices that respond with an extended inquiry response packet. It can then, if desired, make a connection to any one of the discovered devices by means of the previously described page procedure.

The inquiry message broadcast by the source does not contain any information about the source. However, it may indicate which class of devices should respond. There is one general inquiry access code (GIAC) to inquire for any device, and a number of dedicated inquiry access codes (DIAC) that only inquire for a certain type of device. The inquiry access codes are derived from reserved Bluetooth Device Addresses and are further described in Section 6.3.1.

8.4.1 Inquiry Scan substate

The Inquiry Scan substate is very similar to the Page Scan substate. However, instead of scanning for the device's device access code, the receiver shall scan for the inquiry access code long enough to completely scan for 16 inquiry frequencies. Two types of scans are defined: standard and generalized interlaced. In the case of a standard scan the length of this scan period is denoted $T_{w\_inquiry\_scan}$ (11.25 ms default, see [Vol 4] Part E, Section 7.3.22). The standard scan is performed at a single hop frequency as defined by $Xir_{4\text{-}0}$ (see Section 2.6.4.6). The generalized interlaced scan is performed as two back to back scans of $T_{w\_inquiry\_scan}$ where the first scan is on the normal hop frequency and the second scan is defined by [$Xir_{4\text{-}0}$ + interlace_offset] *mod* 32. If the scan interval is not at least twice the scan window then generalized interlaced scan shall not be used. The inquiry procedure uses 32 dedicated inquiry hop frequencies according to the inquiry hopping sequence. These frequencies are determined by the general inquiry address. The phase is determined by the native clock of the device carrying out the inquiry scan; the phase changes every 1.28 s.

The interlace_offset value ranges from 0 to 31. The value 16 should be used unless the pattern of slots that are not available for scanning implies a different value should be used.

Instead of, or in addition to, the general inquiry access code, the device may scan for one or more dedicated inquiry access codes. However, the scanning shall follow the inquiry scan hopping sequence determined by the general inquiry address. If an inquiry message is received during an inquiry wake-up period, the device shall enter the Inquiry Response substate.

The Inquiry Scan substate can be entered from the Standby state or the Connection state. In the Standby state, no connection has been established and the device can use all the capacity to carry out the inquiry scan. Before entering the Inquiry Scan

substate from the Connection state, the device should reserve as much capacity as possible for scanning. If desired, the device may place ACL logical transports in Sniff mode or Hold mode. Synchronous logical transports are preferably not interrupted by the inquiry scan, although eSCO retransmissions should be paused during the scan. In this case, the inquiry scan may be interrupted by the reserved synchronous slots. SCO packets should be used requiring the least amount of capacity (**HV3** packets). The scan window, $T_{w\ inquiry\ scan}$, shall be increased to increase the probability to respond to an inquiry message. If one SCO logical transport is present using HV3 packets and T_{SCO}=6 slots or one eSCO logical transport is present using EV3 packets and T_{eSCO}=6 slots, a total scan window of at least 36 slots (22.5 ms) is recommended; if two SCO links are present using HV3 packets and T_{SCO}=6 slots or two eSCO links are present using EV3 packets and T_{eSCO}=6 slots, a total scan window of at least 54 slots (33.75 ms) is recommended.

The scan interval $T_{inquiry\ scan}$ is defined as the interval between two consecutive inquiry scans. The inquiry scan interval shall be less than or equal to 2.56 s.

8.4.2 Inquiry substate

The Inquiry substate is used to discover new devices. This substate is very similar to the Page substate; the TX/RX timing shall be the same as in paging, see Section 2.4.4 and Figure 2.7. The TX and RX frequencies shall follow the inquiry hopping sequence and the inquiry response hopping sequence, and are determined by the general inquiry access code and the native clock of the discovering device. In between inquiry transmissions, the receiver shall scan for inquiry response messages. When a response is received, the entire packet (an FHS packet) shall be read. If the EIR bit in the FHS packet is set to one, the device should try to receive the extended inquiry response packet 1250 µs after the start of the FHS packet. After this, the device shall continue with inquiry transmissions. The device in an Inquiry substate shall not acknowledge the inquiry response messages. If enabled by the Host (see [Vol 4] Part E, Section 7.3.50), the RSSI value of the inquiry response message shall be measured. It shall keep probing at different hop channels and in between listening for response packets. As in the Page substate, two 10 ms trains **A** and **B** are defined, splitting the 32 frequencies of the inquiry hopping sequence into two 16-hop parts. A single train shall be repeated for at least $N_{inquiry}$=256 times before a new train is used. In order to collect all responses in an error-free environment, at least three train switches must have taken place. As a result, the Inquiry substate may have to last for 10.24 s unless the inquirer collects enough responses and aborts the Inquiry substate earlier. If desired, the inquirer may also prolong the Inquiry substate to increase the probability of receiving all responses in an error-prone environment. When some receive slots are periodically not available, it may require up to 31 train switches to collect all responses in an error-free environment, depending on the pattern of the available receive slots. Before each switch to train **A**, k_{nudge} may be updated. As a result, the Inquiry substate may have to last for 40.96 s. If an inquiry procedure is automatically initiated periodically (say a 10 s period every

minute), then the interval between two inquiry instances shall be determined randomly. This is done to avoid two devices synchronizing their inquiry procedures.

The Inquiry substate is continued until stopped by the Baseband Resource Manager (when it decides that it has sufficient number of responses), when a timeout has been reached (Inquiry_Length + Extended_Inquiry_Length), or by a command from the Host to cancel the inquiry procedure.

The Inquiry substate can be entered from the Standby state or the Connection state. In the Standby state, no connection has been established and the device can use all the capacity to carry out the inquiry. Before entering the Inquiry substate from the Connection state, the device should free as much capacity as possible for inquiry. To ensure this, it is recommended that the ACL logical transports are placed in Sniff mode or Hold mode. However, the reserved slots of synchronous logical transports shall not be disturbed by the inquiry. This means that the inquiry will be interrupted by the reserved SCO and eSCO slots which have higher priority than the inquiry. In order to obtain as much capacity as possible for inquiry, it is recommended to use the SCO packets which use the least amount of capacity (**HV3** packets). If SCO or eSCO links are present, the repetition number $N_{inquiry}$ shall be increased, see Table 8.4.

Here it has been assumed that **HV3** packets are used with an interval T_{SCO}=6 slots or **EV3** packets are used with an interval of T_{eSCO}=6 slots, which would correspond to a 64 kb/s synchronous link.

	No synchronous links	One synchronous link (HV3)	Two synchronous links (HV3)
$N_{inquiry}$	≥ 256	≥ 512	≥ 768

Table 8.4: Increase of train repetition when synchronous links are present

If an extended inquiry response packet could not be received because of higher priority traffic, the reception failed due to HEC or CRC failure, or because the packet type is not supported by the device, the inquiry response shall be reported to higher layers as an extended inquiry response with all-zero data.

8.4.3 Inquiry Response substate

The response substate for inquiries differs completely from the Peripheral Page Response substate applied for pages. When the inquiry message is received in the Inquiry Scan substate, the recipient shall return an inquiry response (FHS) packet containing the recipient's device address (BD_ADDR) and other parameters. If the recipient has non-zero extended inquiry response data to send it shall return an extended inquiry response packet after the FHS packet.

The following protocol in the Peripheral's inquiry response shall be used. On the first inquiry message received in the Inquiry Scan substate the Peripheral shall enter the

Inquiry Response substate. If the Peripheral has non-zero extended inquiry response data to send it shall return an FHS packet with the EIR bit set to one to the Central 625 µs after the inquiry message was received. It shall then return an extended inquiry response packet 1250 µs after the start of the FHS packet. If the Peripheral's extended inquiry response data is all zeroes the Peripheral shall only return an FHS packet with the EIR bit set to zero. A contention problem could arise when several devices are in close proximity to the inquiring device and all respond to an inquiry message at the same time. However, because every device has a free running clock it is highly unlikely that they all use the same phase of the inquiry hopping sequence. In order to avoid repeated collisions between devices that wake up in the same inquiry hop channel simultaneously, a device shall back-off for a random period of time. Thus, if the device receives an inquiry message and returns an FHS packet, it shall generate a random number, RAND, between 0 and MAX_RAND. For scanning intervals ≥ 1.28 s MAX_RAND shall be 1023, however, for scanning intervals < 1.28 s MAX_RAND may be as small as 127. A profile that uses a special DIAC may choose to use a smaller MAX_RAND than 1023 even when the scanning interval is ≥ 1.28 s. The Peripheral shall return to the Connection or Standby state for the duration of at least RAND time slots. Before returning to the Connection and Standby state, the device may go through the Page Scan substate. After at least RAND slots, the device shall add an offset of 1 to the phase in the inquiry hop sequence (the phase has a 1.28 s resolution) and return to the Inquiry Scan substate again. If the Peripheral is triggered again, it shall repeat the procedure using a new RAND. The offset to the clock accumulates each time an **FHS** packet is returned. During a probing window, a Peripheral may respond multiple times, but on different frequencies and at different times. Reserved synchronous slots should have priority over response packets; that is, if a response packet overlaps with a reserved synchronous slot, it shall not be sent but the next inquiry message is awaited. If a device has extended inquiry response data to send but the extended inquiry response packet overlaps with a reserved synchronous slot the FHS packet may be sent with the EIR bit set to zero.

The messaging during the inquiry routines is summarized in Table 8.5. In step 1, the Central transmits an inquiry message using the inquiry access code and its own clock. The Peripheral responds with the **FHS** packet containing the Peripheral’s Bluetooth Device Address, native clock and other Peripheral information. This **FHS** packet is returned at times that tend to be random. The **FHS** packet is not acknowledged in the inquiry routine, but it is retransmitted at other times and frequencies as long as the Central is probing with inquiry messages. If the Peripheral has non-zero extended inquiry response data it sends an extended inquiry response packet to the Central in step 3.

The extended inquiry response packet is an ACL packet with type DM1, DM3, DM5, DH1, DH3 or DH5. To minimize interference it is recommended to use the shortest packet that fits the data. The packet shall be sent on the same frequency as the FHS

packet, 1250 µs after the start of the FHS packet. In the packet header, LT_ADDR shall be set to zero. TYPE shall be one of DM1, DM3, DM5, DH1, DH3 or DH5. FLOW, ARQN and SEQN shall all be set to zero and ignored during receipt. The HEC LFSR shall be initialized with the same DCI (default check initialization) as for the FHS packet. In the payload header, LLID shall contain the value 10 (start of an L2CAP message or no fragmentation). FLOW shall be set to zero and ignored upon receipt. The length of the payload body (LENGTH) shall be smaller than or equal to 240 bytes. The CRC LFSR shall be initialized with the same DCI as for the FHS packet. The data whitening LFSR shall be initialized with the same value as for the FHS packet.

The payload data has two parts, a significant part followed by a non-significant part. The significant part contains a sequence of data structures as defined in [Vol 3] Part C, Section 8. The non-significant part contains all-zero octets.

The Baseband shall not change any octets in the significant part. When transmitting data, the non-significant part octets may be omitted from the payload.

A device shall store a single extended inquiry response packet. This packet shall be used with all IACs.

Step	Message	Packet Type	Direction	Hopping Sequence	Access Code and Clock
1	Inquiry	ID	Central to Peripheral	inquiry	inquiry
2	Inquiry response	FHS	Peripheral to Central	inquiry response	inquiry
3	Extended Inquiry Response	DM1, DM3, DM5, DH1, DH3, DH5	Peripheral to Central	same frequency as step 2	inquiry

Table 8.5: Messaging during inquiry routines

8.5 Connection state

In the Connection state, the connection has been established and packets can be sent back and forth, with the exception of Connectionless Peripheral Broadcast mode, in which case packets are only sent from the Central. In both devices, the channel access code (derived from the Central's BD_ADDR), the Central's Bluetooth clock, and the AFH_channel_map are used. Connection state uses the basic or adapted channel hopping sequence.

There are two ways to enter the Connection state. A device can transition from the Page or Page Scan substates to the Connection state or directly from the Standby state to the Connectionless Peripheral Broadcast mode of the Connection state.

If a device enters from the Page or Page Scan substates, the Connection state starts with a POLL packet sent by the Central to verify the switch to the Central's timing and channel frequency hopping. The Peripheral may respond with a NULL, DM1, or DH1 packet. If the Peripheral does not receive the POLL packet or the Central does not receive the response packet for *newconnectionTO* number of slots, both devices shall return to Page or Page Scan substate.

The first information packets in the Connection state contain control messages that characterize the link and give more details regarding the devices. These messages are exchanged between the link managers of the devices. For example, they may define the SCO logical transport and the sniff parameters. Then the transfer of user information can start by alternately transmitting and receiving packets.

The Connection state is left through a Detach or Reset command. The Detach command is used if the link has been disconnected in the normal way; all configuration data in the Link Controller shall remain valid. The Reset command is a soft reset of the Link Controller. The functionality of the soft reset is described in [Vol 4] Part E, Section 7.3.2.

In the Connection state, if a device is not going to be nominally present on the channel at all times it may describe its unavailability by using Sniff mode or Hold mode (see Figure 8.7).

If a device enters the Connectionless Peripheral Broadcast mode of the Connection state, the Transmitter (Central) starts by sending packets on the CPB logical transport and the Receiver (Peripheral) starts by receiving packets sent on the CPB logical transport.

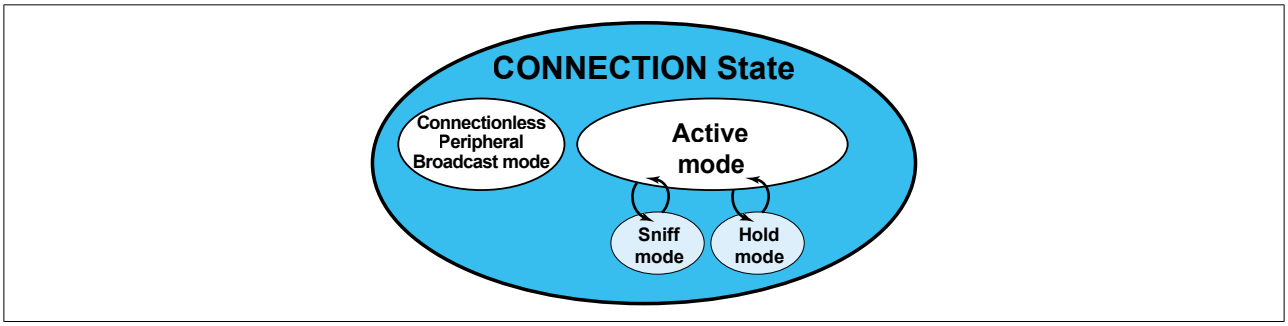

Figure 8.7: Connection state

8.6 Active mode

In the Active mode, both Central and Peripheral actively participate on the channel. Up to seven Peripherals may be in the Active mode at any given time in a piconet. The Central schedules the transmission based on traffic demands to and from the different Peripherals. In addition, it supports regular transmissions to keep Peripherals

synchronized to the channel. Peripherals in the Active mode listen in the Central-to-Peripheral slots for packets. These devices are known as *active Peripherals*. If an active Peripheral is not addressed, it may sleep until the next new Central transmission. Peripherals can derive the number of slots the Central has reserved for transmission from the TYPE field in the packet header; during this time, the non-addressed Peripherals do not have to listen on the Central-to-Peripheral slots. When a device is participating in multiple piconets it should listen in the Central-to-Peripheral slot for the current piconet. It is recommended that a device not be away from each piconet in which it is participating for more than T_{poll} slots. A periodic Central transmission is required to keep the Peripherals synchronized to the channel. Since the Peripherals only need the channel access code to synchronize, any packet type can be used for this purpose.

Only the Peripheral that is addressed by one of its LT_ADDRs (primary or secondary) may return a packet in the next Peripheral-to-Central slot. If no valid packet header is received, the Peripheral may only respond in its reserved SCO or eSCO Peripheral-to-Central slot. In the case of a broadcast message, no Peripheral shall return a packet.

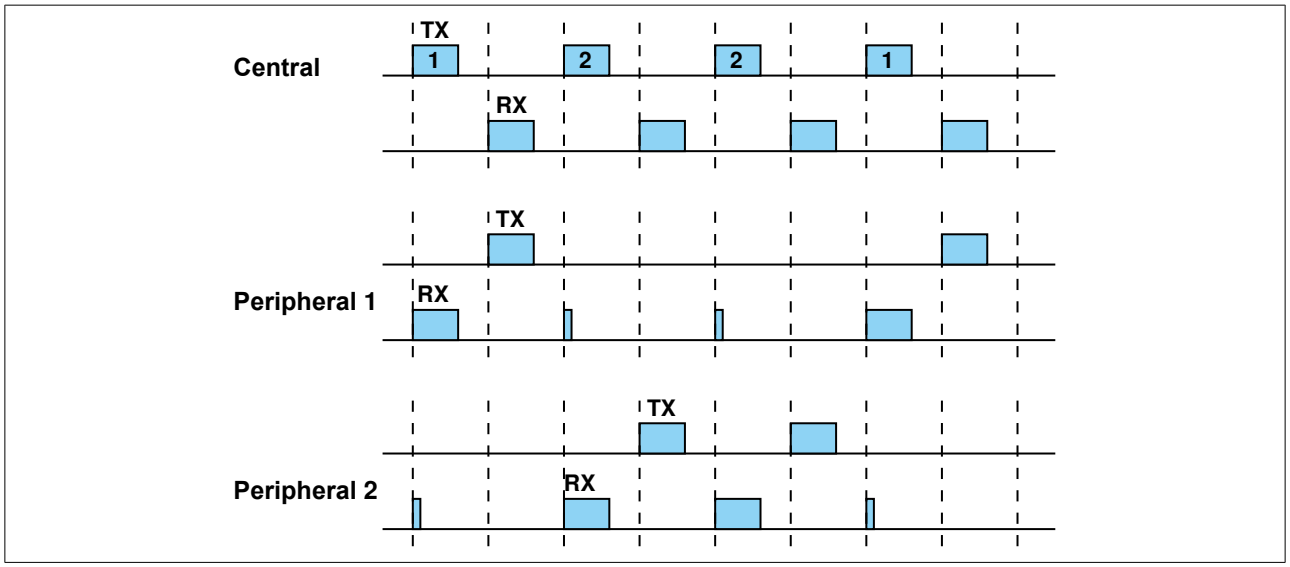

Figure 8.8: RX/TX timing in multi-Peripheral configuration

For ACL logical transports the mode selection may be left to real time packet type selections. The packet type table (ptt) in Section 6.5 allows the selection of Basic Rate or Enhanced Data Rate for each of the packet type codes, however; the DM1 packet is available in all packet type tables. ACL traffic over this given physical or logical link shall utilize the packet types in the given column of Table 6.2.

8.6.1 Polling in the Active mode

The Central always has full control over the piconet. Due to the TDD scheme, Peripherals can only communicate with the Central and not other Peripherals. In order

to avoid collisions on the ACL logical transport, a Peripheral is only allowed to transmit in the Peripheral-to-Central slot when addressed by the LT_ADDR in the packet header in the preceding Central-to-Peripheral slot. If the LT_ADDR in the preceding slot does not match, or a valid packet header was not received, the Peripheral shall not transmit.

The Central normally attempts to poll a Peripheral's ACL logical transport no less often than once every T_{poll} slots. T_{poll} is set by the Link Manager (see [Vol 2] Part C, Section 4.1.8).

The Peripheral's ACL logical transport may be polled with any packet type except for FHS and ID. For example, polling during SCO may use HV packets, since the Peripheral may respond to an HV packet with a DM1 packet (see Section 8.6.2).

8.6.2 SCO

The SCO logical transport shall be established by the Central sending a SCO setup message via the LM protocol. This message contains timing parameters including the SCO interval T_{SCO} and the offset D_{SCO} to specify the reserved slots.

In order to prevent clock wrap-around problems, an initialization flag in the SCO setup message indicates whether initialization procedure 1 or 2 is being used. The Peripheral shall apply the initialization method as indicated by the initialization flag. The Central shall use initialization 1 when the MSB of the Central's current clock (CLK_{27}) is 0; it shall use initialization 2 when the MSB of the Central's current clock (CLK_{27}) is 1. The Central-to-Peripheral SCO slots reserved by the Central and the Peripheral shall be initialized on the slots for which the clock satisfies the applicable equation:

$$CLK_{27-1} \; mod \; T_{SCO} = D_{SCO} \qquad \text{for initialization 1}$$

$$\left(\overline{CLK_{27}}, CLK_{26-1}\right) \; mod \; T_{SCO} = D_{SCO} \qquad \text{for initialization 2}$$

The Peripheral-to-Central SCO slots shall directly follow the reserved Central-to-Peripheral SCO slots. After initialization, the clock value CLK(k+1) for the next Central-to-Peripheral SCO slot shall be derived by adding the fixed interval T_{SCO} to the clock value of the current Central-to-Peripheral SCO slot:

$$CLK_{27-1}(k+1) = CLK_{27-1}(k) + T_{SCO}$$

The Central will send SCO packets to the Peripheral at regular intervals (the SCO interval T_{SCO} counted in slots) in the reserved Central-to-Peripheral slots. An HV1 packet can carry 1.25 ms of speech at a 64 kb/s rate. An HV1 packet shall therefore be sent every two time slots (T_{SCO}=2). An HV2 packet can carry 2.5 ms of speech at a 64 kb/s rate. An HV2 packet shall therefore be sent every four time slots (T_{SCO}=4). An HV3 packet can carry 3.75 ms of speech at a 64 kb/s rate. An HV3 packet shall therefore be sent every six time slots (T_{SCO}=6).

The Peripheral is allowed to transmit in the slot reserved for its SCO logical transport unless a packet with the correct access code was received in the preceding slot and the LT_ADDR did not address this Peripheral (irrespective of whether or not the HEC was correct). If the correct LT_ADDR was received in the preceding slot but the HEC was incorrect, the Peripheral should not transmit in the reserved SCO slot.

Since the DM1 packet is recognized on the SCO logical transport, it may be sent during the SCO reserved slots if a valid packet header with the primary LT_ADDR is received in the preceding slot. DM1 packets sent during SCO reserved slots shall only be used to send ACL-C data.

The Peripheral shall not transmit anything other than an HV packet in a reserved SCO slot unless it decodes its own Peripheral address in the packet header of the packet in the preceding Central-to-Peripheral transmission slot.

8.6.3 eSCO

The eSCO logical transport is established by sending an eSCO setup message via the LM protocol. This message contains timing parameters including the eSCO interval T_{eSCO} and the offset D_{eSCO} to specify the reserved slots.

To enter eSCO, the Central or Peripheral shall send an eSCO setup message via the LM protocol. This message shall contain the eSCO interval T_{eSCO} and an offset D_{eSCO}. In order to prevent clock wrap-around problems, an initialization flag in the eSCO setup message indicates whether initialization procedure 1 or 2 shall be used. The device sending the eSCO setup message shall use initialization 1 when the MSB of the Central's current clock (CLK_{27}) is 0; it shall use initialization 2 when the MSB of the Central's current clock (CLK_{27}) is 1. The device that receives the eSCO setup message shall apply the initialization method as indicated by the initialization flag. The Central-to-Peripheral eSCO slots reserved by the Central and the Peripheral shall be initialized on the slots for which the clock satisfies the applicable equation:

$$CLK_{27-1} \; mod \; T_{eSCO} = D_{eSCO} \quad \text{for initialization 1}$$

$$\left(\overline{CLK_{27}}, CLK_{26-1}\right) \; mod \; T_{eSCO} = D_{eSCO} \quad \text{for initialization 2}$$

The Peripheral-to-Central eSCO slots shall directly follow the reserved Central-to-Peripheral eSCO slots. After initialization, the clock value CLK(k+1) for the next Central-to-Peripheral eSCO slot shall be found by adding the fixed interval T_{eSCO} to the clock value of the current Central-to-Peripheral eSCO slot:

$$CLK_{27-1}(k+1) = CLK_{27-1}(k) + T_{eSCO}$$

When an eSCO logical transport is established, the Central shall assign an additional LT_ADDR to the Peripheral. This provides the eSCO logical transport with an ARQ scheme that is separate from that of the ACL logical transport. All traffic on a particular

eSCO logical transport, and only that eSCO traffic, is carried on the eSCO LT_ADDR. The eSCO ARQ scheme uses the ARQN bit in the packet header, and operates similarly to the ARQ scheme on ACL links.

The Central may send a packet in the reserved Central-to-Peripheral slot. The Peripheral may transmit on the eSCO LT_ADDR in the following slot either if it received a packet on the eSCO LT_ADDR in the previous slot, or if it did not receive a valid packet header in the previous slot. When the Central-to-Peripheral packet type is a three-slot packet, the Peripheral's transmit slot is the fourth slot of the eSCO reserved slots.

A Central shall transmit in an eSCO retransmission window on a given eSCO LT_ADDR only if it addressed that eSCO LT_ADDR or did not transmit any packet in the immediately preceding eSCO reserved slots. A Peripheral shall transmit in an eSCO retransmission window on a given eSCO LT_ADDR only if it received a valid packet header and that LT_ADDR on the eSCO channel in the previous Central-to-Peripheral transmission slot. The Central may transmit on any non-eSCO LT_ADDR in any Central-to-Peripheral transmission slot inside the eSCO retransmission window; if it addresses a Peripheral, that Peripheral may respond on the ACL channel as usual.

The Central shall only transmit on an eSCO LT_ADDR in the retransmission window if there are enough slots left for both the Central and Peripheral packets to complete in the retransmission window. If the Central is transmitting a NULL packet (with ARQN=ACK), then this requires one slot, otherwise it requires enough slots for the Central's negotiated eSCO packet type plus:

- if the Central's packet has ARQN=NAK, then enough slots for the Peripheral's negotiated eSCO packet type;
- if the Central's packet has ARQN=ACK, then one slot.

The Central may refrain from transmitting in any slot during the eSCO retransmission window. When there is no data to transmit from Central to Peripheral, either due to the traffic being unidirectional or due to the Central-to-Peripheral packet having been ACK'ed, the Central shall use the POLL packet. When the Central-to-Peripheral packet has been ACK'ed, and the Peripheral-to-Central packet has been correctly received, the Central shall not address the Peripheral on the eSCO LT_ADDR until the next eSCO reserved slot, with the exception that the Central may transmit a NULL packet with ARQN=ACK on the eSCO LT_ADDR. If the Central is transmitting on the eSCO LT_ADDR during a retransmission slot and there is no data to transmit from Peripheral to Central, either due to the traffic being unidirectional or due to the Peripheral-to-Central packet having been ACK'ed, the Peripheral shall use NULL packets. eSCO traffic should be given priority over ACL traffic in the retransmission window.

Figure 8.9 shows the eSCO window when single slot packets are used.

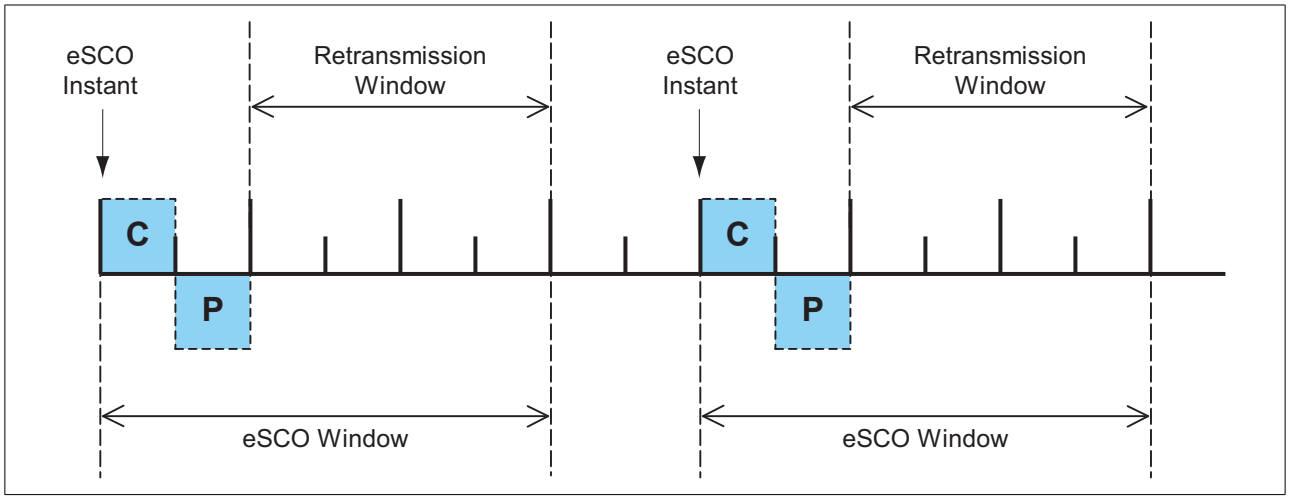

Figure 8.9: eSCO window details for single-slot packets

When multi-slot packets are used in either direction of the eSCO logical transport, the first transmission continues into the following slots. The retransmission window in this case starts the slot after the end of the Peripheral-to-Central packet, i.e. two, four or six slots immediately following the eSCO instant are reserved and should not be used for other traffic. Figure 8.10 shows the eSCO window when multi-slot packets are used in one direction and single-slot packets are used in the other direction.

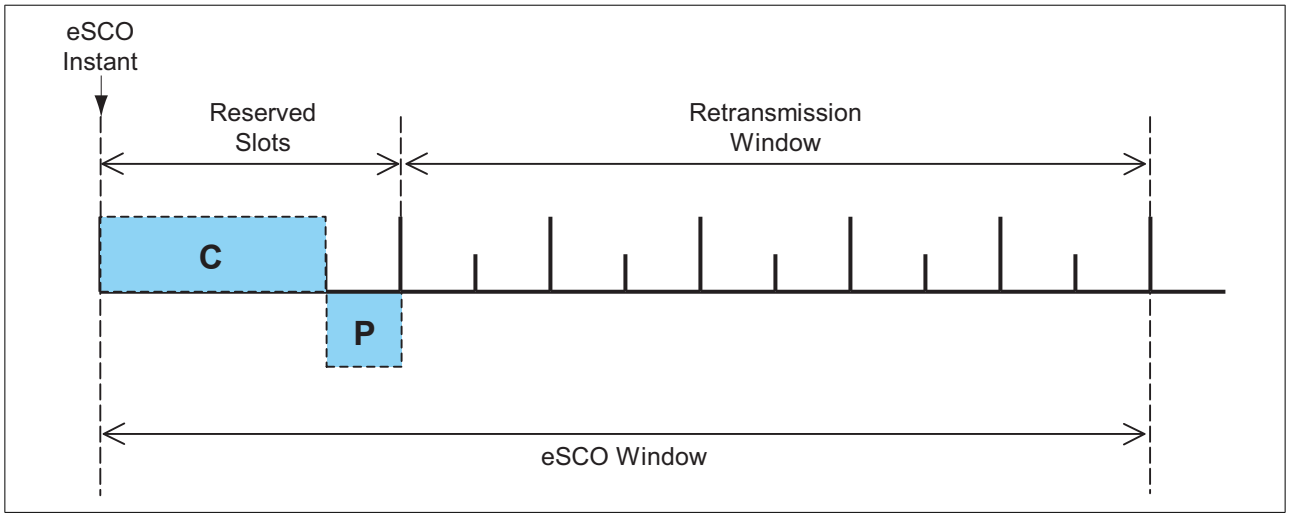

Figure 8.10: eSCO window details for asymmetric traffic

eSCO windows may overlap on the Central, but shall not overlap on an individual Peripheral.

In the reserved slots both Central and Peripheral shall only listen and transmit at their allocated slots at the first transmission time of each eSCO window. Intermittent lapses due to, for instance, time-critical signaling during connection establishment are allowed. Both Central and Peripheral may refrain from sending data and may use instead POLL

and NULL packets respectively. When the Central transmits a POLL packet instead of an eSCO 3-slot packet, or the Peripheral does not receive anything in the reserved Central-to-Peripheral transmission slot, it shall start any transmission in the same slot as if the Central had transmitted the negotiated packet type. For example, if the Central had negotiated an EV5 packet the Peripheral would transmit three slots later. If the Central does not receive a Peripheral transmission in response to an eSCO packet it causes an implicit NAK of the packet in question. The listening requirements for the Peripheral during the retransmission window are the same as for an active ACL logical transport.

8.6.4 Broadcast scheme

The Central of the piconet can broadcast messages to all Peripherals on the APB logical transport. An APB broadcast packet shall have an LT_ADDR set to all zero. If a new broadcast message carries APB-U data, it may be fragmented in the same way as ACL packets. Therefore it shall start with a packet carrying the start of L2CAP message indication (LLID=0b10) and may be followed by packets carrying the continuation of L2CAP message indication (LLID=0b01). If a new broadcast message carries APB-C data, it shall not be fragmented and shall consist of a single packet carrying the LMP message indication (LLID=0b11). In either case, the Central may carry out a number of retransmissions of each of these packets to increase the probability for error-free delivery; see also Section 7.6.5.

A broadcast packet shall never be acknowledged by the Baseband.

The Broadcast LT_ADDR shall use a ptt=0.

8.6.5 Role switch

There are several occasions when a role switch is used:

- A role switch is necessary in order to make a paging device a Peripheral when joining an existing piconet, since by definition the paging device is initially Central of a piconet involving the pager (Central) and the paged (Peripheral) device.
- A role switch is necessary in order for a Peripheral in an existing piconet to set up a new piconet with itself as Central and the original piconet Central as Peripheral. If the original piconet had more than one Peripheral, then this implies a double role for the original piconet Central; it becomes a Peripheral in the new piconet while still maintaining the original piconet as Central.

Prior to the role switch, encryption if present, shall be paused or disabled in the old piconet. A role switch shall not be performed if the physical link is in Sniff or Hold mode, or has any synchronous logical transports.

For the Central and Peripheral involved in the role switch, the switch results in a reversal of their TX and RX timing: a TDD switch. Additionally, since the piconet

parameters are derived from the Bluetooth Device Address and clock of the Central, a role switch inherently involves a redefinition of the piconet as well: a piconet switch. The new piconet's parameters shall be derived from the former Peripheral's device address and clock.

Assume device A is to become Central; device B was the former Central. Then there are two alternatives: either the Peripheral initiates the role switch or the Central initiates the role switch. These alternatives are described in Link Manager Protocol, [Vol 2] Part C, Section 4.4.2. The Baseband procedure is the same regardless of which alternative is used.

To begin the role switch, A and B shall perform a TDD switch using the former hopping scheme (still using the Bluetooth Device Address and clock of device B), so there is no piconet switch yet. The slot offset information sent by A shall not be used yet; it is used when both devices have switched to the new piconet and device B is positioning its correlation window. Device A now becomes the Central, device B the Peripheral.

At the moment of the TDD switch, both devices A and B shall start a timer with a time out of *newconnectionTO*. The timer shall be stopped in B as soon as it receives an FHS packet from A on the TDD-switched channel. The timer shall be stopped in A as soon as it receives an ID packet from B. If the *newconnectionTO* expires, A and B shall return to the old piconet timing and AFH state, taking their old roles of Peripheral and Central respectively. The FHS packet shall be sent by A using the "old" piconet parameters. The LT_ADDR in the FHS packet header shall be the former LT_ADDR used by device A. The LT_ADDR carried in the FHS payload shall be the new LT_ADDR intended for device B when operating on the new piconet. After the FHS acknowledgment, which is the ID packet and shall be sent by B on the old hopping sequence, both A and B shall use the new channel parameters of the new piconet as indicated by the FHS with the sequence selection set to basic channel hopping sequence. If the new Central A has physical links that are *AFH-enabled*, following the piconet switch the new Central is responsible for controlling the AFH operational mode of its new Peripheral B.

Since the old and new Centrals' clocks are synchronized, the clock information sent in the FHS payload shall indicate the new Central's clock at the beginning of the FHS packet transmission. Furthermore, the 1.25 ms resolution of the clock information given in the FHS packet is not sufficient for aligning the slot boundaries of the two piconets. The slot-offset information in the LMP message previously sent by device A shall be used to provide more accurate timing information. The slot offset indicates the delay between the start of the Central-to-Peripheral slots of the old and new piconet channels. This timing information ranges from 0 to 1249 µs with a resolution of 1 µs. It shall be used together with the clock information in the FHS packet to accurately position the correlation window when switching to the new Central's timing after acknowledgment of the FHS packet.

After reception of the FHS packet acknowledgment, the new Central A shall switch to its own timing with the sequence selection set to the basic channel hopping sequence and shall send a POLL packet to verify the switch. Both A and B shall start a new timer with a time out of *newconnectionTO* on FHS packet acknowledgment. The start of this timer shall be aligned with the beginning of the first Central TX slot boundary of the new piconet, following the FHS packet acknowledgment. B shall stop the timer when the POLL packet is received; A shall stop the timer when the POLL packet is acknowledged. The Peripheral B shall respond with a NULL, DM1, or DH1 packet to acknowledge the POLL. Any pending AFH_Instant shall be cancelled once the POLL packet has been received by the Peripheral. If no response is received, A shall re-send the POLL packet until *newconnectionTO* is reached. If this timer expires, both A and B shall return to the old piconet timing with the old roles: B as Central and A as Peripheral. Expiry of the timer shall also restore the state associated with AFH (including any pending AFH_Instant), Channel Quality Driven Data Rate (CQDDR, Link Manager Protocol [Vol 2] Part C, Section 4.1.7) and power control (Link Manager Protocol [Vol 2] Part C, Section 4.1.3). The role switch procedure may then restart from the TDD switch. Aligning the timer with TX boundaries of the new piconet ensures that no device returns to the old piconet timing in the middle of a Central RX slot.

The messaging during a successful role switch is summarized in Table 8.6.

Step	Message or Packet Type	Direction	Central
1	LMP_ACCEPTED	Responder → Initiator	B
2	FHS	A → B	B
3	ID	B → A	B
4	POLL	A → B	A
5	NULL/DM1/DH1	B → A	A

Table 8.6: Messaging during successful role switch

After the role switch the ACL logical transport is reinitialized as if it were a new connection. For example, the SEQN of the first data packet containing a CRC on the new piconet channel shall be set according to the rules in Section 7.6.2.

8.6.6 Scatternet

Multiple piconets can cover the same area. Since each piconet has a different Central, the piconets hop independently, each with their own hopping sequence and phase as determined by the respective Central. In addition, the packets carried on the channels are preceded by different channel access codes as determined by the Centrals' device addresses. As more piconets are added, the probability of collisions increases; a graceful degradation of performance results as is common in frequency-hopping spread spectrum systems.

If multiple piconets cover the same area, a device can participate in two or more overlaying piconets by applying time multiplexing. To participate on the proper channel, it shall use the associated Central's device address and proper clock offset to obtain the correct phase. A device can act as a Peripheral in several piconets, but only as a Central in a single piconet: since two piconets with the same Central are synchronized and use the same hopping sequence, they are one and the same piconet. A group of piconets in which connections exist between different piconets is called a *scatternet*.

A Central or Peripheral can become a Peripheral in another piconet by being paged by the Central of this other piconet. On the other hand, a device participating in one piconet can page the Central or Peripheral of another piconet. Since the paging device always starts out as Central, a role switch is required if a Peripheral role is desired. This is described in Section 8.6.5.

8.6.6.1 Inter-piconet communications

Time multiplexing must be used to switch between piconets. Devices may achieve the time multiplexing necessary to implement scatternet by using Sniff mode or by remaining in an active ACL connection. For an ACL connection in piconets where the device is a Peripheral in the Connection state, it may choose not to listen in every Central slot. In this case it should be recognized that the quality of service on this link can degrade abruptly if the Peripheral is not present enough to match up with the Central polling that Peripheral. Similarly, in piconets where the device is Central it may choose not to transmit in every Central slot. In this case it is important to honor T_{poll} as much as possible. Devices in Sniff mode could have sufficient time to visit another piconet in between sniff slots. When the device is a Peripheral using Sniff mode and there are not sufficient idle slots, the device may choose to not listen to all Central transmission slots in the sniff_attempts period or during the subsequent sniff_timeout period. A Central is not required to transmit during sniff slots and therefore has flexibility for scatternet. If SCO or eSCO links are established, other piconets shall only be visited in the non-reserved slots in between reserved slots. This is only possible if there is a single SCO logical transport using HV3 packets or eSCO links where at least four slots remain in between the reserved slots. Since the multiple piconets are not synchronized, guard time must be left to account for misalignment. This means that only 2 slots can effectively be used to visit another piconet in between the HV3 packets.

Since the clocks of two Centrals of different piconets are not synchronized, a Peripheral participating in two piconets shall maintain two offsets that, added to its own native clock, create the two Centrals' clocks. Since the two Centrals' clocks drift independently, the Peripheral must regularly update the offsets in order to keep synchronization to both Centrals.

8.6.7 Hop sequence switching

Hop sequence adaptation is controlled by the Central and can be set to either *enabled* or *disabled*. Once enabled, hop sequence adaptation shall apply to all logical transports on a physical link. Once enabled, the Central may periodically update the set of *used* and *unused* channels as well as disable hop sequence adaptation on a physical link. When a Central has multiple physical links the state of each link is independent of all other physical links.

When hop sequence adaptation is enabled, the *sequence selection* hop selection kernel input is set to adapted channel hopping sequence and the *AFH_channel_map* input is set to the appropriate set of *used* and *unused* channels. Additionally, the *same channel* mechanism shall be used. When hop sequence adaptation is enabled with all channels *used* this is known as AHS(79).

When hop sequence adaptation is disabled, the *sequence selection* input of the hop selection kernel is set to *basic channel hopping sequence* (the *AFH_channel_map* input is unused in this case) and the *same channel* mechanism shall not be used.

The hop sequence adaptation state shall be changed when the Central sends the LMP_SET_AFH PDU and a Baseband acknowledgment is received. When the Baseband acknowledgment is received prior to the hop sequence switch instant, *AFH_Instant*, (see [Vol 2] Part C, Section 4.1.4) the hop sequence proceeds as shown in Figure 8.11.

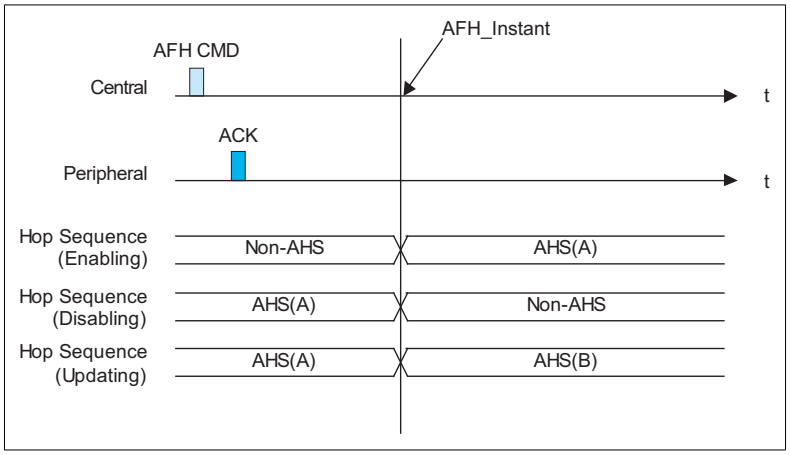

Figure 8.11: Successful hop sequence switching

When the Baseband acknowledgment is not received prior to the *AFH_Instant* the Central shall use a recovery hop sequence for the Peripheral(s) that did not respond with an acknowledgment (this may be because the Peripheral did not hear the Central's transmission or the Central did not hear the Peripheral's transmission). When hop sequence adaptation is being enabled or disabled the recovery sequence shall be the *AFH_channel_map* specified in the LMP_SET_AFH PDU. When the *AFH_channel_map*

is being updated the Central shall choose a recovery sequence that includes all of the RF channels marked as *used* in either the old or new *AFH_channel_map,* e.g. AHS(79). Once the Baseband acknowledgment is received the Central shall use the *AFH_channel_map* in the LMP_SET_AFH PDU starting with the next transmission to the Peripheral. See Figure 8.12.

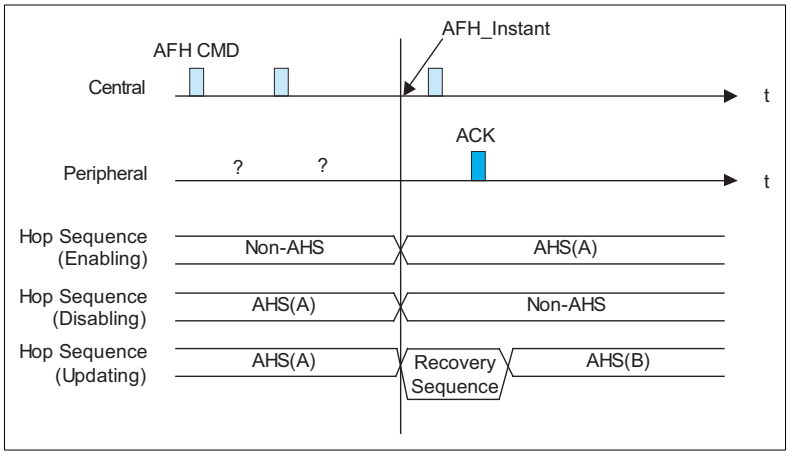

Figure 8.12: Recovery hop sequences

When the *AFH_Instant* occurs during a multi-slot packet transmitted by the Central, the Peripheral shall use the same hopping sequence parameters as the Central used at the start of the multi-slot packet. An example of this is shown in Figure 8.13. In this figure the basic channel hopping sequence is designated f. The first adapted channel hopping sequence is designated with f', and the second adapted channel hopping sequence is designated f''.

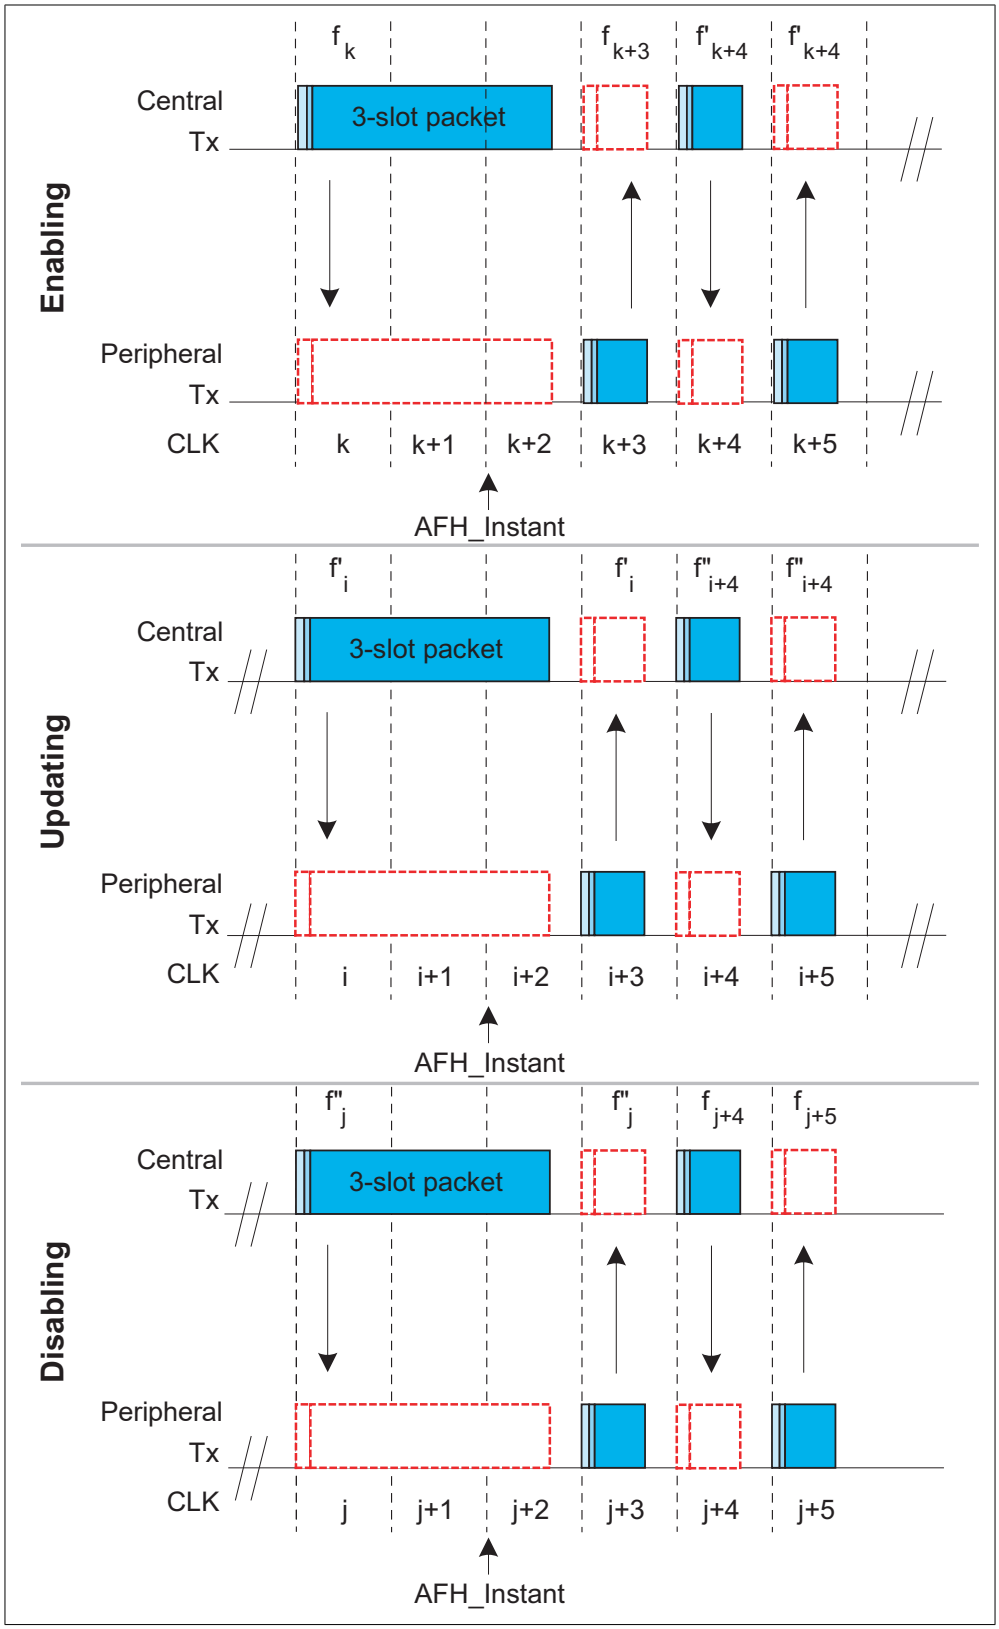

Figure 8.13: AFH_Instant changes during multi-slot packets transmitted by the Central

8.6.8 Channel classification and channel map selection

RF channels are classified as being *unknown, bad or good*. These classifications are determined individually by the Central and Peripherals based on local information (e.g. active or passive channel assessment methods or from the Host via HCI). Information received from other devices via LMP (for example, an *AFH_channel_map* from a Central or a channel classification report from a Peripheral) shall not be included in a device's channel classification.

The three possible channel classifications shall be as defined in Table 8.7.

Classification	Definition
unknown	A channel shall be classified as *unknown* if the channel assessment measurements are insufficient to reliably classify the channel, and the channel is not marked as *bad* in the most recent HCI_ Set_AFH_Host_Channel_Classification command.
bad	A channel may be classified as *bad* if an ACL or synchronous throughput failure measure associated with it has exceeded a threshold (defined by the particular channel assessment algorithm employed). A channel may also be classified as *bad* if an interference-level measure associated with it, determining the interference level that the link poses upon other systems in the vicinity, has exceeded a threshold (defined by the particular channel assessment algorithm employed). A channel shall be classified as *bad* when it is marked as *bad* in the most recent HCI_ Set_AFH_Host_Channel_Classification command.
good	A channel shall be classified as *good* if it is not either *unknown* or *bad*.

Table 8.7: Channel classification descriptions

A Central with AFH-enabled physical links shall determine an *AFH_channel_map* for each such link (two or more links may use the same map) based on any combination of the following information:

- Channel classification from local measurements (e.g. active or passive channel assessment in the Controller), if supported and enabled. The Host may enable or disable local measurements using the HCI_ Write_AFH_Channel_Assessment_Mode command, defined in the HCI Functional Specification [Vol 4] Part E, Section 7.3.54 if HCI is present.
- Channel classification information from the Host using the HCI_ Set_AFH_Host_Channel_Classification command, defined in the HCI Functional Specification [Vol 4] Part E, Section 7.3.46 if HCI is present. Channels classified as *bad* in the most recent *AFH_Host_Channel_Classification* shall be marked as *unused* in the *AFH_channel_map*.
- Channel classification reports received from Peripherals in *LMP_CHANNEL_CLASSIFICATION* PDUs, defined in the LMP Specification [Vol 2] Part C, Section 4.1.5.

The algorithm used by the Central to combine these information sources and generate the *AFH_channel_map* is not defined in the specification and will be implementation specific. At no time shall the number of channels used be less than N_{min}, defined in Section 2.3.1.

If a Central determines that all channels should be *used,* it may keep AFH operation enabled using an *AFH_channel_map* of 79 *used* channels, i.e., AHS(79).

For all devices that support the Synchronization Train substate (see Section 8.11.2), the RF channel indices used for the Synchronization Train (see Section 2.6.4.8) shall be marked as *unused* in the *AFH_channel_map* for all logical links.

8.6.9 Power management

Features are provided to allow low-power operation. These features are both at the microscopic level when handling the packets, and at the macroscopic level when using certain operation modes.

8.6.9.1 Packet handling

In order to minimize power consumption, packet handling is minimized both at TX and RX sides. At the TX side, power is minimized by only sending useful data. This means that if only link control information needs to be exchanged, **NULL** packets may be used. No transmission is required if there is no link control information to be sent, or if the transmission would only involve a NAK (NAK is implicit on no reply). If there is data to be sent, the payload length shall be adapted in order to send only the valid data bytes. At the RX side, packet processing takes place in different steps. If no valid access code is found in the search window, the transceiver may return to sleep. If an access code is found, the receiver device shall start to process the packet header. If the HEC fails, the device may return to sleep after the packet header. A valid header indicates if a payload will follow and how many slots are involved.

8.6.9.2 Slot occupancy

As was described in Section 6.5, the packet type indicates how many slots a packet may occupy. A Peripheral not addressed in the packet header may go to sleep for the remaining slots the packet occupies. This can be read from the TYPE code.

8.6.9.3 Recommendations for low-power operation

The most common and flexible method for reducing power consumption is the use of Sniff mode. Hold mode can also be used by repeated negotiation of hold periods.

8.6.9.4 Enhanced Data Rate

Enhanced Data Rate provides power saving because of the ability to send a given amount of data in either fewer packets or with the same (or similar) number of packets but with shorter payloads.

8.6.10 Piconet clock adjustment

A Central may adjust the piconet clock during the existence of a piconet using two mechanisms: Coarse Clock Adjustment and Clock Dragging. Both mechanisms may be used within the same piconet.

8.6.10.1 Coarse clock adjustment

The Central carries out a coarse clock adjustment by selecting an adjustment instant (clk_adj_instant), which shall be a Central-to-Peripheral slot, and the amount of the adjustment, and then broadcasting these parameters to all Peripherals by sending LMP_CLK_ADJ (see [Vol 2] Part C, Section 4.1.14.1). The amount of the adjustment is specified as two values: clk_adj_slots, which is the change in the value of CLK[27:1] at the clk_adj_instant, and clk_adj_us, which is the number of microseconds between the start of a Central slot in the old clock (CLK_{old}) and in the new clock (CLK_{new}) domains.

The Central shall provide the opportunity for each Peripheral to acknowledge the adjustment with LMP_CLK_ADJ_ACK (see [Vol 2] Part C, Section 4.1.14.1). If the Central receives any other packet than LMP_CLK_ADJ_ACK with the current clk_adj_id, it should poll the Peripheral more times until the expected acknowledgment is received or the Peripheral responds with a NULL packet. If any Peripheral does not acknowledge the adjustment, the Central shall start the Coarse Clock Adjustment Recovery Mode (see Section 8.6.10.2).

When the clk_adj_instant occurs, the Central will add (clk_adj_slots × 625 + clk_adj_us) µs to time_base_offset and the Peripheral(s) will add the same amount to peripheral_clock_offset. If the clk_adj_instant occurs during a multi-slot packet the adjustment is delayed until the start of the following Central-to-Peripheral slot. If a role switch is successful prior to the clk_adj_instant, the pending coarse clock adjustment shall be discarded. The effect of the adjustment is that devices will use the new clock domain starting at clk_adj_instant.

Figure 8.14 shows an example of a positive clock adjustment. In this example the clk_adj_instant is set to slot 12 (which is in the old clock domain), clk_adj_slots is set to 6 and clk_adj_us is set to 400. Time is moved forward clk_adj_slots × 625 + clk_adj_us = 6 × 625 + 400 = 4150 µs. The initial slot in the new clock domain is at CLK_{new}[27:1] = clk_adj_instant + clk_adj_slots = 12 + 6 = 18. This is an even value so the first slot is a Central-to-Peripheral slot. A positive clk_adj_us means that the first slot is assumed to have started clk_adj_us before the clk_adj_instant, and hence

only 625 – clk_adj_us = 225 µs remains after the instant. Since transmissions cannot be started part way through a slot, this partial slot is unusable. The first complete slot after the clk_adj_instant is a Peripheral-to-Central slot which can be used, for example, for eSCO. If clk_adj_slots had been an odd number, the first complete slot would have been a Central-to-Peripheral slot. The first complete Central-to-Peripheral slot in this example happens at $CLK_{new}[27:1] = 20$.

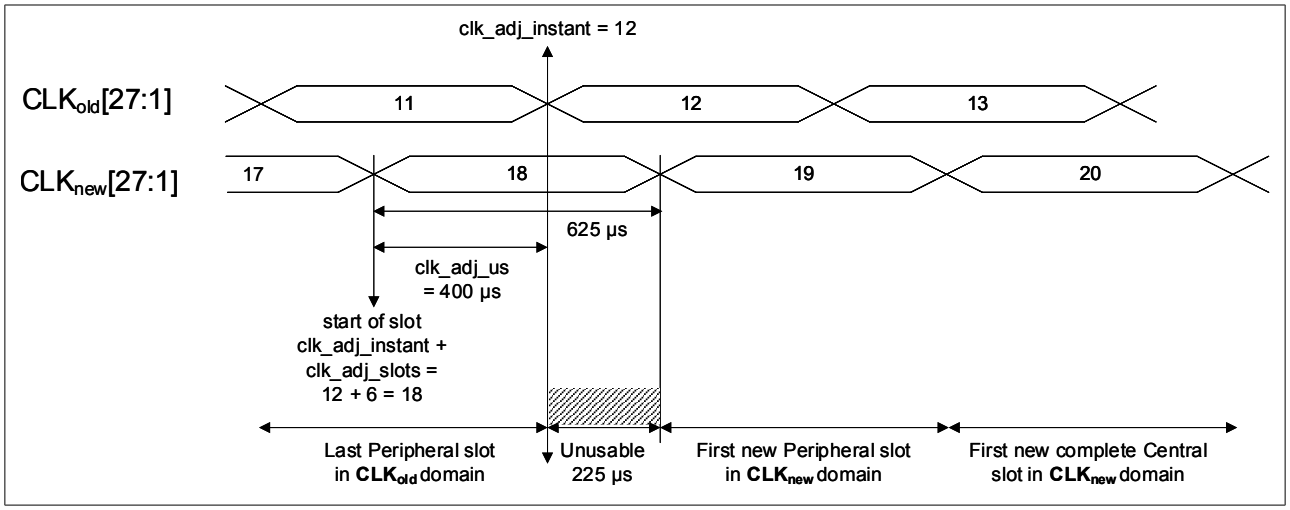

Figure 8.14: Positive coarse clock adjustment

Figure 8.15 shows an example of a negative clock adjustment. In this example the clk_adj_instant is again set to slot 12, clk_adj_slots is set to 0 and clk_adj_us is set to –400. Time is moved by clk_adj_slots × 625 + clk_adj_us = 0 × 625 + (–400) = –400 µs, which is 400 µs backwards. The initial slot in the CLK_{new} domain is at $CLK_{new}[27:1]$ = clk_adj_instant + clk_adj_slots = 12 + 0 = 12. This is an even value so the first slot is a Central-to-Peripheral slot. A negative clk_adj_us means that the first slot in the CLK_{new} domain starts clk_adj_us after clk_adj_instant. The time between the first slot in the CLK_{new} domain and clk_adj_instant (in this case 400 µs) is effectively a continuation of the previous slot, even if its number changes, and hence is unusable. (This is the case whenever clk_adj_us is negative, even when clk_adj_slots is non-zero.)

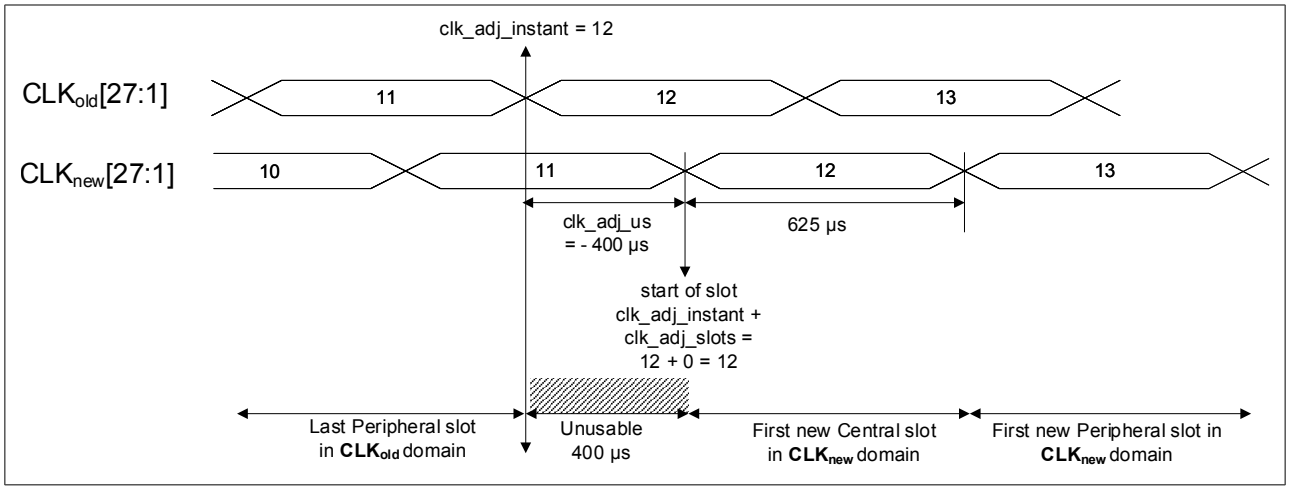

Figure 8.15: Negative coarse clock adjustment

If clk_adj_us is zero then the adjustment alters the slot numbering but not the actual times at which slots start. Therefore all slots remain available for use, though if clk_adj_slots is odd then there will be two consecutive Peripheral-to-Central slots.

8.6.10.2 Coarse Clock Adjustment Recovery mode

In Coarse Clock Adjustment Recovery Mode, the Central enters the Synchronization Train substate (see Section 8.11.2). The Central should remain in this substate and transmit synchronization train packets until all Peripherals have acknowledged the adjustment with the LMP_CLK_ADJ_ACK PDU, or link supervision timeout has expired for the last unresponsive Peripheral. The Central may cancel Coarse Clock Adjustment Recovery Mode to initiate another coarse clock adjustment or for any other reason. During Coarse Clock Adjustment Recovery Mode the Central shall continue broadcasting LMP_CLK_ADJ PDUs (see [Vol 2] Part C, Section 4.1.14.1).

When a Peripheral does not detect any transmissions from its Central it may enter the Synchronization Scan substate (see Section 8.11.1) and scan for synchronization train packets as defined in Section 2.7. $T_{Sync\_Scan\_Window}$ should be set large enough to enable reception of at least one synchronization train packet. A Peripheral that could have lost its connection to the Central due to coarse clock adjustment should prioritize synchronization scan.

A Peripheral that receives a Synchronization Train packet with the BD_ADDR of its Central shall change the value of peripheral_clock_offset to make CLK correspond to the contents of the packet and then exit the Synchronization Scan substate. If the new clock is in the range CLK_{OLD}–LSTO to CLK_{OLD} (where LSTO is the link supervision timeout period), then this shall be treated as a negative change. In this case, the Peripheral shall not transmit any packet and shall ignore all received directed packets until the value of CLK, after being changed, is strictly greater than the value of CLK the last time it transmitted or received (as appropriate) a packet. If the new clock is outside

this range then this shall be treated as a positive change (and thus might involve a clock wrap).

8.6.10.3 Clock Dragging

Clock Dragging means that the Central periodically adjusts its time_base_offset (see Section 2.2.4) until a desired time adjustment has been accomplished.

Each single adjustment shall be performed by a directed packet from the Central to each Peripheral and a response (e.g., Baseband acknowledgment) from each Peripheral. If a Peripheral does not respond, the Central shall suspend its updating of time_base_offset (but should continue to poll that Peripheral) at least until each Peripheral has either responded or has failed to respond for at least *CLK_adj_dragTO*. In case several Peripherals fail to respond, the Central should ensure that each of the failing Peripherals gets at least one *CLK_adj_dragTO* to respond (these may be concurrent for multiple Peripherals). The Central need not allow more than one suspension of *CLK_adj_dragTO* for any given Peripheral during a link supervision timeout for that Peripheral.

A single adjustment shall be less than or equal to 3 µs. Within any period of 125 ms, the total adjustment in a single direction shall be less than or equal to 5 µs.

Note: These requirements apply to the changes to time_base_offset and are applied irrespective of the accuracy of the Central's reference clock (see Section 1.1). This means that Peripherals may observe a change in CLK greater than 20ppm.

If a Central is performing Clock Dragging when it initiates a Coarse Clock Adjustment, a new Clock Dragging, or a sequence containing an instant or timing control flags, or receives a request from a Peripheral to initiate such a sequence, it shall abort the current Clock Dragging before processing the new request or carrying out the sequence. If the Central has suspended clock dragging during *CLK_adj_dragTO*, it shall reject new requests until the timeout period expires or the timeout is cancelled because all of the Peripherals have responded.

8.6.11 Slot Availability Mask (SAM)

Slot Availability Mask (SAM) allows two Bluetooth devices to indicate to each other the availability of their time slots for transmission and reception. From the Baseband point of view, SAM provides a map - the SAM slot map - which marks the availability of Bluetooth slots. The availability arises from either external conditions (e.g., MWS coexistence) or internal conditions (e.g., topology management for scatternets). The SAM slot map marks each slot using one of four type codes defined in [Vol 2] Part C, Section 5.2 and repeated for convenience in Table 8.8.

Slot type code	Meaning
0	The slot is not available for either transmission or reception
1	The slot is available for transmission but not reception
2	The slot is available for reception but not transmission
3	The slot is available for both transmission and reception

Table 8.8: SAM slot types

Note: A Central may mark Central-to-Peripheral slots available for reception and Peripheral-to-Central slots available for transmission, because such slots may be used in this way for multi-slot packets; similarly for a Peripheral. A SAM slot map with all slots set to type 3 is equivalent to not using SAM and simply performing normal scheduling.

Figure 8.16 shows an example of a SAM slot map. The Central-to-Peripheral slots are labeled with the letter 'C' and Peripheral-to-Central slots with the letter 'P'.

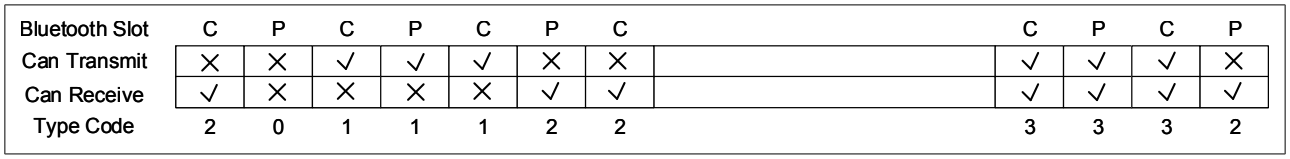

Figure 8.16: An example of a SAM slot map

A SAM slot map has a finite length and is repeated indefinitely until changed by the associated LMP procedures. SAM anchor points are spaced regularly with an interval of T_{SAM}, in units of slots. Between adjacent SAM anchor points, the slot map indicates when the device is able to transmit and receive. The SAM slot map is effectively repeated every T_{SAM} until it is changed.

The SAM interval T_{SAM} is further divided into N_{SAM_SM} sub-intervals of equal length, T_{SAM_SM}, such that $T_{SAM} = T_{SAM\_SM} \times N_{SAM\_SM}$. T_{SAM_SM} shall be an even integer so as to contain TX/RX slot pairs.

The words "SAM submap" (or simply "submap" when there is no ambiguity from the context) will be used to denote a sub-interval of T_{SAM_SM} slots. Each submap is assigned one of the four usage types defined in [Vol 2] Part C, Section 5.2 and repeated for convenience in Table 8.9.

Submaptype code	Meaning
0	Each slot is individually available or unavailable as configured. Slots may have different availabilities for transmission and reception.
1	All slots are available for transmission and reception.

Submaptype code	Meaning
2	All slots are unavailable for transmission and reception.
3	Reserved for future use

Table 8.9: SAM submap types

The SAM facilities specify each SAM slot map at the submap granularity. Figure 8.17 shows an example of a SAM slot map in terms of submaps in the local device. Each box represents a sub-interval of T_{SAM_SM} slots, with the label on the box indicating the type of the submap.

At the submap level of granularity, transmit and receive are handled identically; the difference will only appear inside submaps with type 0.

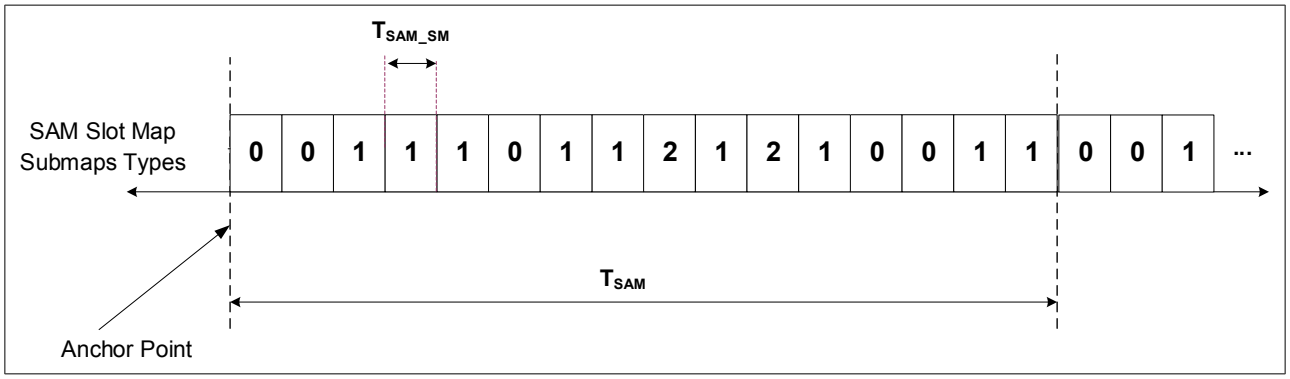

Figure 8.17: Example of a SAM slot map in terms of submaps in the local device

In addition to the SAM slot maps, the Controller also maintains a single "SAM type 0 submap" that is used to specify the availability of individual slots for those submaps shown as having type 0. The Controller then combines the SAM slot map at submap granularity with the first T_{SAM_SM} entries of the type 0 submap to generate the effective maps. Figure 8.18 shows a SAM slot map and a SAM type 0 submap together with the resulting effective map.

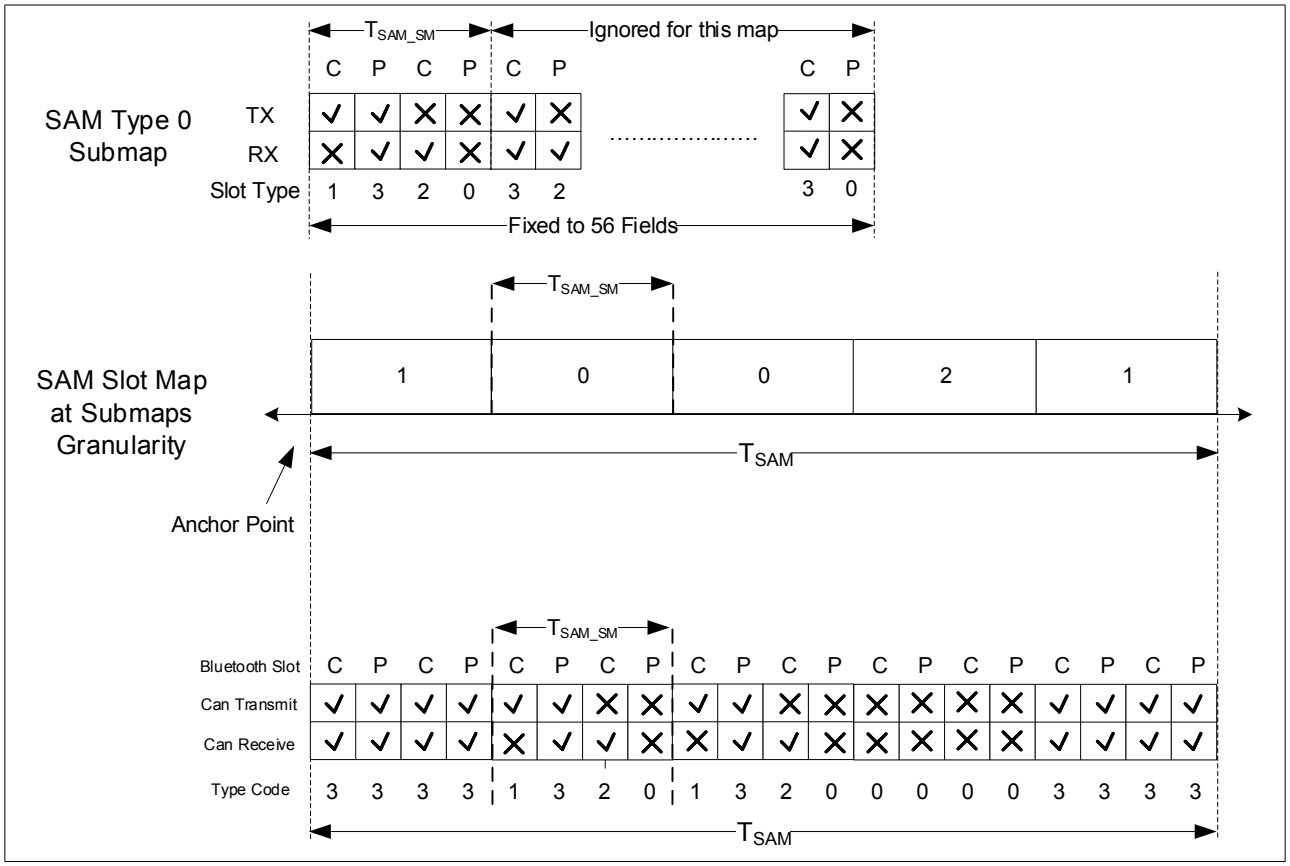

Figure 8.18: Example of a SAM slot map and SAM type 0 submap being combined

Figure 8.19 shows an example of a SAM type 0 submap for a collocated MWS.

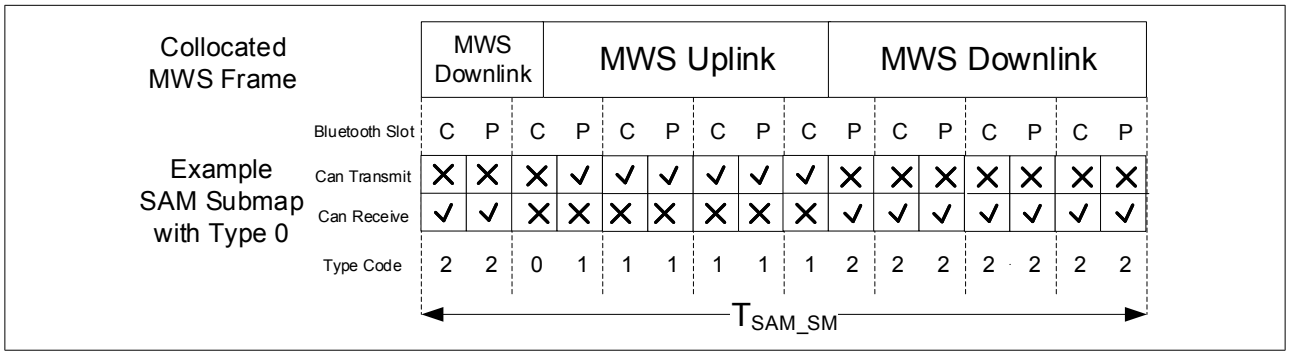

Figure 8.19: Examples of SAM type 0 submap at a Bluetooth device with a collocated MWS

The assumption in the example is that, in order to prevent mutual interference between Bluetooth and MWS radios, Bluetooth transmissions are not available during MWS downlink durations and Bluetooth reception is not available during MWS uplink durations. The MWS frame is 10 ms long and the SAM type 0 submap needs to have the same length, so T_{SAM_SM} is 16.

Figure 8.20 shows another example of a collocated Bluetooth device with a low traffic load in the MWS Uplink. In this case, the implementation chooses to mark the MWS Uplink portion available for both TX and RX, because there is a good chance that it can receive Central packets and respond to them without interference from MWS.

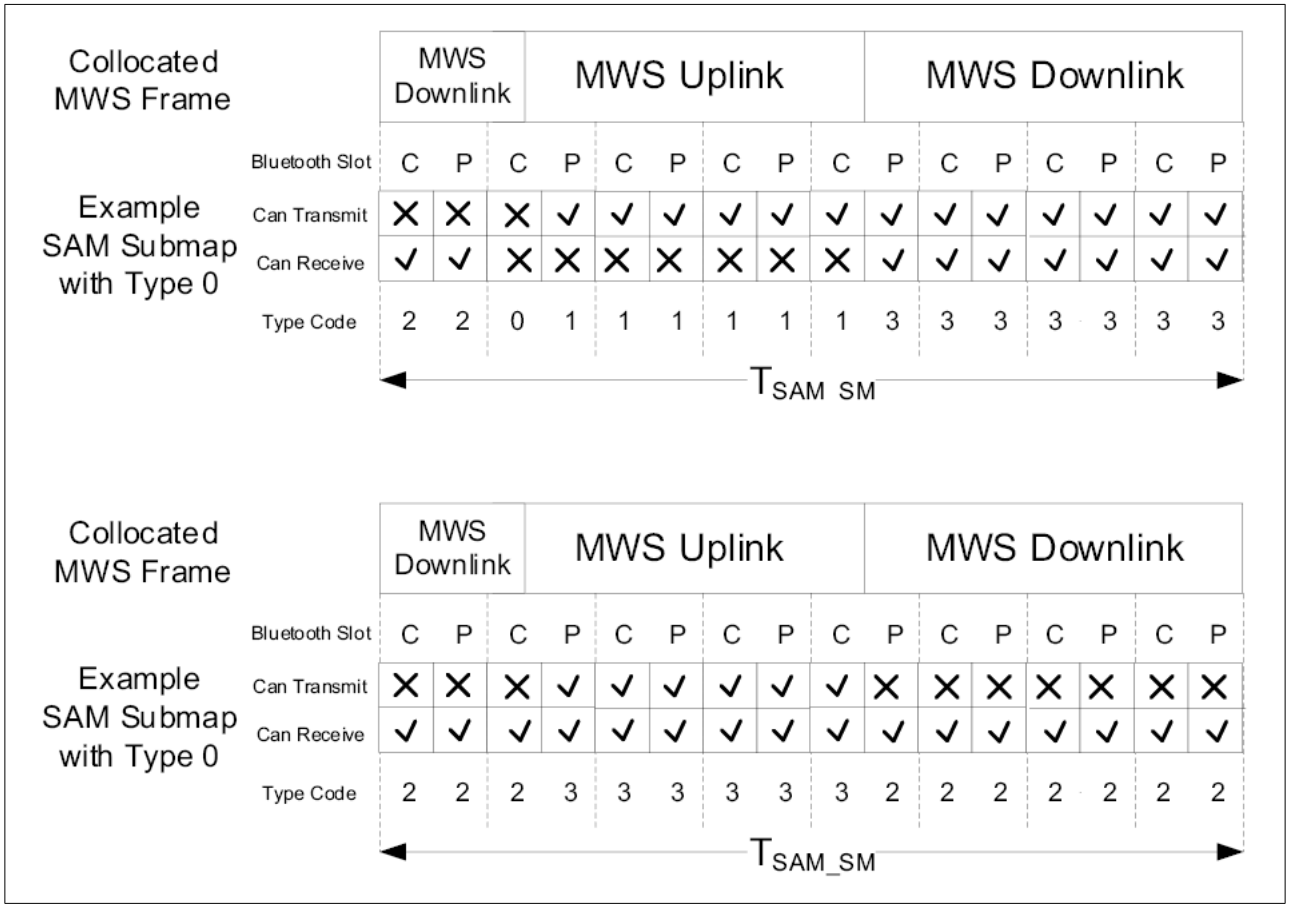

Figure 8.20: Examples of SAM type 0 submap at a Bluetooth device with a collocated MWS with low uplink traffic load

SAM allows each device to send its local slot availability to the other, in which case the availability of slots depends on the combined slot maps. The scheduling recommendations for such a SAM slot map are described in Section 8.6.11.2.

A device that supports the SAM feature shall be capable of storing three distinct SAM slot maps from each connected remote device. A remote device can only define one type 0 submap, which can be referenced by any of its defined SAM slot maps. The remote device may redefine its type 0 submap at any time.

8.6.11.1 SAM anchor point

SAM slot maps are periodic, defined by an interval T_{SAM} and an offset D_{SAM}. Figure 8.21 shows an example of SAM slot maps designed to correspond to periodic MWS active and inactivity cycles.

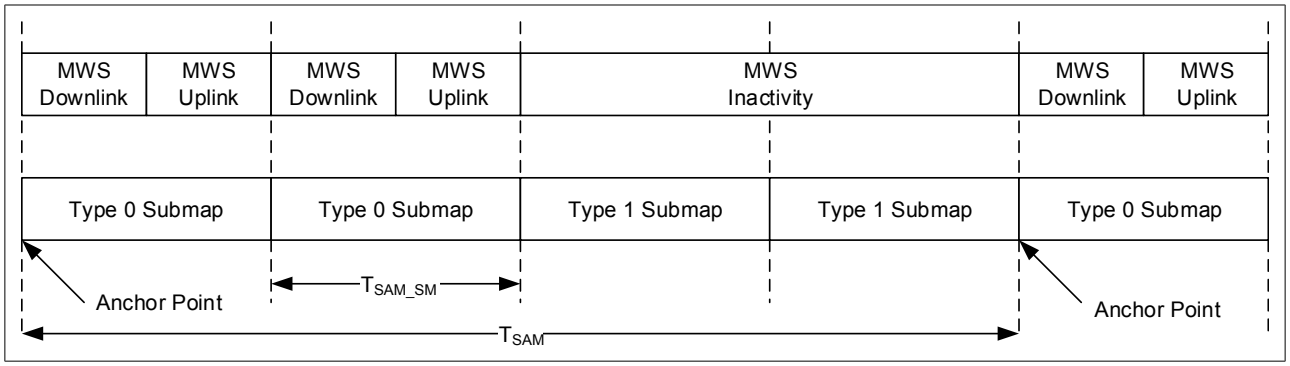

Figure 8.21: An example of SAM slot maps for a periodic MWS active and inactive cycles

SAM anchor points are the start points of the first slot in the SAM slot maps.
SAM anchor points are computed from T_{SAM} and D_{SAM} using the Central's current clock, which is known to both devices. The first SAM anchor point is indicated by SAM_Instant. In order to prevent problems caused by the clock wrap-around, the LMP message carries an additional timing control flag, which indicates whether initialization procedure 1 or 2 shall be used. The initiating device shall use initialization 1 when the MSB of the Central's current clock (CLK_{27}) is 0; it shall use initialization 2 when the MSB of the Central's current clock (CLK_{27}) is 1. The responding device shall apply the initialization method indicated by the initialization flag. The SAM anchor points shall be initialized on the slots for which the clock satisfies the applicable equations:

$$CLK_{27-1} \; mod \; T_{SAM} = D_{SAM} \quad \text{for initialization 1}$$

$$\left(\overline{CLK_{27}}, CLK_{26-1}\right) mod \; T_{SAM} = D_{SAM} \quad \text{for initialization 2}$$

After initialization, the clock value CLK(k+1) for the next SAM anchor point can be found by adding the fixed interval T_{SAM} to the clock value of the current anchor point:

$$CLK_{27-1}(k+1) = CLK_{27-1}(k) + T_{SAM}$$

The SAM anchor point shall be a Central-to-Peripheral slot. As a corollary, the first slot of every SAM submap is also a Central-to-Peripheral slot.

8.6.11.2 SAM scheduling

SAM enables each device to send its local slot availability to the other. The scheduler in the Bluetooth Controller should consider the SAM slot maps from both local and remote devices for packet scheduling. The only effect of using the SAM information is to restrict a device's transmission and reception opportunities.

For all ACL packets and for eSCO packets in the retransmission window:

1. The Central should only transmit a packet if the required Central-to-Peripheral slots are marked as available for transmission in the Central's SAM slot map and available for reception in the Peripheral's SAM slot map.
2. The Peripheral should only transmit a packet if the required slots are marked as available for reception in the Central's SAM slot map and available for transmission in the Peripheral's SAM slot map.
3. The Peripheral may choose not to listen to the Central in Central-to-Peripheral slots that are marked either unavailable for transmission in the Central’s SAM slot map or unavailable for reception in the Peripheral’s SAM slot map.

For all ACL packets, the Central should only transmit a packet if the slot immediately following the Central's packet is marked as available for transmission in the Peripheral's SAM slot map and available for reception in the Central's SAM slot map.

For eSCO packets in the retransmission window, the Central should only transmit a packet if either:

1. the slot immediately following the Central's packet is marked as available for transmission in the Peripheral's SAM slot map and available for reception in the Central's SAM slot map;
2. this is the last opportunity for the Central to transmit this packet in this retransmission window; or
3. for all subsequent Central-to-Peripheral slots in the same retransmission window that provide sufficient remaining slots for the Central to transmit the same packet, the rules in this section state that the Central should not transmit the packet.

In SCO and eSCO reserved slots, either the Central or the Peripheral may choose not to transmit a SCO or eSCO packet unless the required slots are marked both as available for transmission in the local SAM slot map and available for reception in the remote SAM slot map.

Figure 8.22 below illustrates possible scheduling results with combined SAM slot maps from Central and Peripheral.

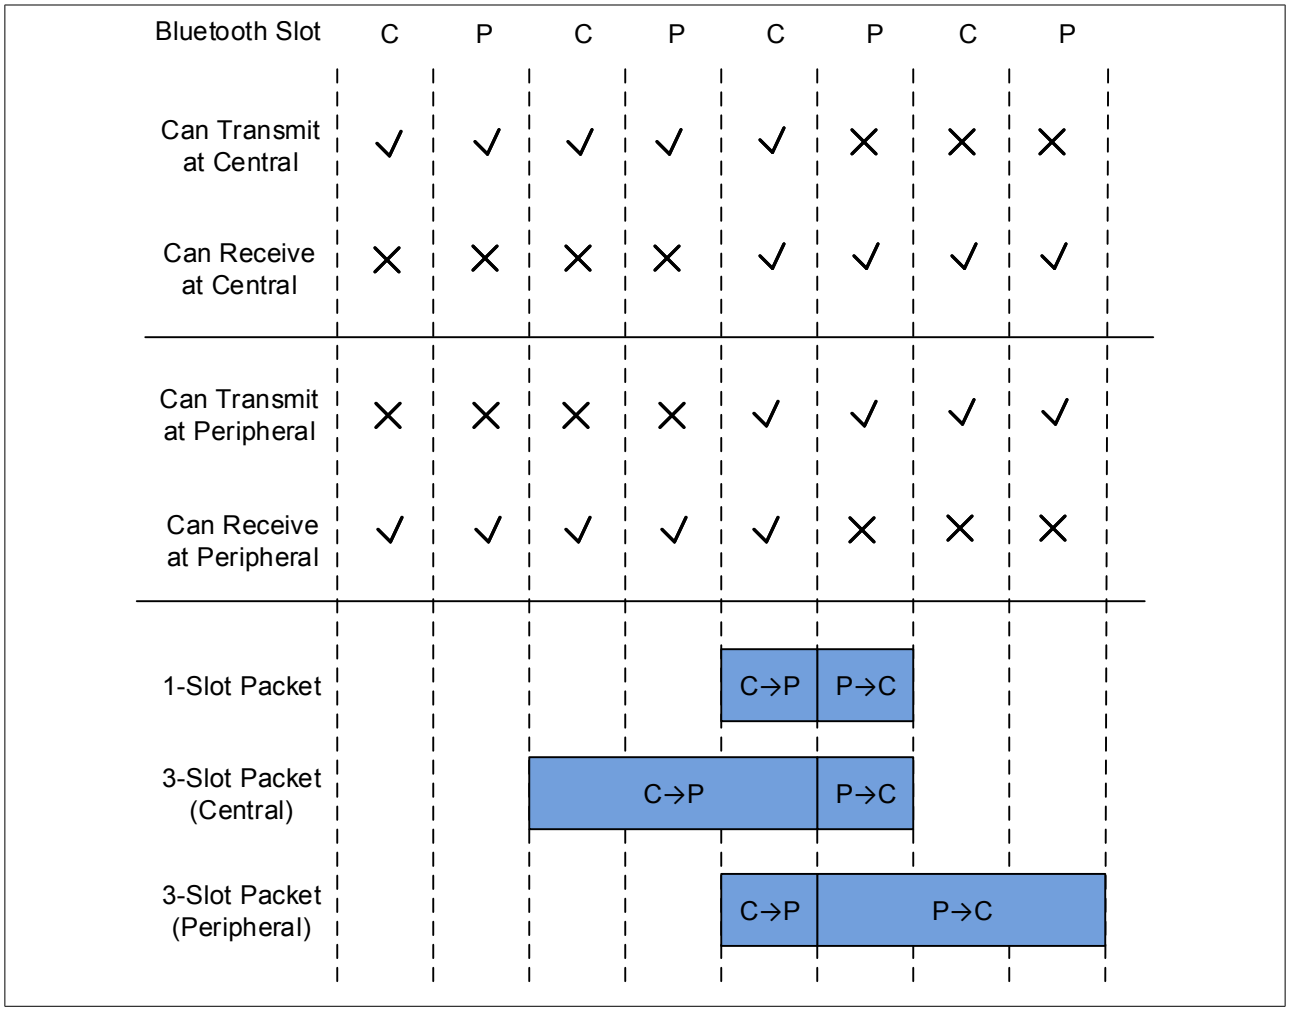

Figure 8.22: Example of possible scheduling results with combined SAM slot maps from Central and Peripheral

8.7 Sniff mode

In Sniff mode, the duty cycle of the Peripheral's activity in the piconet may be reduced. If a Peripheral is in Active mode on an ACL logical transport, it shall listen in every ACL slot to the Central's traffic, unless that link is being treated as a scatternet link or is absent due to Hold mode. With Sniff mode, the time slots when a Peripheral is listening are reduced, so the Central shall only transmit to a Peripheral in specified time slots. The sniff anchor points are spaced regularly with an interval of $T_{sniff.}$

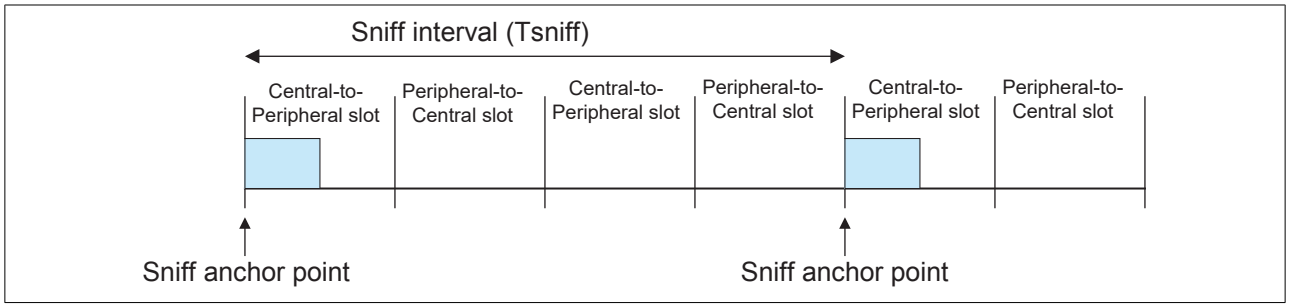

Figure 8.23: Sniff anchor points

The Peripheral listens in Central-to-Peripheral transmission slots starting at the sniff anchor point. It shall use the following rules to determine whether to continue listening:

- If fewer than $N_{sniff\ attempt}$ Central-to-Peripheral transmission slots have elapsed since the sniff anchor point then the Peripheral shall continue listening.
- If the Peripheral has received a packet with a matching LT_ADDR that contains ACL data (DM, DH, or DV packets) in the preceding $N_{sniff\ timeout}$ Central-to-Peripheral transmission slots then it shall continue listening.
- If the Peripheral has transmitted a packet containing ACL data (DM, DH, or DV packets) in the preceding $N_{sniff\ timeout}$ Peripheral-to-Central transmission slots then it shall continue listening.
- If the Peripheral has received any packet with a matching LT_ADDR in the preceding $N_{sniff\ timeout}$ Central-to-Peripheral transmission slots then it may continue listening.
- A device may override the rules above and stop listening prior to $N_{sniff\ timeout}$ or the remaining $N_{sniff\ attempt}$ slots if it has activity in another piconet.

It is possible that activity from one sniff timeout may extend to the next sniff anchor point. Any activity from a previous sniff timeout shall not affect activity after the next sniff anchor point. So in the above rules, only the slots since the last sniff anchor point are considered.

Note: $N_{sniff\ attempt}$=1 and $N_{sniff\ timeout}$=0 cause the Peripheral to listen only at the slot beginning at the sniff anchor point, irrespective of packets received from the Central.

$N_{sniff\ attempt}$ =0 shall not be used.

Sniff mode only applies to asynchronous logical transports and their associated LT_ADDR. Sniff mode shall not apply to synchronous logical transports, therefore, both Centrals and Peripherals shall still respect the reserved slots and retransmission windows of synchronous links.

To enter Sniff mode, the Central or Peripheral shall issue a sniff setup message via the LM protocol. This message includes the sniff interval T_{sniff} and an offset $D_{sniff.}$ In

addition, an initialization flag indicates whether initialization procedure 1 or 2 shall be used. The device sending the sniff request shall use initialization 1 when the MSB of the Central's current clock (CLK_{27}) is 0; it shall use initialization 2 when the MSB of the Central's current clock (CLK_{27}) is 1. The device that receives the sniff request shall apply the initialization method as indicated by the initialization flag irrespective of its own CLK_{27} value. The sniff anchor point determined by the Central and the Peripheral shall be initialized on the slots for which the clock satisfies the applicable equation:

$$\begin{aligned} &\mathrm{CLK}_{27-1} \ mod \ T_{\mathrm{sniff}} = D_{\mathrm{sniff}} && \text{for initialization 1} \\ &\left(\overline{\mathrm{CLK}_{27}}, \mathrm{CLK}_{26-1}\right) \ mod \ T_{\mathrm{sniff}} = D_{\mathrm{sniff}} && \text{for initialization 2} \end{aligned}$$

this implies that D_{sniff} must be even

After initialization, the clock value CLK(k+1) for the next sniff anchor point shall be derived by adding the fixed interval T_{sniff} to the clock value of the current sniff anchor point:

$$\mathrm{CLK}_{27-1}(\mathrm{k}+1) = \mathrm{CLK}_{27-1}(\mathrm{k}) + T_{\mathrm{sniff}}$$

8.7.1 Sniff Transition mode

Sniff Transition mode is a special mode which is used during the transition between Sniff mode and Active mode. It is required because during this transition it is unclear which mode (Sniff or Active) the Peripheral is in and it is necessary to ensure that the Peripheral is polled correctly regardless of which mode it is in.

In Sniff Transition mode the Central shall maintain the Active mode poll interval in case the Peripheral is in Active mode. In addition the Central shall poll the Peripheral at least once in the sniff attempt transmit slots starting at each sniff anchor point. This transmission counts for the Active mode polling as well. The Central shall use its high power accurate clock when in Sniff Transition mode.

The precise circumstances under which the Central enters Sniff Transition mode are defined in [Vol 2] Part C, Section 4.5.3.1.

8.7.2 Sniff subrating

When sniff subrating is enabled by the Link Manager a device alternates between Sniff mode and Sniff Subrating mode. Sniff Subrating mode allows a device to use a reduced number of sniff anchor points. A device shall transition from Sniff mode to Sniff Subrating mode based on the Sniff mode timeout value (see Section 8.7.2.1). A device shall transition from Sniff Subrating mode to Sniff mode whenever ACL-U, APB-U, ACL-C, or APB-C data is received from the remote device.

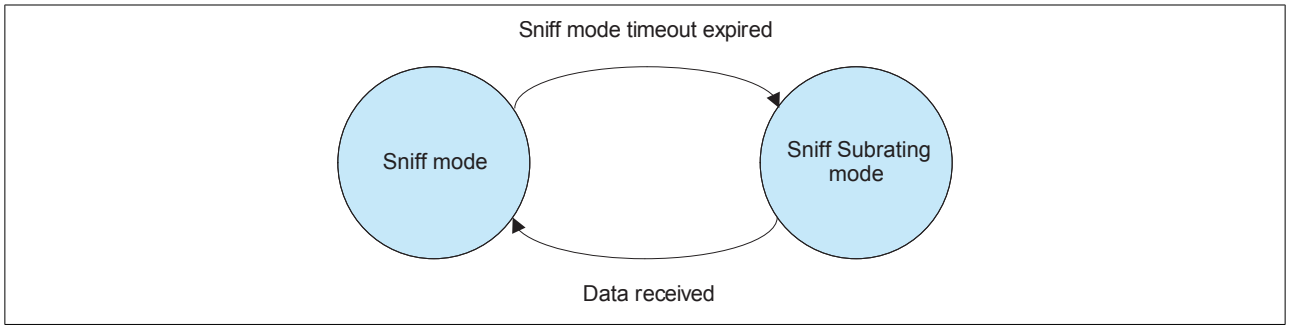

Figure 8.24: Sniff subrating

A Peripheral in Sniff Subrating mode shall also temporarily enter Sniff mode after transmitting a packet requiring acknowledgment until the Baseband acknowledgment is received.

Once sniff subrating is enabled the Central and Peripheral may be in Sniff mode or Sniff Subrating mode at different times. The rules defined in Section 8.7.2.2 describe how the two devices maintain synchronization and can reliably exchange data.

8.7.2.1 Sniff mode timeout

The Sniff mode timeout value $T_{sniff\_mode\_timeout}$ used by a device shall be at least the greater of the value specified by the peer over LMP and any value specified by the Host.

Whenever a packet containing ACL-U, APB-U, ACL-C, or APB-C data is received by a device in Sniff Subrating mode it shall transition to Sniff mode, re-start the Sniff mode timeout timer, and shall then use all sniff anchor points until at least $T_{sniff\_mode\_timeout}$ slots have expired. If ACL-U, APB-U, ACL-C, or APB-C data is received before $T_{sniff\_mode\_timeout}$ slots have passed since the last ACL-U, APB-U, ACL-C, or APB-C data was received, the Sniff mode timeout timer shall be restarted. NULL and POLL packets do not contain ACL or APB data and shall not restart the Sniff mode timeout timer.

8.7.2.2 Sniff Subrating mode

When the Sniff mode timeout has expired a device shall enter sniff subrating mode. In Sniff Subrating mode the mandatory sniff subrating anchor points at which the Central shall transmit to the Peripheral and the Peripheral shall listen for the Central, are defined in Table 8.10 (where M is the max subrate received by the Central, N is the max subrate received by the Peripheral, A is the sniff subrating instant, and k is any positive integer).

$j \leq X$

When sniff subrating is enabled, the rules specified in Section 8.7 for $N_{sniff\ attempt}$ and $N_{sniff\ Timeout}$ shall apply to sniff subrating anchor points.

	Central	Peripheral
M=N	$CLK_{M(k)} = A + [T_{sniff} \times M \times k]$	$CLK_{N(k)} = A + [T_{sniff} \times N \times k]$
M>N	At least once every j anchor points satisfying $CLK_{N(k)} = A + [T_{sniff} \times N \times k]$, where $j = \lfloor M \div N \rfloor$	$CLK_{N(k)} = A + [T_{sniff} \times N \times k]$
M<N	$CLK_{M(k)} = A + [T_{sniff} \times M \times k]$	At least once every j anchor points satisfying $CLK_{M(k)} = A + [T_{sniff} \times M \times k]$, where $j = \lfloor N \div M \rfloor$

Table 8.10: Sniff subrating anchor points

8.8 Hold mode

During the Connection state, the ACL logical transport to a Peripheral can be put in a Hold mode. In Hold mode the Peripheral temporarily shall not support ACL packets on the channel. Any synchronous packet during reserved synchronous slots (from SCO and eSCO links) shall be supported. With the Hold mode, capacity can be made free to do other things like scanning, paging, inquiring, or attending another piconet. The device in Hold mode can also enter a low-power sleep mode. During Hold mode, the Peripheral keeps its logical transport address(es) (LT_ADDR).

Prior to entering Hold mode, Central and Peripheral agree on the time duration the Peripheral remains in Hold mode. A timer shall be initialized with the *holdTO* value. When the timer is expired, the Peripheral shall wake up, synchronize to the traffic on the channel and will wait for further Central transmissions.

8.9 [This section is no longer used]

8.10 Connectionless Peripheral Broadcast mode

In Connectionless Peripheral Broadcast mode, the Transmitter broadcasts packets to zero or more Receivers.

The Transmitter can broadcast messages to multiple Receivers in Connectionless Peripheral Broadcast mode. For this purpose, the Transmitter (Central) shall reserve an LT_ADDR for use only by Connectionless Peripheral Broadcast traffic. In Connectionless Peripheral Broadcast mode, the Transmitter transmits packets at specified intervals.

8.10.1 Connectionless Peripheral Broadcast transmit operation

In Connectionless Peripheral Broadcast mode, the Transmitter transmits packets on the CPB logical transport at intervals requested by the Host in Central-to-Peripheral transmission slots.

If the Host has not yet provided the BR/EDR Controller with any data packets to transmit since enabling the broadcast, or if the length of the data is zero, the BR/EDR Controller shall transmit NULL packets. This is different than the case where the Host has provided data since enabling the broadcast but has not provided new data since the previous broadcast packet. In that case, the BR/EDR Controller resends the most recent data.

The Host may provide Connectionless Peripheral Broadcast data through HCI commands. Because HCI commands are limited to 255 bytes, a single command cannot carry the maximum payloads allowed by larger packets, such as DH5. Therefore, HCI commands for Connectionless Peripheral Broadcast allow fragmentation of large payloads at the HCI level. The BR/EDR Controller shall assemble all HCI fragments of a packet before transmission and shall not transmit incomplete packets. Until such assembly is complete, the Controller shall continue to transmit the previous data (if any).

Figure 8.25 shows the timing of Connectionless Peripheral Broadcast packets.

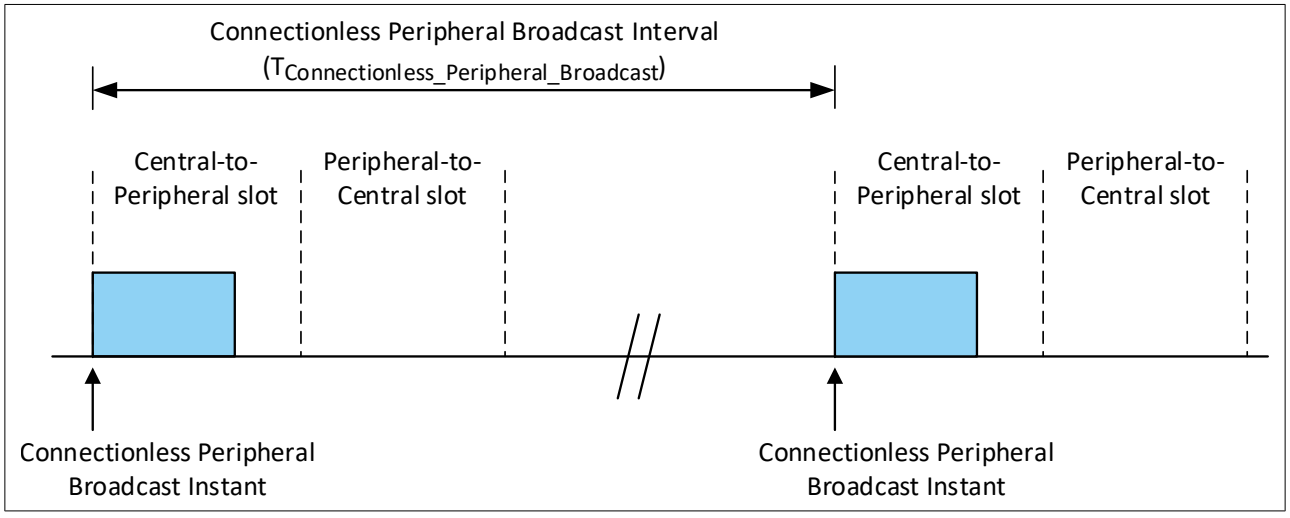

Figure 8.25: Connectionless Peripheral Broadcast timing

Connectionless Peripheral Broadcast Instants are separated by the Connectionless Peripheral Broadcast Interval ($T_{Connectionless\_Peripheral\_Broadcast}$). The Connectionless Peripheral Broadcast interval can be any even value from 0x0002 to 0xFFFE slots and is negotiated between the BR/EDR Controller and the Host during CPB setup. At the start of each Connectionless Peripheral Broadcast Instant, the Connectionless

Peripheral Broadcast packet is transmitted using the adapted piconet physical channel. Connectionless Peripheral Broadcast packets shall not be encrypted.

The Transmitter shall stop transmitting Connectionless Peripheral Broadcast packets after *CPB_supervisionTO* slots have passed without transmission of a Connectionless Peripheral Broadcast packet. *CPB_supervisionTO* may be any even value from 0x0002 to 0xFFFE slots. Connectionless Peripheral Broadcast packets can fail to transmit for a certain continuous period of time due to scheduling conflicts from higher priority traffic.

8.10.2 Connectionless Peripheral Broadcast receive operation

In Connectionless Peripheral Broadcast mode, the Receiver is synchronized to a Connectionless Peripheral Broadcast Transmitter and is receiving profile broadcast data on the LT_ADDR reserved by the Transmitter for the CPB logical transport.

When requesting synchronization establishment, the Host provides the Controller with the Transmitter’s clock offset and the next Connectionless Peripheral Broadcast Instant received from the synchronization train. Because of delays in the Host, it is possible that the Connectionless Peripheral Broadcast Instant occurs in the past. The BR/EDR Controller shall support Connectionless Peripheral Broadcast instants at least 1 second in the past. The Receiver should determine whether the Connectionless Peripheral Broadcast Instant is in the past or the future by using the Transmitter’s clock offset and its own clock to estimate the Transmitter's current clock and start listening from the next broadcast instant.

The Skip parameter is set by the Host and specifies the number of consecutive Connectionless Peripheral Broadcast instants which the receiver may skip after successfully receiving a Connectionless Peripheral Broadcast packet. If the Connectionless Peripheral Broadcast packet is received successfully, the payload data shall be forwarded to the Host. If no Connectionless Peripheral Broadcast packet is received by a Receiver during a Connectionless Peripheral Broadcast Instant, the Receiver shall ignore Skip and instead listen at every scheduled Connectionless Peripheral Broadcast Instant until it is able to successfully receive a Connectionless Peripheral Broadcast packet or until *CPB_supervisionTO* number of slots have passed.

The BR/EDR Controller shall stop listening for Connectionless Peripheral Broadcast packets after *CPB_supervisionTO* slots have passed without receiving a Connectionless Peripheral Broadcast packet.

The BR/EDR Controller may transfer Connectionless Peripheral Broadcast data to the Host through HCI events. Because HCI events are limited to 255 bytes a received packet will not necessarily fit into a single HCI event. The BR/EDR Controller shall fragment and transfer such packets using multiple HCI events.

8.10.3 AFH in Connectionless Peripheral Broadcast

Connectionless Peripheral Broadcast packets shall be transmitted on the adapted piconet channel and the synchronization train shall always contain the current AFH channel map for the PBD logical link.

8.11 Synchronization establishment substates

8.11.1 Synchronization Scan substate

The Synchronization Scan substate is used by Peripherals to receive synchronization train packets from the piconet Central. The Synchronization Scan substate can be entered from the Standby or Connection states. In the Synchronization Scan substate, a device uses the Synchronization Scan procedure (see Section 2.7.3). During each synchronization scan window, the device shall listen on a single frequency with its correlator matched to the Central's channel access code (CAC).

If the correlator exceeds the trigger threshold during the Synchronization Scan procedure, the scanning device shall receive the synchronization train packet, whose contents are defined in Table 8.11. Upon reception of the synchronization train packet the device shall exit the Synchronization Scan substate and return to the Standby or Connection state as appropriate. If the packet is not received the device should stay in the Synchronization Scan substate. If the *synchronization_scanTO* expires before reception of a Synchronization Train packet, the device shall return to the Standby state. A device attempting to synchronize to a Connectionless Peripheral Broadcast transport shall ignore any synchronization train packet whose Connectionless Peripheral Broadcast LT_ADDR field in the payload is set to zero.

The synchronization scan may be interrupted by higher priority traffic. In particular, the reserved synchronous slots should have higher priority than the synchronization scan.

8.11.2 Synchronization Train substate

The Synchronization Train substate is used by the Central of the piconet to transmit synchronization train packets. The Synchronization Train substate can be entered from the Standby or Connection states. In the Synchronization Train substate, a device uses the Synchronization Train procedure (see Section 2.7.2). During the Synchronization

Train procedure, the Central repeatedly transmits synchronization train packets on the channels specified in Section 2.6.4.8. While in the Synchronization Train substate:

- if Connectionless Peripheral Broadcast mode is enabled, the Central shall continue to transmit Connectionless Peripheral Broadcast packets in addition to synchronization train packets;
- if the Central is in Coarse Clock Adjustment Recovery Mode, it shall continue transmitting and receiving on all active logical transports to all Peripherals that have acknowledged the Coarse Clock Adjustment (see [Vol 2] Part C, Section 4.1.14.1).

Reserved SCO and eSCO slots should have higher priority than the synchronization train. Once the Central enters the Synchronization Train substate, it shall remain in the Synchronization Train substate until *synchronization_trainTO* expires or the Host directs otherwise. The Central shall transition to the Standby or Connection state when exiting the Synchronization Train substate.

The synchronization train packet is a basic rate ACL packet with type DM3 and LT_ADDR of zero. FLOW, ARQN and SEQN shall all be set to zero upon transmission and ignored upon receipt. The HEC LFSR shall be initialized with the Central's UAP. In the payload header, the LLID shall contain the value 0b10 (start of an L2CAP message or no fragmentation). FLOW in the payload header shall be set to zero upon transmission and ignored upon reception. The length of the payload body (LENGTH) shall be 28 bytes. The CRC LFSR shall be initialized with the Central's UAP. Data whitening is not used. Encryption is not used.

There are two possible formats. Format 1 shall be used when the synchronization train is being transmitted by a device which is the Central of a piconet where Connectionless Peripheral Broadcast mode is enabled, and format 2 shall be used otherwise. The format of the payload portion of the DM3 packet used in the synchronization train is shown in Table 8.11.

Bytes	Field	Length	Format 1 Description	Format 2 Description
0-3	CLK	4 Bytes	Current piconet clock (CLK)	Current piconet clock (CLK)
4-7	Future Connectionless Peripheral Broadcast Instant	4 Bytes	CLK[27:1] corresponding to the start of a future Connectionless Peripheral Broadcast Instant.	CLK[27:1] + 1600 slots

Bytes	Field	Length	Format 1 Description	Format 2 Description
8-17	AFH Channel Map	10 Bytes	The current AFH_Channel_-Map used for the PBD logical link. The format is the same as the Link Manager AFH_Channel_Map parameter, see [Vol 2] Part C, Table 5.2.	Unspecified
18-23	Central BD_ADDR	6 Bytes	Central's BD_ADDR	Central's BD_ADDR
24-25	Connectionless Peripheral Broadcast Interval	2 Bytes	Time duration in slots from the start of a Connectionless Peripheral Broadcast packet to the start of the next Connectionless Peripheral Broadcast packet. Shall be even.	Unspecified
26	Connectionless Peripheral Broadcast LT_ADDR	1 Byte	The LT_ADDR reserved for the CPB logical transport.	0x00
27	Service Data	1 Byte	Defined by the service using the Connectionless Peripheral Broadcast feature.	0x00

Table 8.11: Synchronization train packet payload body

The Host provides the Service Data for the synchronization train packet payload body when format 1 is used. The BR/EDR Controller provides the data for all other fields.

All devices in the Synchronization Scan substate shall accept payloads of any length from 28 to 121 bytes and shall ignore bytes 28 (counting from 0) and beyond.

When format 1 is used the Future Connectionless Peripheral Broadcast Instant in the synchronization train packet payload shall correspond to one of the next 4 broadcast instants. Figure 8.26 shows an example of valid and invalid values for this field.

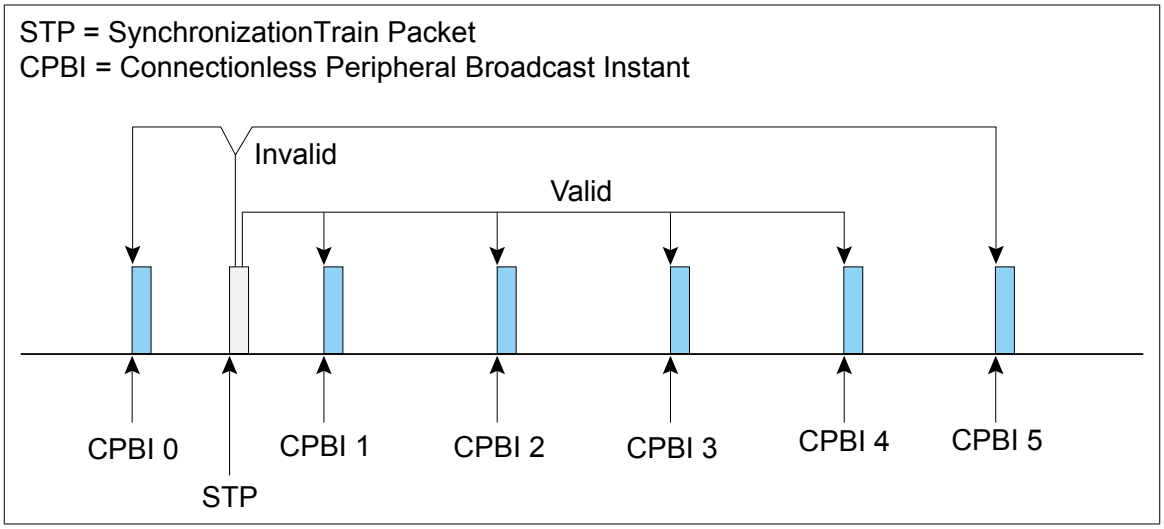

Figure 8.26: Examples of synchronization train pointing to Connectionless Peripheral Broadcast Instant

The Central shall not transmit synchronization train packets in a Connectionless Peripheral Broadcast Instant.

9 AUDIO

On the air-interface, either a 64 kb/s log PCM (Pulse Code Modulation) format (A-law or μ-law) may be used, or a 64 kb/s CVSD (Continuous Variable Slope Delta Modulation) may be used. The latter format applies an adaptive delta modulation algorithm with syllabic companding.

The voice coding on the line interface is designed to have a quality equal to or better than the quality of 64 kb/s log PCM.

Table 9.1 summarizes the voice coding schemes supported on the air interface. The appropriate voice coding scheme is selected after negotiations between the Link Managers.

Voice Codecs	
linear	CVSD
8-bit logarithmic	A-law
	μ-law

Table 9.1: Voice coding schemes supported on the air interface

9.1 LOG PCM codec

Since the synchronous logical transports on the air-interface can support a 64 kb/s information stream, a 64 kb/s log PCM traffic can be used for transmission. Either A-law or μ-law compression may be applied. In the event that the line interface uses A-law and the air interface uses μ-law or vice versa, a conversion from A-law to μ-law shall be performed. The compression method shall follow ITU-T recommendations G. 711.

9.2 CVSD codec

A more robust format for voice over the air interface is delta modulation. This modulation scheme follows the waveform where the output bits indicate whether the prediction value is smaller or larger than the input waveform. To reduce slope overload effects, syllabic companding is applied: the step size is adapted according to the average signal slope. The input to the CVSD encoder shall be 64000 samples per second linear PCM (typically 16 bits, but actual value is implementation specific). Block diagrams of the CVSD encoder and CVSD decoder are shown in Figure 9.1, Figure 9.2 and Figure 9.3. The system shall be clocked at 64 kHz.

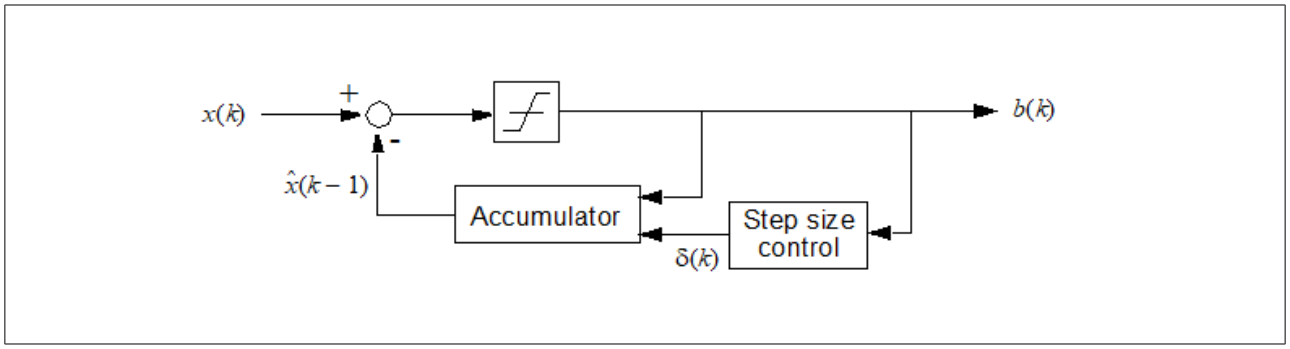

Figure 9.1: Block diagram of CVSD encoder with syllabic companding

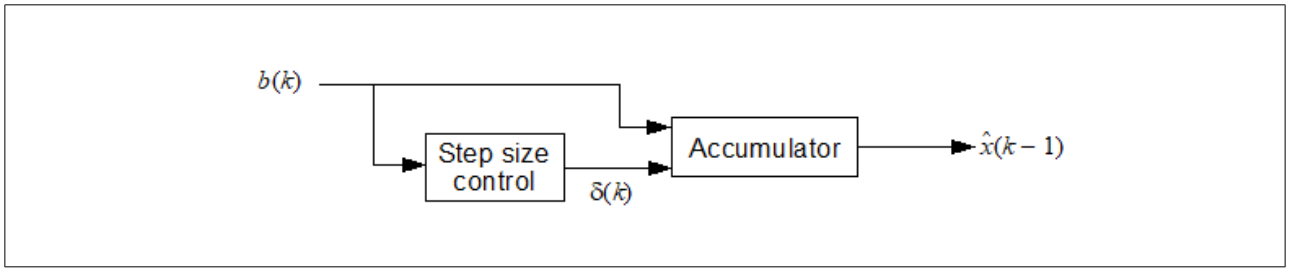

Figure 9.2: Block diagram of CVSD decoder with syllabic companding

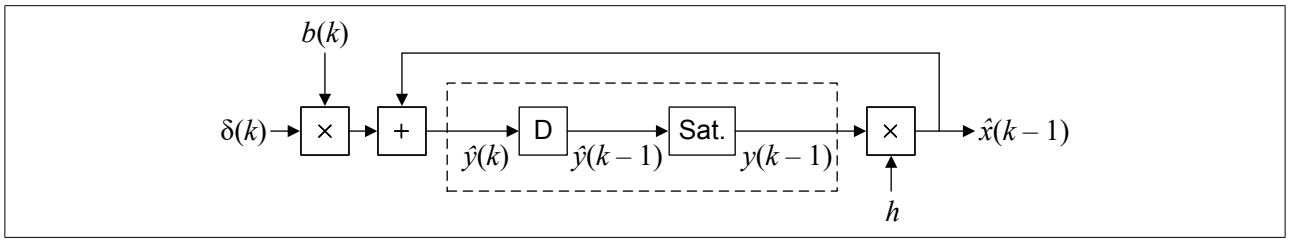

Figure 9.3: Accumulator procedure

Let $\mathrm{sgn}(x) = 1$ for $x \geq 0$, otherwise $\mathrm{sgn}(x) = -1$. On air these numbers shall be represented by the sign bit; i.e. negative numbers are mapped to “1” and positive and zero numbers are mapped to “0”.

Denote the CVSD encoder output bit *b*(*k*), the encoder input *x*(*k*), the accumulator contents *y*(*k*), and the step size $\delta(k)$. Furthermore, let *h* be the decay factor for the accumulator, let β denote the decay factor for the step size, and, let α be the syllabic companding parameter. The latter parameter monitors the slope by considering the *K* most recent output bits.

Let

$$\hat{x}(k) = hy(k). \qquad \text{(EQ 14)}$$

Then, the CVSD encoder internal state shall be updated according to the following set of equations:

$$b(k) = \mathrm{sgn}\{x(k) - \hat{x}(k-1)\}, \quad \text{(EQ 15)}$$

$$\alpha = \begin{cases} 1, & \text{if } J \text{ bits in the last } K \text{ output bits are equal,} \\ 0, & \text{otherwise,} \end{cases} \quad \text{(EQ 16)}$$

$$\delta(k) = \begin{cases} \min\{\delta(k-1) + \delta_{min}, \delta_{max}\}, & \alpha = 1, \\ \max\{\beta\delta(k-1), \delta_{min}\}, & \alpha = 0, \end{cases} \quad \text{(EQ 17)}$$

$$y(k) = \begin{cases} \min\{\hat{y}(k), y_{max}\}, & \hat{y}(k) \geq 0\,. \\ \max\{\hat{y}(k), y_{min}\}, & \hat{y}(k) < 0\,. \end{cases} \quad \text{(EQ 18)}$$

where

$$\hat{y}(k) = \hat{x}(k-1) + b(k)\delta(k)\,. \quad \text{(EQ 19)}$$

In these equations, δ_{min} and δ_{max} are the minimum and maximum step sizes, and, y_{min} and y_{max} are the accumulator's negative and positive saturation values, respectively. Over air, the bits shall be sent in the same order they are generated by the CVSD encoder.

For a 64 kb/s CVSD, the parameters as shown in Table 9.2 shall be used. The numbers are based on a 16 bit signed number output from the accumulator. These values result in a time constant of 0.5 ms for the accumulator decay, and a time constant of 16 ms for the step size decay

Parameter	Value
h	$1 - \frac{1}{32}$
β	$1 - \frac{1}{1024}$
J	4
K	4
δ_{min}	10
δ_{max}	1280
y_{min}	-2^{15} or $-2^{15} + 1$
y_{max}	$2^{15} - 1$

Table 9.2: CVSD parameter values. The values are based on a 16-bit signed number output from the accumulator.

9.3 Error handling

In the DV, HV3, EV3, EV5, 2-EV3, 3-EV3, 2-EV5 and 3-EV5 packets, the voice is not protected by FEC. The quality of the voice in an error-prone environment then depends on the robustness of the voice coding scheme and, in the case of eSCO, the retransmission scheme. CVSD, in particular, is rather insensitive to random bit errors, which are experienced as white background noise. However, when a packet is rejected because either the channel access code, the HEC test was unsuccessful, or the CRC has failed, measures have to be taken to “fill” in the lost speech segment.

The voice payload in the **HV2** and **EV4** packets are protected by a 2/3 rate FEC. For errors that are detected but cannot be corrected, the receiver should try to minimize the audible effects. For instance, from the 15-bit FEC segment with uncorrected errors, the 10-bit information part as found before the FEC decoder should be used. The **HV1** packet is protected by a 3 bit repetition FEC. For this code, the decoding scheme will always assume zero or one-bit errors. Thus, there exist no detectable but uncorrectable error events for **HV1** packets.

9.4 General audio requirements

9.4.1 Signal levels

For A-law and μ-law log-PCM encoded signals the requirements on signal levels shall follow the ITU-T recommendation G.711.

Full swing at the 16 bit linear PCM interface to the CVSD encoder is defined to be 3 dBm0.

9.4.2 CVSD audio quality

For Bluetooth audio quality the requirements are put on the transmitter side. The 64000 samples per second linear PCM input signal should have negligible spectral power density above 4 kHz. The power spectral density in the 4 kHz to 32 kHz band of the decoded signal at the 64000 samples per second linear PCM output, should be more than 20 dB below the maximum in the 0 kHz to 4 kHz range.

Appendix A General audio recommendations

The abbreviations in Table A.1 are used only in this appendix.

A/D	Analog to digital conversion
BTR	Bluetooth Radio
D/A	Digital to analog conversion
ERP	Ear Reference Point
LR	Loudness Rating
MRP	Microphone Reference Point
PGA	Programmable Gain Amplifier
RLR	Receive Loudness Rating
SLR	Send Loudness Rating

Table A.1: Abbreviations for general audio recommendations

A.1 Maximum sound pressure

It is the sole responsibility of each manufacturer to design their audio products in a safe way with regards to injury to the human ear. The Bluetooth Specification doesn't specify maximum sound pressure from an audio device.

A.2 [This section is no longer used]

A.3 Audio levels for Bluetooth

Audio levels shall be calculated as SLR and RLR. The calculation methods are specified in ITU-T Recommendation P.79.

The physical test set-up for Handsets and Headsets is described in ITU-T Recommendation P.51 and P.57

The physical test set-up for speakerphones and "Vehicle hands-free systems" is specified in ITU-T Recommendation P.34.

A general equation for computation of LR for telephone sets is given by ITU-T recommendations P.79 and is given by

$$LR = -\frac{10}{m} log_{10}\left(\sum_{i=N_1}^{N_2} 10^{m(s_i - w_i) \div 10}\right), \quad \text{(EQ 20)}$$

where

m is a constant (~ 0.2).
w_i = weighting coefficient (different for the various LRs).
S_i = the sensitivity at frequency F_i , of the electro-acoustic path
N_1,N_2, consecutive filter bank numbers (Art. Index: 200 Hz to 4000 Hz)

(EQ 20) is used for calculating the SLR according to Figure A.1, and RLR according to Figure A.2. When calculating LRs one must only include those parts of the frequency band where an actual signal transmission can occur in order to ensure that the additive property of LRs is retained. Therefore ITU-T P.79 uses only the frequency band 200 Hz to 4000 Hz in LR computations.

A.4 Microphone path

SLR measurement model

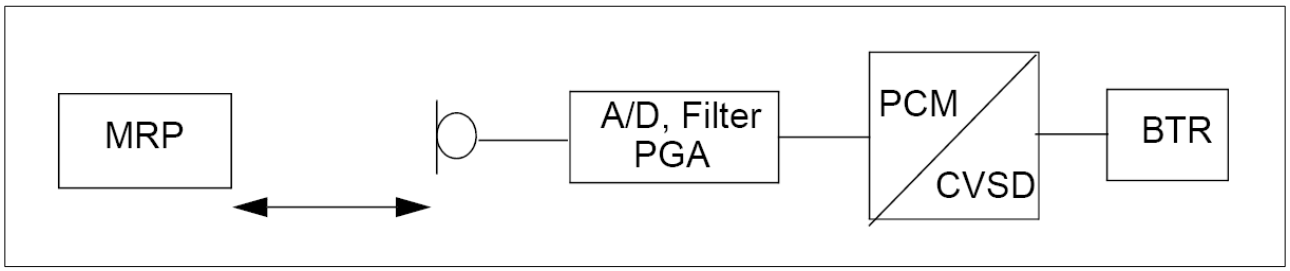

Figure A.1: SLR measurement set-up

A.5 Loudspeaker path

RLR measurement model

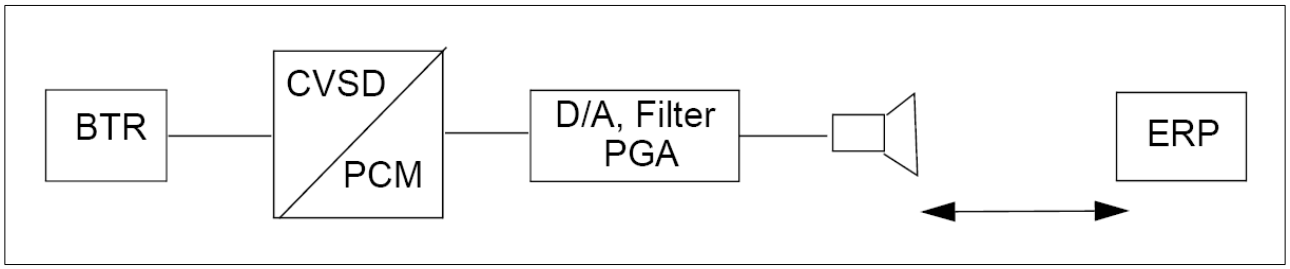

Figure A.2: RLR measurement set-up

A.6 Bluetooth voice interface

The specification for the Bluetooth voice interface should follow in the first place the *ITU-T Recommendations P.79*, which specifies the loudness ratings for telephone sets. These recommendations give general guidelines and specific algorithms used for calculating the loudness ratings of the audio signal with respect to ERP.

For Bluetooth voice interface to the different cellular system terminals, loudness and frequency recommendations based on the cellular standards should be used. For example, GSM 03.50 gives recommendation for both the loudness ratings and frequency mask for a GSM terminal interconnection with Bluetooth.

1- The output of the CVSD decoder are 16-bit linear PCM digital samples, at a sampling frequency of 8000 samples per second. Bluetooth also supports 8-bit log PCM samples of A-law and μ-law type. The sound pressure at the ear reference point for a given 16-bit CVSD sample, should follow the sound pressure level given in the cellular standard specification.

2- A maximum sound pressure which can be represented by a 16-bit linear PCM sample at the output of the CVSD decoder should be specified according to the loudness rating, in ITU P.79 and at PGA value of 0 dB. PGAs are used to control the audio level at the terminals by the user. For conversion between various PCM representations: A-law, μ-law and linear PCM, ITU-T G.711, G.712, G.714 give guidelines and PCM value relationships. Zero-code suppression based on ITU-T G.711 is also recommended to avoid network mismatches.

A.7 Frequency mask

When interfacing a Bluetooth terminal to a digital cellular mobile terminal, the CVSD decoder signal should conform to the frequency mask given in the GSM cellular standard so that the speech coders operate in the intended manner. A recommendation for a frequency mask is given in Table A.2. Figure A.3 shows a plot of the frequency mask for Bluetooth (solid line). The GSM frequency mask (dotted line) is shown in Figure A.3 for comparison.

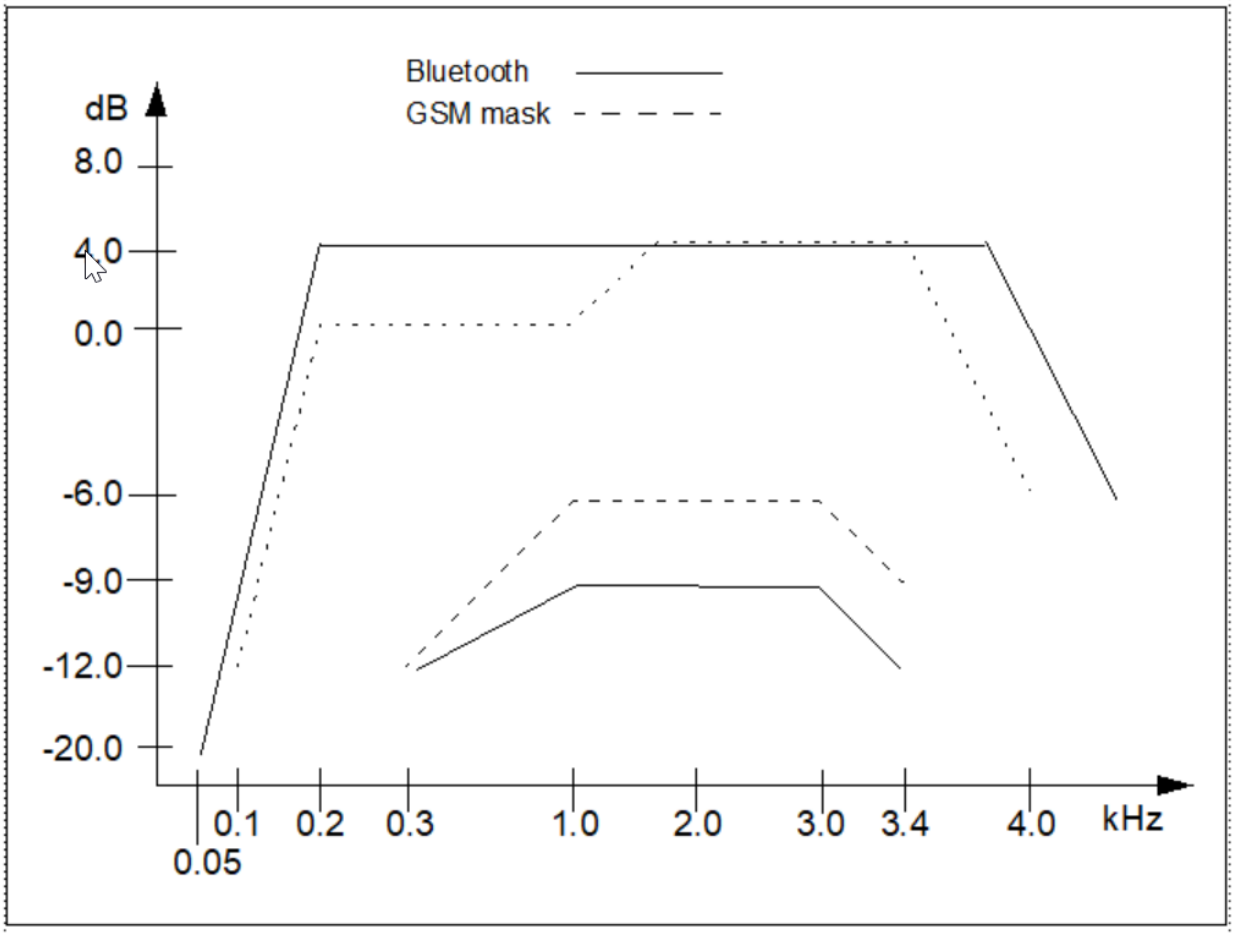

Figure A.3: Plot of recommended frequency mask for Bluetooth. The GSM send frequency mask is given for comparison (dotted line).

Frequency (Hz)	Upper Limit (dB)	Lower Limit (dB)
50	-20	none
300	4	-12
1000	4	-9
2000	4	-9
3000	4	-9
3400	4	-12
4000	0	none

Table A.2: Recommended frequency mask for Bluetooth

Appendix B Timers

This appendix contains a list of Baseband timers related to inactivity timeout defined in the specification. Definitions and default values of the timers are listed below

All timer values are given in slots.

B.1 List of timers

B.1.1 inquiryTO

The *inquiryTO* defines the number of slots the Inquiry substate shall last. The timer value may be changed by the Host. HCI provides a command to change the timer value.

B.1.2 pageTO

The *pageTO* defines the number of slots the Page substate can last before a response is received when the *extended_pageTO* is zero. The timer value may be changed by the Host. HCI provides a command to change the timer value.

B.1.3 extended_pageTO

The *extended_pageTO* defines the number of additional slots the Page substate can last beyond *pageTO* before a response is received. The timer value may be changed by the Host. HCI provides a command to change the timer value.

B.1.4 pagerespTO

In the Peripheral, *pagerespTO* defines the number of slots the Peripheral shall await the Central's response, FHS packet, after sending the page acknowledgment ID packet. In the Central, *pagerespTO* defines the number of slots the Central should wait for the FHS packet acknowledgment before returning to Page substate. Both Central and Peripheral units should use the same value for this timeout, to allow common page/scan intervals after reaching *pagerespTO*.

The *pagerespTO* value is 8 slots.

B.1.5 newconnectionTO

Every time a new connection is started through paging, scanning, or role switch, the Central sends a POLL packet as the first packet in the new connection. Transmission and acknowledgment of this POLL packet is used to confirm the new connection. If the POLL packet is not received by the Peripheral or the response packet is not received by

the Central for *newconnectionTO* number of slots, both the Central and the Peripheral should return to the previous substate.

newconnectionTO value is 32 slots.

B.1.6 supervisionTO

The *supervisionTO* is used by both the Central and Peripheral to monitor link loss. If a device does not receive any packets that pass the HEC check and have the proper LT_ADDR for a period of *supervisionTO*, it shall consider the link to be disconnected. The supervision timer keeps running in Hold mode and Sniff mode.

The *supervisionTO* value may be changed by the Host. HCI provides a command to change the timer value. At the Baseband level a default value equivalent to 20 seconds should be used.

B.1.7 CPB_supervisionTO

The *CPB_supervisionTO* is used by the Peripheral to monitor connection loss and by the Central to monitor scheduling conflicts and shall be between 0x0002 to 0xFFFE with only even values valid. At the Baseband level a default value equivalent to 5.12 seconds should be used. The Host can change the value of *CPB_supervisionTO*.

B.1.8 synchronization_trainTO

The *synchronization_trainTO* is used by the Central to determine how long to continue broadcasting Synchronization Train packets and shall be between 0x00000002 to 0x07FFFFFE with only even values valid. At the Baseband level a default value equivalent to 120 seconds should be used for Connectionless Peripheral Broadcast and a default value equivalent to 20 seconds should be used for Coarse Clock Adjustment Recovery Mode. The Host may change the value of *synchronization_trainTO* that is used during Connectionless Peripheral Broadcast.

B.1.9 synchronization_scanTO

The *synchronization_scanTO* is used by the Peripheral to determine when to stop scanning for synchronization train packets. It shall be between 0x0022 to 0xFFFE with only even values valid. At the Baseband level a default value equivalent to 5.12 seconds should be used for Connectionless Peripheral Broadcast and a default value equivalent to 20 seconds should be used during Coarse Clock Adjustment Recovery Mode. The Host may change the value of *synchronization_scanTO* that is used during Connectionless Peripheral Broadcast.

B.1.10 authenticatedPayloadTO

The *authenticatedPayloadTO* is the maximum amount of time, in seconds, allowed between receiving packets containing a MIC. The Host can change the value of *authenticatedPayloadTO*.

The default value for *authenticatedPayloadTO* is 30 seconds.

B.1.11 CLK_adj_dragTO

The *CLK_adj_dragTO* is the minimum amount of time, in seconds, the drag shall be suspended when a Peripheral has not responded after the Central has dragged the clock.

The *CLK_adj_dragTO* value shall be 1 second.

Appendix C Recommendations for AFH operation in Hold, Sniff, and Connectionless Peripheral Broadcast modes

The three possible AFH operation modes for an AFH capable Peripheral in Hold mode and Sniff mode are the same three AFH operation modes used during Connection state:

- *Enabled* (using an AHS with some RF channels unused)
- *Enabled* (using AHS(79))
- *Disabled*

The Central may place an AFH capable Peripheral in any of the three AFH operating modes.

C.1 Operation at the Central

A Central that has one or more Peripherals in Hold mode or Sniff mode and decides to update them simultaneously shall schedule an *AFH_Instant* for a time that allows it to update all these Peripherals (as well as its active Peripherals) with the new adaptation.

A Central that has multiple Peripherals with non-overlapping “wake” times (e.g. Peripherals in Sniff mode with different timing parameters) may keep them *enabled* on the same adaptation provided that its scheduling of the *AFH_Instant* allows enough time to update them all.

This timing is summarized in Figure C.1. In this example the Central decides that a hop sequence adaptation applying to all its Peripherals at the same time is required. However it cannot schedule an *AFH_Instant* until it has informed its active Peripheral, its Peripheral in Hold mode, and its Peripheral in Sniff mode.

If it decides that only some Peripherals require the new adaptation, it need only take those Peripherals into account when scheduling the *AFH_Instant*.

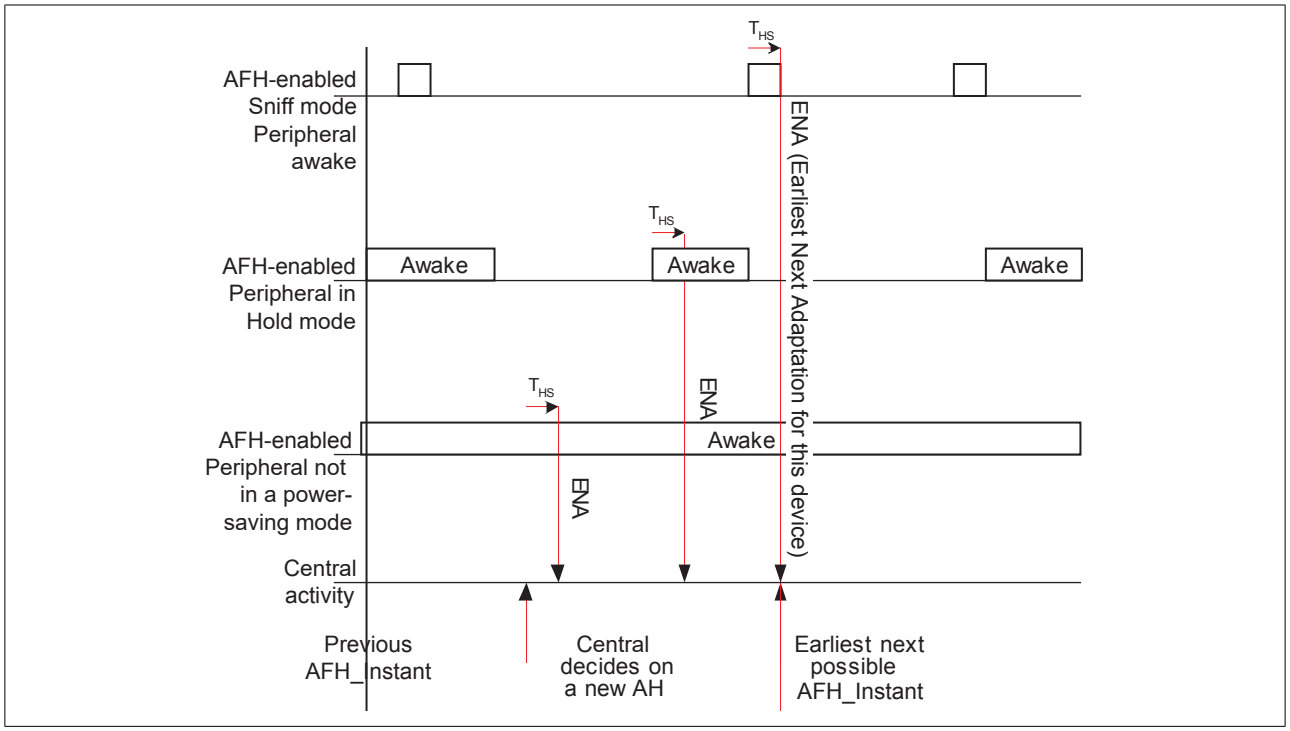

Figure C.1: Timing constraint on AFH_Instant with Peripherals in Hold and Sniff modes

C.2 [This section is no longer used]

C.3 AFH operation in Sniff mode

Once a Peripheral has been placed in Sniff mode, the Central may periodically change its AHS without taking the Peripheral out of Sniff mode.

C.4 AFH operation in Hold mode

A Peripheral that is in Hold mode cannot send or receive any LMP messages. Once the Peripheral has left Hold mode the Central may subsequently update the Peripheral's adaptation.

C.5 AFH operation in Connectionless Peripheral Broadcast

After the Transmitter's BR/EDR Controller notifies the Transmitter's Host that the AFH channel map has changed for the PBD logical link, the Transmitter's Host may restart the synchronization train to allow Receivers to obtain the updated AFH channel map. This is shown in Figure C.2.

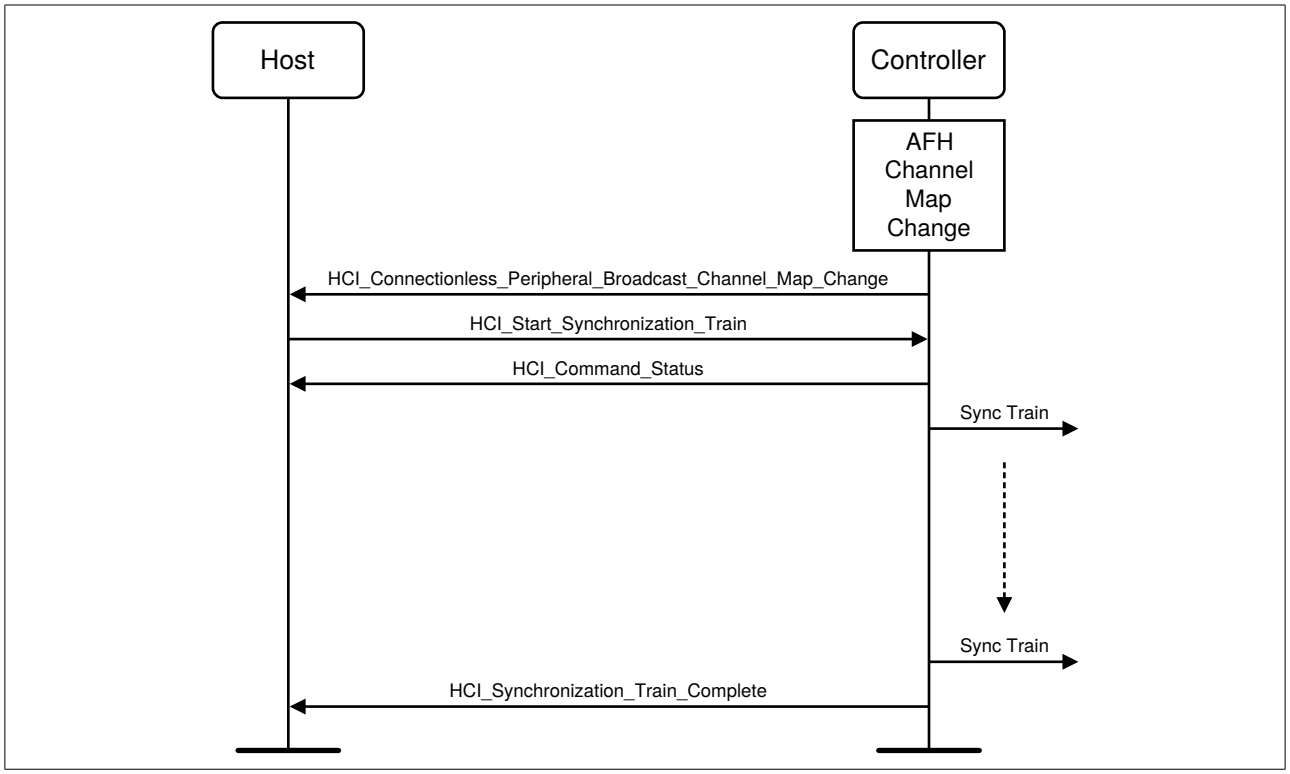

Figure C.2: AFH map change – Connectionless Peripheral Broadcast Transmitter

Modification of the AFH channel map will affect Receivers using a different AFH channel map. Depending on the overlap between a Receiver's current AFH channel map and the current AFH channel map of the Transmitter (Central), the Receiver may miss some Connectionless Peripheral Broadcast instants and, in the case of disjoint or nearly disjoint AFH channel maps, the Receiver may lose synchronization. Receivers should monitor the Connectionless Peripheral Broadcast reception rate and obtain the current AFH channel map of the Transmitter (via the synchronization train) if degradation exceeds desired thresholds.

BR/EDR Controller
Part C

LINK MANAGER PROTOCOL SPECIFICATION

This Part describes the Link Manager protocol (LMP) which is used for link set-up and control. The signals are interpreted and filtered out by the Link Manager on the receiving side and are not propagated to higher layers.

CONTENTS

1 INTRODUCTION

The Link Manager Protocol (LMP) is used to control and negotiate all aspects of the operation of the Bluetooth connection between two devices. This includes the set-up and control of logical transports and logical links, and for control of physical links.

The Link Manager Protocol is used to communicate between the Link Managers (LM) on the two devices. All LMP messages shall apply solely to the physical link and associated logical links and logical transports between the sending and receiving devices.

The protocol is made up of a series of messages which shall be transferred over the ACL-C or APB-C logical link between two devices. LMP messages shall be interpreted and acted-upon by the LM and shall not be directly propagated to higher protocol layers.

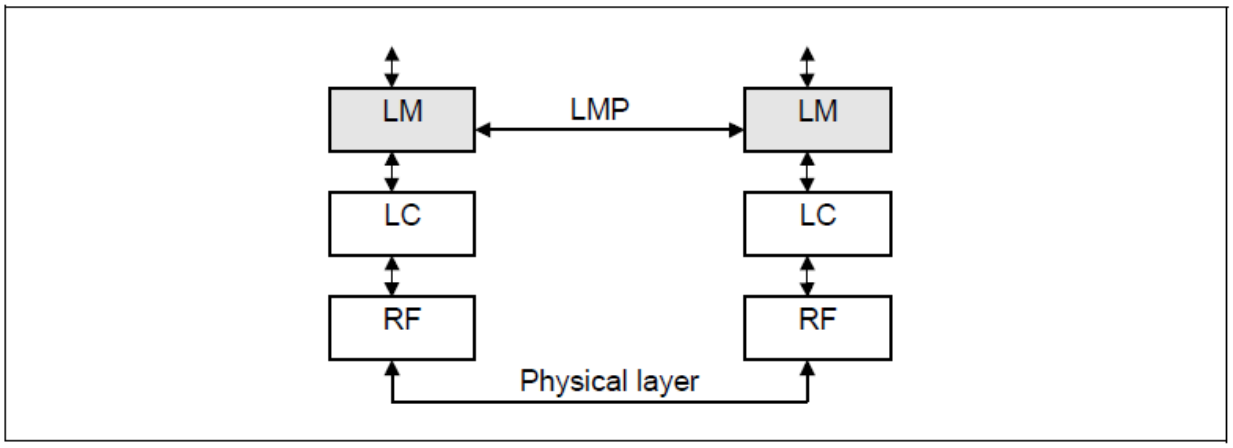

Figure 1.1: Link Manager Protocol signaling layer

2 GENERAL RULES

2.1 Message transport

LMP messages shall be exchanged over the ACL-C logical link that is carried on the default ACL logical transport ([Vol 2] Part B, Section 4.4) or over the APB-C logical link that is carried on the APB logical transport ([Vol 2] Part B, Section 4.6). LMP messages shall be carried on the default ACL logical transport unless specified otherwise in Sections 4 and 5. The ACL-C and APB-C logical links are distinguished from the ACL-U and APB-U logical links (which carry L2CAP and user data) by the Logical Link Identifier (LLID) field carried in the payload header of variable-length packets ([Vol 2] Part B, Section 6.6.2).

The control logical links have a higher priority than other traffic - see [Vol 2] Part B, Section 5.6.

The error detection and correction capabilities of the Baseband ACL logical transport are generally sufficient for the requirements of the LMP. Therefore LMP messages do not contain any additional error detection information beyond what can be realized by means of sanity checks performed on the contents of LMP messages. Any such checks and protections to overcome undetected errors in LMP messages is an implementation matter.

2.2 Synchronization

This section explains why many of the LMP message sequences are defined as they are. It does not create any requirements.

LMP messages are carried on the ACL-C and APB-C logical links, which do not guarantee a time to deliver or acknowledge packets. LMP procedures take account of this when synchronizing state changes in the two devices. For example, criteria are defined that specify when a logical transport address (LT_ADDR) may be re-used after it becomes available due to a device leaving the piconet. Other LMP procedures, such as hold or role switch include the Bluetooth clock as a parameter in order to define a fixed synchronization point. The transitions into and out of Sniff mode are protected with a transition mode.

The LC normally attempts to communicate with each Peripheral no less often than every T_{poll} slots (see Section 4.1.8) based on the T_{poll} for that Peripheral.

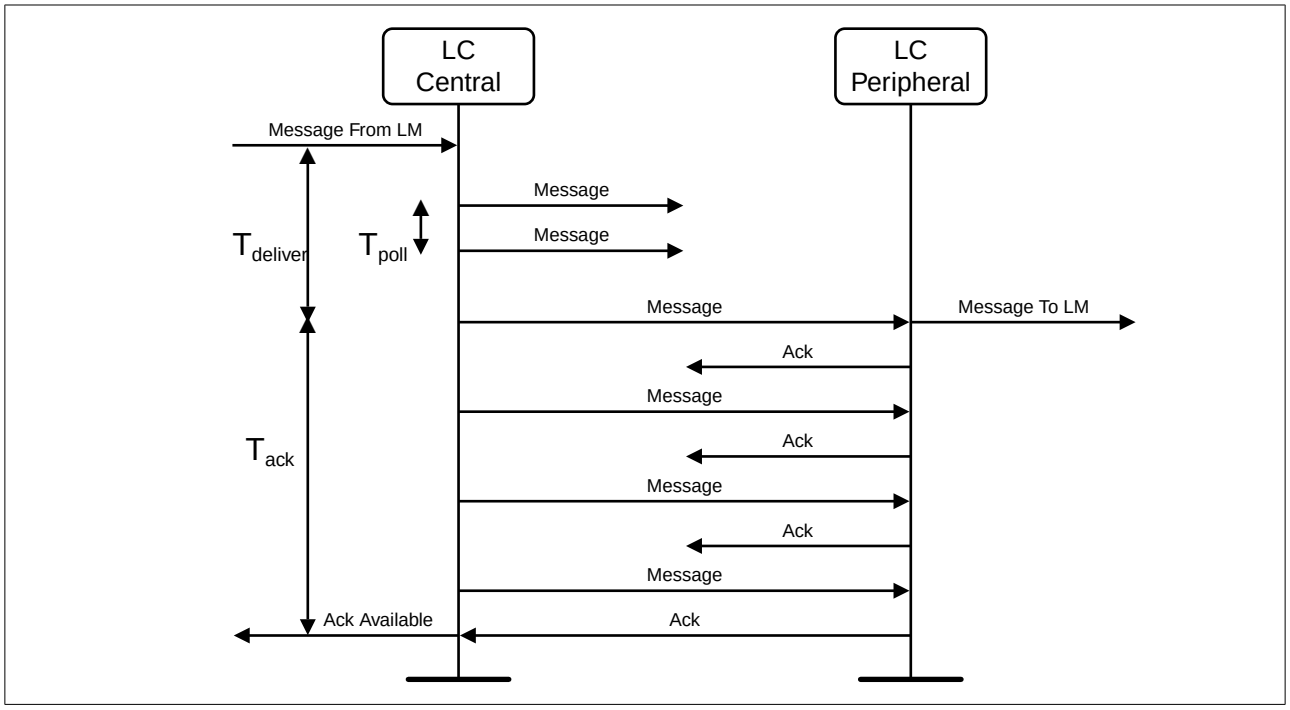

Figure 2.1: Transmission of a message from Central to Peripheral[1]

Figure 2.1 illustrates the fundamental problem. It shows the transmission of a packet from the Central to the Peripheral in conditions of heavy interference for illustrative purposes. It is obvious that neither side can determine the value of either $T_{deliver}$ or T_{ack}. It is therefore not possible to use simple messages to identify uniquely the instant at which a state change occurs in the other device.

2.3 Packet format

Each PDU is assigned either a 7 or a 15 bit opcode used to uniquely identify different types of PDUs, see Table 5.1. The first 7 bits of the opcode and a transaction ID are located in the first byte of the payload body. If the initial 7 bits of the opcode have one of the special escape values 124 to 127 then an additional byte of opcode is located in the second byte of the payload and the combination uniquely identifies the PDU.

The FLOW bit in the packet header is always 1 and shall be ignored on reception.

If the PDU contains one or more parameters these are placed in the payload starting immediately after the opcode, i.e. at byte 2 if the PDU has a 7 bit opcode or byte 3 if the PDU has a 15 bit opcode. The number of bytes used depends on the length of the parameters. The representation of each parameter is determined by its type as specified in [Vol 1] Part E, Section 2.9.

[1]Note the diagram shows the limiting case where the Central transmits the message at intervals of T_{poll}. In the case of heavy interference improved performance is gained by transmitting more often.

LMP messages shall be transmitted using DM1 packets, however if an HV1 SCO link is in use and the length of the payload is no greater than 9 bytes then DV packets may be used.

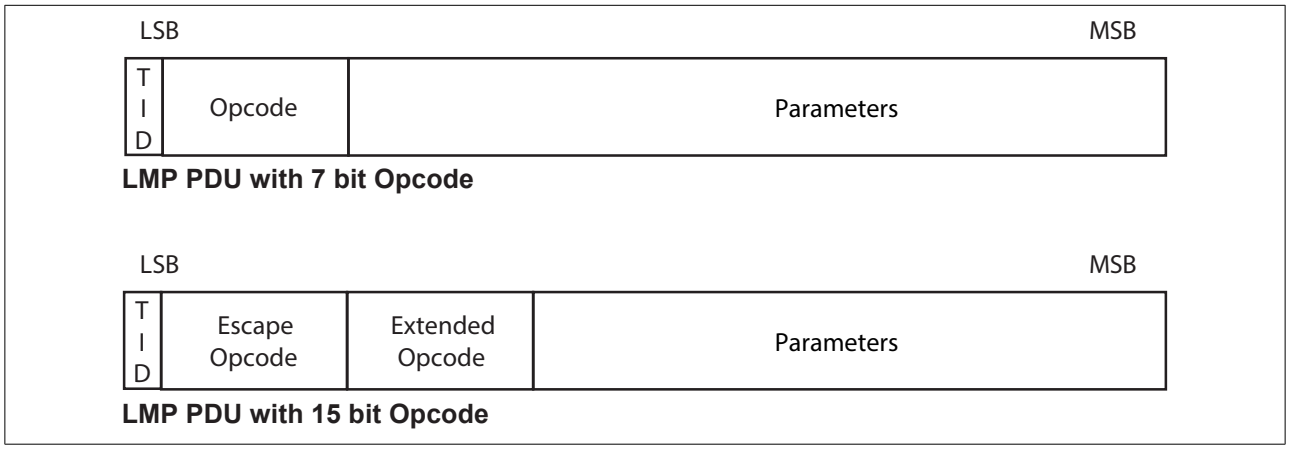

Figure 2.2: Payload body when LMP PDUs are sent

2.4 Transactions

The LMP operates in terms of transactions. A transaction is a connected set of message exchanges which achieve a particular purpose. All PDUs which form part of the same transaction shall have the same value for the transaction ID which is stored as part of the first byte of the opcode (see Section 2.3).

The transaction ID is in the least significant bit. It shall be 0 if the PDU forms part of a transaction that was initiated by the Central and 1 if the transaction was initiated by the Peripheral.

Each sequence described in Section 4 shall be defined as a transaction. For pairing, see Section 4.2.2, and encryption, see Section 4.2.5, all sequences belonging to each section shall be counted as one transaction and shall use the same transaction ID. For connection establishment, see Section 4.1.1, LMP_HOST_CONNECTION_REQ and the response with LMP_ACCEPTED or LMP_NOT_ACCEPTED shall form one transaction and have the transaction ID of 0. LMP_SETUP_COMPLETE is a stand-alone PDU, which forms a transaction by itself.

For error handling, see Section 2.5, the PDU to be rejected and LMP_NOT_ACCEPTED or LMP_NOT_ACCEPTED_EXT shall form a single transaction.

2.4.1 LMP response timeout

The time between receiving a Baseband packet carrying an LMP PDU and sending a Baseband packet carrying a valid response PDU, according to the procedure rules in

Section 4, shall be less than the LMP Response Timeout. The value of this timeout is 30 seconds. The LMP Response Timeout is applied not only to sequences described in Section 4, but also to the series of the sequences defined as the transactions in Section 4. It shall also be applied to the series of LMP transactions that take place during a period when traffic on the ACL-U logical link is disabled for the duration of the series of LMP transactions, for example during the enabling of encryption.

The LMP Response Timeout shall restart each time an LMP PDU which requires a reply is queued for transmission by the Baseband.

LMP messages sent on the APB-C logical link have special rules and are not subject to the LMP Response Timeout.

2.5 Error handling

If the LM receives a PDU with an unknown opcode (e.g. one added in a higher version of the specification), it shall respond with LMP_NOT_ACCEPTED or LMP_NOT_ACCEPTED_EXT with the Error_Code *Unknown LMP PDU* (0x19). The Opcode parameter shall be the unrecognized opcode.

If the LM receives a PDU which contains valid parameters followed by extra data, it shall either ignore the extra data or shall respond with LMP_NOT_ACCEPTED or LMP_NOT_ACCEPTED_EXT with the Error_Code *Invalid LMP Parameters* (0x1E).

If the LM receives a PDU which is too short to hold all the parameters, it shall either continue with implementation-specific values for the missing or damaged parameters or shall respond with LMP_NOT_ACCEPTED or LMP_NOT_ACCEPTED_EXT with the Error_Code *Invalid LMP Parameters* (0x1E).

If the LM receives a PDU with the correct length but with invalid parameters, it shall respond with LMP_NOT_ACCEPTED or LMP_NOT_ACCEPTED_EXT with the Error_Code *Invalid LMP Parameters* (0x1E).

If the maximum response time (see Section 2.4.1) is exceeded or if a link loss is detected (see [Vol 2] Part B, Section 3.1), the party that waits for the response shall conclude that the procedure has terminated unsuccessfully.

Erroneous LMP messages can be caused by errors on the channel or systematic errors at the transmit side. To detect the latter case, the LM should monitor the number of erroneous messages and disconnect if it exceeds a threshold, which is implementation-dependent.

When the LM receives a PDU that is not allowed, and the PDU normally expects a PDU reply, for example LMP_HOST_CONNECTION_REQ, the LM shall return PDU LMP_NOT_ACCEPTED or LMP_NOT_ACCEPTED_EXT with the Error_Code *LMP*

PDU Not Allowed (0x24). If the PDU normally doesn't expect a reply, for example LMP_SRES or LMP_TEMP_KEY, the PDU shall be ignored.

If the LM recognizes the PDU as optional but unsupported then it shall reply with LMP_NOT_ACCEPTED or LMP_NOT_ACCEPTED_EXT with the Error_Code *Unsupported LMP Feature* (0x1A) if the PDU would normally generate a reply; otherwise it shall ignore the PDU and no reply is generated.

2.5.1 Transaction collision resolution

Since LMP PDUs are not interpreted in real time, collision situations can occur where both LMs initiate the same procedure and both cannot be completed. In this situation, the Central shall reject the Peripheral-initiated procedure by sending LMP_NOT_ACCEPTED or LMP_NOT_ACCEPTED_EXT with the Error_Code *LMP Error Transaction Collision / LL Procedure Collision* (0x23). The Central-initiated procedure shall then be completed.

Collision situations can also occur where both LMs initiate different procedures and both cannot be completed. In this situation, the Central shall reject the Peripheral-initiated procedure by sending LMP_NOT_ACCEPTED or LMP_NOT_ACCEPTED_EXT with the Error_Code *Different Transaction Collision* (0x2A). The Central-initiated procedure shall then be completed.

2.6 Procedure rules

Each procedure is described and depicted with a sequence diagram. The symbols in Figure 2.3 are used in the sequence diagrams:

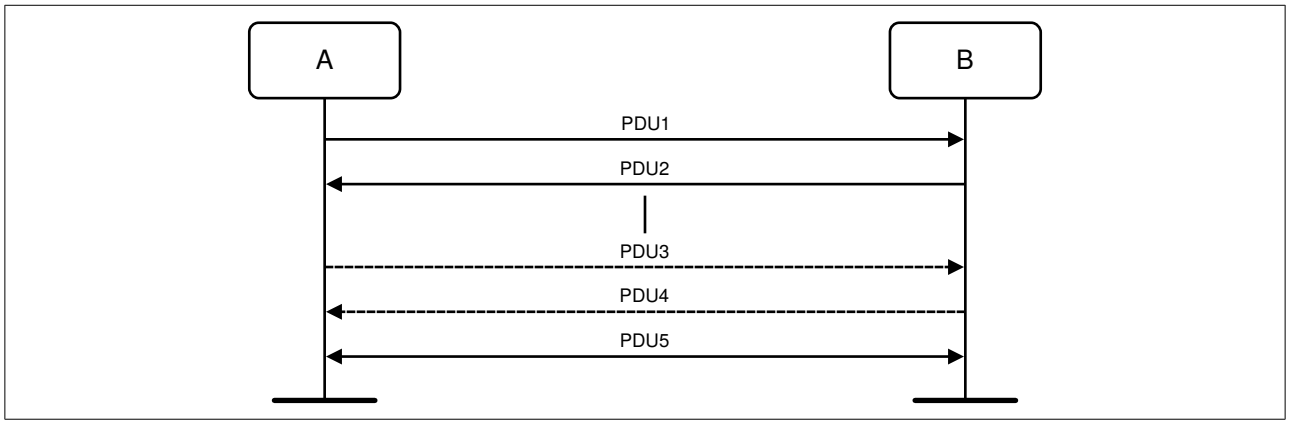

Figure 2.3: Symbols used in sequence diagrams

PDU1 is a PDU sent from A to B. PDU2 is a PDU sent from B to A. PDU3 is a PDU that is optionally sent from A to B. PDU4 is a PDU that is optionally sent from B to A. PDU5 is a PDU sent from either A or B. A vertical line indicates that more PDUs can optionally be sent.

2.7 General response messages

The PDUs LMP_ACCEPTED, LMP_ACCEPTED_EXT, LMP_NOT_ACCEPTED and LMP_NOT_ACCEPTED_EXT are used as response messages to other PDUs in a number of different procedures. LMP_ACCEPTED or LMP_ACCEPTED_EXT includes the opcode of the message which is accepted. LMP_NOT_ACCEPTED or LMP_NOT_ACCEPTED_EXT includes the opcode of the message which is not accepted and the error code why it is not accepted.

LMP_ACCEPTED_EXT and LMP_NOT_ACCEPTED_EXT shall be used when the opcode is 15 bits in length. LMP_ACCEPTED and LMP_NOT_ACCEPTED shall be used when the opcode is 7 bits in length.

M/O	PDU	Contents
M	LMP_ACCEPTED	Opcode
M	LMP_NOT_ACCEPTED	Opcode Error_Code
O	LMP_ACCEPTED_EXT	Escape_Opcode Extended_Opcode
O	LMP_NOT_ACCEPTED_EXT	Escape_Opcode Extended_Opcode Error_Code

Table 2.1: General response messages

2.8 LMP message constraints

The following principles are used in the design of LMP.

- No LMP message exceeds the maximum payload length of a single DM1 packet i.e. 17 bytes in length ([Vol 2] Part B, Section 6.5.4.1).
- All LMP messages are of fixed length.
- The LMP version number is not used to indicate the presence or absence of functionality.

3 DEVICE FEATURES

3.1 General description

Each PDU is either Mandatory or Optional as defined by the M/O field in the tables of Section 4. An M in this field shall indicate that support for the PDU is mandatory. An O in this field shall indicate that support for the PDU is optional and it shall be followed by the number(s) of the feature(s) involved in brackets.

Some features have associated LMP feature bits. Support of these features may be required by Section 3.5 but the LM still considers them to be optional since it must interoperate with devices which do not support them.

The LM does not need to be able to transmit a PDU which is optional. Support of optional PDUs is indicated by a device's features mask. The features mask can be read (see Section 4.3.4). An LM shall not send or be sent any PDU which is incompatible with the features signaled in its or its peer's features mask, as detailed in Section 3.2.

The set of features supported by the LM shall not change while the Controller has a connection to another device. A peer device may cache the device's feature mask or extended feature mask, or the LM may cache a peer's feature mask or extended feature mask, during a connection.

3.2 Feature definitions

Feature	Definition
3-slot Enhanced Data Rate ACL packets	This feature indicates whether the device supports the transmission and reception of three-slot Enhanced Data Rate packets on the ACL-U logical link.
3-slot Enhanced Data Rate eSCO packets	This feature indicates whether the device supports the transmission and reception of 3-slot Enhanced Data Rate packets for the transport of traffic on the eSCO logical transport.
3 slot packets	This feature indicates whether the device supports the transmission and reception of both DM3 and DH3 packets for the transport of traffic on the ACL-U logical link.
5-slot Enhanced Data Rate ACL packets	This feature indicates whether the device supports the transmission and reception of 5-slot Enhanced Data Rate packets for the transport of traffic on the ACL-U logical link.
5 slot packets	This feature indicates whether the device supports the transmission and reception of both DM5 and DH5 packets for the transport of traffic on the ACL-U logical link.
AFH capable Central	This indicates whether the device is able to support the Adaptive Frequency Hopping mechanism as a Central as defined in [Vol 2] Part B, Section 2.3 using the LMP sequences defined in Section 4.1.4.

Feature	Definition
AFH capable Peripheral	This feature indicates whether the device is able to support the Adaptive Frequency Hopping mechanism as a Peripheral as defined in [Vol 2] Part B, Section 2.3 using the LMP sequences defined in Section 4.1.4.
AFH classification Central	This feature indicate whether the device is able to support the AFH classification mechanism as a Central as defined in [Vol 2] Part B, Section 8.6.8 using the LMP sequences defined in Section 4.1.5.
AFH classification Peripheral	This feature indicates whether the device is able to support the AFH classification mechanism as a Peripheral as defined in [Vol 2] Part B, Section 8.6.8 using the LMP sequences defined in Section 4.1.5.
A-law log synchronous data	This feature indicates whether the device is capable of supporting A-law Log format data as defined in [Vol 2] Part B, Section 9.1 on the SCO and eSCO logical transports.
Broadcast encryption	This feature indicates whether the device is capable of supporting broadcast encryption as defined in [Vol 2] Part H, Section 4.2 and also the LMP sequences defined in Section 4.2.6 and Section 4.2.4.
Channel Quality Driven Data Rate	This feature indicates whether the LM is capable of recommending a packet type (or types) depending on the channel quality using the LMP sequences defined in Section 4.1.7.
Coarse Clock Adjustment	This feature indicates whether the device is able to support coarse clock adjustments using the LMP sequences defined in Section 4.1.14.
Connectionless Peripheral Broadcast - Receiver Operation	This feature indicates whether the device supports Connectionless Peripheral Broadcast as Receiver.
Connectionless Peripheral Broadcast - Transmitter Operation	This feature indicates whether the device supports Connectionless Peripheral Broadcast as Transmitter.
CVSD synchronous data	This feature indicates whether the device is capable of supporting CVSD format data as defined in [Vol 2] Part B, Section 9.2 on the SCO and eSCO logical transports.
Encapsulated PDU	This feature indicates whether the device is capable of supporting the Encapsulated PDU mechanism as defined in Section 4.1.12.1.
Encryption	This feature indicates whether the device supports the encryption of packet contents using the LMP sequence defined in Section 4.2.5.
Enhanced Data Rate ACL 2 Mb/s mode	This feature indicates whether the device supports the transmission and reception of 2-DH1 packets for the transport of traffic on the ACL-U logical link.
Enhanced Data Rate ACL 3 Mb/s mode	This feature indicates whether the device supports the transmission and reception of 3-DH1 packets for the transport of traffic on the ACL-U logical link.

Feature	Definition
Enhanced Data Rate eSCO 2 Mb/s mode	This feature indicates whether the device supports the transmission and reception of 2-EV3 packets for the transport of traffic on the eSCO logical transport.
Enhanced Data Rate eSCO 3 Mb/s mode	This feature indicates whether the device supports the transmission and reception of 3-EV3 packets for the transport of traffic on the eSCO logical transport.
Enhanced power control	This feature indicates whether the device is able to support enhanced power control using the LMP sequences defined in Section 4.1.3.1.
Erroneous Data Reporting	This feature indicates whether the device is able to support the Packet_Status_Flag and the HCI commands HCI_Write_Default_Erroneous_Data_Reporting and HCI_Read_Default_Erroneous_Data_Reporting.
EV4 packets	This feature indicates whether the device is capable of supporting the EV4 packet type defined in [Vol 2] Part B, Section 6.5.3.2 on the eSCO logical transport.
EV5 packets	This feature indicates whether the device is capable of supporting the EV5 packet type defined in [Vol 2] Part B, Section 6.5.3.3 on the eSCO logical transport.
Extended features	This feature indicates whether the device is able to support the extended features mask using the LMP sequences defined in Section 4.3.4.
Extended Inquiry Response	This feature indicates whether the device supports extended inquiry response as defined in [Vol 2] Part B, Section 8.4.3.
Extended SCO link	This feature indicates whether the device is able to support the eSCO logical transport as defined in [Vol 2] Part B, Section 5.5 and the EV3 packet defined in [Vol 2] Part B, Section 6.5.3.1 using the LMP sequences defined in Section 4.6.2.
Flow control lag	This is defined as the total amount of ACL-U data that can be sent following the receipt of a valid payload header with the payload header flow bit set to 0 and is in units of 256 bytes. See further in [Vol 2] Part B, Section 6.6.2.
Generalized interlaced scan	This feature indicates whether the device is able to support the generalized interlaced scan mechanism described in [Vol 2] Part B, Section 8.3.1 and Section 8.4.1. The presence of this feature has only local meaning and does not imply support for any additional LMP PDUs or sequences.
Hold mode	This feature indicates whether the device is able to support Hold mode as defined in [Vol 2] Part B, Section 8.8 using the LMP sequences defined in Section 4.5.1.
HV2 packets	This feature indicates whether the device is capable of supporting the HV2 packet type as defined in [Vol 2] Part B, Section 6.5.2.2 on the SCO logical transport.
HV3 packets	This feature indicates whether the device is capable of supporting the HV3 packet type as defined in [Vol 2] Part B, Section 6.5.2.3 on the SCO logical transport.
Inquiry Response Notification event	This feature bit indicates whether the device supports sending the HCI_Inquiry_Response_Notification event to the Host.

Feature	Definition
Interlaced inquiry scan	This feature indicates whether the device is capable of supporting the interlaced inquiry scan mechanism as defined in [Vol 2] Part B, Section 8.4.1. The presence of this feature has only local meaning and does not imply support for any additional LMP PDUs or sequences.
Interlaced page scan	This feature indicates whether the device is capable of supporting the interlaced page scan mechanism as defined in [Vol 2] Part B, Section 8.3.1. The presence of this feature has only local meaning and does not imply support for any additional LMP PDUs or sequences.
LE Supported (Controller)	This feature indicates whether the Controller supports LE. The local Host uses this feature bit to determine whether the Controller supports LE. A remote device does not use this feature bit.
LE Supported (Host)	This feature indicates that the Host supports LE. The local Host sets this feature bit to indicate to a remote device that the local device is capable of supporting LE. A remote Host uses this feature bit to determine whether an LE connection to the peer device is possible.
Link Supervision Timeout Changed event	This feature bit indicates whether the device supports the sending the HCI_Link_Supervision_Timeout_Changed event to the Host.
μ-law log synchronous data	This feature indicates whether the device is capable of supporting μ-law Log format data as defined in [Vol 2] Part B, Section 9.1 on the SCO and eSCO logical transports.
Non-flushable Packet Boundary Flag	This feature indicates that the device supports the capability to correctly handle HCI ACL Data packets with a Packet_Boundary_Flag value of 00 (Non-Automatically-Flushable packet).
Paging parameter negotiation	This feature indicates whether the LM is capable of supporting the signaling of changes in the paging scheme as defined in Section 4.1.9.
Pause Encryption	When this feature bit is enabled on both sides, then the encryption pause and resume sequences shall be used. If either side does not support the Pause Encryption feature bit, then the encryption pause and resume sequences shall not be used.
Ping	This feature indicates whether the device supports the transmission and reception of ping messages.
Power control	This feature indicates whether the device is capable of adjusting its transmission power. This feature indicates the ability to receive the LMP_INCR_POWER and LMP_DECR_POWER PDUs and transmit the LMP_MAX_POWER and LMP_MIN_POWER PDUs, using the LMP sequences defined in Section 4.1.3. These sequences may be used even if the remote device does not support the power control feature, as long as it supports the Power control requests feature.

Feature	Definition
Power control requests	This feature indicates whether the device is capable of determining if the transmit power level of the other device should be adjusted and will send the LMP_INCR_POWER and LMP_DECR_POWER PDUs to request the adjustments. It indicates the ability to receive the LMP_MAX_POWER and LMP_MIN_POWER PDUs, using the LMP sequences defined in Section 4.1.3. These sequences may be used even if the remote device does not support the RSSI feature, as long as it supports the power control feature.
Role switch	This feature indicates whether the device supports the exchange of Central and Peripheral roles as defined by [Vol 2] Part B, Section 8.6.5 using the LMP sequence defined in Section 4.4.2.
RSSI with inquiry results	This feature indicates whether the device is capable of reporting the RSSI with inquiry results as defined in [Vol 2] Part B, Section 8.4.2. The presence of this feature has only local meaning and does not imply support for any additional LMP PDUs or sequences.
SCO link	This feature shall indicate whether the device is able to support the SCO logical transport as defined in [Vol 2] Part B, Section 4.3, the HV1 packet defined in [Vol 2] Part B, Section 6.5.2.1 and receiving the DV packet defined in [Vol 2] Part B, Section 6.5.2.4 using the LMP sequence defined in Section 4.6.1.
Secure Connections (Controller Support)	This feature indicates whether the Controller is able to support AES-CCM, the P-256 Elliptic Curve for Secure Simple Pairing, and enhanced authentication using the LMP sequences defined in Section 4.2.7.
Secure Connections (Host Support)	This feature indicates whether the Host is capable of supporting Secure Connections. If HCI is supported, this bit shall be set if the HCI_Write_Secure_Connections_Host_Support command has been issued by the Host. When HCI is not supported, this bit may be set using a vendor specific mechanism.
Secure Simple Pairing (Controller Support)	This feature indicates whether the Link Manager is capable of supporting Secure Simple Pairing as defined in Section 4.2.7.
Secure Simple Pairing (Host Support)	This feature indicates whether the Host is capable of supporting Secure Simple Pairing as defined in Section 4.2.7. If HCI is supported, this bit shall be set if the HCI_Write_Simple_Pairing_Mode command has been issued to enable the Secure Simple Pairing feature. When HCI is not supported, this bit may be set using a vendor specific mechanism.
Simultaneous LE and BR/EDR to Same Device Capable (Controller)	This feature indicates that the Controller supports simultaneous LE and BR/EDR links to the same remote device. The local Host uses this feature bit to determine whether the Controller is capable of supporting simultaneous LE and BR/EDR connections to a remote device. A remote device does not use this feature bit.
Slot Availability Mask	This feature indicates whether the device is able to support Slot Availability Mask using the LMP sequences defined in Section 4.1.15.
Slot offset	This feature indicates whether the LM supports the transfer of the slot offset using the LMP sequence defined in Section 4.4.1.

Feature	Definition
Sniff mode	This feature indicates whether the device is able to support Sniff mode as defined in [Vol 2] Part B, Section 8.7 using the LMP sequences defined in Section 4.5.3.
Sniff subrating	This feature indicates whether the device is able to support sniff subrating as defined in [Vol 2] Part B, Section 8.7.2 using the LMP sequences defined in Section 4.5.3.3.
Synchronization Scan	This feature indicates whether the device supports Synchronization Scan as Peripheral.
Synchronization Train	This feature indicates whether the device supports Synchronization Train as Central.
Timing accuracy	This feature indicates whether the LM supports requests for timing accuracy using the LMP sequence defined in Section 4.3.1.
Train nudging	This feature indicates whether the device is able to support the train nudging mechanism described in [Vol 2] Part B, Section 8.3.2 and Section 8.4.2. The presence of this feature has only local meaning and does not imply support for any additional LMP PDUs or sequences.
Transparent synchronous data	This feature indicates whether the device is capable of supporting transparent synchronous data as defined in [Vol 2] Part B, Section 6.4.3 on the SCO and eSCO logical transports.
Variable Inquiry TX Power Level	This feature indicates whether the device is capable of setting the TX power level for Inquiry.

Table 3.1: Feature definitions

3.3 Feature mask definition

The features are represented as a bit mask when they are transferred in LMP messages. For each feature a single bit is specified which shall be set to 1 if the feature is supported and set to 0 otherwise. The single exception is the flow control lag which is coded as a 3 bit field with the least significant bit in byte 2 bit 4 and the most significant bit in byte 2 bit 6. All unassigned feature bits are reserved for future use.

No.	Supported feature	Byte	Bit
0	3 slot packets	0	0
1	5 slot packets	0	1
2	Encryption	0	2
3	Slot offset	0	3
4	Timing accuracy	0	4
5	Role switch	0	5

Note: Feature bit 27 (“Enhanced Inquiry Scan”) is no longer used in the specification. Devices may set this bit but are not required to.

3.4 Link Manager interoperability policy

Link managers of any version shall interpret using the lowest common subset of functionality by reading the LMP features mask (defined in Table 3.2).

An optional LMP PDU shall only be sent to a device if the corresponding feature bit is set in its feature mask. The exception to this are certain PDUs (see Section 4.1.1) which can be sent before the features mask is requested.

Note: A higher version device with a restricted feature set is indistinguishable from a lower version device with the same features.

3.5 Feature requirements

Note: In the tables in this section, numbers in parentheses before feature names are the corresponding feature bit numbers (see Section 3.3).

Any device supporting any feature with a feature bit number greater than or equal to 64 shall support Extended features and shall set feature bit 63.

The features listed in Table 3.5 are mandatory in this version of the specification (see Section 3.1) and these feature bits shall be set.

Feature
(2) Encryption
(51) Secure Simple Pairing (Controller Support)
(52) Encapsulated PDU

Table 3.5: Mandatory features

For each row of Table 3.6, either every feature named in that row shall be supported or none of the features named in that row shall be supported.

Features	
(7) Sniff mode	(41) Sniff subrating

Table 3.6: Mutually supporting features

For each row of Table 3.7, not more than one feature in that row shall be supported.

Features	
(23) Broadcast encryption	(134) Coarse clock adjustment

Table 3.7: Mutually exclusive features

For each row of Table 3.8, if the feature named in the first column is supported then the feature named in the second column shall be supported.

Feature	Required feature
(5) Role switch	(3) Slot offset
(12) HV2 packets	(11) SCO link
(13) HV3 packets	(11) SCO link
(14) μ-law log synchronous data	(11) SCO link *or* (31) Extended SCO link (EV3 packets)
(15) A-law log synchronous data	(11) SCO link *or* (31) Extended SCO link (EV3 packets)
(16) CVSD log synchronous data	(11) SCO link *or* (31) Extended SCO link (EV3 packets)
(19) Transparent synchronous data	(11) SCO link *or* (31) Extended SCO link (EV3 packets)
(26) Enhanced Data Rate ACL 3 Mb/s mode	(25) Enhanced Data Rate ACL 2 Mb/s mode
(32) EV4 packets	(31) Extended SCO link (EV3 packets)
(33) EV5 packets	(31) Extended SCO link (EV3 packets)
(36) AFH classification Peripheral	(35) AFH capable Peripheral

Feature	Required feature
(39) 3-slot Enhanced Data Rate ACL packets	(25) Enhanced Data Rate ACL 2 Mb/s mode
(40) 5-slot Enhanced Data Rate ACL packets	(25) Enhanced Data Rate ACL 2 Mb/s mode
(44) AFH classification Central	(43) AFH capable Central
(45) Enhanced Data Rate eSCO 2 Mb/s mode	(31) Extended SCO link (EV3 packets)
(46) Enhanced Data Rate eSCO 3 Mb/s mode	(45) Enhanced Data Rate eSCO 2 Mb/s mode
(47) 3-slot Enhanced Data Rate eSCO packets	(45) Enhanced Data Rate eSCO 2 Mb/s mode
(48) Extended inquiry response	(30) RSSI with inquiry results
(49) Simultaneous LE and BR/EDR to Same Device Capable (Controller)	(38) LE Supported (Controller)
(53) Erroneous data reporting	(11) SCO link *or* (31) Extended SCO link (EV3 packets)
(58) Enhanced power control	(9) Power control requests *and* (18) Power control
(65) LE Supported (Host)	(38) LE Supported (Controller)
(67) Secure Connections (Host Support)	(64) Secure Simple Pairing (Host Support) *and* (136) Secure Connections (Controller Support)

3.5.1 [This section is no longer used]

3.5.2 [This section is no longer used]

4 PROCEDURE RULES

4.1 Connection control

4.1.1 Connection establishment

After the paging procedure, LMP procedures for clock offset request, LMP version, supported features, name request and detach may then be initiated.

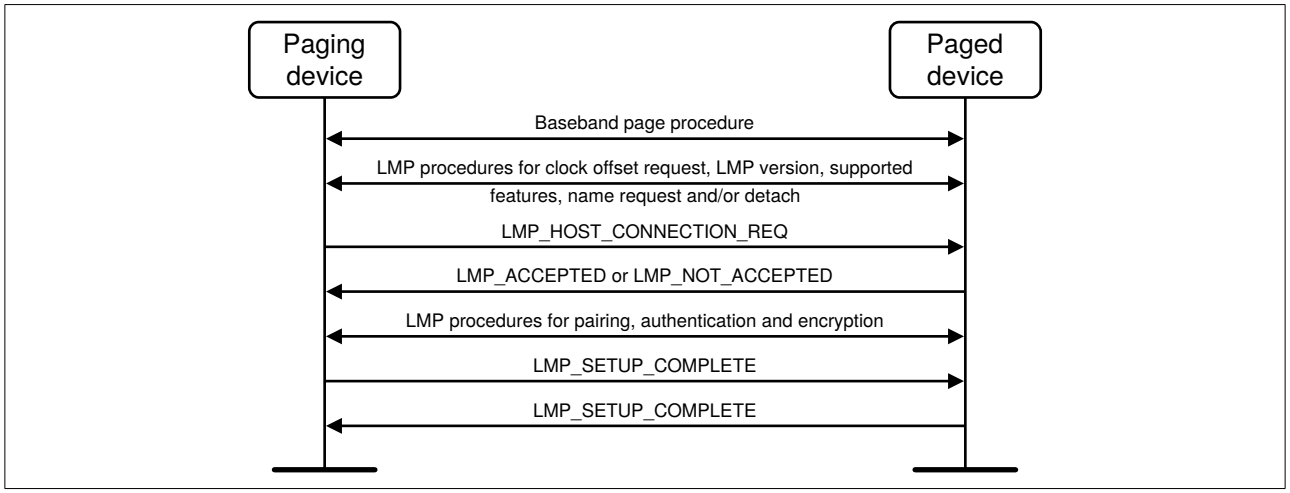

Figure 4.1: Connection establishment

When the paging device wishes to create a connection involving layers above LM, it sends an LMP_HOST_CONNECTION_REQ PDU. When the other side receives this message, the Host is informed about the incoming connection. The remote device can accept or reject the connection request by sending an LMP_ACCEPTED PDU or an LMP_NOT_ACCEPTED PDU. Alternatively, if the Peripheral needs a role switch, see Section 4.4.2, it sends an LMP_SLOT_OFFSET PDU and LMP_SWITCH_REQ PDU after it has received an LMP_HOST_CONNECTION_REQ PDU. If the role switch fails the LM shall continue with the creation of the connection unless this cannot be supported due to limited resources in which case the connection shall be terminated with an LMP_DETACH PDU with Error_Code *Remote Device Terminated Connection due to Low Resources* (0x14). When the role switch has been successfully completed, the old Peripheral will reply with an LMP_ACCEPTED PDU or an LMP_NOT_ACCEPTED PDU to the LMP_HOST_CONNECTION_REQ PDU (with the transaction ID set to 0).

If the paging device receives an LMP_NOT_ACCEPTED PDU in response to LMP_HOST_CONNECTION_REQ it shall immediately disconnect the link using the mechanism described in Section 4.1.2.

If the LMP_HOST_CONNECTION_REQ PDU is accepted, LMP security procedures (pairing, authentication and encryption) may be invoked. When a device is not going to initiate any more security procedures during connection establishment it sends an LMP_SETUP_COMPLETE PDU. When both devices have sent LMP_SETUP_COMPLETE PDUs the traffic can be transferred on the BR/EDR ACL logical transport.

M/O	PDU	Contents
M	LMP_HOST_CONNECTION_REQ	*none*
M	LMP_SETUP_COMPLETE	*none*

Table 4.1: Connection establishment PDU

4.1.2 Detach

The connection between two Bluetooth devices may be detached anytime by the Central or the Peripheral. An Error_Code parameter is included in the message to inform the other party of why the connection is detached.

M/O	PDU	Contents
M	LMP_DETACH	Error_Code

Table 4.2: Detach PDU

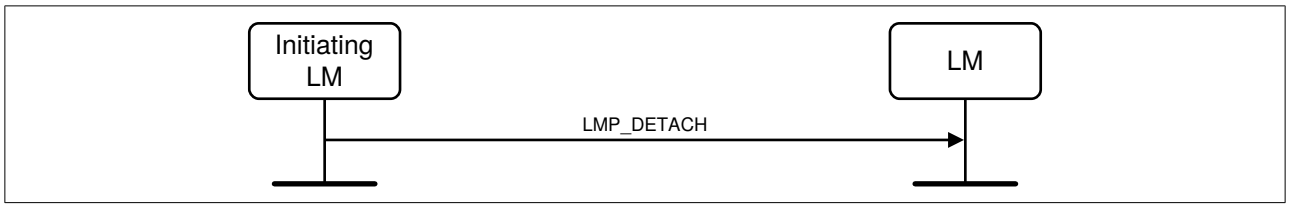
The initiating LM shall pause traffic on the ACL-U logical link (see [Vol 2] Part B, Section 5.3.1). The initiating LM then queues the LMP_DETACH for transmission and it shall start a timer for $6 \times T_{poll}$ slots where T_{poll} is the poll interval for the connection. If the initiating LM receives the Baseband acknowledgment before the timer expires it starts a timer for $3 \times T_{poll}$ slots. When this timer expires, and if the initiating LM is the Central, the LT_ADDR(s) may be re-used immediately. If the initial timer expires then the initiating LM drops the link and starts a timer for $T_{linksupervisiontimeout}$ slots after which the LT_ADDR(s) may be re-used if the initiating LM is the Central.

When the receiving LM receives the LMP_DETACH, it shall start a timer for $6 \times T_{poll}$ slots if it is the Central and $3 \times T_{poll}$ if it is the Peripheral. On timer expiration, the link shall be detached and, if the receiving LM is the Central, the LT_ADDR(s) may be re-used immediately. If the receiver never receives the LMP_DETACH then a link supervision timeout will occur, the link will be detached, and the LT_ADDR may be re-used immediately.

If at any time during this or any other LMP sequence the Link supervision timeout expires then the link shall be terminated immediately and the LT_ADDR(S) may be re-used immediately.

If the connection is in Hold mode, the initiating LM shall wait for Hold mode to end before initiating the procedure defined above. If the connection is in Sniff mode,

the initiating LM shall perform the procedure to exit Sniff mode before initiating the procedure defined above. If the procedure to exit Sniff mode does not complete within the LMP response timeout (30 seconds) the procedure defined above shall be initiated anyway.



Sequence 1: Connection closed by sending LMP_DETACH

If there are any SCO or eSCO connections open on the same physical link, sending or receiving the LMP_DETACH PDU implicitly removes them and the initiating LM should not send separate PDUs for this purpose when detaching.

4.1.3 Power control

If the received signal characteristics differ too much from the preferred value of a Bluetooth device, it may request an increase or a decrease of the other device's transmit power level. A device's transmit power level is a property of the physical link, and affects all logical transports carried over the physical link. Power control requests carried over the default ACL-C logical link shall only affect the physical link associated with the requesting device's default ACL-C logical link; they shall not affect the power level used on the physical links to other Peripherals.

Two power control mechanisms are specified: legacy power control (see Table 4.3) and enhanced power control (see Table 4.4 and Section 4.1.3.1).

M/O	PDU	Contents
O(9)	LMP_INCR_POWER_REQ	Reserved
O(9)	LMP_DECR_POWER_REQ	Reserved
O(18)	LMP_MAX_POWER	*none*
O(18)	LMP_MIN_POWER	*none*

Table 4.3: Legacy power control PDU

M/O	PDU	Contents
O(58)	LMP_POWER_CONTROL_REQ	Power_Adj_Req
O(58)	LMP_POWER_CONTROL_RES	Power_Adj_Rsp

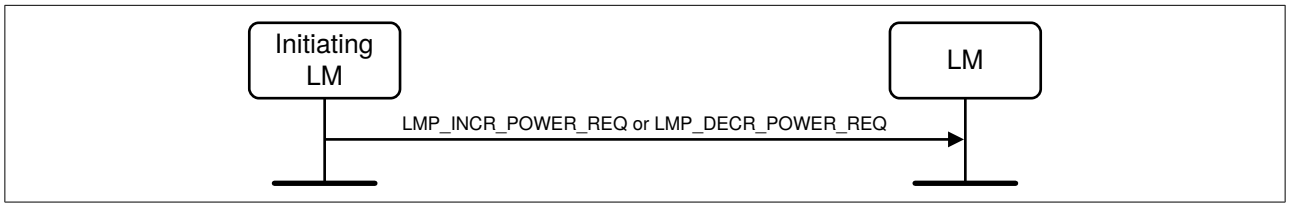
Table 4.4: Enhanced power control PDU

The power adjustment requests may be made at any time using the legacy power control mechanism following a successful Baseband Paging procedure and before

the link manager supported features responses have been processed. After the Link Manager supported features responses have been processed, if both devices support enhanced power control (see Section 4.1.3.1) then only enhanced power control shall be used. Otherwise, if either device supports only the legacy power control mechanism then only legacy power control shall be used.

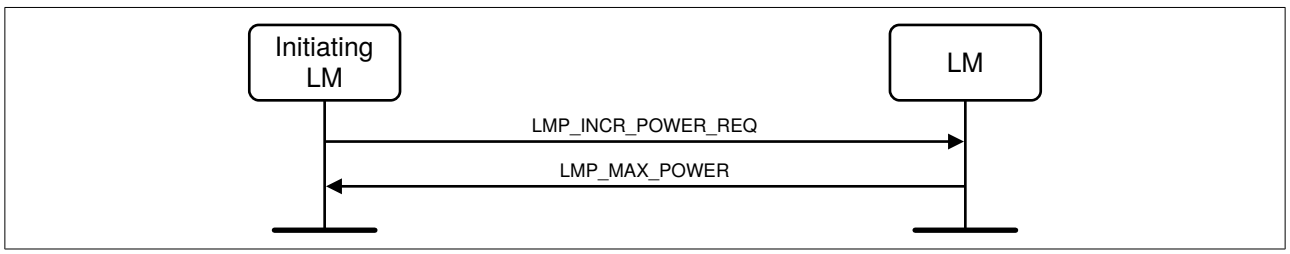
If a device does not support power control requests this is indicated in the supported features list and thus no power control requests shall be sent after the supported features response has been processed. Prior to this time, a power control adjustment might be sent, and if the recipient does not support power control, it shall send LMP_MAX_POWER in response to LMP_INCR_POWER_REQ and LMP_MIN_POWER in response to LMP_DECR_POWER_REQ or shall send LMP_NOT_ACCEPTED with the Error_Code *Unsupported LMP Feature* (0x1A) in response to either PDU.

Upon receipt of an LMP_INCR_POWER_REQ PDU or LMP_DECR_POWER_REQ PDU the output power shall be increased or decreased one step. See [Vol 2] Part A, Section 5.2 for the definition of the step size.

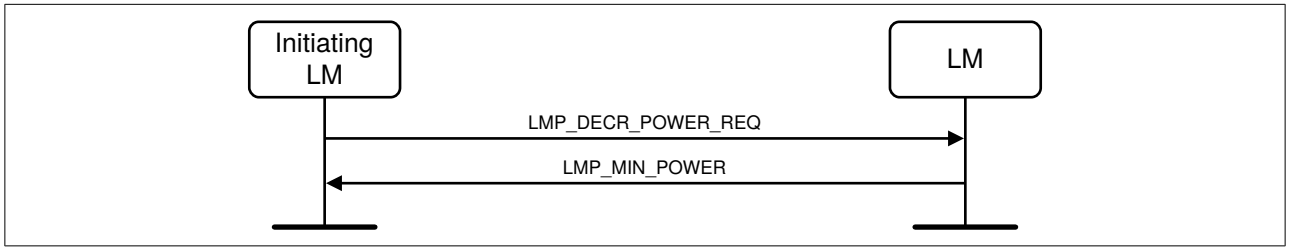


Sequence 2: A device requests a change of the other device's TX power

If the receiver of LMP_INCR_POWER_REQ is at maximum power LMP_MAX_POWER shall be returned. The device shall only request an increase again after having requested a decrease at least once. If the receiver of LMP_DECR_POWER_REQ is at minimum power then LMP_MIN_POWER shall be returned and the device shall only request a decrease after having requested an increase at least once.



Sequence 3: The TX power cannot be increased



Sequence 4: The TX power cannot be decreased

One byte in LMP_INCR/DECR_POWER_REQ is reserved for future use.

4.1.3.1 Enhanced power control

Enhanced power control shall only be used when both devices support the enhanced power control LMP feature. Legacy power control shall not be used when both devices support the enhanced power control LMP feature.

4.1.3.1.1 Sending enhanced power control requests

To adjust the remote device's output power, a device shall send the LMP_POWER_CONTROL_REQ PDU with the Power_Adj_Req parameter.

The Power_Adj_Req parameter may be set to: one step up, one step down, or all the way to the max power level. The remote device shall respond with an LMP_POWER_CONTROL_RES PDU. The responder shall transmit the LMP_POWER_CONTROL_RES PDU at the new power level. Upon reception of the LMP_POWER_CONTROL_RES PDU, the initiating device should restart any processes used to determine whether additional power level changes are required.

If the receiver of the LMP_POWER_CONTROL_REQ PDU has indicated that the output power levels for all of the supported modulation modes are at maximum the requesting device shall only request an increase again after having requested a decrease at least once. If the receiver of the LMP_POWER_CONTROL_REQ PDU has indicated that the output power levels for all of the supported modulation modes are at minimum the requesting device shall only request a decrease after having requested an increase at least once.

A new LMP_POWER_CONTROL_REQ PDU shall not be sent until an LMP_POWER_CONTROL_RES PDU has been received.

4.1.3.1.2 Responding to enhanced power control requests

When a device receives an LMP_POWER_CONTROL_REQ PDU with the Power_Adj_Req parameter set to "increment one step," all supported modulations that are not at the maximum level shall be increased one step.

When a device receives an LMP_POWER_CONTROL_REQ PDU with the Power_Adj_Req parameter set to "decrement one step", all supported modulations that are not at the minimum level shall be decreased one step.

Implementations shall not violate the relative power level between modulations (see [Vol 2] Part A, Section 5.2).

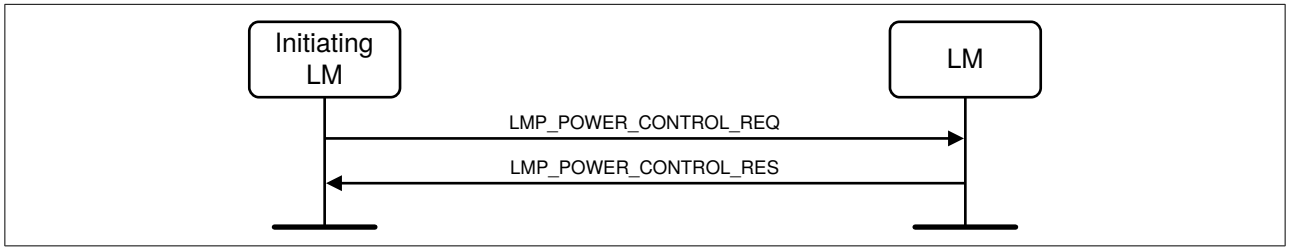
When a device receives an LMP_POWER_CONTROL_REQ PDU with the Power_Adj_Req parameter set to "increment power to maximum value", each supported modulation mode shall be set to its maximum power level.

Note: See [Vol 2] Part A, Section 5.2 for requirements on the relative power levels of different modulation modes.

The responding LM shall send the LMP_POWER_CONTROL_RES PDU to indicate the status for every modulation. The Power_Adj_Rsp parameter has three 2-bit fields indicating the status for each modulation mode: GFSK, π/4-DQPSK and 8DPSK. Each 2-bit field shall be set to one of the following values: *not supported*, *changed one step, max power*, or *min power*. The changed one step value shall only be used when the power level for that modulation mode has not reached the minimum or maximum level.

The *not supported* value shall be used for each unsupported modulation type.

The responder shall transmit the LMP_POWER_CONTROL_RES PDU at the new transmit power level and shall not change its power level until requested by the remote device by a subsequent LMP_POWER_CONTROL_REQ PDU.



Sequence 5: A device responds to a power control request

4.1.4 Adaptive frequency hopping

AFH is used to improve the performance of physical links in the presence of interference as well as reducing the interference caused by physical links on other devices in the ISM band. AFH shall only be used during Connection state.

M/O	PDU	Contents
O(35) Rx O(43) Tx	LMP_SET_AFH	AFH_Instant, AFH_Mode, AFH_Channel_Map

Table 4.5: AFH PDU

The LMP_SET_AFH PDU contains three parameters: AFH_Instant, AFH_Mode, and AFH_Channel_Map. The parameter, AFH_Instant, specifies the instant at which the hopset switch shall become effective. This is specified as a Bluetooth Clock value of the Central's clock, that is available to both devices. The AFH instant is chosen by the Central and shall be an even value at least $6 \times T_{poll}$ or 96 slots (whichever is greater) in the future. The AFH_Instant shall be within 12 hours of the current clock value. The parameter AFH_Mode, specifies whether AFH shall be enabled or disabled. The parameter AFH_Channel_Map, specifies the set of channels that shall be used if AFH is enabled.

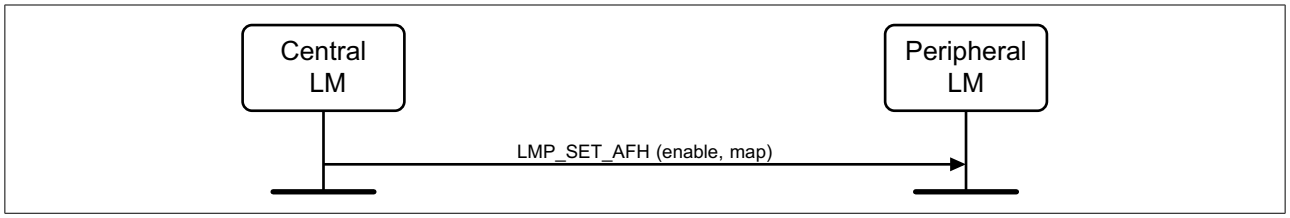
When the LMP_SET_AFH PDU is received the AFH instant shall be compared with the current Bluetooth clock value. If it is in the past then the AFH_Instant has passed and the Peripheral shall immediately configure the hop selection kernel (see [Vol 2] Part B, Section 2.6.3) with the new AFH_Mode and AFH_Channel_Map specified in the LMP_SET_AFH PDU. If it is in the future then a timer shall be started to expire at the AFH instant. When this timer expires it shall configure the hop selection kernel with the new AFH_Mode and AFH_Channel_Map.

The Central shall not send a new LMP_SET_AFH PDU to a Peripheral until it has received the Baseband acknowledgment for any previous LMP_SET_AFH addressed to that Peripheral and the instant has passed.

Role switch while AFH is enabled shall follow the procedures define by [Vol 2] Part B, Section 8.6.5.

4.1.4.1 Central enables AFH

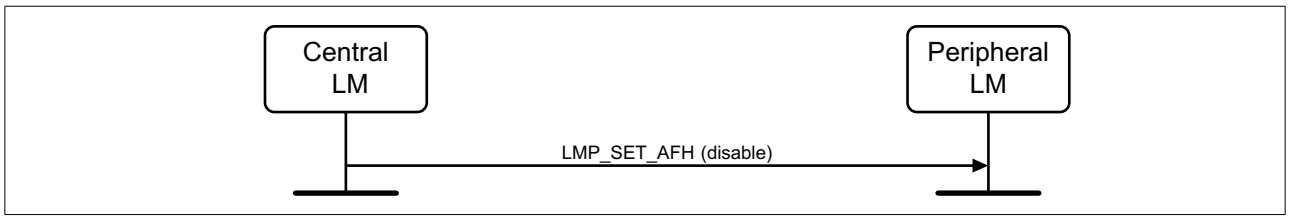
Prior to enabling AFH the Central LM shall pause traffic on the ACL-U logical link (see [Vol 2] Part B, Section 5.3.1). The Central shall then enable AFH on a physical link by sending the LMP_SET_AFH PDU with AFH_Mode set to enabled, the AFH_Channel_Map parameter containing the set of used and unused channels, and an AFH_instant. The LM shall not calculate the AFH instant until after traffic on the ACL-U logical link has been stopped. The Central considers the physical link to have entered AFH-enabled operation once the Baseband acknowledgment has been received and the AFH_Instant has passed. Once the Baseband acknowledgment has been received the Central shall restart transmission on the ACL-U logical link.



Sequence 6: Central enables AFH

4.1.4.2 Central disables AFH

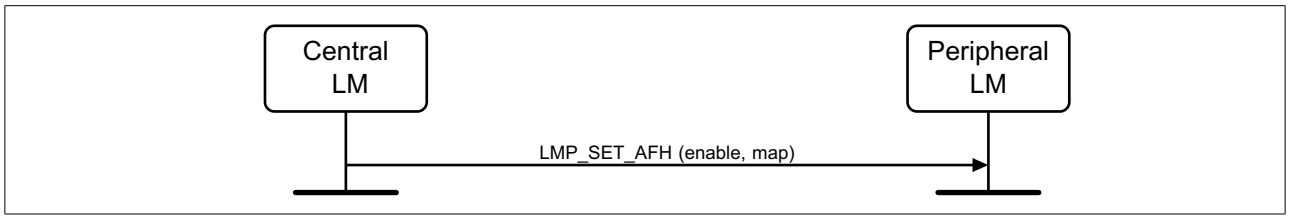
Prior to disabling AFH the Central LM shall pause traffic on the ACL-U logical link ([Vol 2] Part B, Section 5.3.1). The Central shall then disable AFH operation on a physical link by sending the LMP_SET_AFH PDU with AFH_mode set to disabled and an AFH_Instant. The AFH_Channel_Map parameter is not valid when AFH_Mode is disabled. The LM shall not calculate the AFH instant until after traffic on the ACL-U logical link has been stopped. The Central considers the physical link to have entered AFH-disabled operation once the Baseband acknowledgment has been received and the AFH_Instant has passed. Once the Baseband acknowledgment has been received the Central shall restart transmission on the ACL-U logical link.



Sequence 7: Central disables AFH

4.1.4.3 Central updates AFH

A Central shall update the AFH parameters on a physical link by sending the LMP_SET_AFH PDU with AFH_Mode set to enabled, an AFH_Instant and a new AFH_Channel_Map. The Central shall consider the Peripheral to have the updated AFH parameters once the Baseband acknowledgment has been received and the AFH_Instant has passed.



Sequence 8: Central updates AFH

4.1.4.4 AFH operation in Hold and Sniff modes

A Peripheral in Hold mode or Sniff mode shall retain the AFH_Mode and AFH_Channel_Map it was using prior to entering those modes. A Central may change the AFH_Mode while a Peripheral is in Sniff mode.

A Central that receives a request from an AFH-enabled Peripheral to enter Hold mode or Sniff mode and decides to operate the Peripheral using a different hop sequence shall respond with an LMP_SET_AFH PDU specifying the new hop sequence.

The Central continues with the LMP signaling, for Hold or Sniff initiation, once the Baseband acknowledgment for the LMP_SET_AFH PDU has been received. Optionally, the Central may delay the continuation of this LMP signaling until after the instant. An AFH capable Peripheral shall support both of these cases.

A Central that receives a request from an AFH-enabled Peripheral to enter Hold mode or Sniff mode and decides not to change the Peripheral's hop sequence shall respond exactly as it would do without AFH. In this case, AFH operation has no effect on the LMP signaling.

4.1.5 Channel classification

A Central may request channel classification information from a Peripheral that supports AFH.

A Peripheral that supports the AFH_classification_Peripheral feature shall perform channel classification and reporting according to its AFH_reporting_mode. The Central shall control the AFH_reporting_mode using the LMP_CHANNEL_CLASSIFICATION_REQ PDU. The Peripheral shall report its channel classification using the LMP_CHANNEL_CLASSIFICATION PDU.

The Peripheral shall report pairs of channels as *good*, *bad* or *unknown*. See Table 5.2 for the detailed format of the AFH_Channel_Classification parameter. When one channel in the n^{th} channel pair is good and the other channel is unknown the n^{th} channel pair shall be reported as good. When one channel in the n^{th} channel pair is bad and the other is unknown the n^{th} channel pair shall be reported as bad. It is implementation dependent what to report when one channel in a channel pair is good and the other is bad.

M/O	PDU	Contents
O(36) Rx O(44) Tx	LMP_CHANNEL_CLASSIFICATION_REQ	AFH_Reporting_Mode, AFH_Min_Interval, AFH_Max_Interval
O(36) Tx O(44) Rx	LMP_CHANNEL_CLASSIFICATION	AFH_Channel_-Classification

Table 4.6: Channel classification PDU

The LMP_CHANNEL_CLASSIFICATION_REQ PDU contains three parameters: AFH_Reporting_Mode, AFH_Min_Interval, and AFH_Max_Interval. In the disabled state, the Peripheral shall not generate any channel classification reports. The parameter AFH_min_interval, defines the minimum amount of time from the last LMP_CHANNEL_CLASSIFICATION command that was sent before the next LMP_CHANNEL_CLASSIFICATION PDU may be sent. The parameter AFH_max_interval, defines the maximum amount of time between the change in the channel classification being detected by a Peripheral and its generation of an LMP_CHANNEL_CLASSIFICATION PDU. The AFH_max_interval shall be equal to or larger than AFH_min_interval.

The AFH_reporting_mode parameter shall determine if the Peripheral is in the enabled or disabled state. The default state, prior to receipt of any LMP_CHANNEL_CLASSIFICATION_REQ PDUs, shall be disabled.

AFH_reporting_mode is implicitly set to the disabled state when any of the following occur:

- Establishment of a connection at the Baseband level
- Role switch
- Entry to Hold mode operation

and may be implicitly set to the disabled state when any of the following occur:

- The Peripheral disables AFH after receipt of an LMP_SET_AFH PDU (see Section 4.1.4)
- AFH_reporting_mode is set to enabled when the Peripheral has AFH disabled

AFH_reporting_mode is implicitly restored to its former value when any of the following occur:

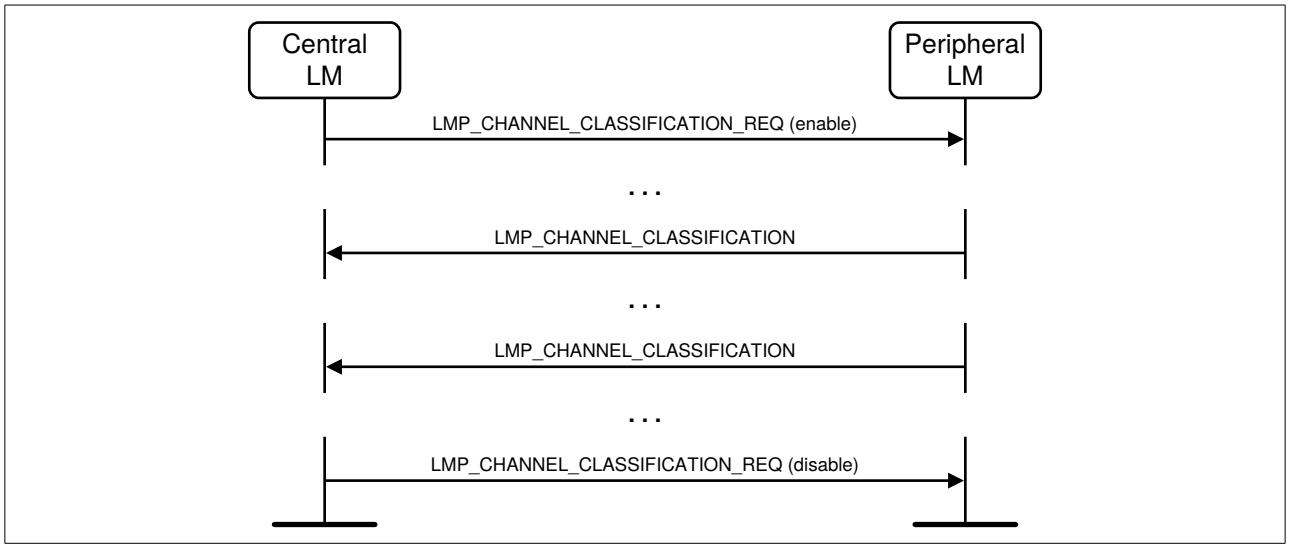
- Exit from Hold mode
- Failure of role switch
- The Peripheral enables AFH after receipt of an LMP_SET_AFH PDU

4.1.5.1 Channel classification reporting enabling and disabling

A Central enables Peripheral channel classification reporting by sending the LMP_CHANNEL_CLASSIFICATION_REQ PDU with the AFH_reporting_mode parameter set to enabled.

When a Peripheral has had classification reporting enabled by the Central it shall send the LMP_CHANNEL_CLASSIFICATION PDU according to the information in the latest LMP_CHANNEL_CLASSIFICATION_REQ PDU. The LMP_CHANNEL_CLASSIFICATION PDU shall not be sent if there has been no change in the Peripheral's channel classification.

A Central disables Peripheral channel classification reporting by sending the LMP_CHANNEL_CLASSIFICATION_REQ PDU with the AFH_reporting_mode parameter set to disabled.



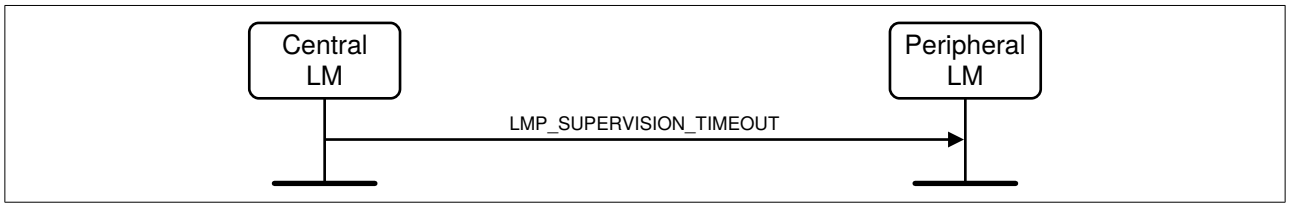
Sequence 9: Channel classification reporting

4.1.6 Link supervision

Each physical link has a timer that is used for link supervision. This timer is used to detect physical link loss caused by devices moving out of range, or being blocked by interference, a device's power-down, or other similar failure cases. Link supervision is specified in [Vol 2] Part B, Section 3.1.

M/O	PDU	Contents
M	LMP_SUPERVISION_TIMEOUT	Supervision_Timeout

Table 4.7: Set supervision timeout PDU



Sequence 10: Setting the link supervision timeout

4.1.7 Channel quality driven data rate change (CQDDR)

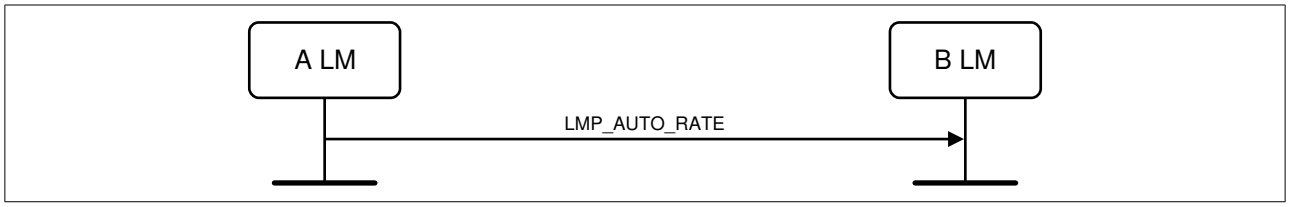
The data throughput for a given packet type depends on the quality of the RF channel. Quality measurements in the receiver of one device can be used to dynamically control the packet type transmitted from the remote device for optimization of the data throughput. Device A sends the LMP_AUTO_RATE PDU once to notify device B to enable this feature. Once enabled, device B may request packet type(s) that A should transmit by sending the LMP_PREFERRED_RATE PDU. This PDU has a parameter which determines the preferred error coding (with or without 2/3 FEC) and optionally the preferred size in slots of the packets. Device A is not required to change to the packet type specified by this parameter. Device A shall not send a packet that is larger than max slots (see Section 4.1.10) even if the preferred size is greater than this value.

The Data_Rate parameter includes the preferred rate for Basic Rate and Enhanced Data Rate modes. When operating in Basic Rate mode, the device shall use bits 0 to 2 to determine the preferred data rate. When operating in Enhanced Data Rate mode, the device shall use bits 3 to 6 to determine the preferred data rate. For devices that support Enhanced Data Rate, the preferred rates for both Basic Rate and Enhanced Data Rate modes shall be valid at all times.

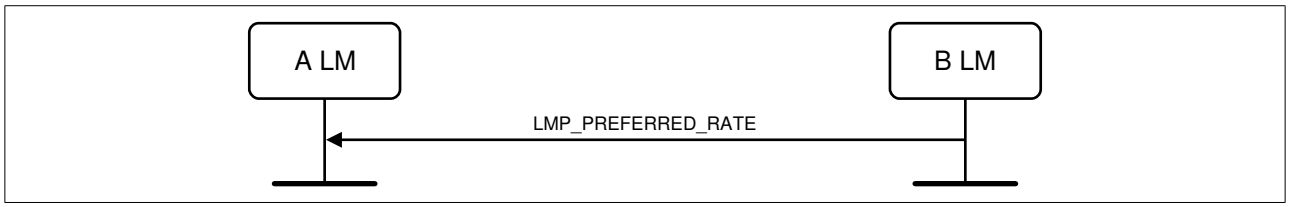
These PDUs may be sent at any time after connection setup is completed.

M/O	PDU	Contents
O(10)	LMP_AUTO_RATE	*none*
O(10)	LMP_PREFERRED_RATE	Data_Rate

Table 4.8: Quality-driven change of the data rate PDU



Sequence 11: A notifies B to enable CQDDR



Sequence 12: B sends A a preferred packet type

4.1.8 Quality of service (QoS)

The LM provides QoS capabilities. A poll interval, T_{poll} , that is defined as the maximum time between transmissions from the Central to a particular Peripheral on the ACL logical transport, is used to support bandwidth allocation and latency control - see [Vol 2] Part B, Section 8.6.1 for details. The poll interval shall be met in the Active and Sniff modes except when there are collisions with page, page scan, inquiry and inquiry scan, during time critical LMP sequences in the current piconet and any other piconets in which the Bluetooth device is a member, and during critical Baseband sequences (such as the page response, initial Connection state until the first POLL, and role switch). These PDUs may be sent at any time after connection setup is completed.

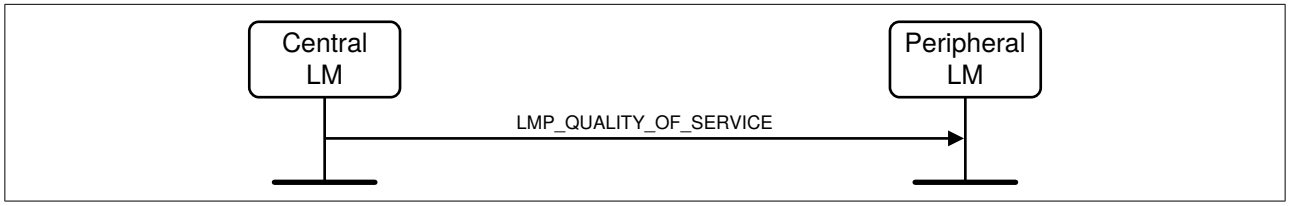
Central and Peripheral negotiate the number of repetitions for broadcast packets (N_{BC}), see [Vol 2] Part B, Section 7.6.5.

M/O	PDU	Contents
M	LMP_QUALITY_OF_SERVICE	Poll_Interval N_{BC}
M	LMP_QUALITY_OF_SERVICE_REQ	Poll_Interval N_{BC}

Table 4.9: Quality of service PDU

4.1.8.1 Central notifies Peripheral of the quality of service

The Central notifies the Peripheral of the new poll interval and N_{BC} by sending the LMP_QUALITY_OF_SERVICE PDU. The Peripheral cannot reject the notification.

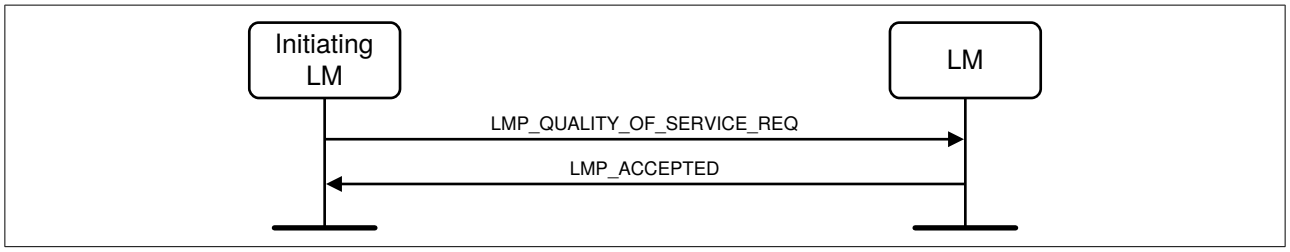


Sequence 13: Central notifies Peripheral of quality of service

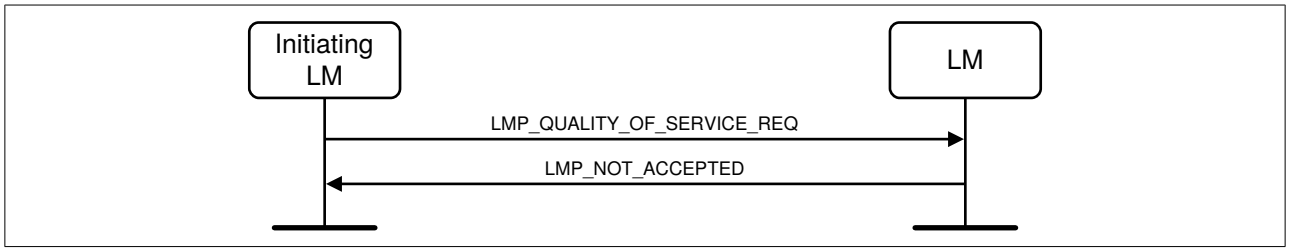
4.1.8.2 Device requests new quality of service

Either the Central or the Peripheral may request a new poll interval and N_{BC} by sending an LMP_QUALITY_OF_SERVICE_REQ PDU. The parameter N_{BC} is meaningful only when it is sent by a Central to a Peripheral. For transmission of LMP_QUALITY_OF_SERVICE_REQ PDUs from a Peripheral, this parameter shall be ignored by the Central. The request can be accepted or rejected. This allows the Central and Peripheral to dynamically negotiate the quality of service as needed.

The selected poll interval by the Peripheral shall be less than or equal to the specified Access Latency for the outgoing traffic of the ACL link (see [Vol 3] Part A, Section 5.3).



Sequence 14: Device accepts new quality of service



Sequence 15: Device rejects new quality of service

4.1.9 Paging scheme parameters

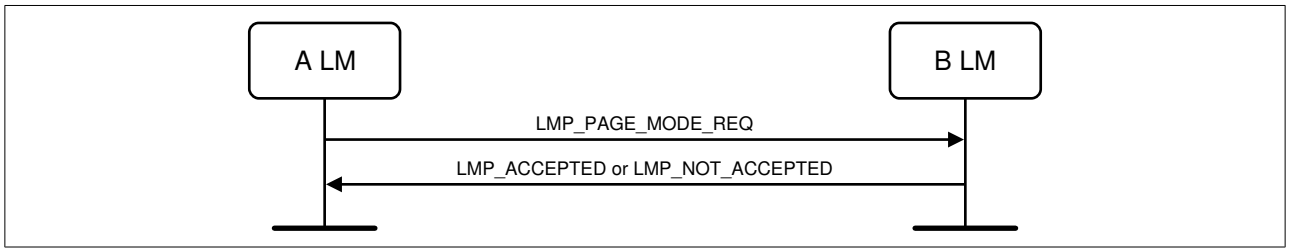
LMP provides a means to negotiate the paging scheme parameters that are used the next time a device is paged.

M/O	PDU	Contents
O(17)	LMP_PAGE_MODE_REQ	Paging_Scheme Paging_Scheme_Settings
O(17)	LMP_PAGE_SCAN_MODE_REQ	Paging_Scheme Paging_Scheme_Settings

Table 4.10: Paging scheme request PDU

4.1.9.1 Page mode

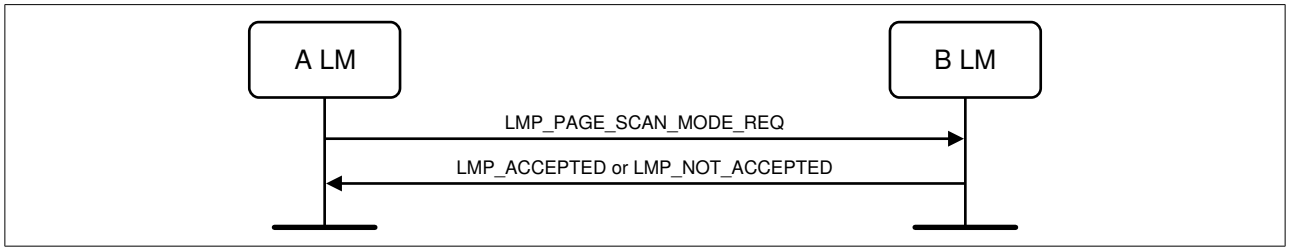
This procedure is initiated from device A and negotiates the paging scheme used when device A pages device B. Device A proposes a paging scheme including the parameters for this scheme and device B can accept or reject. On rejection the old setting shall not be changed. A request to switch to a reserved paging scheme shall be rejected.



Sequence 16: Negotiation for Page mode

4.1.9.2 Page Scan mode

This procedure is initiated from device A and negotiates the paging scheme and paging scheme settings used when device B pages device A. Device A proposes a paging scheme and paging scheme settings and device B may accept or reject. On reject the old setting is not changed. A request specifying the mandatory scheme shall be accepted. A request to switch to a reserved scheme shall be rejected. This procedure should be used when device A changes its paging scheme settings. A Peripheral should also send this message to the Central after connection establishment, to inform the Central of the Peripheral's current paging scheme and paging scheme settings.



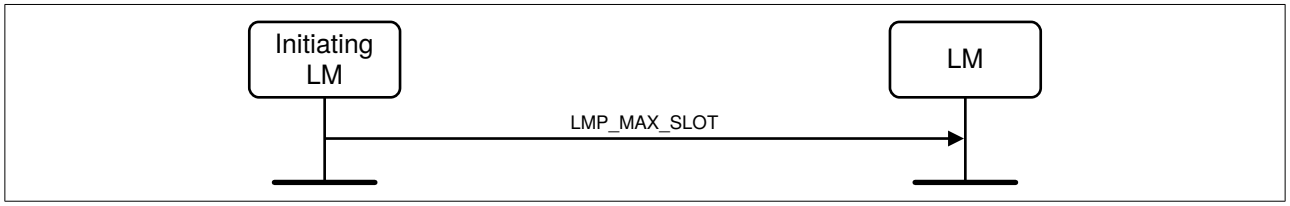
Sequence 17: Negotiation for Page Scan mode

4.1.10 Control of multi-slot packets

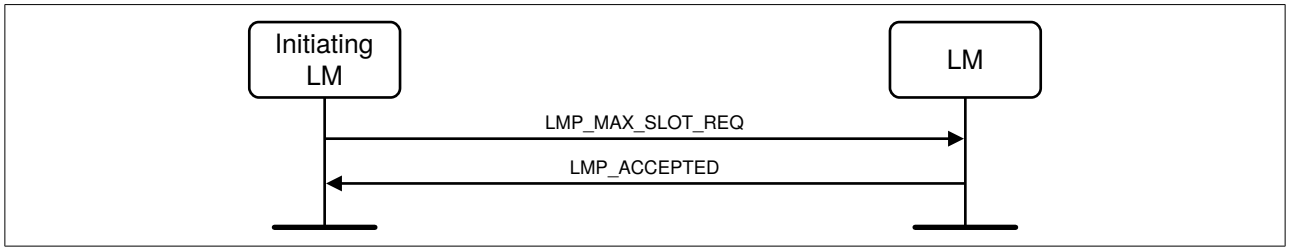
The number of consecutive slots used by a device on an ACL-U logical link can be limited. It does not affect traffic on the eSCO links where the packet sizes are defined as part of link setup. A device allows the remote device to use a maximum number of slots by sending the PDU LMP_MAX_SLOT providing a Max_Slots parameter. Each device can request to use a maximal number of slots by sending the PDU LMP_MAX_SLOT_REQ providing a Max_Slots parameter. After a new connection (as a result of page or page scan), or after a role switch, the value shall be 1 slot. These PDUs can be sent at any time after connection setup is completed.

M/O	PDU	Contents
M	LMP_MAX_SLOT	Max_Slots
M	LMP_MAX_SLOT_REQ	Max_Slots

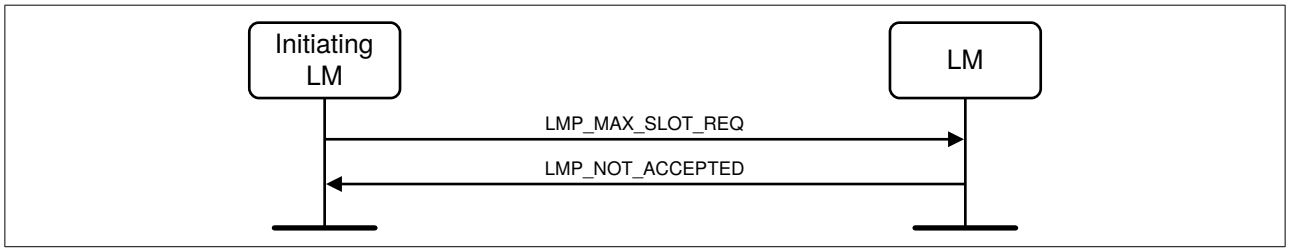
Table 4.11: Multi-slot packet control PDU



Sequence 18: Device allows Remote Device to use a maximum number of slots



Sequence 19: Device requests a maximum number of slots. Remote Device accepts.



Sequence 20: Device requests a maximum number of slots. Remote Device rejects

4.1.11 Enhanced Data Rate

A device may change the packet type table, ptt, to select which if any of the packets and optional modulation modes are to be used on an ACL logical transport.

Either the Central or the Peripheral may request a new packet type table and therefore the packets and modulation mode to be used on this ACL link. After a new Baseband connection, as a result of page or page scan, the default value for ptt shall be 0.

The change of the modulation mode for an ACL logical transport shall not affect the packet and packet types used for an associated SCO logical transport on the same LT_ADDR.

Note: Enhanced Data Rate eSCO links are negotiated using the LMP eSCO link_req as described in Section 4.6.2.

Before changing the packet type table, the initiator shall finalize the transmission of the current ACL packet with ACL-U information and shall stop ACL-U transmissions. It shall then send the LMP_PACKET_TYPE_TABLE_REQ PDU.

If the receiver rejects the change, then it shall respond with an LMP_NOT_ACCEPTED_EXT PDU.

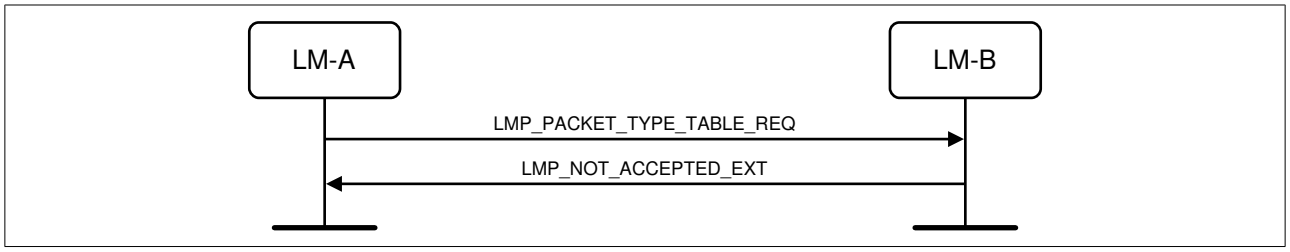
If the receiver accepts the change, then it shall finalize the transmission of the current ACL packet with ACL-U information and shall stop ACL-U transmissions, it shall change to the new packet type table and shall respond with an LMP_ACCEPTED_EXT PDU. When it receives the Baseband acknowledgment for the LMP_ACCEPTED_EXT PDU it shall restart ACL-U transmissions.

When the initiator receives an LMP_NOT_ACCEPTED_EXT PDU the initiator shall restart ACL-U transmissions.

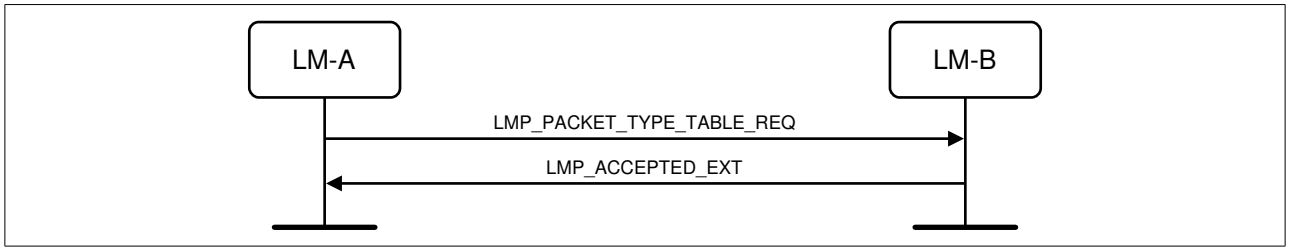
When the initiator receives an LMP_ACCEPTED_EXT PDU it shall change the packet type table and restart ACL-U transmissions.

M/O	PDU	Contents
O(25)	LMP_PACKET_TYPE_TABLE_REQ	Packet_Type_Table

Table 4.12: Enhanced Data Rate PDUs



Sequence 21: Packet type table change is rejected



Sequence 22: Packet type table change is accepted

4.1.12 Encapsulated LMP PDUs

Some transactions require sending LMP payload data that is longer than 16 octets. To enable a link manager to send a large PDU, an encapsulated LMP PDU is defined. An encapsulated LMP PDU is composed of a minimum of two LMP messages, a header PDU and one or more payload PDUs.

M/O	PDU	Contents
O(52)	LMP_ENCAPSULATED_HEADER	Encap_Major_Type Encap_Minor_Type Encap_Payload_Length
O(52)	LMP_ENCAPSULATED_PAYLOAD	Encap_Data

Table 4.13: Encapsulated LMP PDUs

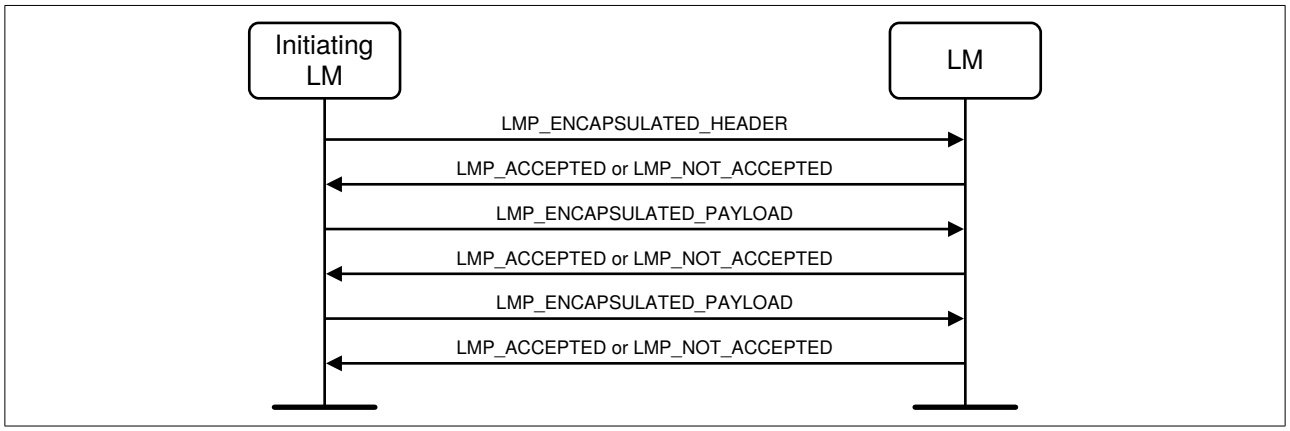
4.1.12.1 Sending an encapsulated PDU

The LMP_ENCAPSULATED_HEADER PDU shall be sent by the initiating device when it needs to send an encapsulated PDU. This PDU shall be either accepted or rejected using the LMP_ACCEPTED or LMP_NOT_ACCEPTED PDUs. If the major and minor types are not supported the PDU shall be rejected with Error_Code *Unsupported LMP Parameter Value* (0x20). If the LMP_ENCAPSULATED_HEADER PDU is accepted, then one or more LMP_ENCAPSULATED_PAYLOAD PDUs will be sent with the encapsulated data sent in sequence, 16 octets at a time, or if this is last packet, the correct number of octets and then zero padded.

Each LMP_ENCAPSULATED_PAYLOAD PDU shall be accepted or rejected. If the LMP_ENCAPSULATED_HEADER PDU is rejected, then the

opcode in the LMP_NOT_ACCEPTED PDU shall be the opcode for the LMP_ENCAPSULATED_HEADER and not the Encap_Major_Type or Encap_Minor_Type. If the LMP_ENCAPSULATED_PAYLOAD PDU is rejected, then the opcode in the LMP_NOT_ACCEPTED PDU shall be the opcode for the LMP_ENCAPSULATED_PAYLOAD.

A responding device may reject the final LMP_ENCAPSULATED_PAYLOAD PDU after accepting the LMP_ENCAPSULATED_HEADER PDU. This is so that the link manager can still reject an encapsulated message after all the data has been received.



Sequence 23: Sending an encapsulated PDU

Between sending an LMP_ENCAPSULATED_HEADER PDU and an LMP_ENCAPSULATED_PAYLOAD PDU, or between each of the LMP_ENCAPSULATED_PAYLOAD PDUs, either device shall be able to send the following LMP PDUs without causing a "different transaction collision" error.

- LMP_CHANNEL_CLASSIFICATION
- LMP_DECR_POWER_REQ
- LMP_DETACH
- LMP_INCR_POWER_REQ
- LMP_MAX_POWER
- LMP_MAX_SLOT
- LMP_MIN_POWER
- LMP_PREFERRED_RATE
- LMP_SET_AFH

4.1.13 Ping

When both devices support the Ping feature, a Link Manager may verify the presence of the remote Link Manager by using the LMP ping mechanism. The LMP ping mechanism

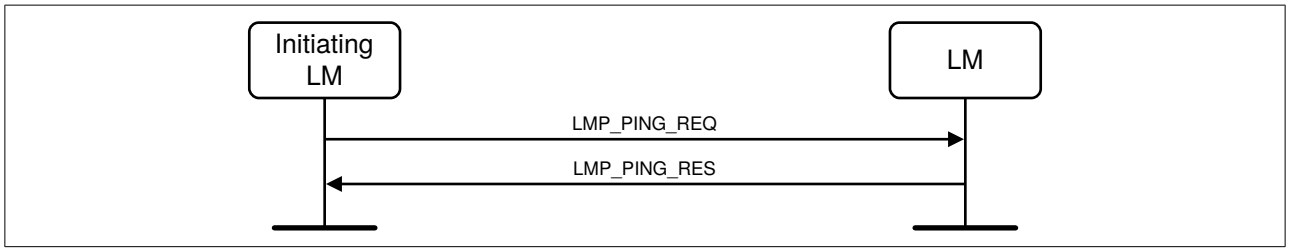
may also be used to verify message integrity on the ACL logical transport by forcing the remote device to send an ACL packet that contains a MIC.

Note: Since the LMP_PING_RES PDU contains a MIC and will update the packet counter, the sender of the LMP_PING_REQ PDU can verify that packets with earlier packet counter values have not been deliberately suppressed by an attacker.

M/O	PDU	Contents
O(137)	LMP_PING_REQ	*none*
O(137)	LMP_PING_RES	*none*

Table 4.14: Ping PDUs

The initiating link manager sends the LMP_PING_REQ PDU. The responding link manager responds with the LMP_PING_RES PDU. The initiating link manager may be a Central or Peripheral.



Sequence 24: Ping PDUs

The Link Manager shall send an LMP_PING_REQ PDU when the remote device has not sent a packet containing a payload protected by a MIC within an authenticated payload timeout set by the Host (see [Vol 4] Part E, Section 7.3.94). The Link Manager should send an LMP_PING_REQ PDU in advance enough of the expiration of the authenticated payload timeout to allow the remote device reasonable time to respond with an LMP_PING_RES PDU before the timeout expires.

4.1.14 Piconet clock adjustment

The Central may adjust the piconet clock (e.g. to align with an external time base) by initiating the Coarse Clock Adjustment or Clock Dragging procedures. A Peripheral may request that the Central adjust the piconet clock.

M/O	PDU	Contents
O(134)	LMP_CLK_ADJ	Clk_Adj_ID Clk_Adj_Instant Clk_Adj_Offset Clk_Adj_Slots Clk_Adj_Mode Clk_Adj_Clk
O(134)	LMP_CLK_ADJ_ACK	Clk_Adj_ID
O(134)	LMP_CLK_ADJ_REQ	Clk_Adj_Offset Clk_Adj_Slots Clk_Adj_Period

Table 4.15: Piconet clock adjustment PDUs

Piconet clock adjustment requests may be made at any time after the Link Manager supported features responses have been processed.

The Central is free to reject any request for an adjustment; an implementation may, for instance, accept coarse clock adjustment requests from one Peripheral but reject all requests from any other Peripheral.

4.1.14.1 Central coarse adjustment of piconet clock

The coarse clock adjustment procedure shall only be used if all connected Peripherals declare support for the Coarse Clock Adjustment feature.

For all devices that may use Coarse Clock Adjustment Recovery Mode (see [Vol 2] Part B, Section 8.6.10.2), the RF channel indices used for the Synchronization Train (see [Vol 2] Part B, Section 2.6.4.8) shall be marked as unused in the AFH_Channel_Map for all logical links.

The Central may use the Clk_Adj_Period parameter from one or more Peripherals, in addition to other scheduling considerations, to select an optimal value of Clk_Adj_Slots.

The Central selects the parameters of the coarse clock adjustment. Some parameters shall remain the same for every LMP_CLK_ADJ PDU associated with a given adjustment. These are the number of slots (Clk_Adj_Slots) between 0 and 255, an offset within a slot (Clk_Adj_Offset) between –624 µs and 624 µs, a coarse clock adjustment instant (Clk_Adj_Instant), which is specified in the old time domain before the instant, and an identifier for the instant (Clk_Adj_ID). The Clk_Adj_Instant shall be at least 12 slots in the future and no more than 12 hours away. The Clk_Adj_ID shall be different for any two adjacent adjustments and for any two adjustments whose instants are closer together in time than the longest Link Supervision Timeout period

for any Peripheral. Each LMP_CLK_ADJ PDU also contains the value of CLK when it is transmitted (Clk_Adj_Clk) and a flag Clk_Adj_Mode, which shall be set to Before Instant if the LMP_CLK_ADJ PDU is sent before the instant or to After Instant if the LMP_CLK_ADJ PDU is sent on or after the instant.

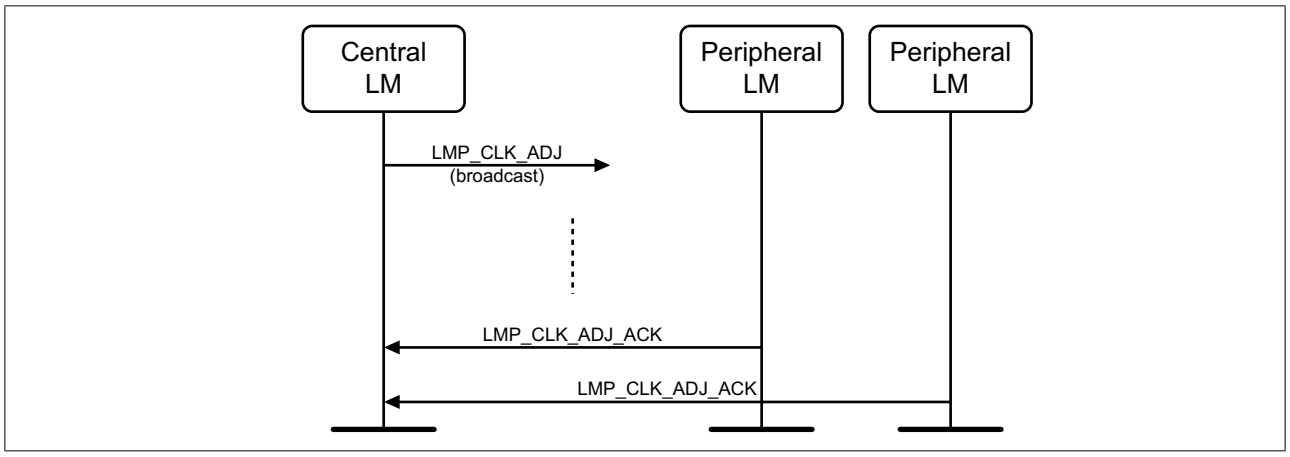
To initiate the coarse adjustment, the Central starts broadcasting the LMP_CLK_ADJ PDU using the APB-C logical link and, unless all Peripherals have acknowledged, it should broadcast the LMP_CLK_ADJ PDU at least 6 times before the adjustment instant. The Central shall continue to broadcast the LMP_CLK_ADJ PDU until all Peripherals have acknowledged the adjustment with an LMP_CLK_ADJ_ACK PDU or the Central has left Coarse Clock Adjustment Recovery Mode.

The Central shall not initiate a coarse clock adjustment if there are any transactions outstanding that involve LMP PDUs containing an instant or timing control flags including, but not limited to: role switch, adaptive frequency hopping, SCO, eSCO, sniff, sniff subrating, hold, and encryption pause and resume.

The Central shall not initiate another sequence containing an instant or timing control flags before an outstanding clock adjustment instant has been reached, while waiting for *CLK_adj_dragTO* to expire (see [Vol 2] Part B, Appendix B), or while in Coarse Clock Adjustment Recovery Mode (see [Vol 2] Part B, Section 8.6.10.2); however the latter may be terminated by the Central in order to initiate the request. If a request to initiate such a sequence is received before an outstanding clock adjustment instant is reached or *CLK_adj_dragTO* has been cancelled or has expired, the request shall be rejected with the Error_Code *Different Transaction Collision* (0x2A).

A Peripheral shall discard and not acknowledge an LMP_CLK_ADJ PDU with a value of Clk_Adj_ID that is the same as that in the most recently received LMP_CLK_ADJ PDU, if any, and any LMP_CLK_ADJ PDU with any parameters outside the valid range (see Section 5.2).

On receipt of an LMP_CLK_ADJ PDU that passes these checks, the Peripheral shall reply with an LMP_CLK_ADJ_ACK PDU (on the ACL-C logical link) containing the same value of Clk_Adj_ID as in the LMP_CLK_ADJ PDU and shall change the value of peripheral_clock_offset, if not already performed, as described in [Vol 2] Part B, Section 8.6.10.1, either at the adjustment instant or, if that has passed, immediately.



Sequence 25: Central initiates a coarse clock adjustment

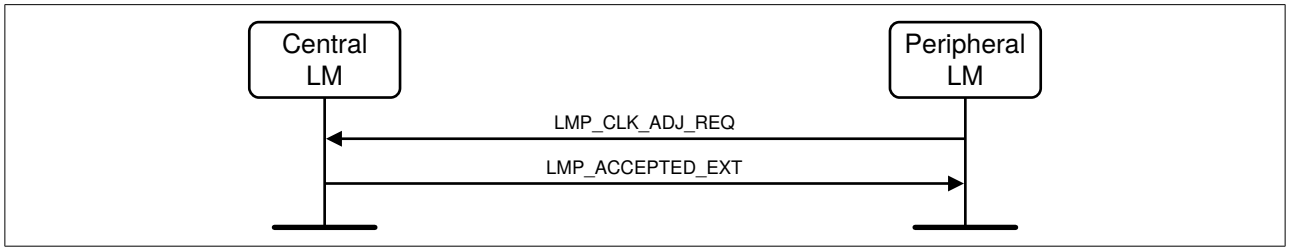
4.1.14.2 Peripheral request for coarse adjustment of piconet clock

The Peripheral may request a coarse adjustment of the piconet clock by sending the LMP_CLK_ADJ_REQ PDU to the Central. The LMP_CLK_ADJ_REQ PDU contains three parameters: Clk_Adj_Offset, Clk_Adj_Slots, and Clk_Adj_Period. The parameters Clk_Adj_Offset and Clk_Adj_Slots have the same meaning as in the LMP_CLK_ADJ PDU and Clk_Adj_Slots or Clk_Adj_Offset shall be non-zero. If non-zero, the parameter Clk_Adj_Period is an indication to the Central that the request is for any of a set of possible adjustments, all of which are equally acceptable to the Peripheral. These adjustments are those where the number of slots is equal to Clk_Adj_Slots + N × Clk_Adj_Period, where N is zero or a positive integer, and the offset within a slot equals Clk_Adj_Offset. For example, if Clk_Adj_Slots is 18 and Clk_Adj_Period is 48, then the acceptable adjustments are 18, 66, 114, 162, and 210 slots. A value of zero for Clk_Adj_Period indicates that an adjustment of any number of slots is equally acceptable to the Peripheral (that is, the Central may ignore the value of Clk_Adj_Slots). A request for a coarse adjustment shall also update the Central's local record of Clk_Adj_Period for the Peripheral.

The Peripheral may indicate its preferred Clk_Adj_Period to the Central without requesting a clock adjustment. In this case it shall set Clk_Adj_Slots and Clk_Adj_Offset to zero. Upon receiving an LMP_CLK_ADJ_REQ PDU with Clk_Adj_Slots and Clk_Adj_Offset set to zero, the Central shall respond with an LMP_ACCEPTED_EXT PDU and update its local record of Clk_Adj_Period for the Peripheral, but shall not initialize any clock adjustment. The Central is not required to honor a Peripheral's preferred Clk_Adj_Period when making coarse clock adjustments.

The Central may accept the coarse clock adjustment request from the Peripheral by sending an LMP_ACCEPTED_EXT PDU. This indicates that the Central intends to carry out a coarse clock adjustment with the requested value of Clk_Adj_Offset;

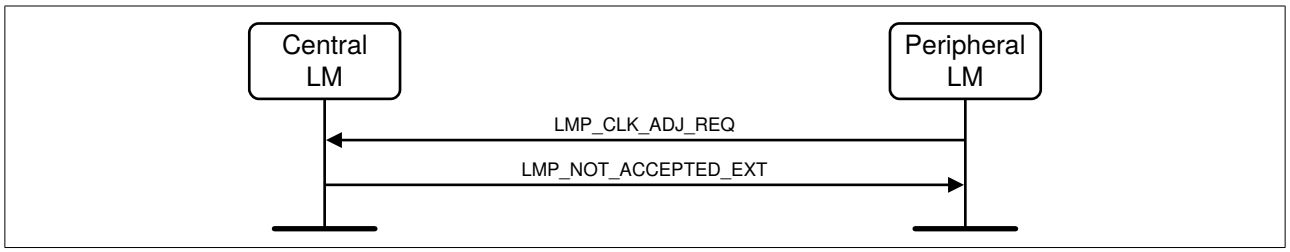
however, the value of Clk_Adj_Slots may be different to that requested and might not follow the Clk_Adj_Period parameter.



Sequence 26: Central accepts Peripheral request for a coarse clock adjustment

The Central may reject the coarse clock adjustment request from the Peripheral by sending an LMP_NOT_ACCEPTED_EXT PDU with the Error_Code *Command Disallowed* (0x0C) (see [Vol 1] Part F, Section 2.12). The Central's decision not to follow the Clk_Adj_Slots or Clk_Adj_Period parameters does not constitute a rejection.

The Central may implement the coarse clock adjustment request from the Peripheral by carrying out clock dragging (see [Vol 2] Part B, Section 8.6.10.3) to achieve the requested clock adjustment. If so, it shall send an LMP_NOT_ACCEPTED_EXT PDU with the Error_Code *Coarse Clock Adjustment Rejected but Will Try to Adjust Using Clock Dragging* (0x40) (see [Vol 1] Part F, Section 2.61).



Sequence 27: Central rejects a Peripheral request for coarse clock adjustment

4.1.15 Slot Availability Mask

SAM LMP sequences may be initiated at any time after Link Manager supported features responses have been processed.

Either the Central or the Peripheral may initiate the LMP_SAM_SET_TYPE0 PDU to configure the SAM type 0 submap of the local device. The initiation may be triggered by the HCI command HCI_Set_External_Frame_Configuration for MWS coexistence.

Either the Central or the Peripheral may initiate the LMP_SAM_DEFINE_MAP PDU to define a new or modify an existing local SAM slot map. The initiation may be triggered by the HCI command HCI_Set_MWS_PATTERN_Configuration for MWS coexistence. If a type 0 submap is used with the LMP_SAM_DEFINE_MAP PDU, the Controller shall

first execute the SAM set type 0 LMP sequence to configure the SAM type 0 submap, then the SAM define map LMP sequence itself.

Either the Central or the Peripheral may initiate the LMP_SAM_SWITCH PDU to switch to a local SAM slot map that has been defined by previous SAM set type 0 and SAM define map LMP sequences. This may be triggered by the real-time signals (e.g. MWS_PATTERN_Index, FRAME_SYNC, etc.) from the Coexistence Logical Interface (see [Vol 7] Part A), which contain information for the SAM_Index to be activated and the SAM anchor point for MWS coexistence. Piconet Clock Adjustment may be performed to create more available slot pairs per MWS frame before initiating the SAM switch LMP sequence.

These SAM LMP sequences will be described in detail in the following subsections.

M/O	PDU	Contents
O(138)	LMP_SAM_SET_TYPE0	Update_Mode SAM_Type0_Submap
O(138)	LMP_SAM_DEFINE_MAP	SAM_Index T_{SAM_SM} N_{SAM_SM} SAM_Submaps
O(138)	LMP_SAM_SWITCH	SAM_Index Timing_Control_Flags D_{SAM} SAM_Instant

Table 4.16: PDUs used for SAM negotiation

The LMP_SAM_SET_TYPE0 PDU contains the following SAM parameters from the sender:

1. Update_Mode: When Update_Mode is set to 0, the existing slot maps containing the type 0 submap are invalidated and the corresponding SAM_Index shall not be used until the map with that index has been redefined in a subsequent SAM define map LMP sequence. When Update_Mode is set to 1, the new type 0 submap shall take effect immediately. When Update_Mode is set to 2, the new type 0 submap shall take effect at the start of the next sub-interval.
2. SAM_Type0_Submap: This parameter specifies the types of each slot in the type 0 submap. The length of this parameter corresponds to 56 slots but, when it is used in a map, only the first T_{SAM_SM} entries are significant.

   Different maps can have different values of T_{SAM_SM}.

The LMP_SAM_DEFINE_MAP PDU contains the following parameters from the sender:

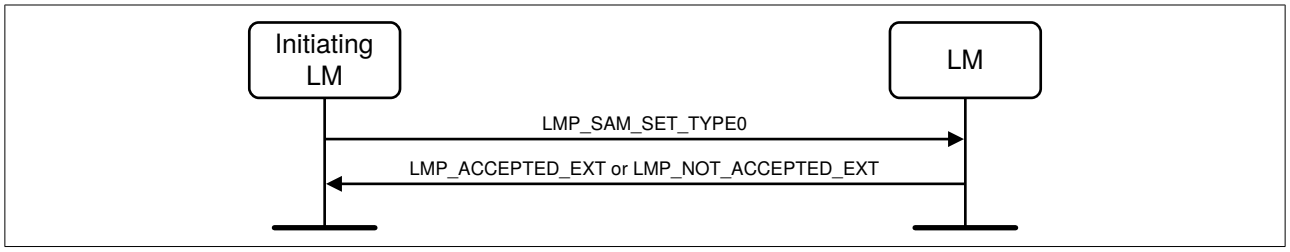
1. SAM_Index: Index of the SAM slot map this PDU applies to. If the same SAM_Index has been previously defined, then the previous map parameters associated with the map shall be discarded and replaced by the parameters contained in this PDU.
2. T_{SAM_SM}: Length of each SAM submap in slots. It shall be an even integer in the range 2 to 56.
3. N_{SAM_SM}: The number of SAM submaps in the SAM slot map.
4. SAM_Submaps: This parameter specifies the types of the SAM submaps, using 2 bits for each submap. The length of this parameter corresponds to 48 submaps, but only the first N_{SAM_SM} entries are significant.

The LMP_SAM_SWITCH PDU contains the following parameters from the sender:

1. SAM_Index: Index of the SAM slot map. It shall either be the index of a valid map, in which case SAM should be enabled and that map selected, or shall be 0xFF, which indicates that SAM should be disabled (meaning that, for SAM purposes, all slots are available for both transmission and reception). Disabling SAM does not invalidate a SAM slot map or the type 0 submap.
2. Timing_Control_Flags: This parameter is used to avoid clock wrap-around during the sequence, using one of the two initialization rules.
3. D_{SAM}: SAM offset that is used to compute the SAM anchor point. Only even values are valid.
4. SAM_Instant: Bits 27:1 of the Central's clock value when the SAM slot map is to be activated. This is used to indicate the first anchor point of the slot map. The new SAM slot map may be activated at SAM_Instant even if the Baseband acknowledgment is not received.

4.1.15.1 SAM type 0 submap configuration

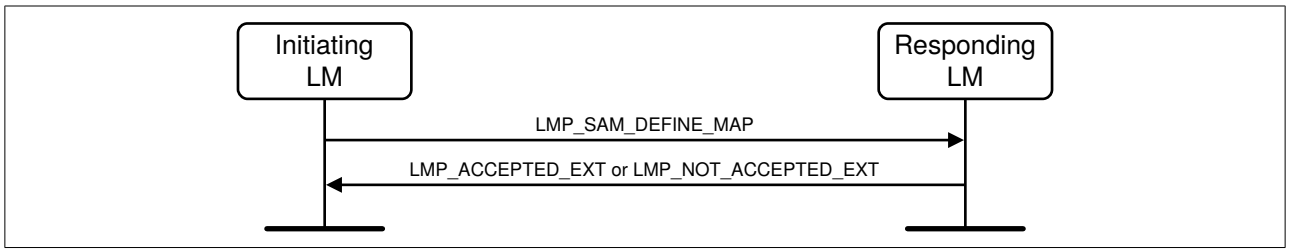
Either the Central or the Peripheral may initiate the SAM type 0 submap configuration sequence by sending an LMP_SAM_SET_TYPE0 PDU to the responder. Both devices shall save the SAM parameters contained in this PDU. Update_Mode shall not be set to 0 if the active SAM slot map contains a type 0 submap. If the responder can accept the parameters, it shall send an LMP_ACCEPTED_EXT PDU. If the Update_Mode parameter is set to 0 and the active SAM slot map contains a type 0 submap, it shall send an LMP_NOT_ACCEPTED_EXT PDU with the Error_Code *Invalid LMP Parameters* (0x1E).



Sequence 28: SAM type 0 submap configuration sequence

4.1.15.2 SAM slot map define

Either the Central or the Peripheral may initiate the SAM slot map define sequence by sending an LMP_SAM_DEFINE_MAP PDU. If N_{SAM_SM} is set to zero, the map shall be deleted. The SAM_Index parameter shall not be 0xFF or that of the currently selected map. The slot map may only contain a type 0 submap if the LMP_SAM_SET_TYPE0 sequence has already been used to define the type 0 submap. If the responder can accept the parameters, it shall send an LMP_ACCEPTED_EXT PDU. If a SAM type 0 submap is used in an LMP_SAM_DEFINE_MAP PDU without successfully completing the LMP_SAM_SET_TYPE0 sequence in advance, it shall send an LMP_NOT_ACCEPTED_EXT PDU with the Error_Code *Type0 Submap Not Defined* (0x41).



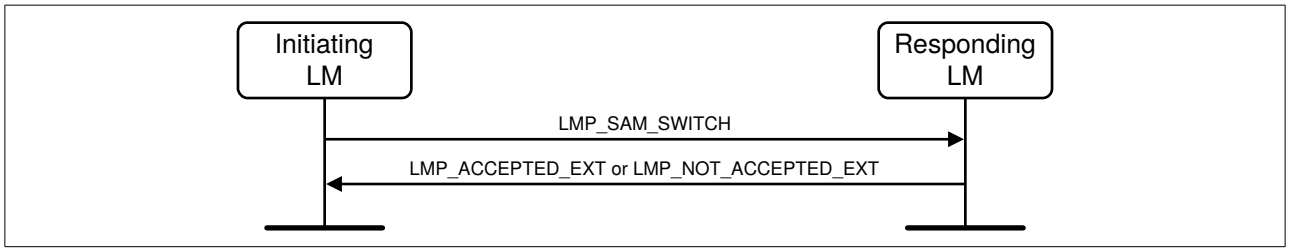
Sequence 29: SAM slot map define sequence

4.1.15.3 SAM switch sequence

Either the Central or the Peripheral may initiate the SAM switch sequence by sending an LMP_SAM_SWITCH PDU to the responder. There are two initialization procedures to prevent problems caused by clock wrap-around; see [Vol 2] Part B, Section 8.6.11.1 for details. The SAM_Index shall refer to a SAM slot map that is currently valid (the special value 0xFF is always valid). If the responder can accept the parameters, it shall send an LMP_ACCEPTED_EXT PDU. If the SAM_Index is invalid (e.g., the associated SAM_Index configuration has not yet been defined with LMP_SAM_DEFINE_MAP_SEQUENCE), it shall send an LMP_NOT_ACCEPTED_EXT PDU with the Error_Code *Invalid LMP Parameters* (0x1E).

Each Controller shall notify its Host of a successful SAM switch sequence specifying a different SAM_Index to that currently selected (it may, but need not, notify the Host if the

sequence specifies the current map). The currently selected map remains in effect if the change is not accepted.



Sequence 30: SAM switch sequence

4.1.15.4 SAM change during the transmission of a multi-slot packet

SAM slot map changes do not affect the transmission of a multi-slot packet that spans the change instant. In the case of a Central-to-Peripheral packet, the new map can mean that the Peripheral may choose not to reply to the packet.

4.1.15.5 SAM and role switching

The Central and Peripheral shall disable SAM at the role switch instant. If the role switch fails, both devices shall resume using the SAM parameters prior to the role switch instant

SAM mode may be reconfigured and re-enabled after the successful completion of a role switch using the new piconet clock.

4.1.15.6 SAM and Sniff mode

If sniff negotiation is requested when SAM is already enabled, the device should align sniff with SAM by choosing the sniff anchor point to be an available Central-to-Peripheral slot and the sniff period to be an integer multiple of T_{SAM}. If such alignment is not possible, the sniff configuration shall take precedence, even if this requires a device to transmit or receive on a slot marked as unavailable by SAM. The SAM slot maps shall be reinstated when devices exit Sniff mode.

Note: Even though Sniff mode overrides the SAM slot maps, a device still might not be able to transmit or receive because of scatternet commitments, a coexistence clash, or some other reason.

4.2 Security

Each random number mentioned in this section shall be created according to [Vol 2] Part H, Section 2.

4.2.1 Authentication

Two authentication procedures are defined: legacy and secure authentication. Legacy authentication shall be performed when at least one device does not support both the Secure Connections (Controller Support) and Secure Connections (Host Support) features and the local device allows legacy authentication to be used. Secure authentication shall be performed when both devices support the Secure Connections (Controller Support) and Secure Connections (Host Support) features.

The legacy authentication procedure is based on a challenge-response scheme as described in [Vol 2] Part H, Section 3.2.2. The verifier sends an LMP_AU_RAND PDU that contains a random number (the challenge) to the claimant. The claimant calculates a response, that is a function of this challenge, the claimant's BD_ADDR and a secret key. The response is sent back to the verifier, which checks if the response was correct or not. The response shall be calculated as described in [Vol 2] Part H, Section 6.1. A successful calculation of the authentication response requires that two devices share a secret key. This key is created as described in Section 4.2.2. Both the Central and the Peripheral can be verifiers. The sequences for legacy authentication are described in Section 4.2.1.1 and Section 4.2.1.2.

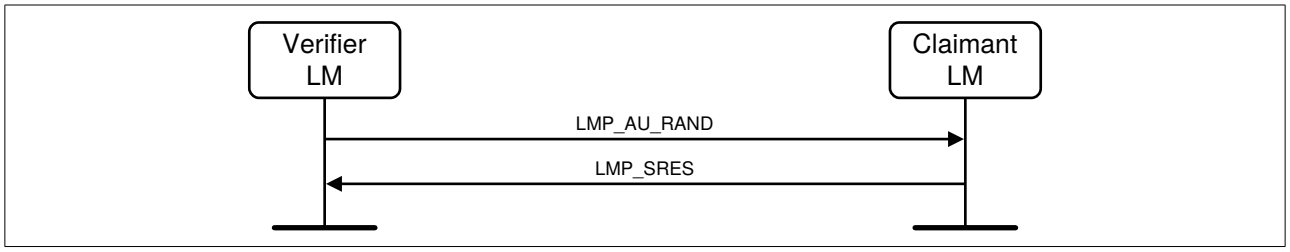
The secure authentication procedure is a challenge-response scheme as described in [Vol 2] Part H, Section 5. The verifier sends an LMP_AU_RAND PDU that contains a random number (the challenge) to the claimant. The claimant responds with another LMP_AU_RAND PDU also containing a random number. Both Link Managers calculate the Device Authentication Key using the h4 function (see [Vol 2] Part H, Section 7.7.7) and then calculate the SRES_C, SRES_P and ACO values using the h5 function (see [Vol 2] Part H, Section 7.7.8). The Peripheral (regardless of whether it was the verifier or claimant) sends its response (SRES_P) to the Central. The Central sends its response (SRES_C) to the Peripheral. A successful calculation of the authentication response requires that two devices share a secret key. The sequences for secure authentication are described in Section 4.2.1.2 and Section 4.2.1.4.

M/O	PDU	Contents
M	LMP_AU_RAND	Random_Number
M	LMP_SRES	Authentication_Rsp

Table 4.17: Authentication PDUs

4.2.1.1 Claimant has link key (legacy authentication)

If the claimant has a link key associated with the verifier, it shall calculate the response and sends it to the verifier with LMP_SRES. The verifier checks the response. If the response is not correct, the verifier may end the connection by sending an LMP_DETACH PDU with the Error_Code *Authentication Failure* (0x05), see Section 4.1.2.



Sequence 31: Authentication. Claimant has link key.

Upon reception of an LMP_AU_RAND, an LM shall reply with LMP_SRES before initiating its own authentication.

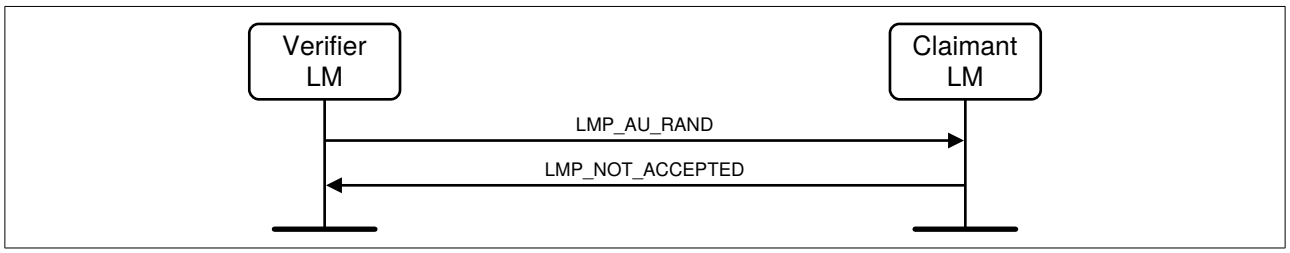
Note: There can be conflicting actions from the Central and the Peripheral which could lead to the two devices having different Authenticated Ciphering Offsets (ACOs, see [Vol 2] Part H, Section 6.1) when they calculate the encryption key. The following procedures assure that this cannot occur:

- procedure in Section 2.5.1 (Transaction Collision Resolution) when the Central and Peripheral simultaneously initiate an authentication.
- procedure in Section 4.2.5.1 when encryption parameters are being negotiated.

4.2.1.2 Claimant has no link key (legacy authentication and secure authentication)

If the claimant does not have a link key associated with the verifier it shall send an LMP_NOT_ACCEPTED PDU with the Error_Code *PIN or Key Missing* (0x06) after receiving an LMP_AU_RAND PDU ([Vol 1] Part F, Section 2.6).

Note: This sequence is identical for legacy authentication and secure authentication.



Sequence 32: Authentication fails. Claimant has no link key.

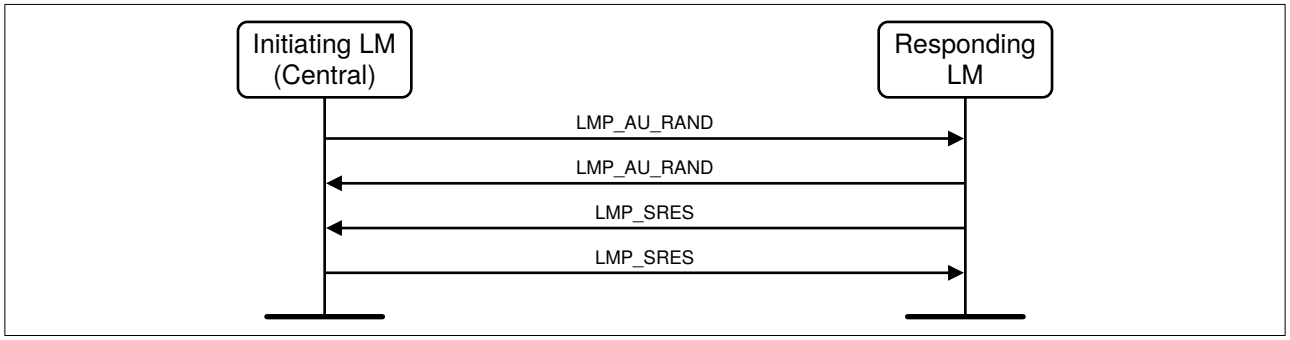
4.2.1.3 Repeated attempts

The scheme described in [Vol 2] Part H, Section 5.1 shall be applied when an authentication fails.

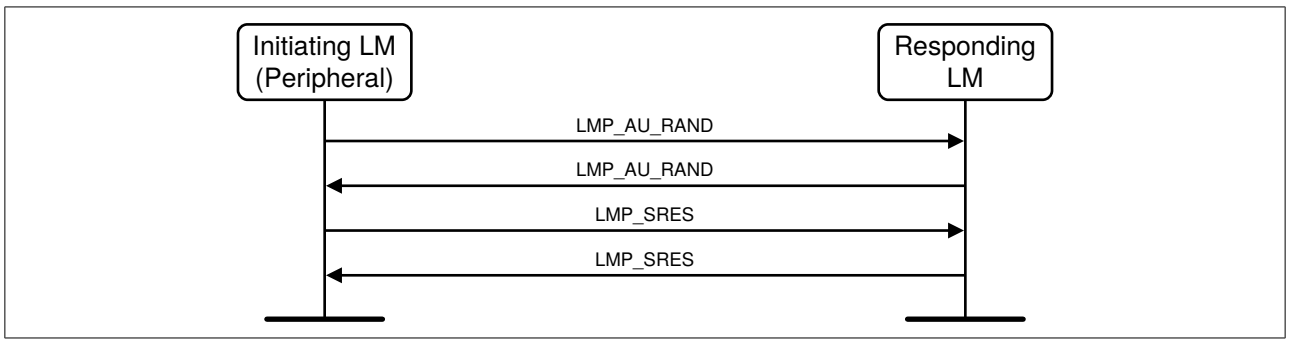
4.2.1.4 Responder has link key (secure authentication)

Both the Central and Peripheral LM act as verifier and claimant. The initiator is the device that sends the LMP_AU_RAND PDU first.

The initiator sends an LMP_AU_RAND PDU to the responder. If the responder has a link key associated with the initiator, it shall respond with an LMP_AU_RAND PDU. The initiator and responder shall calculate the response. The Peripheral responds first with an LMP_SRES PDU containing SRES_P. The Central shall then respond with an LMP_SRES PDU containing SRES_C. The Central shall verify that the SRES_P sent by the Peripheral matches the SRES_P calculated by the Central. The Peripheral shall verify that the SRES_C sent by the Central matches the SRES_C calculated by the Peripheral. If the response is not correct, then the device receiving the wrong SRES value may end the connection by sending an LMP_DETACH PDU with the Error_Code *Authentication Failure* (0x05) (see Section 4.1.2).



Sequence 33: Secure authentication. Responder has link key. Initiator is Central.



Sequence 34: Secure authentication. Responder has link key. Initiator is Peripheral.

In the case where the Central and Peripheral both initiate the secure authentication sequence, the Central shall reject the Peripheral's LMP_AU_RAND PDU with an LMP_NOT_ACCEPTED PDU with the Error_Code *LMP Error Transaction Collision / LL Procedure Collision* (0x23). The Peripheral shall send another LMP_AU_RAND PDU with transaction ID set to 0 (Central).

Note: Secure Authentication is a mutual authentication.

4.2.2 Pairing

When two devices do not have a common link key an initialization key (K_{init}) shall be created using either the pairing or Secure Simple Pairing procedures. When pairing is used, K_{init} shall be created based on a PIN, and a random number and a BD_ADDR. K_{init} shall be created as specified in [Vol 2] Part H, Section 6.3. When both devices have calculated K_{init} the link key shall be created, and a mutual authentication is performed. The pairing procedure starts with a device sending an LMP_IN_RAND PDU; this device is referred to as the "initiating LM" or "initiator" in Section 4.2.2.1 - Section 4.2.2.5. The other device is referred to as the "responding LM" or "responder". The PDUs used in the pairing procedure are:

M/O	PDU	Contents
M	LMP_IN_RAND	Random_Number
M	LMP_AU_RAND	Random_Number
M	LMP_SRES	Authentication_Rsp
M	LMP_COMB_KEY	Random_Number
M	LMP_UNIT_KEY	Key

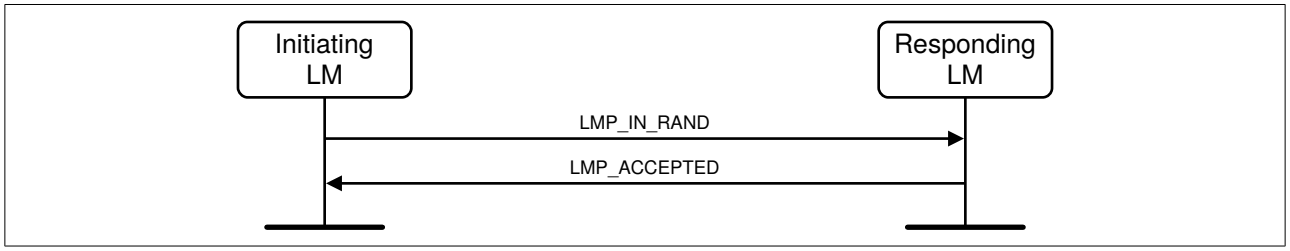
Table 4.18: Pairing PDUs

The Link Manager shall not send an LMP_UNIT_KEY PDU.

All sequences described in Section 4.2.2, including the mutual authentication after the link key has been created, shall form a single transaction. The transaction ID from the first LMP_IN_RAND shall be used for all subsequent sequences.

4.2.2.1 Responder accepts pairing and has a variable PIN

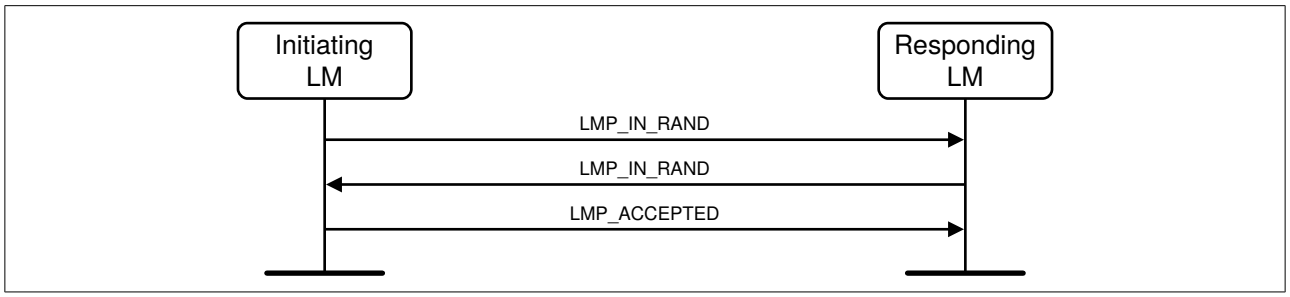
If the responder accepts the pairing and has a variable PIN, then it shall reply with an LMP_ACCEPTED PDU. Both devices shall then calculate K_{init} based on the BD_ADDR of the responder and the procedure continues with creation of the link key; see Section 4.2.2.4.



Sequence 35: Pairing accepted. Responder has a variable PIN. Initiator has a variable or fixed PIN.

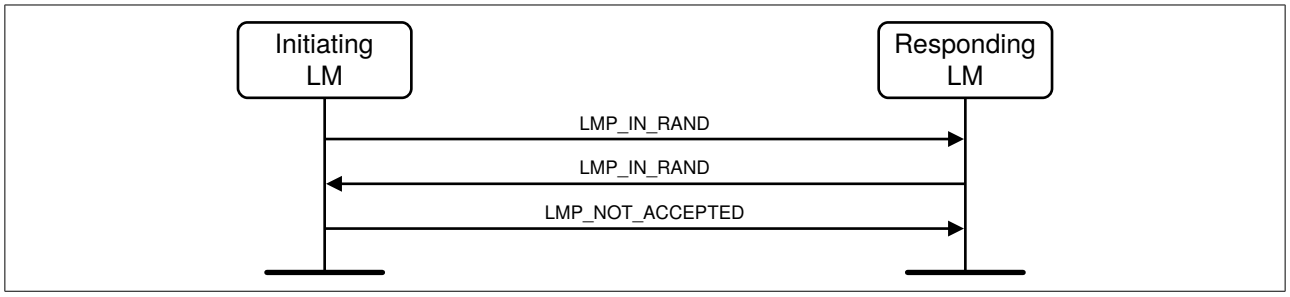
4.2.2.2 Responder accepts pairing and has a fixed PIN

If the responder accepts the pairing and has a fixed PIN, then it shall generate a new random number and send it back in an LMP_IN_RAND PDU. If the initiator has a variable PIN, then it shall accept the LMP_IN_RAND PDU and shall respond with an LMP_ACCEPTED PDU. Both sides shall then calculate K_{init} based on the last IN_RAND and the BD_ADDR of the initiator. The procedure continues with creation of the link key; see Section 4.2.2.4.



Sequence 36: Responder has a fixed PIN and initiator has a variable PIN

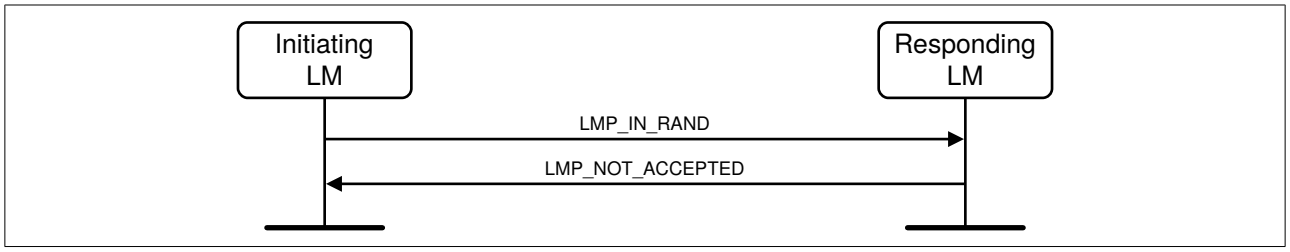
If the responder has a fixed PIN and the initiator also has a fixed PIN, then the second LMP_IN_RAND shall be rejected by the initiator sending an LMP_NOT_ACCEPTED PDU with the Error_Code *Pairing not Allowed* (0x18).



Sequence 37: Both devices have a fixed PIN

4.2.2.3 Responder rejects pairing

If the responder rejects pairing (e.g., because the user has disabled pairing on the device) it shall send an LMP_NOT_ACCEPTED PDU with the Error_Code *Pairing not Allowed* (0x18) after receiving an LMP_IN_RAND PDU.



Sequence 38: Responder rejects pairing

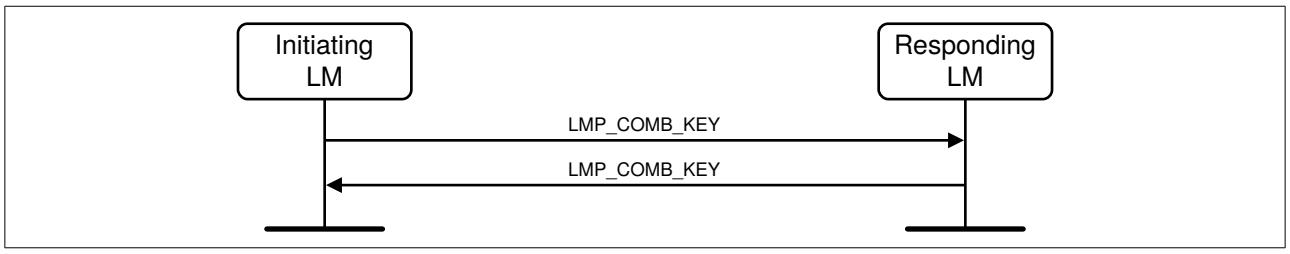
4.2.2.4 Creation of the link key

When K_{init} is calculated in both devices the link key shall be created. This link key will be used in the authentication between the two devices for all subsequent connections until it is changed; see Section 4.2.3 and Section 4.2.4. The link key created in the pairing procedure will be a combination key; both devices send an LMP_COMB_KEY PDU and the link key shall be calculated as described in [Vol 2] Part H, Section 3.2.

The content of the LMP_COMB_KEY PDU is LK_RAND bitwise XORed with K_{init}. Any device configured to use a combination key shall store the link key.

When the new link key has been created mutual authentication shall be performed to confirm that the same link key has been created in both devices. After mutual authentication, if encryption is enabled, the initiating device shall pause and immediately resume encryption to produce a new encryption key.

Note: This will cause a new encryption key to be generated from the ACO created during the mutual authentication process and, when E0 encryption is used, the random number sent in the LMP_START_ENCRYPTION_REQ PDU which occurs in response to the resumption of encryption.



Sequence 39: Creation of the link key

If, in sequence 39, either device sends an LMP_UNIT_KEY PDU, the other device shall respond with an LMP_NOT_ACCEPTED PDU with the Error_Code set to *Pairing with Unit Key Not Supported* (0x29).

4.2.2.5 Repeated attempts

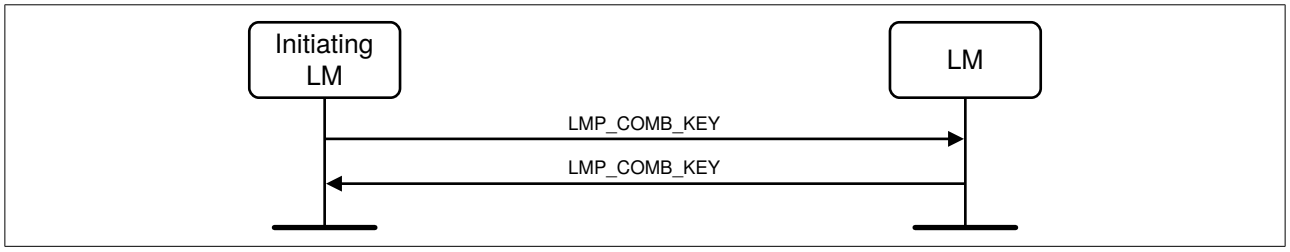
When the authentication after creation of the link key fails because of an incorrect Authentication_Rsp, the scheme described in [Vol 2] Part H, Section 5.1 shall be applied.

4.2.3 Change link key

The link key can be changed. The contents of the LMP_COMB_KEY PDU is protected by a bitwise XOR with the current link key.

M/O	PDU	Contents
M	LMP_COMB_KEY	Random_Number

Table 4.19: Change link key PDU



Sequence 40: Successful change of the link key

The new link key shall be stored and the old link key shall be discarded. The new link key shall be used as link key for all the following connections between the two devices until the link key is changed again. The new link key also becomes the current link key. It will remain the current link key until the link key is changed again, or until a temporary link key is created, see Section 4.2.4.

When the new link key has been created, mutual or secure authentication shall be performed to confirm that the same link key has been created in both devices.

If both devices support the Secure Connections (Controller Support) and Secure Connections (Host Support) features, the device that initiated the change link key shall initiate the Secure Authentication procedure. Otherwise, the first authentication in the mutual authentication is performed with the device that initiated the change link key as verifier. When finalized an authentication in the reverse direction is performed.

After mutual or secure authentication, if encryption is enabled, the initiating device shall pause and immediately resume encryption to produce a new encryption key.

Note: This will cause a new encryption key to be generated from the ACO created during the mutual authentication process, and when E0 encryption is used, the random number sent in the LMP_START_ENCRYPTION_REQ PDU which occurs in response to the resumption of encryption.

4.2.4 Change current link key type

The current link key can be a semi-permanent link key or a temporary link key. It may be changed temporarily, but the change shall only be valid for the current connection, see [Vol 2] Part H, Section 3.1. Changing to a temporary link key is necessary if the piconet is to support encrypted broadcast. The current link key shall not be changed before the connection establishment procedure has completed.

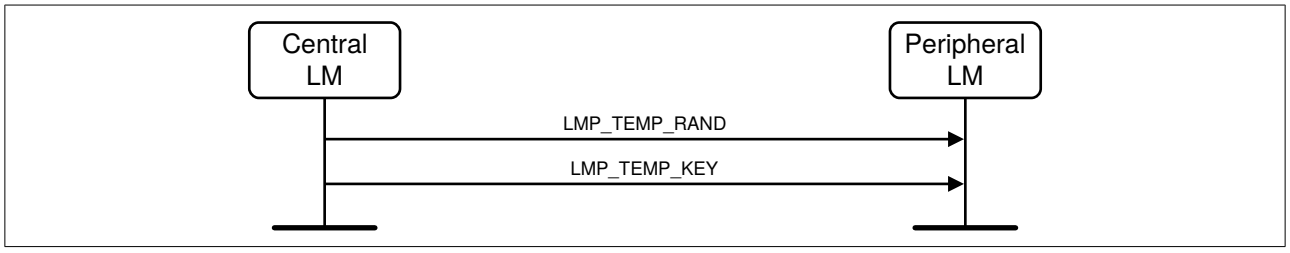
M/O	PDU	Contents
O(23)	LMP_TEMP_RAND	Random_Number
O(23)	LMP_TEMP_KEY	Key
O(23)	LMP_USE_SEMI_PERMANENT_KEY	*none*

Table 4.20: Change current link key PDU

4.2.4.1 Change to a temporary link key

The Central starts by creating the temporary link key K_temp as specified in [Vol 2] Part H (EQ 4). Then the Central shall generate a random number, RAND, and shall send it to the Peripheral in an LMP_TEMP_RAND PDU. Both sides then calculate an overlay denoted OVL as OVL= E_{22} (current link key, RAND, 16). The Central shall then send K_temp protected by XORing with OVL to the Peripheral in an LMP_TEMP_KEY PDU. The Peripheral calculates K_temp, based on OVL, that becomes the current link key. It shall be the current link key until the devices fall back to the semi-permanent link key, see Section 4.2.4.2.

Note: The terminology in this section is the same as used in [Vol 2] Part H, Section 3.2.8.



Sequence 41: Change to a temporary link key

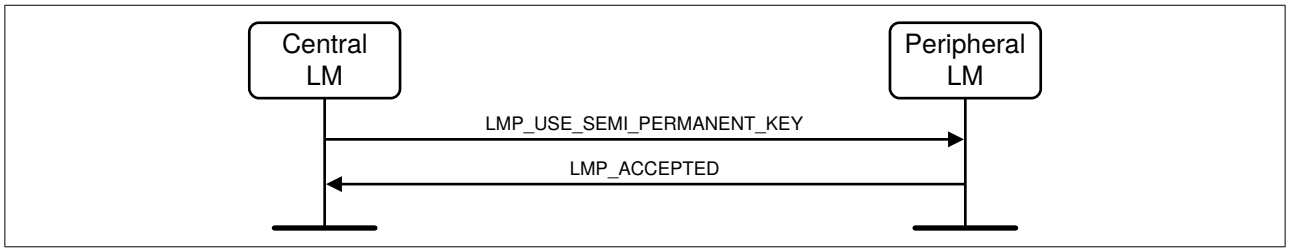
All sequences described in Section 4.2.4.1, including the mutual authentication after K_temp has been created, shall form a single transaction. The transaction ID shall be set to 0.

When the devices have changed to the temporary key, a mutual authentication shall be made to confirm that the same link key has been created in both devices. The first authentication in the mutual authentication shall be performed with the Central as verifier. When finalized an authentication in the reverse direction is performed.

If the mutual authentication fails at either side, then the LM of the verifier shall start the detach procedure.

4.2.4.2 Semi-permanent link key becomes current link key

After the current link key has been changed to K_temp, this change can be undone and the semi-permanent link key becomes the current link key again. If encryption is used on the link, the procedure to go back to the semi-permanent link key shall be immediately followed by the Central stopping encryption using the procedure described in Section 4.2.5.4. Encryption may be restarted by the Central according to the procedures in Section 4.2.5.3. This is to assure that encryption with encryption parameters known by other devices in the piconet is not used when the semi-permanent link key is the current link key.



Sequence 42: Link key changed to the semi-permanent link key

4.2.5 Encryption

If at least one authentication has been performed encryption may be used. Two encryption mechanisms are defined: E0 encryption (legacy) and AES-CCM encryption. If both devices support the Secure Connections (Controller Support) and Secure Connections (Host Support) features, then AES-CCM shall be used when encryption is enabled. If at least one device does not support both the Secure Connections (Controller Support) and Secure Connections (Host Support) features, then E0 shall be used when encryption is enabled.

In order for the Central to use the same encryption parameters for all Peripherals in the piconet where E0 encryption would be used it shall issue a temporary key, K_temp. The Central shall make this key the current link key for all Peripherals in the piconet where E0 encryption would be used before encryption is started, see Section 4.2.4. This is required if broadcast packets are to be encrypted.

Note: Packets encrypted with broadcast encryption can not be received by Peripherals that have AES-CCM encryption enabled. When the local Controller supports Secure Connections and there are not any Peripherals in the piconet that do not support Secure Connections, broadcast packets will not be encrypted and may be received by Peripherals that support Secure Connections.

M/O	PDU	Contents
O (2)	LMP_ENCRYPTION_MODE_REQ	Encryption_Mode
O (2)	LMP_ENCRYPTION_KEY_SIZE_REQ	Key_Size
O (2)	LMP_START_ENCRYPTION_REQ	Random_Number
O (2)	LMP_STOP_ENCRYPTION_REQ	*none*
O (42)	LMP_PAUSE_ENCRYPTION_REQ	*none*
O (42)	LMP_RESUME_ENCRYPTION_REQ	*none*
O (136)	LMP_PAUSE_ENCRYPTION_AES_REQ	Random_Number

Table 4.21: Encryption handling PDU

All sequences described in Section 4.2.5 shall form a single transaction. The transaction ID from the LMP_ENCRYPTION_MODE_REQ PDU shall be used for all start encryption and stop encryption sequences.

Where the specification requires a device to resume encryption as part of one procedure and then pause it as part of a following procedure, the device may omit both the resume and the subsequent pause.

4.2.5.1 Encryption mode

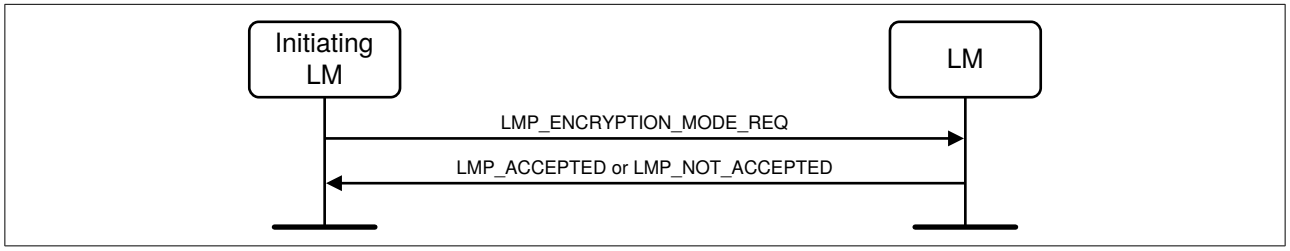
The Central and the Peripheral must agree upon whether to use encryption (Encryption_Mode=1 in LMP_ENCRYPTION_MODE_REQ) or not (Encryption_Mode=0). If the semi-permanent key is used, encryption shall only apply to point-to-point packets. If the temporary link key is used, encryption shall apply to both point-to-point packets and broadcast packets. If Central and Peripheral agree on the encryption mode, the Central continues to give more detailed information about the encryption.

If a device receives an LMP_ENCRYPTION_MODE_REQ with an Encryption_Mode value of 2 then the device should treat it as if the Encryption_Mode value was 1.

If both devices support both the Secure Connections (Controller Support) and Secure Connections (Host Support) features, setting the Encryption_Mode to 0 shall not be allowed. If a device receives an LMP_ENCRYPTION_MODE_REQ PDU with Encryption_Mode set to 0, it shall respond with an LMP_NOT_ACCEPTED PDU with Error_Code *Encryption Mode Not Allowed* (0x25).

The initiating LM shall pause traffic on the ACL-U logical link (see [Vol 2] Part B, Section 5.3.1). The initiating device shall then send the LMP_ENCRYPTION_MODE_REQ PDU. If the responding device accepts the change in encryption mode then it shall complete the transmission of the current packet on the ACL logical transport and shall then suspend transmission on the ACL-U logical link. The responding device shall then send the LMP_ACCEPTED PDU.

ACL-U logical link traffic shall only be resumed after the attempt to encrypt or decrypt the logical transport is completed, i.e. at the end of Sequence 43 (on failure), 45, 46, or 47.



Sequence 43: Negotiation for encryption mode

After a device has sent an LMP_ENCRYPTION_MODE_REQ PDU it shall not send an LMP_AU_RAND PDU before encryption is started. After a device has received an LMP_ENCRYPTION_MODE_REQ PDU and sent an LMP_ACCEPTED PDU it shall not send an LMP_AU_RAND PDU before encryption is started. If an LMP_AU_RAND PDU is sent violating these rules, the claimant shall respond with an LMP_NOT_ACCEPTED PDU with the Error_Code *LMP PDU Not Allowed* (0x24). This assures that devices will not have different ACOs when they calculate the encryption key. If the encryption mode is not accepted or the encryption key size negotiation results in disagreement the devices may send an LMP_AU_RAND PDU again.

4.2.5.2 Encryption key size

Note: This section uses the same terms as in [Vol 2] Part H, Section 4.1.

The Central sends an LMP_ENCRYPTION_KEY_SIZE_REQ PDU including the suggested key size L_sug_c, that shall initially be equal to L_max_c. If L_min_p ≤ L_sug_c ≤ L_max_p, the Peripheral shall respond with an LMP_ACCEPTED PDU and L_sug_c shall be used as the key size.

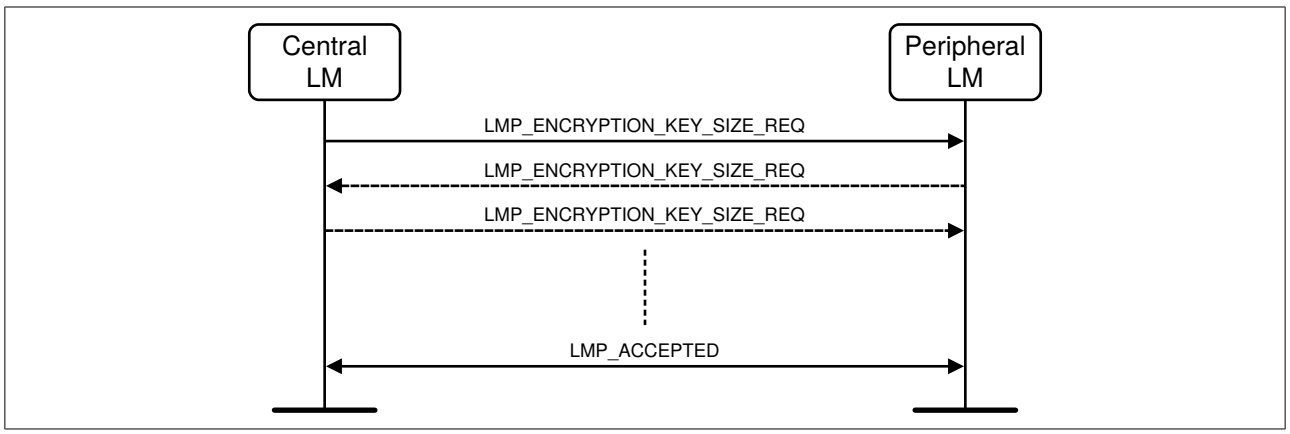
If L_sug_c > L_max_p, the Peripheral shall send back an LMP_ENCRYPTION_KEY_SIZE_REQ PDU including the Peripheral's suggested key size L_sug_p set to L_max_p. If L_sug_c < L_min_p, the Peripheral shall send back an LMP_NOT_ACCEPTED PDU with the Error_Code *Unsupported LMP Parameter Value* (0x20) and the devices shall not communicate using encryption.

If the Peripheral sends back an LMP_ENCRYPTION_KEY_SIZE_REQ PDU, then the Central performs the corresponding test on the Peripheral's suggestion. This procedure is repeated until a key size agreement is reached or it becomes clear that no such agreement can be reached. If an agreement is reached a device sends an LMP_ACCEPTED PDU and the key size in the last LMP_ENCRYPTION_KEY_SIZE_REQ PDU shall be used.

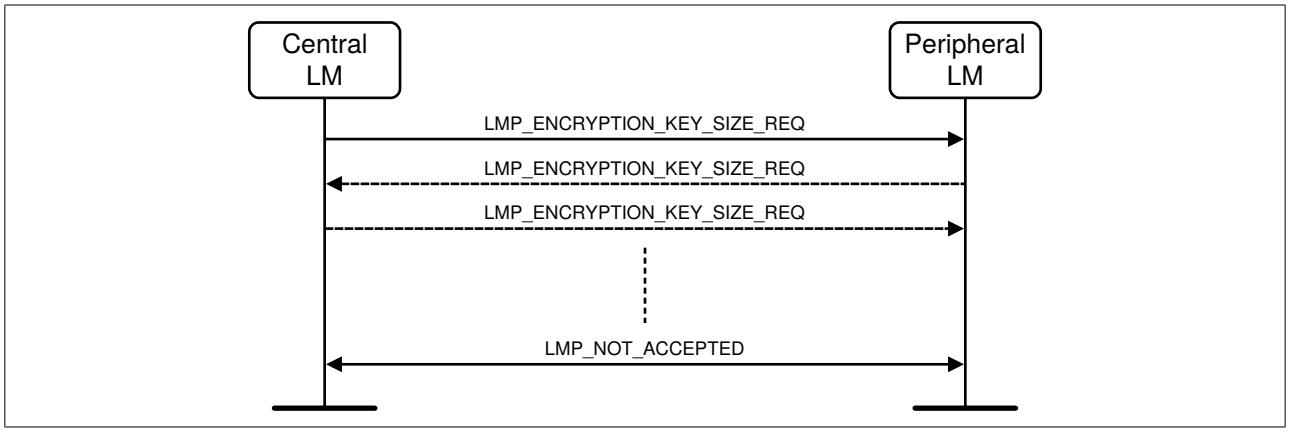
If a key size is agreed, encryption is then started; see Section 4.2.5.3. If an agreement is not reached a device sends an LMP_NOT_ACCEPTED PDU with the Error_Code *Unsupported LMP Parameter Value* (0x20) and the devices shall not communicate using encryption.

L_max_c and L_max_p shall be set to at least 7 octets. L_min_c and L_min_p should be set to at least 7 octets. The values of L_max_c, L_min_c, L_max_p, and L_min_p shall not change during an ACL connection between the Central and the Peripheral.

Note: If the Host of either the Central or the Peripheral uses services that require security mode 4 (see [Vol 3] Part C, Section 5.2.2.8), a key size longer than the key size negotiated by the two Link Managers can be enforced.



Sequence 44: Encryption key size negotiation successful



Sequence 45: Encryption key size negotiation failed

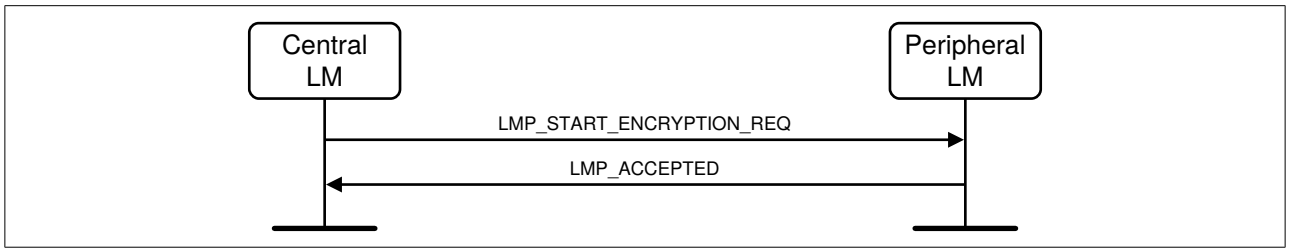
4.2.5.3 Start encryption

To start encryption, the Central issues the random number EN_RAND and calculates the encryption key. See [Vol 2] Part H, Section 3.2.5. The random number shall be the same for all Peripherals in the piconet when broadcast encryption is used. The Central then sends an LMP_START_ENCRYPTION_REQ PDU, that includes EN_RAND.

The Peripheral shall calculate the encryption key when this message is received and shall acknowledge with an LMP_ACCEPTED PDU. For E0, the encryption key shall be calculated using the E3 algorithm (see [Vol 2] Part H, Section 6.4). For AES-CCM, the encryption key shall be calculated using the h3 algorithm (see [Vol 2] Part H, Section 7.7.6).

Note: For AES-CCM, the EN_RAND is not used when creating the encryption key.

If encryption has been paused, then this sequence shall not be used.



Sequence 46: Start encryption

Starting encryption shall be performed in three steps:

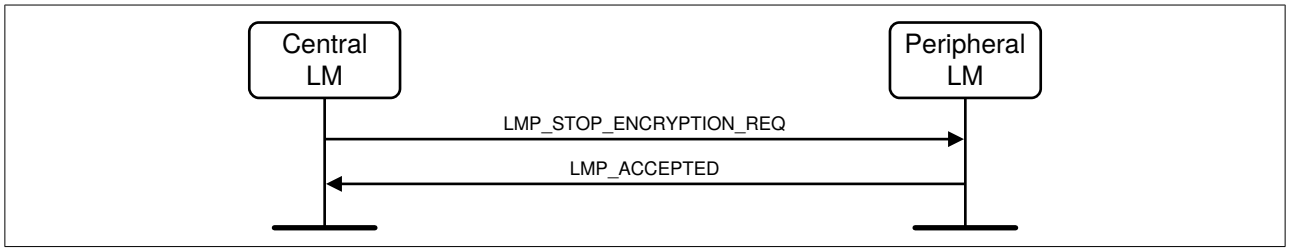
1. Central is configured to transmit unencrypted packets and to receive encrypted packets.
2. Peripheral is configured to transmit and receive encrypted packets.
3. Central is configured to transmit and receive encrypted packets.

Between step 1 and step 2, Central-to-Peripheral transmission is possible. This is when an LMP_START_ENCRYPTION_REQ PDU is transmitted. Step 2 is triggered when the Peripheral receives this message. Between step 2 and step 3, Peripheral-to-Central transmission is possible. This is when an LMP_ACCEPTED PDU is transmitted. Step 3 is triggered when the Central receives this message.

4.2.5.4 Stop encryption

To stop encryption a device shall send an LMP_ENCRYPTION_MODE_REQ PDU with the parameter Encryption_Mode equal to 0 (no encryption). The other device responds with an LMP_ACCEPTED PDU or an LMP_NOT_ACCEPTED PDU (the procedure is described in Sequence 43 in Section 4.2.5.1). If accepted, encryption shall be stopped by the Central sending an LMP_STOP_ENCRYPTION_REQ PDU and the Peripheral shall respond with an LMP_ACCEPTED PDU according to Sequence 47.

If encryption has been paused, then this sequence shall not be used.



Sequence 47: Stop encryption

Stopping encryption shall be performed in three steps, similar to the procedure for starting encryption.

1. Central is configured to transmit encrypted packets and to receive unencrypted packets.
2. Peripheral is configured to transmit and receive unencrypted packets.
3. Central is configured to transmit and receive unencrypted packets.

Between step 1 and step 2 Central to Peripheral transmission is possible. This is when an LMP_STOP_ENCRYPTION_REQ PDU is transmitted. Step 2 is triggered when the Peripheral receives this message. Between step 2 and step 3 Peripheral to Central

transmission is possible. This is when an LMP_ACCEPTED PDU is transmitted. Step 3 is triggered when the Central receives this message.

4.2.5.5 Pause encryption

For E0 encryption:

- To pause encryption without disabling encryption, a device shall finalize the transmission of the current ACL-U data packet and then send an LMP_PAUSE_ENCRYPTION_REQ PDU (with the transaction ID set to the role of the device at the time the LMP_PAUSE_ENCRYPTION_REQ PDU is sent).

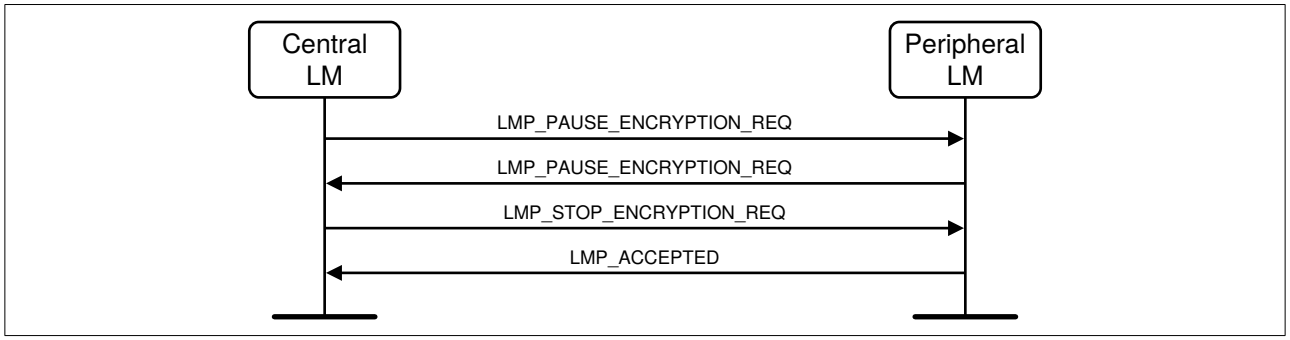
For AES-CCM encryption:

- To pause encryption without disabling encryption, a device shall finalize the transmission of the current ACL-U data packet and then send an LMP_PAUSE_ENCRYPTION_AES_REQ PDU (with the transaction ID set to the role of the device at the time the LMP_PAUSE_ENCRYPTION_AES_REQ PDU is sent). The LMP_PAUSE_ENCRYPTION_AES_REQ PDU includes a random number EN_RAND.

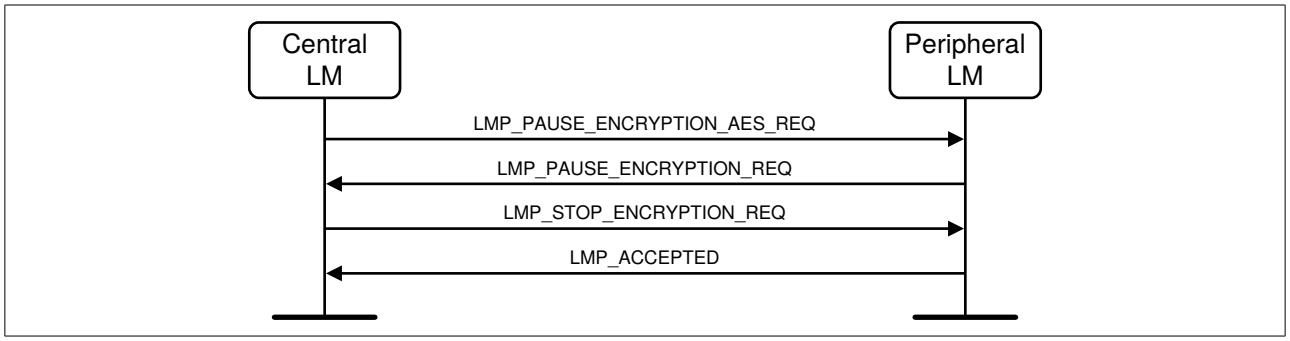
If the responding device is a Central, then the Central shall finalize the transmission of the current ACL-U data packet and then respond with an LMP_STOP_ENCRYPTION_REQ PDU to the Peripheral.

If the responding device is a Peripheral, then the Peripheral shall finalize the transmission of the current ACL-U data packet and then respond with an LMP_PAUSE_ENCRYPTION_REQ PDU. The Central shall respond to the LMP_PAUSE_ENCRYPTION_REQ PDU with an LMP_STOP_ENCRYPTION_REQ PDU to the Peripheral.

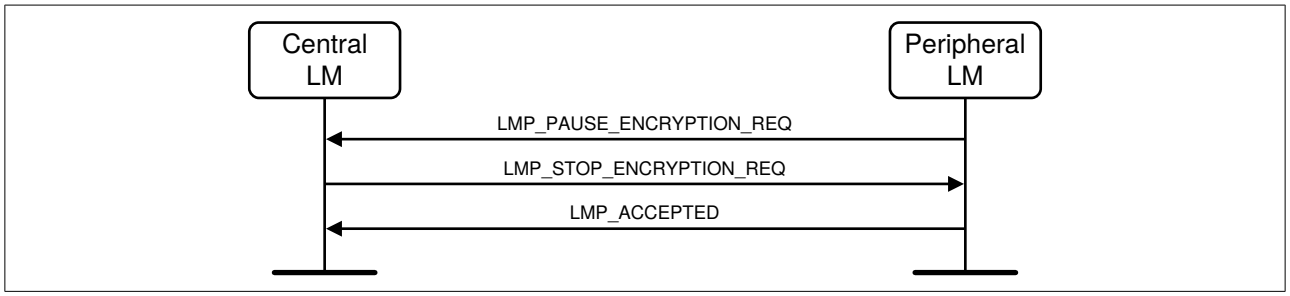
When the Peripheral receives the LMP_STOP_ENCRYPTION_REQ PDU it shall respond with an LMP_ACCEPTED PDU.



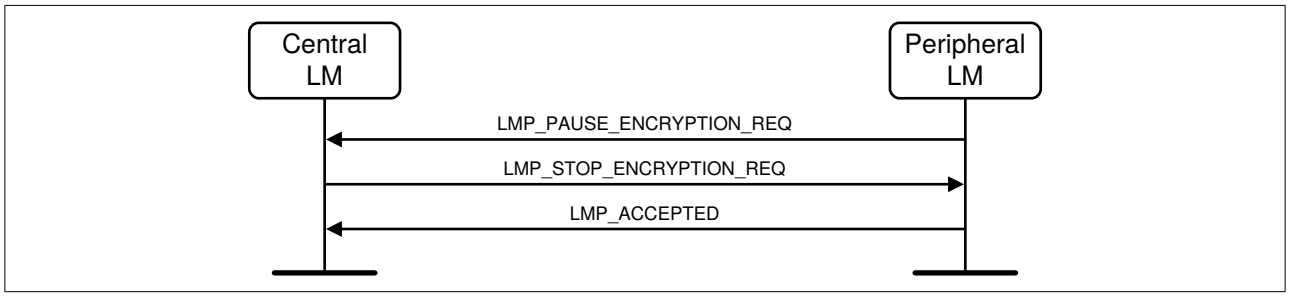
Sequence 48: Central-initiated pausing of encryption (E0)



Sequence 49: Central-initiated pausing of encryption (AES-CCM)



Sequence 50: Peripheral-initiated pausing of encryption (E0)



Sequence 51: Peripheral-initiated pausing of encryption (AES-CCM)

For E0 encryption:

- The LMP_PAUSE_ENCRYPTION_REQ PDU and LMP_STOP_ENCRYPTION_REQ PDU shall only be rejected when a transaction collision needs to be resolved.

For AES-CCM encryption:

- The LMP_PAUSE_ENCRYPTION_AES_REQ PDU and LMP_STOP_ENCRYPTION_REQ PDU shall only be rejected when a transaction collision needs to be resolved.

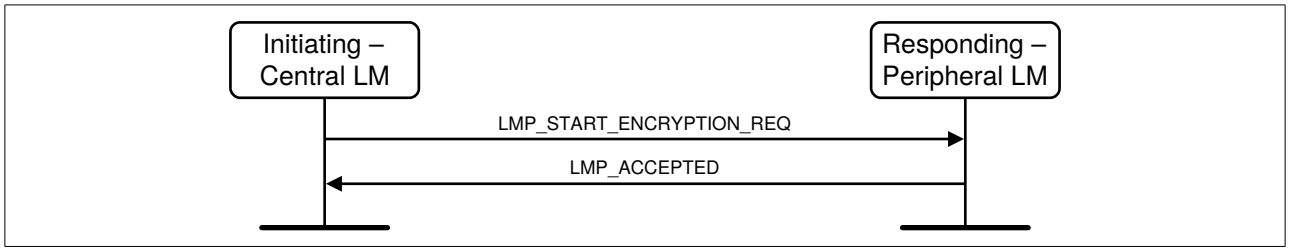
Pausing encryption shall be performed in three steps, similar to the procedure for stopping encryption.

1. Central is configured to transmit encrypted packets and to receive unencrypted packets.
2. Peripheral is configured to transmit and receive unencrypted packets.
3. Central is configured to transmit and receive unencrypted packets.

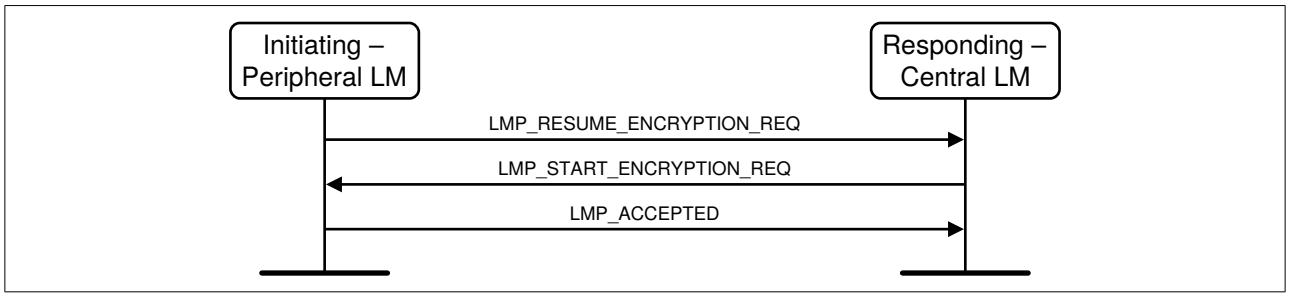
Between step 1 and step 2 Central-to-Peripheral transmission is possible. This is when the LMP_STOP_ENCRYPTION_REQ PDU is transmitted from the Central to the Peripheral. Step 2 is triggered when the Peripheral receives this message. Between step 2 and step 3 Peripheral-to-Central transmission is possible. This is when an LMP_ACCEPTED PDU is transmitted. Step 3 is triggered when the Central receives this message.

Note: A device can only restart ACL-U data traffic by resuming encryption using the procedures in Section 4.2.5.6.

4.2.5.6 Resume encryption



Sequence 52: Initiating Central LM resumes encryption



Sequence 53: Initiating Peripheral LM resumes encryption

For E0 encryption:

- If the responding device is a Peripheral, then the Peripheral shall calculate the encryption key and respond with an LMP_ACCEPTED PDU.
- If the responding device is a Central, then the Central shall respond with an LMP_START_ENCRYPTION_REQ PDU. The Peripheral, upon receiving the

LMP_START_ENCRYPTION_REQ PDU from the Central, shall calculate the encryption key and respond with an LMP_ACCEPTED PDU.

For AES-CCM encryption:

- If the resume encryption was the result of a Change Connection Link Key procedure, the LMs shall calculate a new encryption key using the h3 algorithm (see [Vol 2] Part H, Section 7.7.6).
- If the responding device is a Peripheral, then the Peripheral shall respond with an LMP_ACCEPTED PDU.
- If the responding device is a Central, then the Central shall respond with an LMP_START_ENCRYPTION_REQ PDU. The Peripheral, upon receiving the LMP_START_ENCRYPTION_REQ PDU from the Central, shall respond with an LMP_ACCEPTED PDU.

Note: When AES-CCM is used, the EN_RAND value in the LMP_START_ENCRYPTION_REQ PDU is not used.

The LMP_RESUME_ENCRYPTION_REQ PDU and the LMP_START_ENCRYPTION_REQ PDU shall not be rejected.

Resuming encryption shall be performed in three steps, similar to the procedure for starting encryption:

1. Central is configured to transmit unencrypted packets and to receive encrypted packets.
2. Peripheral is configured to transmit and receive encrypted packets.
3. Central is configured to transmit and receive encrypted packets.

Between step 1 and step 2, Central-to-Peripheral transmission is possible. This is when the LMP_START_ENCRYPTION_REQ PDU is transmitted from the Central. Step 2 is triggered when the Peripheral receives this message. Between step 2 and step 3, Peripheral-to-Central transmission is possible. This is when an LMP_ACCEPTED PDU is transmitted. Step 3 is triggered when the Central receives this message.

Note: For a Peripheral-initiated resumption of encryption, step 1 is not started when the Central has received the LMP_RESUME_ENCRYPTION_REQ PDU from the Peripheral, but when the Central sends the LMP_START_ENCRYPTION_REQ PDU.

Once encryption has been resumed, the device shall restart ACL-U traffic.

4.2.5.7 Change encryption key or random number

If the encryption key or encryption random number need to be changed, or if the current link key needs to be changed according to the procedures in Section 4.2.3

and Section 4.2.4, encryption shall be paused and resumed after completion, using the procedures in Section 4.2.5.5 and Section 4.2.5.6, for the new parameters to be valid. If the Pause Encryption feature is not supported by both devices, encryption shall be stopped and re-started after completion, using the procedures in Section 4.2.5.3 and Section 4.2.5.4, for the new parameters to be valid.

4.2.5.8 Encryption key refresh

When E0 encryption is used, the Link Manager shall refresh the encryption key within 2^{28} ticks of the Bluetooth clock from the previous start or resume of encryption. When AES-CCM encryption is used, the Link Manager shall refresh the encryption key before either the PayloadCounter or dayCounter roll over. To refresh the encryption key, the Link Manager shall Pause encryption using the procedure in Section 4.2.5.5 and immediately Resume encryption using the procedure in Section 4.2.5.6.

Note: The roll over will occur at least 2^{38} ticks of the Bluetooth clock after the previous start of encryption.

If the encryption key has not been refreshed before the rollover event, the link shall be terminated immediately.

4.2.6 Request supported encryption key size

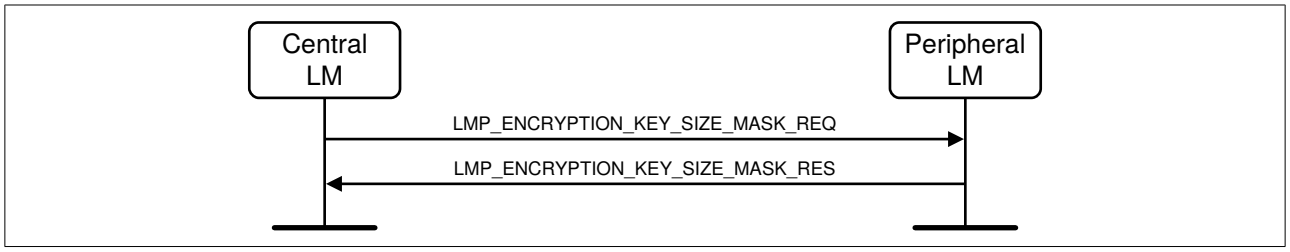
It is possible for the Central to request a Peripheral's supported encryption key sizes.

M/O	PDU	Contents
O(23)	LMP_ENCRYPTION_KEY_SIZE_MASK_REQ	*none*
O(23)	LMP_ENCRYPTION_KEY_SIZE_MASK_RES	Key_Size_Mask

Table 4.22: Encryption key size request PDU

The Central shall send an LMP_ENCRYPTION_KEY_MASK_REQ PDU to the Peripheral to obtain the Peripheral’s supported encryption key sizes.

The Peripheral shall return a bit mask indicating all broadcast encryption key sizes supported. The least significant bit shall indicate support for a key size of 1, the next most significant bit shall indicate support for a key size of 2 and so on up to a key size of 16. In all cases a bit set to 1 shall indicate support for a key size; a bit set to 0 shall indicate that the key size is not supported.



Sequence 54: Request for supported encryption key sizes

4.2.7 Secure Simple Pairing

There are four stages defined in the Secure Simple Pairing LM process:

- IO capabilities exchange
- Public key exchange
- Authentication stage 1
- Authentication stage 2

The devices shall first exchange the IO capabilities to determine the proper algorithm to be used. Three algorithms have been specified: Numeric comparison, Passkey entry, Out of band.

In following sections, the device requesting the IO capabilities is referred to as the "Initiating LM" or "Initiator". The other device is referred to as the "LM" or "Responder". This designation remains throughout the entire Secure Simple Pairing procedure.

M/O	PDU	Contents
O(51)	LMP_IO_CAPABILITY_REQ	IO_Capabilities, OOB_Auth_Data, Authentication_Requirements
O(51)	LMP_IO_CAPABILITY_RES	IO_Capabilities, OOB_Auth_Data, Authentication_Requirements
O(51)	LMP_SIMPLE_PAIRING_CONFIRM	Commitment_Value
O(51)	LMP_SIMPLE_PAIRING_NUMBER	Nonce_Value
O(51)	LMP_DHKEY_CHECK	Confirmation_Value
O(51)	LMP_NUMERIC_COMPARISON_FAILED	*none*
O(51)	LMP_OOB_FAILED	*none*

M/O	PDU	Contents
O(51)	LMP_KEYPRESS_NOTIFICATION	Notification_Type
O(51)	LMP_PASSKEY_ENTRY_FAILED	*none*

Table 4.23: Secure simple pairing PDUs

4.2.7.1 IO capability exchange

The Link Managers shall use the local and remote IO capabilities to determine which association model shall be used.

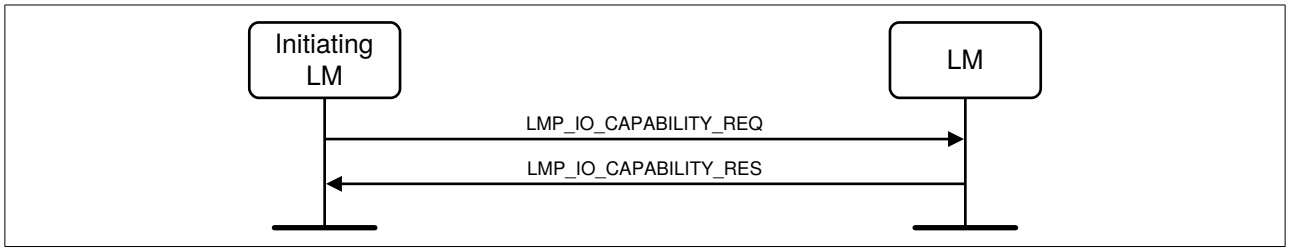
If Simple_Pairing_Mode is set to enabled, the Initiator shall request the IO capabilities from the Host. The initiator shall send an LMP_IO_CAPABILITY_REQ PDU to the Responder. If Simple_Pairing_Mode is set to enabled on the responding device, it shall reply with an LMP_IO_CAPABILITY_RES PDU containing its IO capabilities description.

The OOB_Auth_Data parameter shall be set as shown in Table 4.24.

			Local Device	
			Does not support Secure Connections	**Supports Secure Connections**
Remote Device	**Does not have OOB Data**		No OOB Data Received	No OOB Data Received
	Does not support Secure Connections. P-192 OOB Data Available		OOB Data Received	OOB Data Received
	Supports Secure Connections	Only P-192 OOB Data Available	OOB Data Received	No OOB Data Received
		P-192 OOB Data and P-256 OOB Data Available	OOB Data Received [1]	OOB Data Received
		Only P-256 OOB Data Available	No OOB Data Received [1]	OOB Data Received

Table 4.24: Setting the OOB_Auth_Data parameter

[1] A device that does not support Secure Connections cannot generate P-256 OOB data.

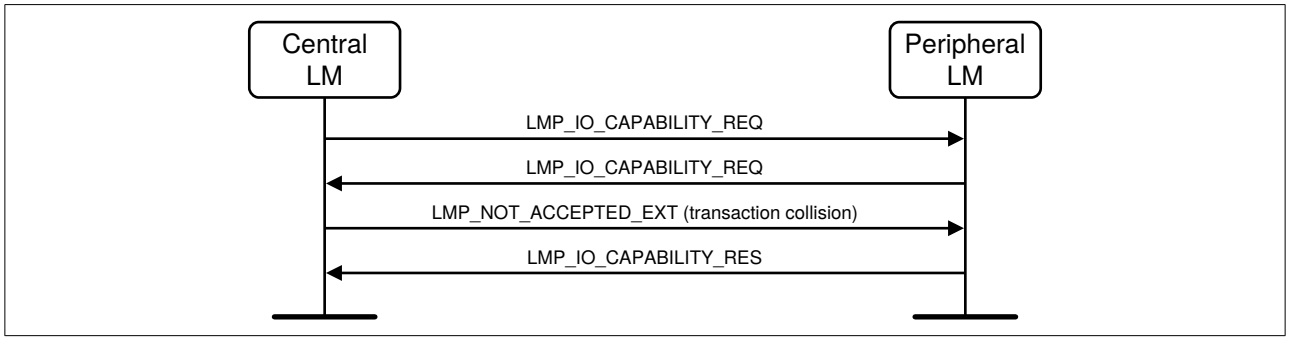


Sequence 55: IO capability exchange

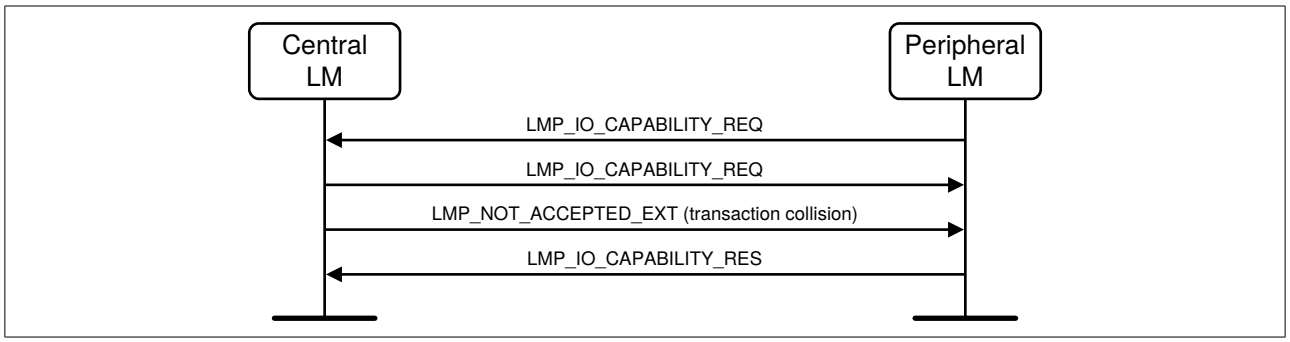
4.2.7.1.1 IO capability exchange transaction collision and resolution

If both Link Managers attempt to become the initiator of the IO capability exchange, the Central's Link Manager shall send an LMP_NOT_ACCEPTED_EXT PDU with Error_Code *LMP Error Transaction Collision / LL Procedure Collision* (0x23). The Peripheral's Link Manager shall respond with the LMP_IO_CAPABILITY_RES PDU.

The Central's LM shall remain the initiating LM for the remainder of the Secure Simple Pairing sequences.



Sequence 56: IO capability exchange with transaction collision (Central transmitting LMP_IO_CAPABILITY_REQ first) and resolution



Sequence 57: IO capability exchange with transaction collision (Peripheral transmitting LMP_IO_CAPABILITY_REQ first) and resolution

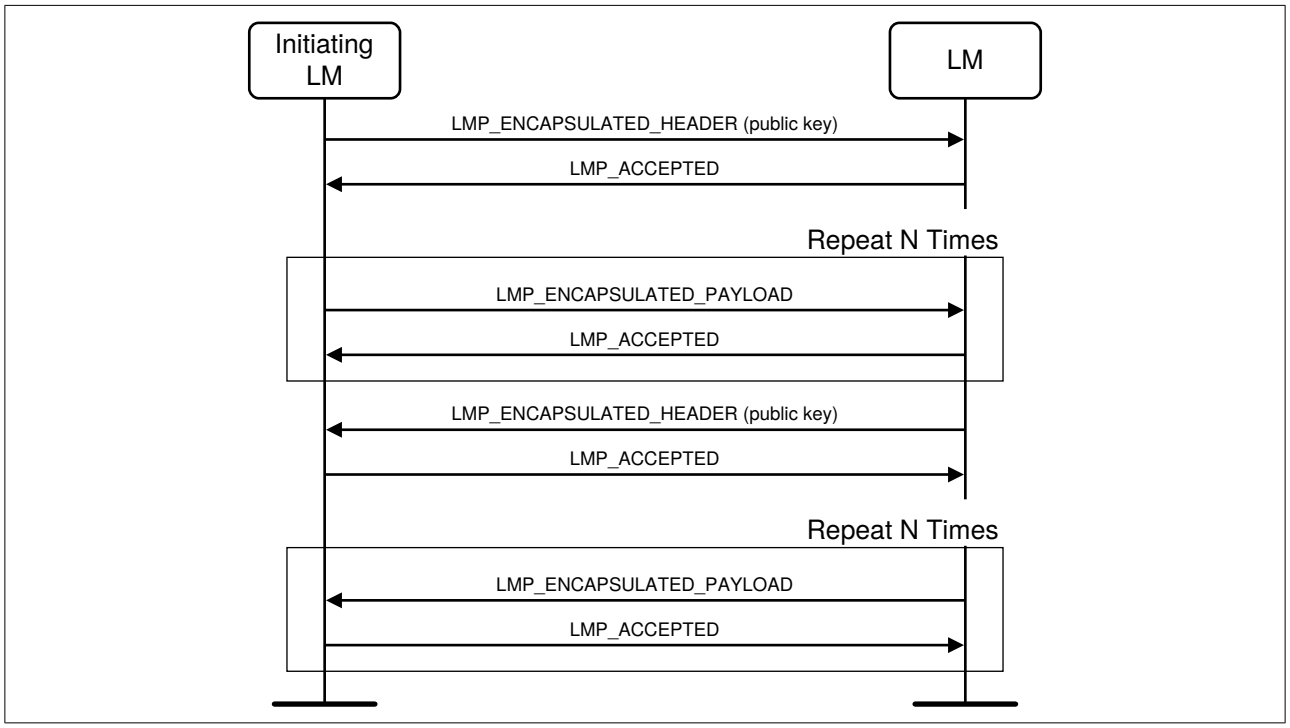
4.2.7.2 Public key exchange

Once the IO capabilities are exchanged, public keys shall be exchanged between the two devices.

Since the public key size is longer than the payload body length of a DM1 packet, the exchange shall be done using the LMP_ENCAPSULATED_HEADER and LMP_ENCAPSULATED_PAYLOAD PDUs as defined in Section 4.1.12.

When at least one device does not support Secure Connections, the P-192 curve shall be used for calculating the public and private keys. When both devices support Secure Connections, the P-256 curve shall be used for calculating the public and private keys.

The Initiator shall first send its public key, and the Responder shall reply with its public key.



Sequence 58: Public key exchange

A public key shall be considered as received when the last LMP_ENCAPSULATED_PAYLOAD has been received and the associated LMP_ACCEPTED PDU has been sent.

The device can then start computing its Diffie Hellman Key.

4.2.7.3 Authentication stage 1

One of the following procedures shall be used in Authentication stage 1:

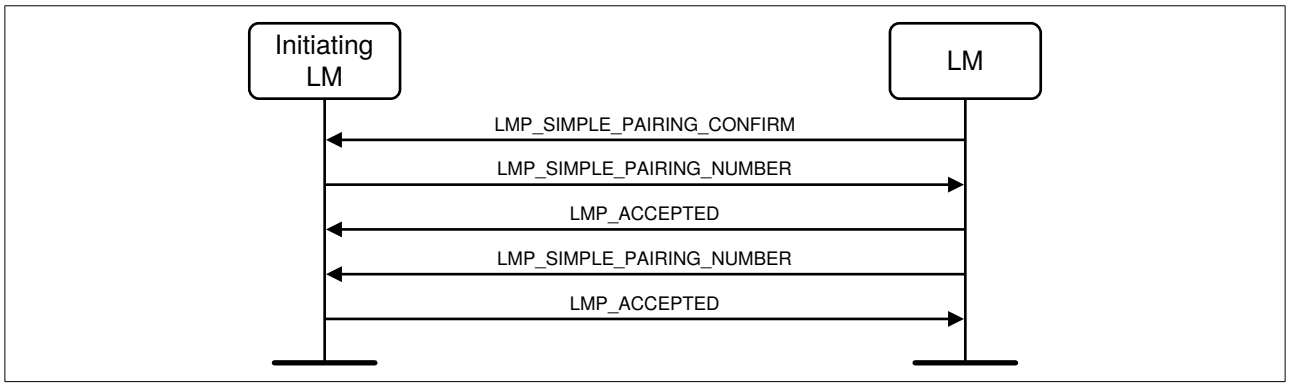
- If one or both devices have the OOB_Auth_Data parameter set to Received, the Out-of-Band procedure shall be used.
- If both devices have the Authentication_Requirements parameter set to one of the man-in-the middle (MITM) Protection Not Required options, the Numeric Comparison procedure shall be used.
- If one or both devices have the Authentication_Requirements parameter set to one of the MITM Protection Required options, the Passkey Entry procedure shall be used if the either the local or remote IO Capability is set to KeyboardOnly and the other IO capability is not set to NoInputNoOutput. Otherwise, the Numeric Comparison authentication procedure shall be used.

4.2.7.3.1 Authentication stage 1: Numeric Comparison

Once public keys have been exchanged, both devices shall generate a random number.

The Responder shall compute its commitment as defined in [Vol 2] Part H, Section 7.7.1, and shall send this value to the Initiator by using LMP_SIMPLE_PAIRING_CONFIRM PDU. The Initiator shall then send an LMP_SIMPLE_PAIRING_NUMBER PDU with its generated random number. The Responder shall acknowledge by sending an LMP_ACCEPTED PDU.

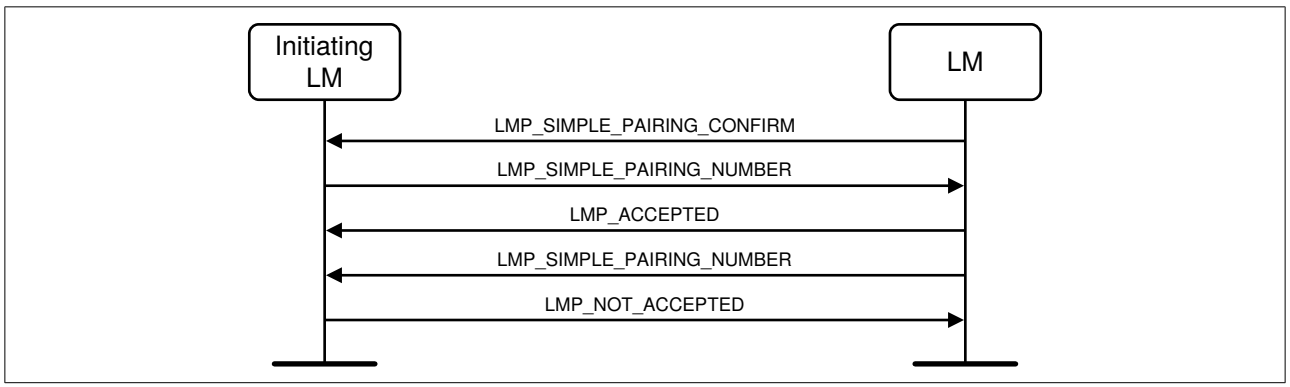
The Responder shall then send an LMP_SIMPLE_PAIRING_NUMBER containing its own generated random number. Upon reception, the Initiator shall calculate the commitment as defined in [Vol 2] Part H, Section 7.7.1 and compare it to the one received previously with the LMP_SIMPLE_PAIRING_CONFIRM PDU. If both values are equal, the Initiator shall respond with an LMP_ACCEPTED PDU.



Sequence 59: Numeric Comparison Authentication: Commitment check success

4.2.7.3.1.1 Commitment check failure

If the calculated commitment by the Initiator is not equal to the received commitment, the Initiator shall abort the Secure Simple Pairing process by sending an LMP_NOT_ACCEPTED PDU with reason "Authentication Failure."

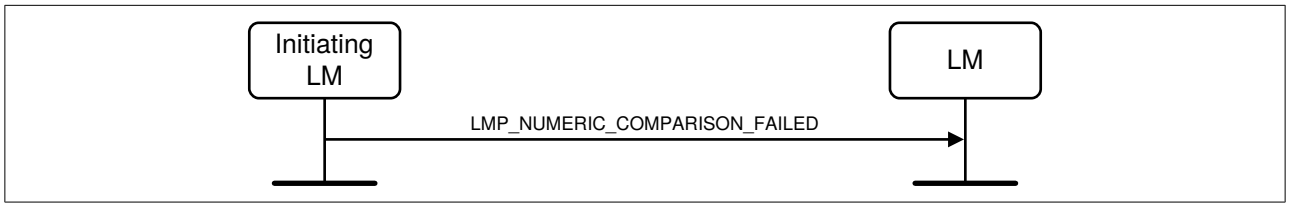


Sequence 60: Numeric Comparison authentication: Commitment check failure

4.2.7.3.1.2 Numeric Comparison failure on Initiator side

If the user on the initiating side indicates that the confirm values do not match (e.g., as indicated by the HCI_User_Confirmation_Request_Negative_Reply command) the initiating LM shall send an LMP_NUMERIC_COMPARISON_FAILURE PDU.

The Secure Simple Pairing process shall then be aborted. The Link Managers shall not disconnect the connection.

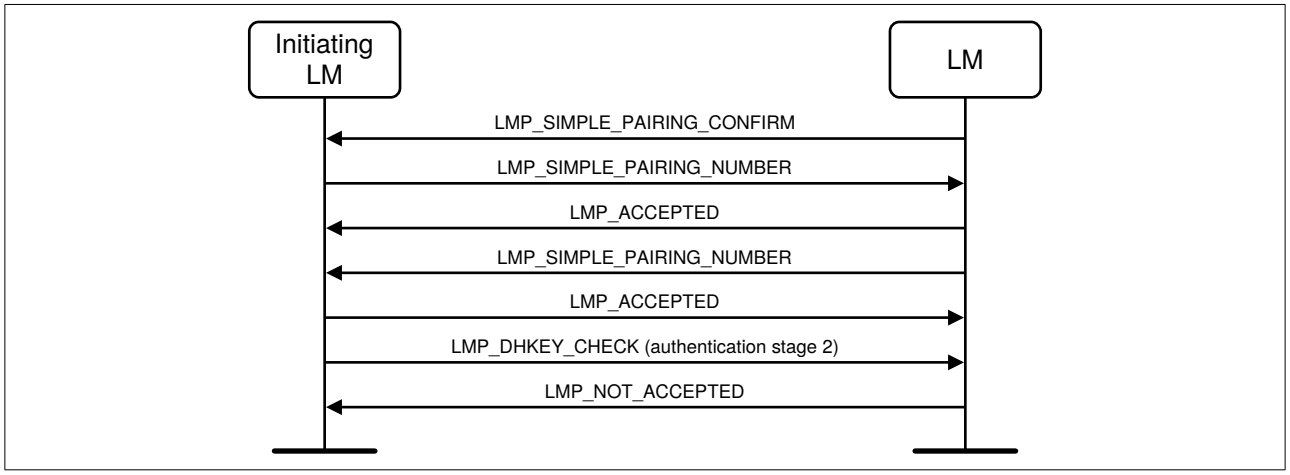


Sequence 61: Authentication stage 1: Numeric Comparison failure on Initiator side

4.2.7.3.1.3 Numeric Comparison failure on Responder side

If the user on the responding side indicates that the confirm values do not match (e.g., as indicated by the HCI_User_Confirmation_Request_Negative_Reply command) the responding LM shall send an LMP_NOT_ACCEPTED PDU in response to the LMP_DHKEY_CHECK PDU sent in authentication stage 2 (see Section 4.2.7.4).

The Secure Simple Pairing process shall then be aborted. The Link Managers shall not disconnect the connection.

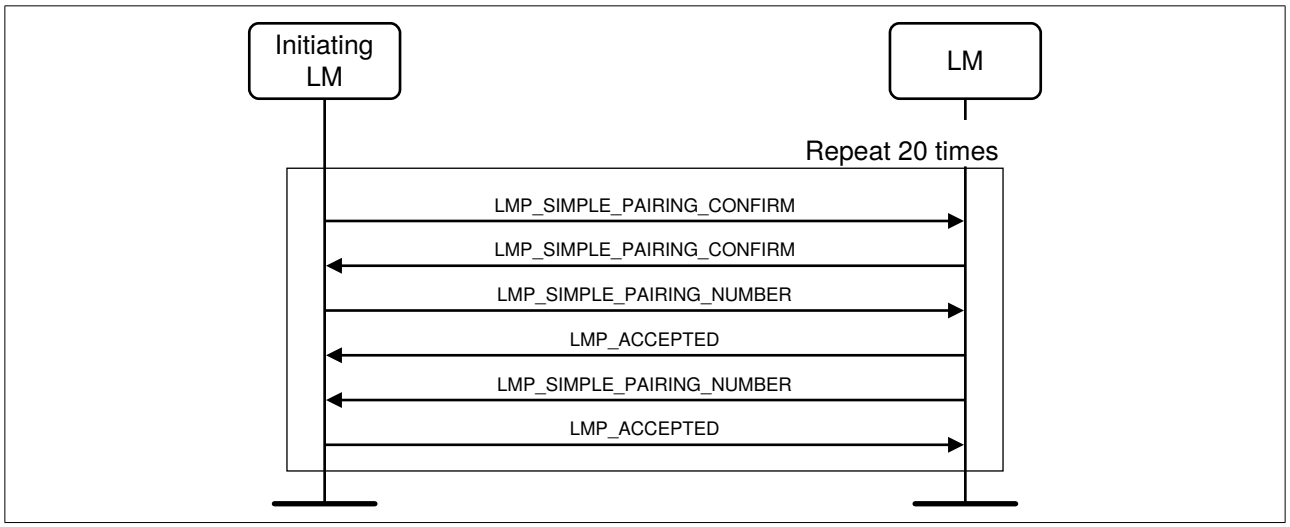


Sequence 62: Authentication stage 1: Numeric Comparison failure on Responder side

4.2.7.3.2 Authentication stage 1: Passkey Entry Authentication

The initiating LM shall start the following procedure after receiving the Passkey Reply from the Host. This procedure shall be repeated 20 times:

1. The Initiator and the Responder shall generate a new random number.
2. The Initiator and the Responder shall calculate the local commitment value using the exchanged public keys, the local random number, and the passkey from the local Host, according to [Vol 2] Part H, Section 7.7.1.
3. The Initiator shall send an LMP_SIMPLE_PAIRING_CONFIRM PDU with the commitment it calculated in step 2.
4. The Responder shall respond with an LMP_SIMPLE_PAIRING_CONFIRM PDU with the commitment it calculated in step 2.
5. The Initiator shall then send an LMP_SIMPLE_PAIRING_NUMBER PDU with the random number it generated in step 1.
6. The Responder shall then calculate commitment from the exchanged public keys, the random number it received and the passkey from the local Host, according to [Vol 2] Part H, Section 7.7.1. If the calculated commitment and the received commitment are equal, the Responder shall reply with an LMP_ACCEPTED PDU.
7. The Responder shall then send an LMP_SIMPLE_PAIRING_NUMBER PDU with the random value it generated in step 1.
8. The Initiator shall calculate the commitment using the exchanged public keys, the random number it received, and the passkey from the local Host, according to [Vol 2] Part H, Section 7.7.1. If the calculated commitment is equal to the received commitment, the Initiator shall reply with an LMP_ACCEPTED PDU.



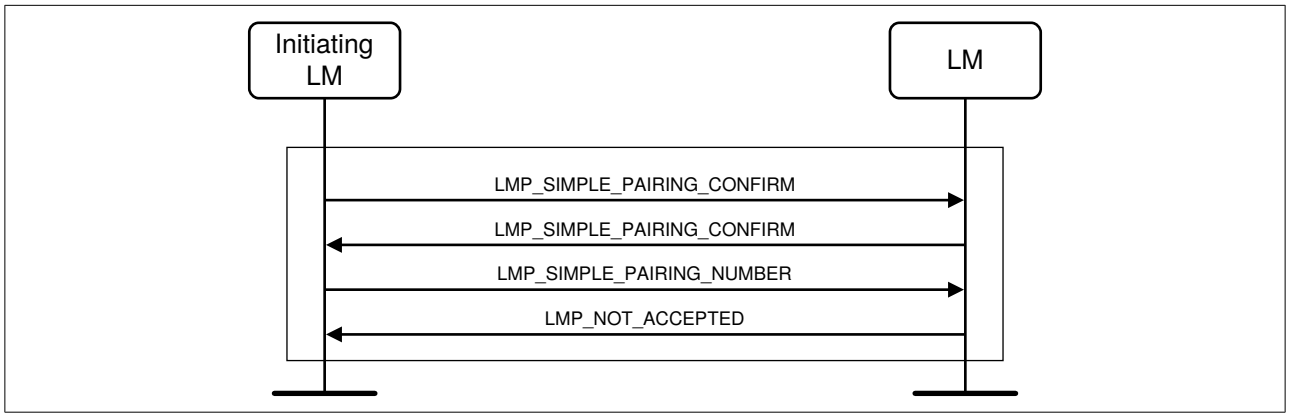
Sequence 63: Authentication passkey entry

When this procedure has successfully passed 20 times, the Secure Simple Pairing process continues with the Authentication step 2 as described in Section 4.2.7.4.

4.2.7.3.2.1 Commitment check failure on the Responder side

If during one of the 20 repetitions, the commitment calculated by the Responder is not equal to the one received from the Initiator (step 6), the Responder shall abort the Secure Simple Pairing process by sending an LMP_NOT_ACCEPTED PDU with reason "Authentication Failure."

Secure Simple Pairing procedures shall then be aborted. The Link Managers shall not disconnect the connection.

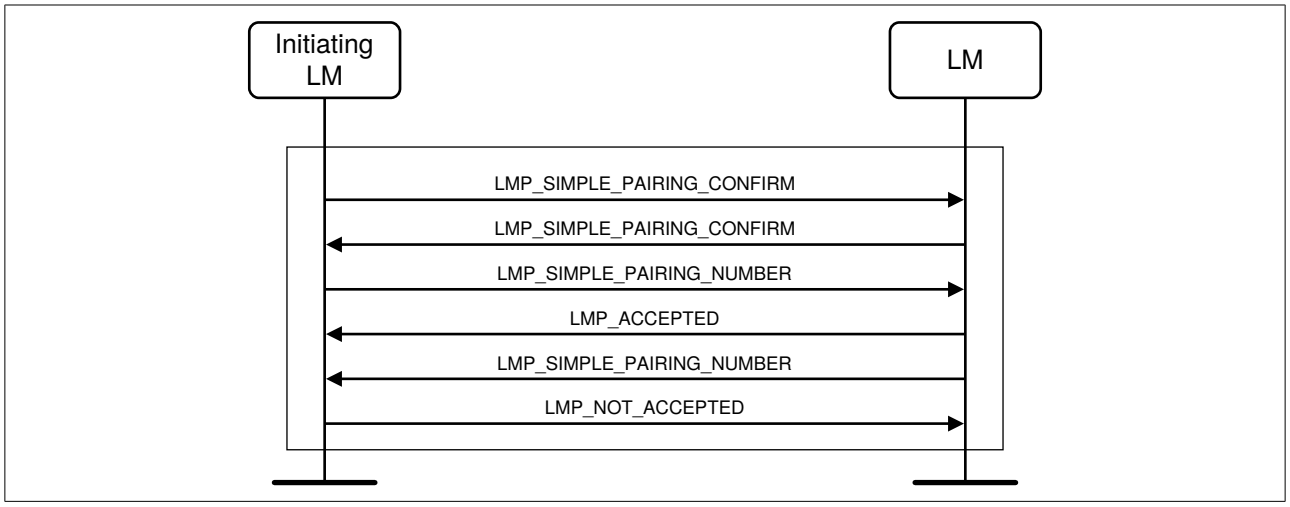


Sequence 64: Authentication passkey entry: Commitment check failure on the Responder side

4.2.7.3.2.2 Commitment check failure on the Initiator side

If during one of the 20 repetitions, the commitment calculated by the Initiator is not equal to the one received from the Responder (step 8), the Initiator shall abort the Secure Simple Pairing process by sending an LMP_NOT_ACCEPTED PDU with reason "Authentication Failure".

Secure Simple Pairing procedures shall then be aborted. The Link Managers shall not disconnect the connection.

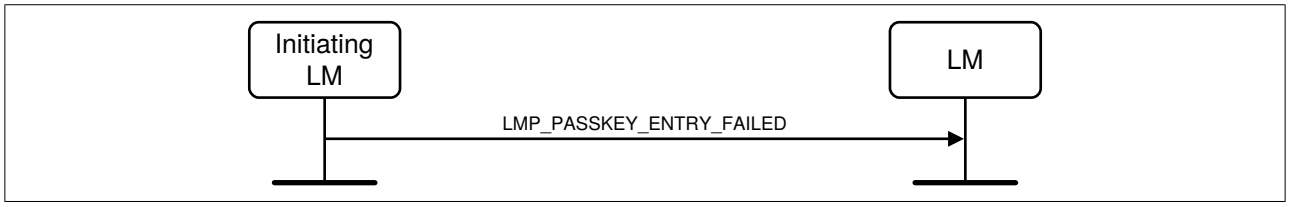


Sequence 65: Authentication passkey entry: Commitment check failure on the Initiator side

4.2.7.3.2.3 Passkey Entry failure on Initiator side

If the initiating side indicates that the passkey was not entered or canceled (e.g., as indicated by the HCI_User_Passkey_Request_Negative_Reply command) the initiating LM shall send an LMP_PASSKEY_ENTRY_FAILED PDU.

Secure Simple Pairing process shall then be aborted. The Link Managers shall not disconnect the connection.

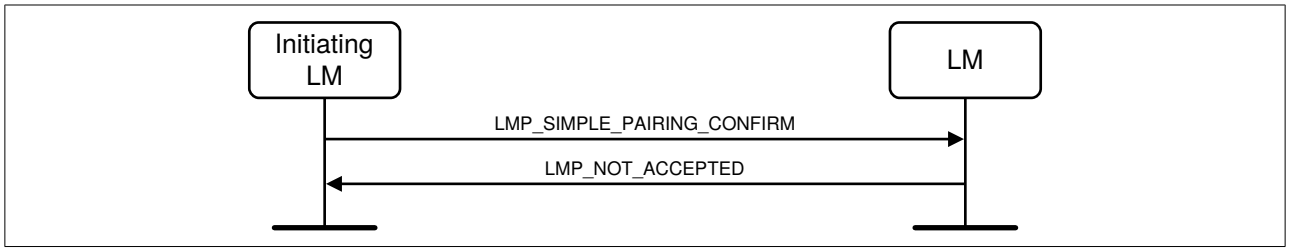


Sequence 66: Authentication stage 1: Passkey Entry failure on Initiator side

4.2.7.3.3 Passkey Entry failure on Responding side

If the responding side indicates that the passkey was not entered or canceled (e.g., as indicated by the HCI_User_Passkey_Request_Negative_Reply command), the responding LM shall send an LMP_NOT_ACCEPTED PDU in response to the LMP_SIMPLE_PAIRING_CONFIRM PDU.

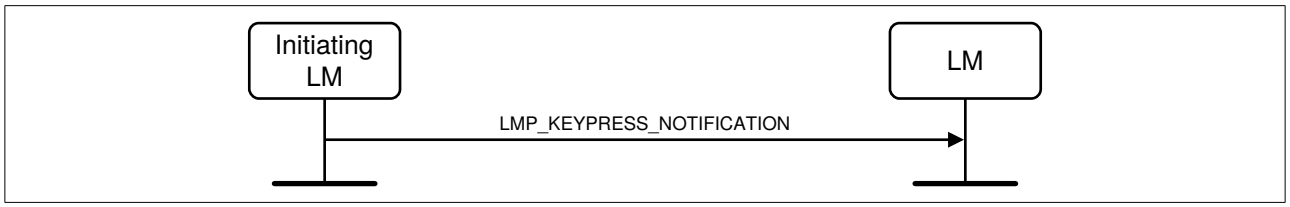
The Secure Simple Pairing process shall then be aborted. The Link Managers shall not disconnect the connection.



Sequence 67: Authentication stage 1: Passkey Entry failure on Responding side

4.2.7.3.4 Keypress notifications

A Controller that allows the Host to change its IO capabilities shall send notifications on key presses to the remote side using the LMP_KEYPRESS_NOTIFICATION PDU when the Host sets the IO capabilities to KeyboardOnly IO and when Secure Simple Pairing is supported on the Host and Controller.



Sequence 68: Keypress notifications

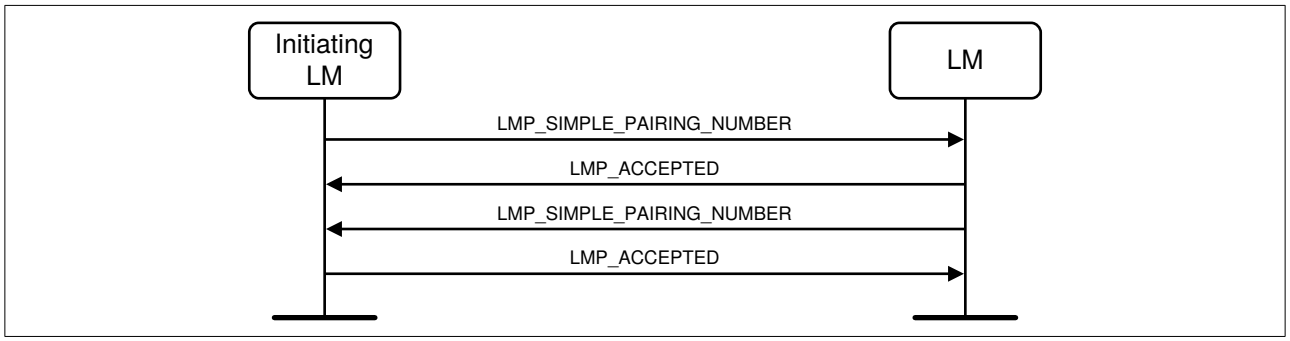
4.2.7.3.5 Authentication stage 1: OOB

Upon reception of the OOB information (as defined in [Vol 2] Part H, Section 7.2.2) from the Host, the devices shall compare the received commitment from its Host, with the one calculated using the secret number received from the Host and the public key received from the remote device. If the local Host has not set the OOB Authentication Data Present, the LM shall set the remote secret number to zero and base the subsequent calculations on this value.

If the commitment check on the initiator is valid, the Initiator shall then generate a random number (nonce) and send it to the Responder using an LMP_SIMPLE_PAIRING_NUMBER PDU. If the commitment succeeds, the Responder shall acknowledge by sending an LMP_ACCEPTED PDU otherwise it shall send an LMP_NOT_ACCEPTED PDU. The Responder shall then generate a random number (nonce) and send it to the Initiator using an LMP_SIMPLE_PAIRING_NUMBER PDU. If the commitment succeeds, the Initiator shall acknowledge by sending an LMP_ACCEPTED PDU otherwise it shall send an LMP_NOT_ACCEPTED PDU.

If the commitment values don't match in the Initiator, the procedure in Section 4.2.7.3.5.2 shall apply.

If the commitment values don't match in the Responder, the procedure in Section 4.2.7.3.5.1 shall apply.



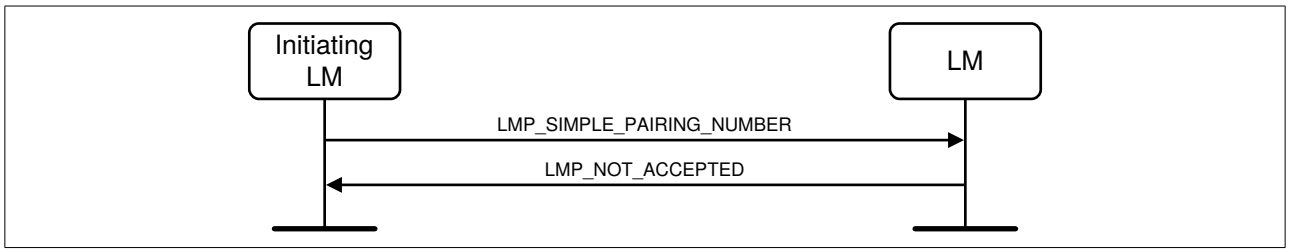
Sequence 69: Authentication OOB: Only one device is OOB-r capable

When these operations have been passed successfully, Secure Simple Pairing procedures continue with Authentication step 2 as described in Section 4.2.7.4.

4.2.7.3.5.1 Commitment check failure on the Responder side

If the commitment received OOB from the Host is not equal to the calculated commitment, the Responder shall send an LMP_NOT_ACCEPTED PDU with reason "Authentication Failure" in response to the LMP_SIMPLE_PAIRING_NUMBER PDU.

Secure Simple Pairing process shall then be aborted. The Link Managers shall not disconnect the connection.

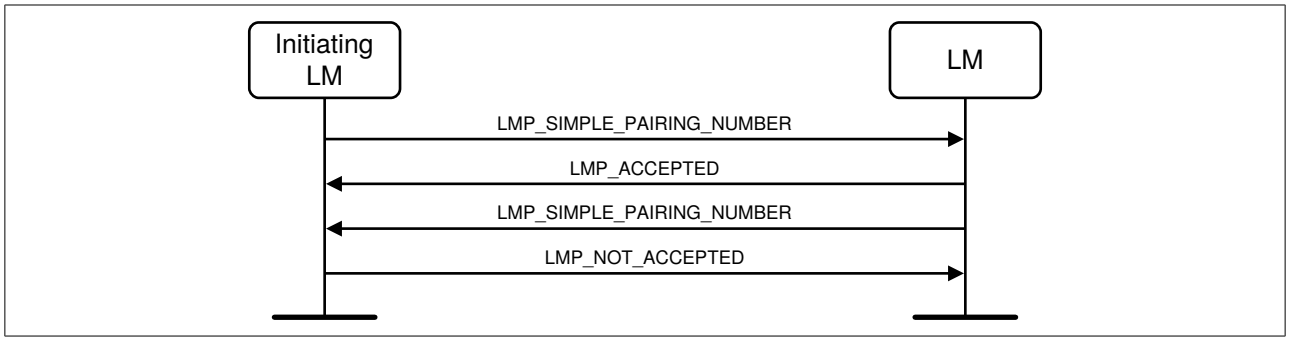


Sequence 70: Authentication stage 1 OOB: Commitment check failure on the Responder side

4.2.7.3.5.2 Commitment check failure on the Initiator side

If the commitment received OOB from the Host is not equal to the calculated commitment, the Initiator shall send an LMP_NOT_ACCEPTED PDU with reason "Authentication Failure" in response to the LMP_SIMPLE_PAIRING_NUMBER PDU.

Secure Simple Pairing process shall then be aborted. The Link Managers shall not disconnect the connection.

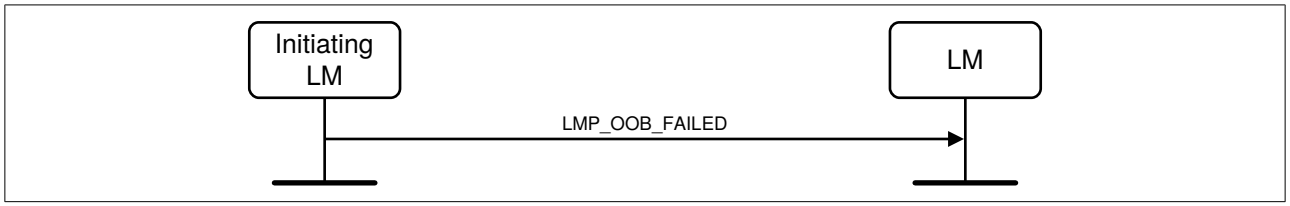


Sequence 71: Authentication stage 1 OOB: Commitment check failure on the Initiator side

4.2.7.3.6 Out-of-band information not available on the Initiator side

If the Host on the initiating side does not have out-of-band information the Initiator shall send an LMP_OOB_FAILED PDU.

The Secure Simple Pairing process shall then be aborted. The Link Managers shall not disconnect the connection.



Sequence 72: Authentication stage 1 OOB: OOB information not available on the Initiator side

4.2.7.4 Authentication stage 2: DHKey check

At this stage, both devices compute new confirmation values based on Diffie-Hellman key and previously exchanged information according to [Vol 2] Part H, Section 7.7.4.

The Initiator shall send an LMP_DHKEY_CHECK PDU to the Responder. If the Initiator has determined that the received public key is invalid (see [Vol 2] Part H, Section 7.6), the PDU shall include a confirmation value that is different from the computed confirmation value (for example, substituting a randomly generated number). Otherwise, the PDU shall include the computed confirmation value.

Upon reception, if the received value is not equal to the one calculated according to [Vol 2] Part H, Section 7.7.4, or if the received public key is invalid (see [Vol 2] Part H, Section 7.6), then the Responder shall follow the procedure in Section 4.2.7.4.1. Otherwise it shall reply with an LMP_ACCEPTED PDU.

The Responder shall then send an LMP_DHKEY_CHECK PDU, including the confirmation value it has computed, to the Initiator. Upon reception, if the received value is not equal to the one calculated according to [Vol 2] Part H, Section 7.7.4,

or if the received public key is invalid (see [Vol 2] Part H, Section 7.6), then the Initiator shall follow the procedure in Section 4.2.7.4.1. Otherwise it shall reply with an LMP_ACCEPTED PDU.

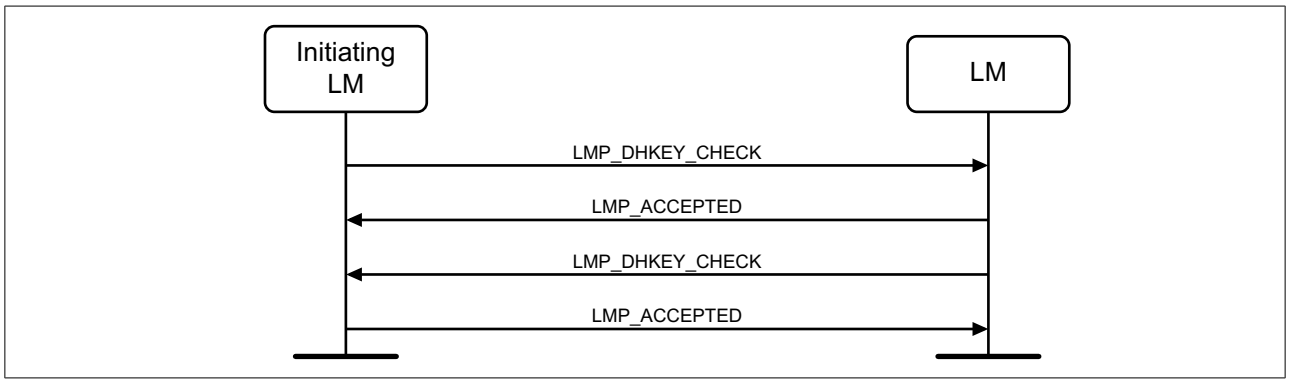
At this point, both devices shall compute the link key according to [Vol 2] Part H, Section 7.7.3.

If at least one device does not support both the Secure Connections (Controller Support) and the Secure Connections (Host Support) features, the Initiator shall then start standard mutual authentication as described in Section 4.2.1.1

If both devices support both the Secure Connections (Controller Support) and the Secure Connections (Host Support) features, the Initiator shall then start secure authentication as described in Section 4.2.1.4.

After secure authentication, if encryption is enabled, the initiating device shall pause and immediately resume encryption to produce a new encryption key.

Note: This will cause a new encryption key to be generated using the h3 function including the ACO created during the secure authentication process.



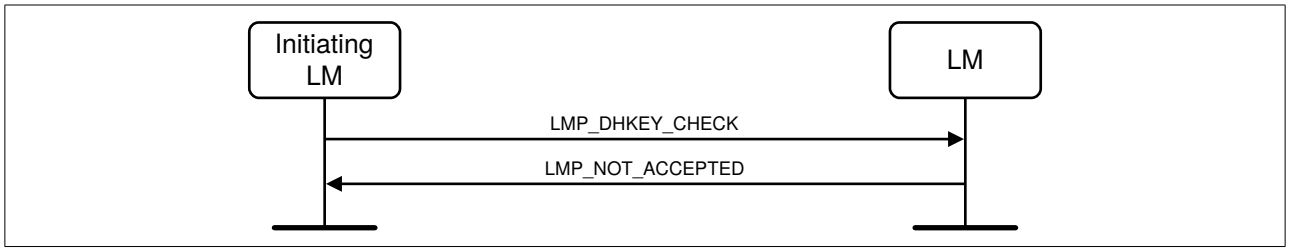
Sequence 73: DHKey check

A device that detects an invalid public key (see [Vol 2] Part H, Section 7.6) from the peer at any point during the Secure Simple Pairing process shall fail the pairing process and therefore not create a link key.

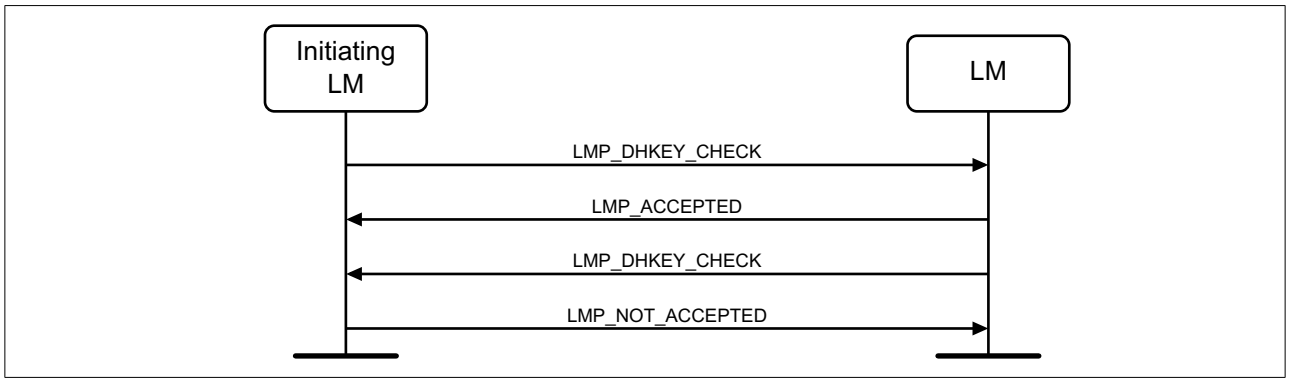
4.2.7.4.1 Check failure

If either Link Manager receives a public key that is invalid (see [Vol 2] Part H, Section 7.6), it shall send an LMP_NOT_ACCEPTED PDU with reason "Authentication Failure". If either Link Manager receives a confirmation value via LMP that is not equal to the one it has calculated according to [Vol 2] Part H, Section 7.7.4, it shall send an LMP_NOT_ACCEPTED PDU with reason "Authentication Failure".

The Secure Simple Pairing procedures shall then be aborted. The Link Managers shall not disconnect the connection.



Sequence 74: DHKey check: Check failure on the Responder side



Sequence 75: DHKey check: Check failure on the Initiator side

4.2.7.4.1.1 [This section is no longer used]

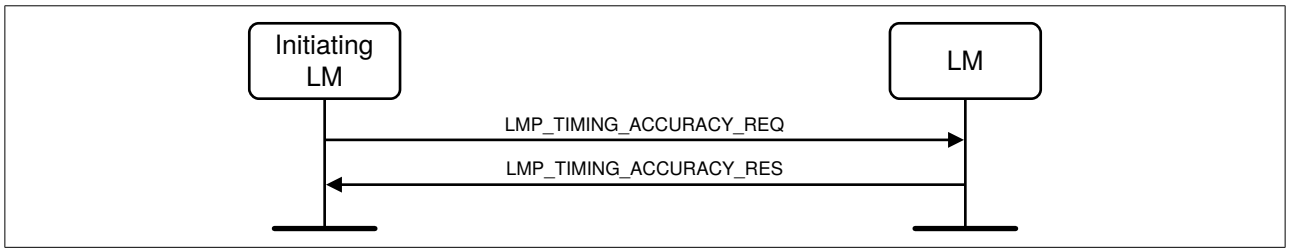
4.3 Informational requests

4.3.1 Timing accuracy

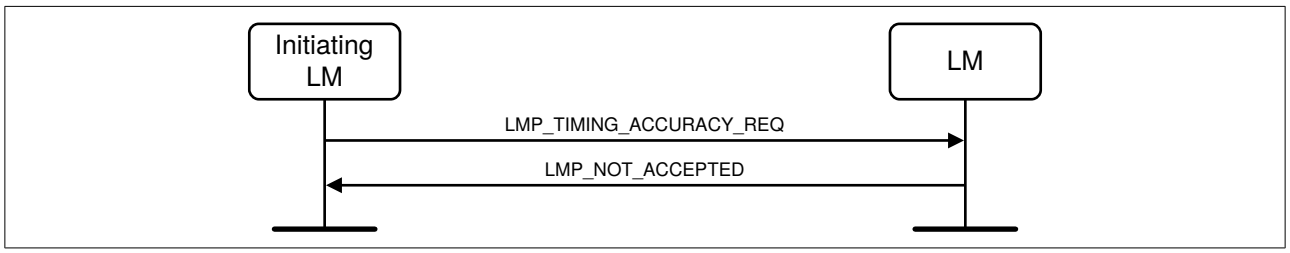
LMP supports requests for the timing accuracy. This information can be used to minimize the scan window during piconet physical channel re-synchronization (see [Vol 2] Part B, Section 2.2.5.2). The timing accuracy parameters returned are the long term drift measured in ppm and the long term jitter measured in µs of the worst case clock used. These parameters are fixed for a certain device and shall be identical when requested several times. Reported time accuracy shall not include changes caused by performing Piconet Clock Adjustment. If timing accuracy information has not been received from the remote device, the worst-case values (drift = 250 ppm and jitter = 10 µs) shall be used.

M/O	PDU	Contents
O(4)	LMP_TIMING_ACCURACY_REQ	*none*
O(4)	LMP_TIMING_ACCURACY_RES	Drift Jitter

Table 4.25: Request limited timing PDU



Sequence 76: The requested device supports timing accuracy information



Sequence 77: The requested device does not support timing accuracy information

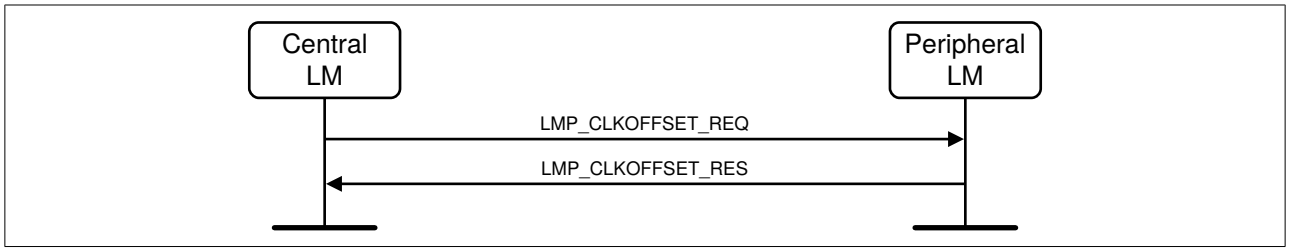
4.3.2 Clock offset

The clock offset can be used to speed up the paging time the next time the same device is paged. The Central can request the clock offset at anytime following a successful Baseband Paging procedure (i.e., before, during or after connection setup). The clock offset shall be defined by the following equation:

$(CLKN_{16\text{-}2\ Peripheral} - CLKN_{16\text{-}2\ Central})$ *mod* 2^{15}.

M/O	PDU	Contents
M	LMP_CLKOFFSET_REQ	*none*
M	LMP_CLKOFFSET_RES	Clock_Offset

Table 4.26: PDUs used for clock offset request



Sequence 78: Clock offset requested

4.3.3 LMP version

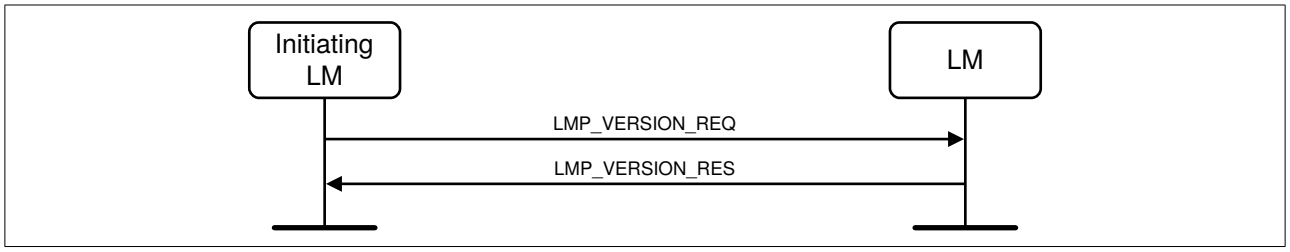
LMP supports requests for the version of the LM protocol. The LMP_VERSION_REQ and LMP_VERSION_RES PDUs contain three parameters: Version, Company_Identifier and Subversion. Version specifies the version of the Bluetooth LMP specification that the device supports. All companies that create a unique implementation of the LM shall have their own Company_Identifier. The same company is also responsible for the administration and maintenance of the Subversion. It is recommended that each company has a unique Subversion for each RF/BB/LM implementation. For a given Version and Company_Identifier, the values of the Subversion shall increase each time a new implementation is released. For both Company_Identifier and Subversion the value 0xFFFF means that no valid number applies. There is no ability to negotiate the version of the LMP. The sequence below is only used to exchange the parameters. LMP version can be requested at anytime following a successful Baseband Paging procedure.

Note: A given value for Version does not indicate that the device supports all the features in the corresponding version of the specification; the relevant feature bits (see Section 4.3.4) should be checked instead.

Note: A larger value for Version does not necessarily indicate a higher version of the specification.

M/O	PDU	Contents
M	LMP_VERSION_REQ	Version Company_Identifier Subversion
M	LMP_VERSION_RES	Version Company_Identifier Subversion

Table 4.27: PDUs used for LMP version request



Sequence 79: Request for LMP version

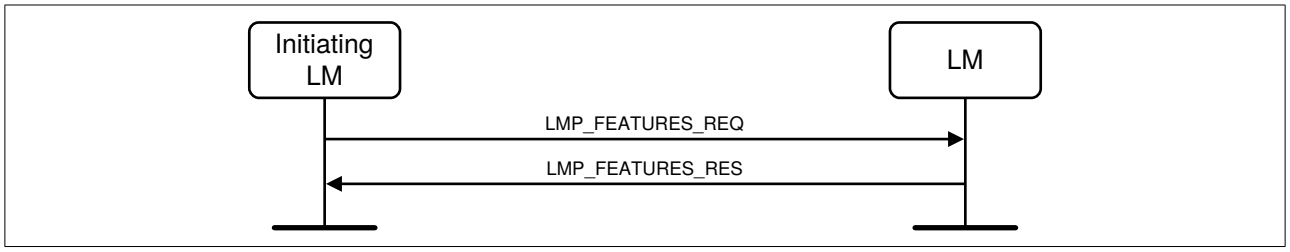
4.3.4 Supported features

The supported features may be requested at anytime following a successful Baseband Paging procedure by sending the LMP_FEATURES_REQ PDU. Upon reception of an LMP_FEATURES_REQ PDU, the receiving device shall return an LMP_FEATURES_RES PDU.

The extended features mask provides support for more than 64 features. Support for the extended features mask is indicated by the presence of the appropriate bit in the LMP features mask. The LMP_FEATURES_REQ_EXT and LMP_FEATURES_RES_EXT PDUs operate in precisely the same way as the LMP_FEATURES_REQ and LMP_FEATURES_RES PDUs except that they allow the various pages of the extended features mask to be requested. The LMP_FEATURES_REQ_EXT may be sent at any time following the exchange of the LMP_FEATURES_REQ and LMP_FEATURES_RSP PDUs.

The LMP_FEATURES_REQ_EXT PDU contains a Features_Page parameter that specifies which page is requested and the contents of that page for the requesting device. Pages are numbered from 0 to 255 with page 0 corresponding to the normal features mask. Each page consists of 64 bits. If a device does not support any page number it shall return an Extended_Features parameter with every bit set to 0. It also contains the maximum features page number containing any non-zero bit for this device. The recipient of an LMP_FEATURES_REQ_EXT PDU shall respond with an LMP_FEATURES_RES_EXT PDU containing the same page number and the appropriate features page along with its own maximum features page number.

If the extended features request is not supported then all bits in all extended features pages for that device shall be assumed to be zero.



Sequence 80: Request for supported features

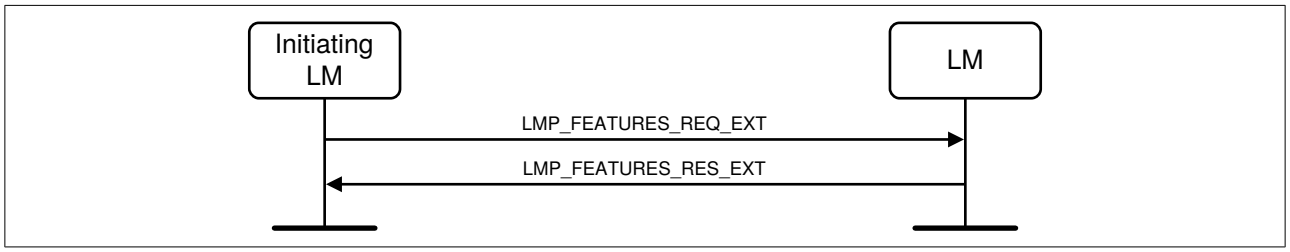
M	LMP_FEATURES_RES	Features
O(63)	LMP_FEATURES_REQ_EXT	Features_Page Max_Supported_Page Extended_Features
O(63)	LMP_FEATURES_RES_EXT	Features_Page Max_Supported_Page Extended_Features

Table 4.28: PDUs used for features request



Sequence 81: Request for extended features

4.3.5 Name request

LMP supports name request to another device. The name is a user-friendly name associated with the device and consists of a maximum of 248 bytes coded according to the UTF-8 standard (more specifically, the type utf8s{248z} defined in [Vol 1] Part E, Section 2.9.3). The name is fragmented over one or more DM1 packets. When an LMP_NAME_REQ PDU is sent, a Name_Offset indicates which fragment is expected. The corresponding LMP_NAME_RES PDU carries the same Name_Offset,

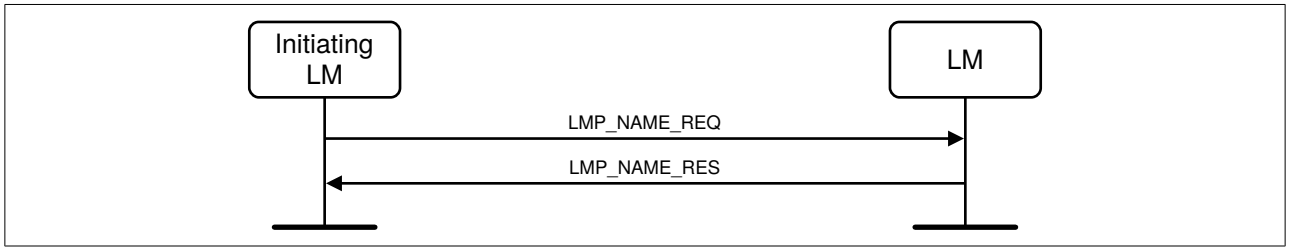
the Name_Length indicating the total number of bytes in the name of the device and the Name_Fragment, where:

- Name_Fragment(N) = name(N + Name_Offset), if (N + Name_Offset) < Name_Length
- Name_Fragment(N) = 0,otherwise.

Here 0 ≤ N ≤ 13. In the first sent LMP_NAME_REQ PDU, Name_Offset=0. Sequence 82 is then repeated until the initiator has collected all fragments of the name. The name request may be made at any time following a successful Baseband Paging procedure.

M/O	PDU	Contents
M	LMP_NAME_REQ	Name_Offset
M	LMP_NAME_RES	Name_Offset Name_Length Name_Fragment

Table 4.29: Name request PDUs



Sequence 82: Request for device name

4.4 Role switch

4.4.1 Slot offset

With LMP_SLOT_OFFSET the information about the difference between the slot boundaries in different piconets is transmitted. The LMP_SLOT_OFFSET PDU may be sent anytime after the Baseband Paging procedure has completed if the ACL logical transport is in Active mode and a synchronous logical transport is not being negotiated by the LM. This PDU carries the parameters Slot_Offset and BD_ADDR. The Slot_Offset shall be the time, in microseconds, from the start of a Central transmission in the current piconet to the start of the next following Central transmission in the piconet where the BD_ADDR device (normally the Peripheral) is Central at the time that the request is interpreted by the BD_ADDR device.

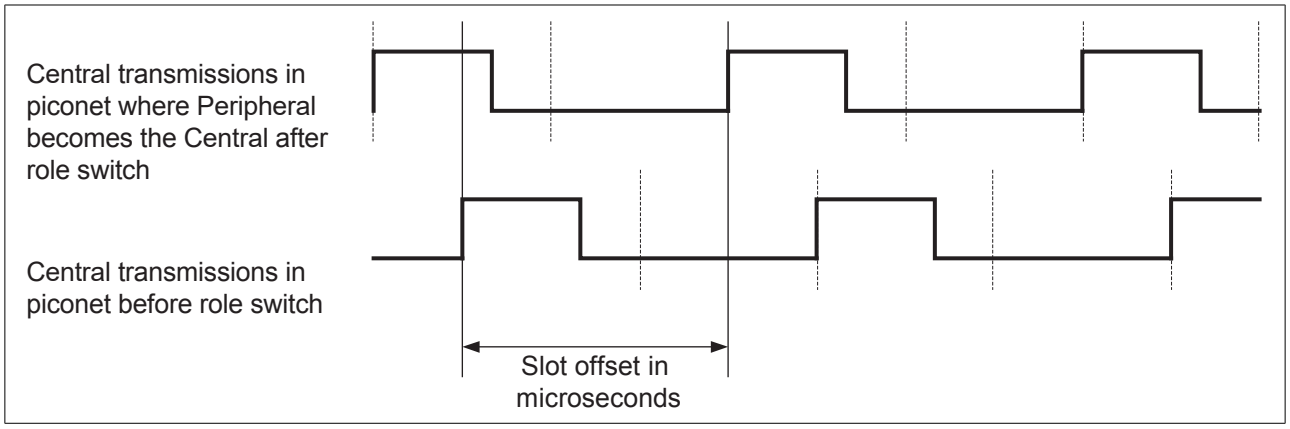


Figure 4.2: Slot offset for role switch

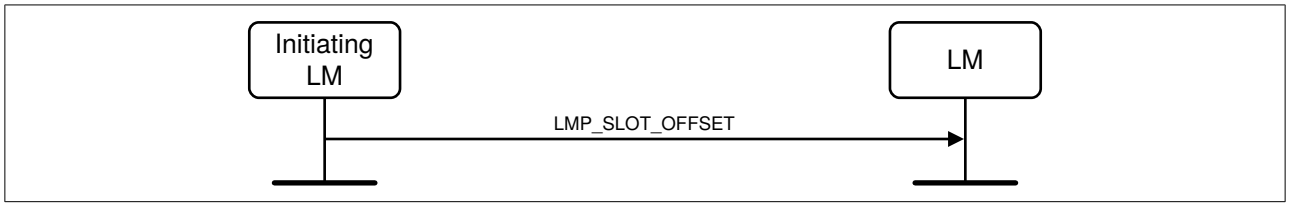
See Section 4.4.2 for the use of LMP_SLOT_OFFSET in the context of the role switch. In the case of role switch the BD_ADDR is that of the Peripheral.

M/O	PDU	Contents
O(3)	LMP_SLOT_OFFSET	Slot_Offset BD_ADDR

Table 4.30: Slot offset PDU



Sequence 83: Slot offset information is sent

4.4.2 Role switch

Since the paging device always becomes the Central of the piconet, a role switch is sometimes needed; see [Vol 2] Part B, Section 8.6.5. A role switch may be performed as part of connection establishment (see Section 4.1.1) or any time after connection establishment has completed.

The LMP_SWITCH_REQ shall be sent only if the ACL logical transport is in Active mode, encryption is stopped or paused, and all synchronous logical transports on the same physical link are disabled. LMP_SWITCH_REQ shall not be initiated or accepted while a synchronous logical transport is being negotiated by the LM.

M/O	PDU	Contents
O(5)	LMP_SWITCH_REQ	Switch_Instant
O(5)	LMP_SLOT_OFFSET	Slot_Offset BD_ADDR

Table 4.31: Role switch PDUs

Role switch is performed by an initiating device and a responding device.

First, the initiating LM shall pause traffic on the ACL-U logical link (see [Vol 2] Part B, Section 5.3.1). Next, if the Encryption_Mode is set to "encryption" then it shall initiate either the pause encryption sequence (see Section 4.2.5.5.) if both devices support pausing encryption or the stop encryption sequence (see Section 4.2.5.4) otherwise. If it is the Peripheral, it shall next send an LMP_SLOT_OFFSET PDU. Finally, it shall send an LMP_SWITCH_REQ PDU.

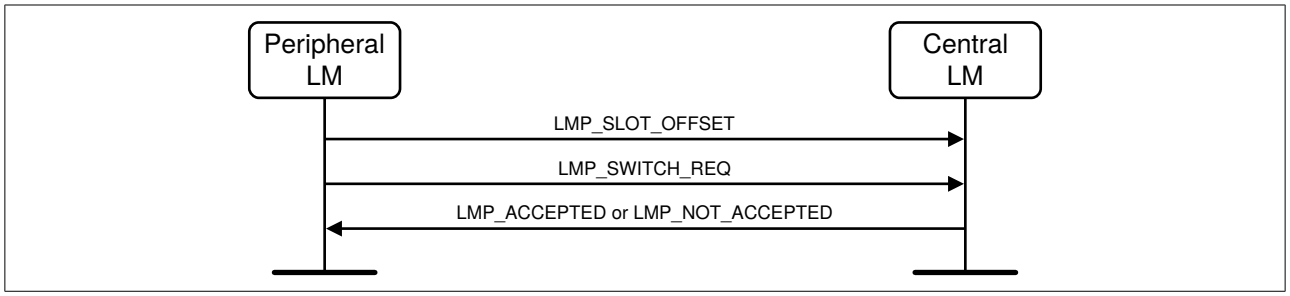
If the responding device accepts the role switch, then first it shall pause traffic on the ACL-U logical link if it is not already paused. If it is the Peripheral, it shall next send an LMP_SLOT_OFFSET PDU. Finally, it shall send an LMP_ACCEPTED PDU. The two devices shall then perform the Baseband Role Switch procedure. If it rejects the role switch, it shall send an LMP_NOT_ACCEPTED PDU.

When the role switch has been completed at the Baseband level (successfully or not), or has been rejected, then:

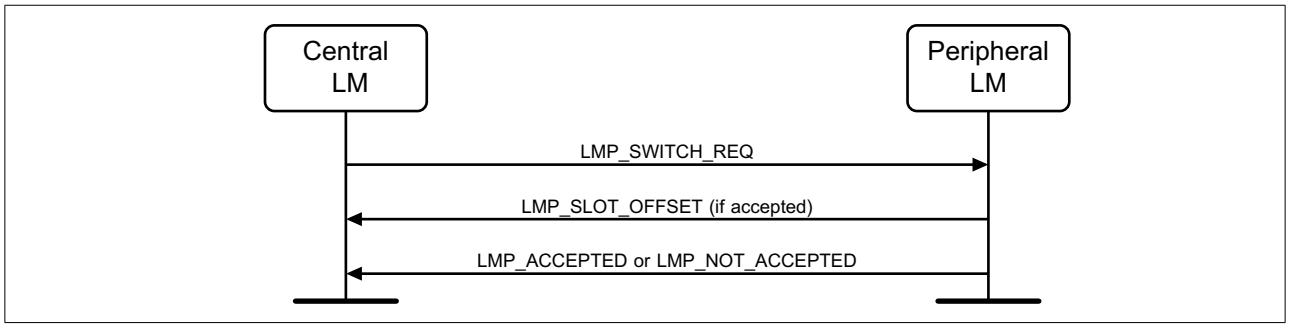
- If the initiating device had paused encryption, it shall initiate the resume encryption sequence (see Section 4.2.5.6). When AES-CCM encryption is used, the LMs shall calculate a new encryption key using the h3 algorithm (see [Vol 2] Part H, Section 7.7.6) with the BD_ADDRs for the new Central and Peripheral prior to resuming encryption.
- If the initiating device had stopped encryption, it shall initiate the start encryption sequence (see Section 4.2.5.3).

Both devices shall then re-enable transmission on the ACL-U logical link.

The transaction ID for the role switch PDUs in the sequence (LMP_SLOT_OFFSET and LMP_SWITCH_REQ along with the associated LMP_ACCEPTED or LMP_NOT_ACCEPTED) shall be set to 0 when the initiating device is the Central and 1 when it is the Peripheral.



Sequence 84: Role switch (Peripheral initiated)



Sequence 85: Role switch (Central initiated)

The LMP_SWITCH_REQ PDU contains a parameter, Switch_Instant, which specifies the instant at which the TDD switch is performed. This is specified as a Bluetooth clock value of the Central's clock, that is available to both devices. This instant is chosen by the sender of the message and shall be at least $2 \times T_{poll}$ or 32 (whichever is greater) slots in the future. The switch instant shall be within 12 hours of the current clock value to avoid clock wrap.

The sender of the LMP_SWITCH_REQ PDU selects the switch instant and queues the LMP_SWITCH_REQ PDU to LC for transmission and starts a timer to expire at the switch instant. When the timer expires it initiates the mode switch. In the case of a Central initiated switch if the LMP_SLOT_OFFSET PDU has not been received by the switch instant the role switch is carried out without an estimate of the Peripheral's slot offset. If an LMP_NOT_ACCEPTED PDU is received before the timer expires then the timer is stopped and the role switch shall not be initiated.

When the LMP_SWITCH_REQ is received the switch instant is compared with the Central's current clock value. If it is in the past then the instant has been passed and an LMP_NOT_ACCEPTED PDU with the Error_Code *Instant Passed* (0x28) shall be returned. If it is in the future then an LMP_ACCEPTED PDU shall be returned, assuming the role switch is accepted, and a timer is started to expire at the switch instant. When this timer expires the role switch shall be initiated.

After a successful role switch the supervision timeout and poll interval (T_{poll}) shall be set to their default values. The authentication state and the ACO shall remain unchanged.

Adaptive Frequency Hopping shall follow the procedures described in [Vol 2] Part B, Section 8.6.5. The default value for Max_Slots shall be used.

A role switch, whether successful or failed, does not affect the state of the Link Manager and of the ACL-C and ACL-U logical links except where explicitly stated.

4.5 Modes of operation

4.5.1 Hold mode

The ACL logical transport of a connection between two Bluetooth devices can be placed in Hold mode for a specified hold time. See [Vol 2] Part B, Section 8.8 for details.

M/O	PDU	Contents
O(6)	LMP_HOLD	Hold_Time, Hold_Instant
O(6)	LMP_HOLD_REQ	Hold_Time, Hold_Instant

Table 4.32: Hold mode PDUs

The LMP_HOLD and LMP_HOLD_REQ PDUs both contain a parameter, Hold_Instant, that specifies the instant at which the hold becomes effective. This is specified as a Bluetooth clock value of the Central's clock, that is available to both devices. The hold instant is chosen by the sender of the message and should be at least $6 \times T_{poll}$ slots in the future. The hold instant shall be within 12 hours of the current clock value to avoid clock wrap.

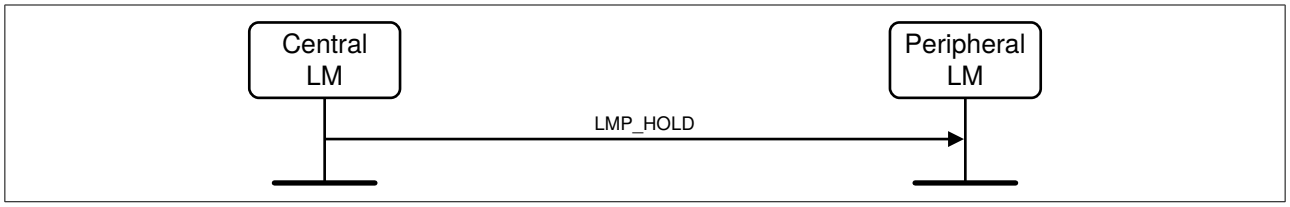
4.5.1.1 Central forces Hold mode

The Central may force Hold mode if there has previously been a request for Hold mode that has been accepted by the Peripheral. The hold time included in the PDU when the Central forces Hold mode shall not be longer than any hold time the Peripheral has previously accepted when there was a request for Hold mode.

The Central LM shall first pause traffic on the ACL-U logical link (see [Vol 2] Part B, Section 5.3.1). It shall select the hold instant and queue the LMP_HOLD PDU to its LC for transmission. It shall then start a timer to wait until the hold instant occurs. When this timer expires then the connection shall enter Hold mode. If the Baseband acknowledgment for the LMP_HOLD PDU is not received then the Central may enter Hold mode, but it shall not use its low accuracy clock during the hold.

When the Peripheral LM receives an LMP_HOLD PDU it compares the hold instant with the Central's current clock value. If it is in the future then it starts a timer to expire at this instant and enters Hold mode when it expires.

When the Central LM exits from Hold mode it re-enables transmission on the ACL-U logical link.



Sequence 86: Central forces Peripheral into Hold mode

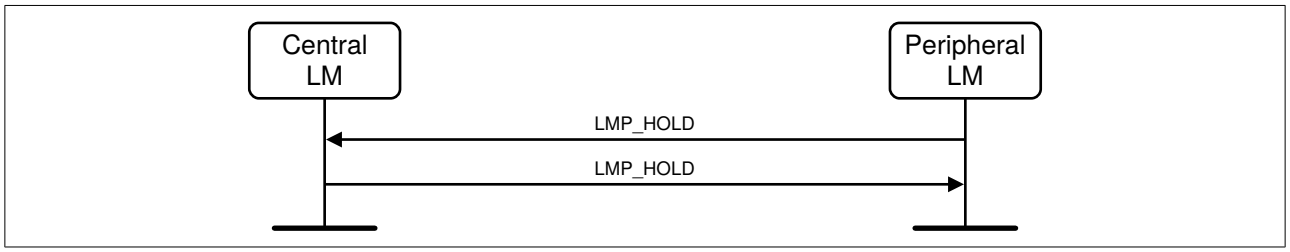
4.5.1.2 Peripheral forces Hold mode

The Peripheral may force Hold mode if there has previously been a request for Hold mode that has been accepted by the Central. The hold time included in the PDU when the Peripheral forces Hold mode shall not be longer than any hold time the Central has previously accepted when there was a request for Hold mode.

The Peripheral LM shall first complete the transmission of the current packet on the ACL logical transport and then shall suspend transmission on the ACL-U logical link. It shall select the hold instant and queue the LMP_HOLD PDU to its LC for transmission. It shall then wait for an LMP_HOLD PDU from the Central acting according to the procedure described in Section 4.5.1.1.

When the Central LM receives an LMP_HOLD PDU it shall pause traffic on the ACL-U logical link (see [Vol 2] Part B, Section 5.3.1). It shall then inspect the hold instant. If this is less than $6 \times T_{poll}$ slots in the future it shall modify the instant so that it is at least $6 \times T_{poll}$ slots in the future. It shall then send an LMP_HOLD PDU using the mechanism described in Section 4.5.1.1.

When the Central and Peripheral LMs exit from Hold mode they shall re-enable transmission on the ACL-U logical link.



Sequence 87: Peripheral forces Central into Hold mode

4.5.1.3 Central or Peripheral requests Hold mode

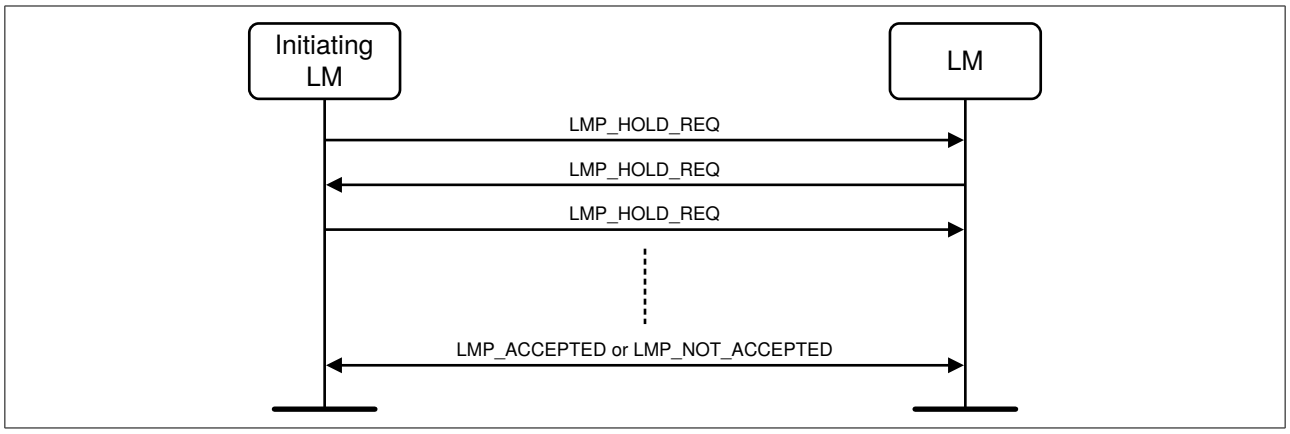
The Central or the Peripheral may request to enter Hold mode. Upon receipt of the request, the same request with modified parameters may be returned or the negotiation may be terminated. If an agreement is seen an LMP_ACCEPTED PDU terminates the negotiation and the ACL link is placed in Hold mode. If no agreement is seen, an

LMP_NOT_ACCEPTED PDU with the Error_Code *Unsupported LMP Parameter Value* (0x20) terminates the negotiation and Hold mode is not entered.

The initiating LM shall pause traffic on the ACL-U logical link (see [Vol 2] Part B, Section 5.3.1). On receiving an LMP_HOLD_REQ PDU the receiving LM shall complete the transmission of the current packet on the ACL logical transport and then shall suspend transmission on the ACL-U logical link.

The LM sending the LMP_HOLD_REQ PDU selects the hold instant, that shall be at least $9 \times T_{poll}$ slots in the future. If this is a response to a previous LMP_HOLD_REQ PDU and the contained hold instant is at least $9 \times T_{poll}$ slots in the future then this shall be used. The LMP_HOLD_REQ PDU shall then be queued to its LC for transmission and a timer shall be started to expire at this instant and the connection enters Hold mode when it expires unless an LMP_NOT_ACCEPTED or LMP_HOLD_REQ PDU is received by its LM before that point. If the LM receiving LMP_HOLD_REQ PDU agrees to enter Hold mode it shall return an LMP_ACCEPTED PDU and shall start a timer to expire at the hold instant. When this timer expires it enters Hold mode.

When each LM exits from Hold mode it shall re-enable transmission on the ACL-U logical link.



Sequence 88: Negotiation for Hold mode

4.5.2 [This section is no longer used]

4.5.3 Sniff mode

To enter Sniff mode, Central and Peripheral negotiate a sniff interval T_{Sniff} and a sniff offset, D_{Sniff}, that specifies the timing of the sniff slots. The offset determines the time of the first sniff slot; after that the sniff slots follow periodically with the sniff interval T_{Sniff}. To avoid clock wrap-around during the initialization, one of two options is chosen for the calculation of the first sniff slot. The Timing_Control_Flags parameter in the sniff request message indicates this.

When the ACL logical transport is in Sniff mode the Central shall only start a transmission in the sniff slots. Two parameters control the listening activity in the Peripheral: the Sniff_Attempt and the Sniff_Timeout. The Sniff_Attempt parameter determines for how many slots the Peripheral shall listen when the Peripheral is not treating this as a scatternet link, beginning at the sniff slot, even if it does not receive a packet with its own LT_ADDR. The Sniff_Timeout parameter determines for how many additional slots the Peripheral shall listen when the Peripheral is not treating this as a scatternet link if it continues to receive only packets with its own LT_ADDR. It is not possible to modify the sniff parameters while the device is in Sniff mode.

4.5.3.1 Central or Peripheral requests Sniff mode

Either the Central or the Peripheral may request entry to Sniff mode. The process is initiated by sending an LMP_SNIFF_REQ PDU containing a set of parameters. The receiving LM shall then decide whether to reject the attempt by sending an LMP_NOT_ACCEPTED PDU, to suggest different parameters by replying with an LMP_SNIFF_REQ PDU or to accept the request.

M/O	PDU	Contents
O(7)	LMP_SNIFF_REQ	Timing_Control_Flags D_{Sniff} T_{Sniff} Sniff_Attempt Sniff_Timeout
O(7)	LMP_UNSNIFF_REQ	-
O(41)	LMP_SNIFF_SUBRATING_REQ	Max_Sniff_Subrate Min_Sniff_Mode_Timeout Sniff_Subrating_Instant
O(41)	LMP_SNIFF_SUBRATING_RES	Max_Sniff_Subrate Min_Sniff_Mode_Timeout Sniff_Subrating_Instant

Table 4.33: Sniff mode PDUs

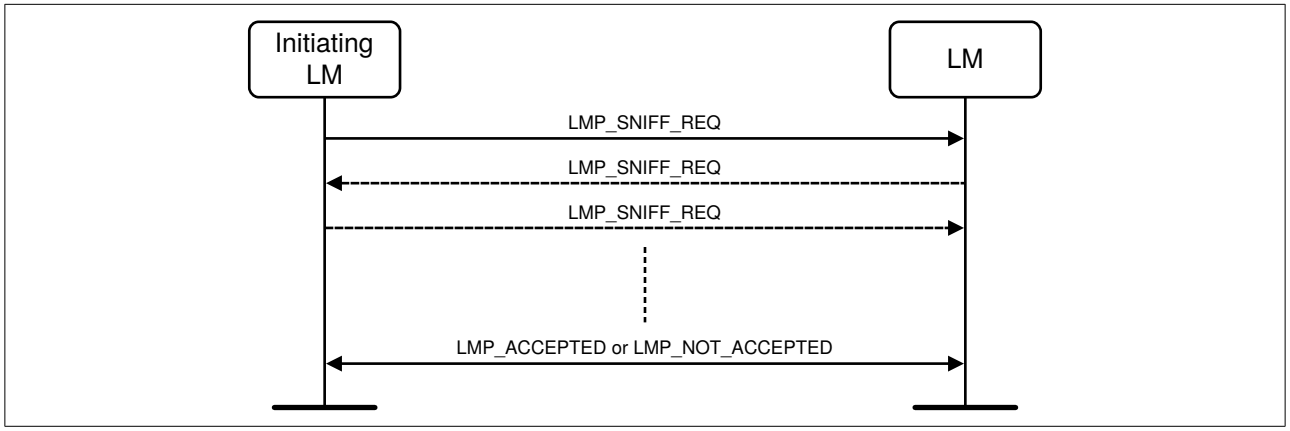
Before the first time that the Central sends LMP_SNIFF_REQ in a transaction it shall enter Sniff Transition mode. If the Central receives or sends an LMP_NOT_ACCEPTED PDU it shall exit from Sniff Transition mode.

If the Central receives an LMP_SNIFF_REQ PDU it shall enter Sniff Transition mode (if not already in it) and then determine whether to accept the request. The Central may reply with an LMP_NOT_ACCEPTED PDU or, if it can enter Sniff mode but requires a different set of parameters, it shall respond with an LMP_SNIFF_REQ PDU containing the new parameters. If the Central decides that the parameters are acceptable then it

shall send an LMP_ACCEPTED PDU; when it receives the Baseband acknowledgment for this PDU it shall exit Sniff Transition mode and enter Sniff mode.

If the Central receives an LMP_ACCEPTED PDU the Central shall exit from Sniff Transition mode and enter Sniff mode.

If the Peripheral receives an LMP_SNIFF_REQ PDU it shall determine whether to accept the request. The Peripheral may reply with an LMP_NOT_ACCEPTED PDU to reject the request or, if it can enter Sniff mode but requires a different set of parameters, it shall respond with an LMP_SNIFF_REQ PDU containing the new parameters. If the Peripheral decides that the parameters are acceptable then it shall send an LMP_ACCEPTED PDU and enter Sniff mode. If the Peripheral receives an LMP_NOT_ACCEPTED PDU it shall terminate the attempt to enter Sniff mode.



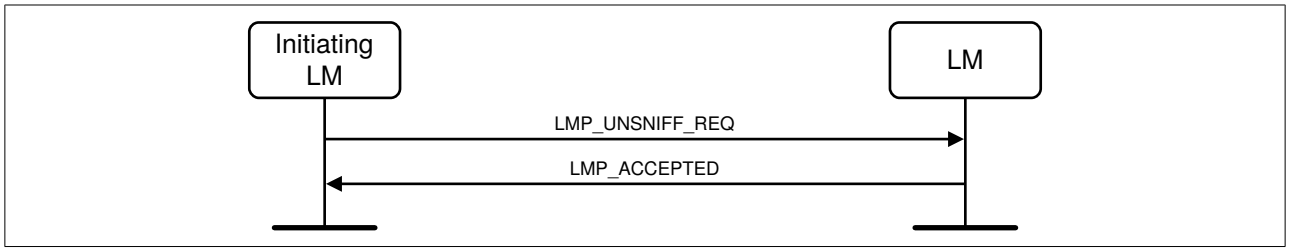
Sequence 89: Negotiation for Sniff mode

4.5.3.2 Moving a Peripheral from Sniff mode to Active mode

Sniff mode may be exited by either the Central or the Peripheral sending an LMP_UNSNIFF_REQ PDU. The requested device shall reply with an LMP_ACCEPTED PDU.

If the Central requests an exit from Sniff mode it shall enter Sniff Transition mode and then send an LMP_UNSNIFF_REQ PDU. When the Peripheral receives the LMP_UNSNIFF_REQ it shall exit from Sniff mode and reply with an LMP_ACCEPTED PDU. When the Central receives the LMP_ACCEPTED PDU it shall exit from Sniff Transition mode and enter Active mode.

If the Peripheral requests an exit from Sniff mode it shall send an LMP_UNSNIFF_REQ PDU. When the Central receives the LMP_UNSNIFF_REQ PDU it shall enter Sniff Transition mode and then send an LMP_ACCEPTED PDU. When the Peripheral receives the LMP_ACCEPTED PDU it shall exit from Sniff mode and enter Active mode. When the Central receives the Baseband acknowledgment for the LMP_ACCEPTED PDU it shall leave Sniff Transition mode and enter Active mode.



Sequence 90: Peripheral moved from Sniff mode to Active mode

4.5.3.3 Sniff subrating

Once Sniff mode has been started, sniff subrating may be initiated by either Link Manager.

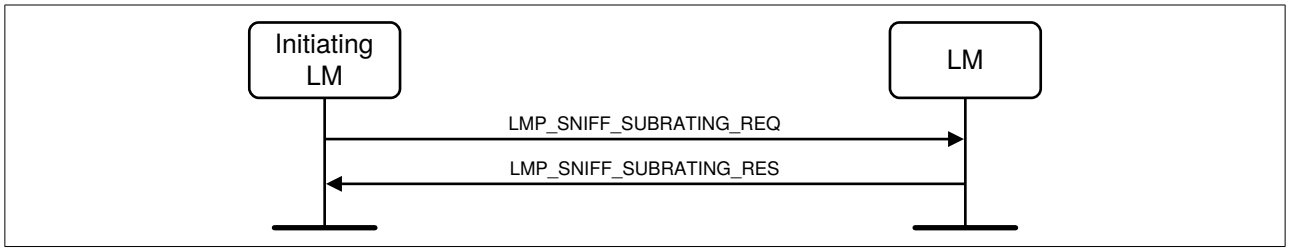
The LMP_SNIFF_SUBRATING_REQ and LMP_SNIFF_SUBRATING_RES PDUs specify parameters that the peer and initiating device shall use respectively for sniff subrating.

The Sniff_Subrating_Instant value shall be used to calculate the first sniff subrating anchor point. The Sniff_Subrating_Instant value shall be a maximum of 2^{16} time slots (40.9 seconds) from the Central's current clock and shall be a sniff anchor point. The Sniff_Subrating_Instant value should indicate a clock value in the future with respect to the clock value when the LMP message is first sent.

If the LMP_SNIFF_SUBRATING_REQ PDU is sent by the Central, the Sniff_Subrating_Instant value shall be used. The Peripheral shall reply with an LMP_SNIFF_SUBRATING_RES PDU using the same Sniff_Subrating_Instant value given by the Central.

When the LMP_SNIFF_SUBRATING_REQ PDU is sent by the Peripheral, the Sniff_Subrating_Instant value shall be ignored. The Central shall reply with an LMP_SNIFF_SUBRATING_RES PDU with the Sniff_Subrating_Instant value that shall be used for sniff subrating.

The initiating device shall not transition to the new sniff subrating parameters until the sniff subrating instant has passed and the LMP_SNIFF_SUBRATING_RES PDU has been received. The non-initiating device shall remain in Sniff mode and shall not transition to the new sniff subrating parameters until after the sniff subrating instant has passed and the Baseband acknowledgment of the LMP_SNIFF_SUBRATING_RES PDU has been received.



Sequence 91: LM accepts sniff subrating request

A device shall not send a new LMP_SNIFF_SUBRATING_REQ PDU until the previous sniff subrating transaction has completed and the sniff subrating instant has passed.

The maximum clock interval between two sniff subrating anchor points shall be less than the link supervision timeout. If the link supervision timeout needs to be updated to a shorter value than the clock interval between two sniff subrating anchor points, the Central shall disable sniff subrating, shall send the LMP_SUPERVISION_TIMEOUT PDU with the new supervision timeout value, and shall start using the new supervision timeout value after receiving a Baseband acknowledgment for the LMP_SUPERVISION_TIMEOUT PDU. Upon reception of the LMP_SUPERVISION_TIMEOUT PDU the Peripheral shall disable sniff subrating and shall start using the new supervision timeout value.

The Central shall initiate sniff subrating with the Max_Sniff_Subrate parameter less than the new supervision timeout. The Peripheral shall respond with the LMP_SNIFF_SUBRATING_RES PDU with the Max_Sniff_Subrate parameter less than the new supervision timeout.

4.6 Logical transports

When a connection is first established between two devices the connection consists of the ACL logical transport (carrying the ACL-C logical link for LMP messages and the ACL-U logical link for L2CAP data) and the APB logical transport carrying the APB-C logical links for LMP messages and the APB-U logical link for L2CAP data. One or more synchronous logical transports (SCO or eSCO) may then be added. A new logical transport shall not be created if it would cause all slots to be allocated to reserved slots on secondary LT_ADDRs.

4.6.1 SCO logical transport

The SCO logical transport reserves slots separated by the SCO interval, T_{sco}. The first slot reserved for the SCO logical transport is defined by T_{sco} and the SCO offset, D_{sco}. See [Vol 2] Part B, Section 8.6.2 for details. A device shall initiate a request for HV2 or HV3 packet type only if the other device supports that type. A device shall initiate CVSD, μ-law or A-law coding or uncoded (transparent) data only if the other device supports the corresponding feature. To avoid problems with a wrap-around of

the clock during initialization of the SCO logical transport, the Timing_Control_Flags parameter is used to indicate how the first SCO slot shall be calculated. The SCO link is distinguished from all other SCO links by a SCO handle. The SCO handle zero shall not be used.

The Link Manager shall not initiate a SCO connection, and shall reject any request for a SCO connection, while AES-CCM encryption is in use.

Note: The Peripheral interprets the initialization flag in the Timing_Control_Flags in terms of the Central's Bluetooth clock. See [Vol 2] Part B, Section 8.6.2.

M/O	PDU	Contents
O(11)	LMP_SCO_LINK_REQ	SCO_Handle Timing_Control_Flags D_{sco} T_{sco} SCO_Packet Air_Mode
O(11)	LMP_REMOVE_SCO_LINK_REQ	SCO_Handle Error_Code

Table 4.34: SCO link management PDUs

4.6.1.1 Central initiates a SCO link

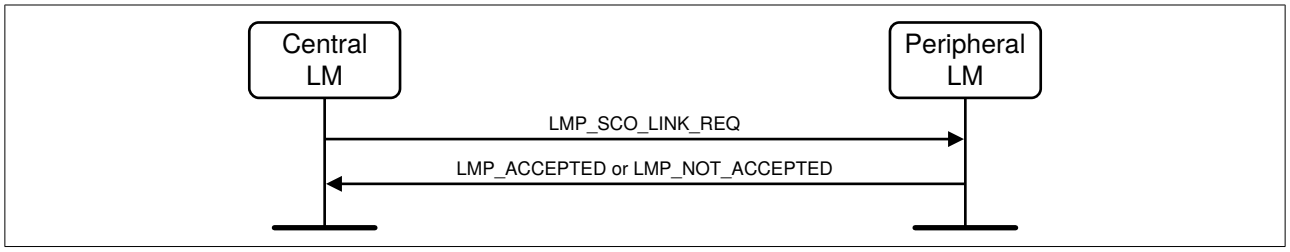
When establishing a SCO link the Central sends a request, a LMP_SCO_LINK_REQ PDU, with parameters that specify the timing, packet type and coding that will be used on the SCO link. Each of the SCO packet types supports three different voice coding formats on the air-interface: μ-law log PCM, A-law log PCM and CVSD. The air coding by log PCM or CVSD may be deactivated to achieve a transparent synchronous data link at 64 kb/s.

The slots used for the SCO links are determined by three parameters controlled by the Central: T_{sco}, D_{sco} and a flag indicating how the first SCO slot is calculated. After the first slot, the SCO slots follow periodically at an interval of T_{sco}.

If the Peripheral does not accept the SCO link, but can operate with a different set of SCO parameters, it can indicate what it does not accept in the Error_Code parameter of an LMP_NOT_ACCEPTED PDU. The Central may then issue a new request with modified parameters.

The SCO handle in the message shall be different from existing SCO link(s).

If the SCO packet type is HV1 the LMP_ACCEPTED shall be sent using the DM1 packet.

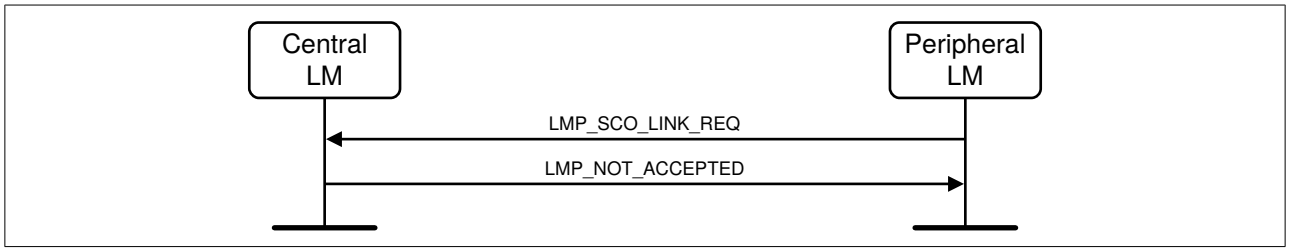


Sequence 92: Central requests a SCO link

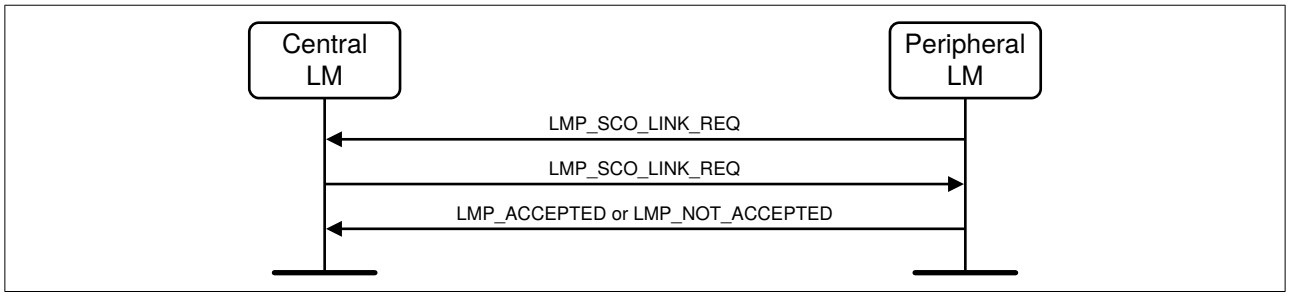
4.6.1.2 Peripheral initiates a SCO link

The Peripheral may initiate the establishment of a SCO link. The Peripheral sends an LMP_SCO_LINK_REQ PDU with the SCO handle set to zero; the Timing_Control_Flags parameter shall be ignored by the Central, while the D_{SCO} parameter should be set to 0. If the Central is not capable of establishing a SCO link, it replies with an LMP_NOT_ACCEPTED PDU. Otherwise it sends back an LMP_SCO_LINK_REQ PDU. This message includes the assigned SCO handle, D_{sco} and the timing control flags. The Central should try to use the same parameters as in the Peripheral request; if the Central cannot meet that request, it is allowed to use other values. The Peripheral shall then reply with LMP_ACCEPTED or LMP_NOT_ACCEPTED PDU.

If the SCO packet type is HV1 the LMP_ACCEPTED shall be sent using the DM1 packet.



Sequence 93: Central rejects Peripheral's request for a SCO link



Sequence 94: Central accepts Peripheral's request for a SCO link

4.6.1.3 Central requests change of SCO parameters

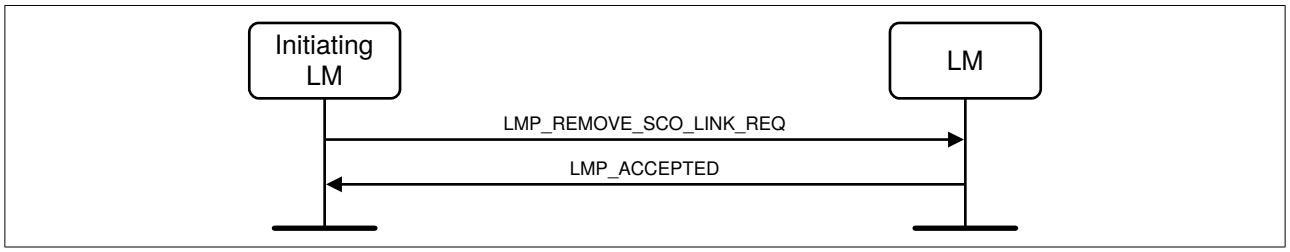
The Central sends an LMP_SCO_LINK_REQ PDU, where the SCO_Handle is the handle of the SCO link the Central wishes to change parameters for. If the Peripheral accepts the new parameters, it replies with an LMP_ACCEPTED PDU and the SCO link will change to the new parameters. If the Peripheral does not accept the new parameters, it shall reply with an LMP_NOT_ACCEPTED PDU and the SCO link is left unchanged. When the Peripheral replies with an LMP_NOT_ACCEPTED PDU it shall indicate in the Error_Code parameter what it does not accept. The Central may then try to change the SCO link again with modified parameters. The sequence is the same as in Section 4.6.1.1.

4.6.1.4 Peripheral requests change of SCO parameters

The Peripheral sends an LMP_SCO_LINK_REQ PDU, where the SCO_Handle is the handle of the SCO link to be changed. The parameters Timing_Control_Flags and D_{sco} in this PDU shall be ignored by the Central. If the Central does not accept the new parameters it shall reply with an LMP_NOT_ACCEPTED PDU and the SCO link is left unchanged. If the Central accepts the new parameters it shall reply with an LMP_SCO_LINK_REQ PDU containing the same parameters as in the Peripheral request. When receiving this message the Peripheral replies with an LMP_NOT_ACCEPTED PDU if it does not accept the new parameters. The SCO link is then left unchanged. If the Peripheral accepts the new parameters it replies with an LMP_ACCEPTED PDU and the SCO link will change to the new parameters. The sequence is the same as in Section 4.6.1.2.

4.6.1.5 Remove a SCO link

The Central or Peripheral may remove the SCO link by sending a request including the SCO handle of the SCO link to be removed and an Error_Code indicating why the SCO link is removed. The receiving side shall respond with an LMP_ACCEPTED PDU.



Sequence 95: SCO link removed

4.6.2 eSCO logical transport

After an ACL link has been established, one or more extended SCO (eSCO) links can be set up to the remote device. The eSCO links are similar to SCO links using

timing control flags, an interval T_{eSCO} and an offset D_{eSCO}. As opposed to SCO links, eSCO links have a configurable data rate that may be asymmetric, and can be set up to provide limited retransmissions of lost or damaged packets inside a retransmission window of size W_{eSCO}. The D_{eSCO} shall be based on CLK.

Note: The Peripheral interprets the initialization flag in the Timing_Control_Flags in terms of the Central's Bluetooth clock. See [Vol 2] Part B, Section 8.6.2.

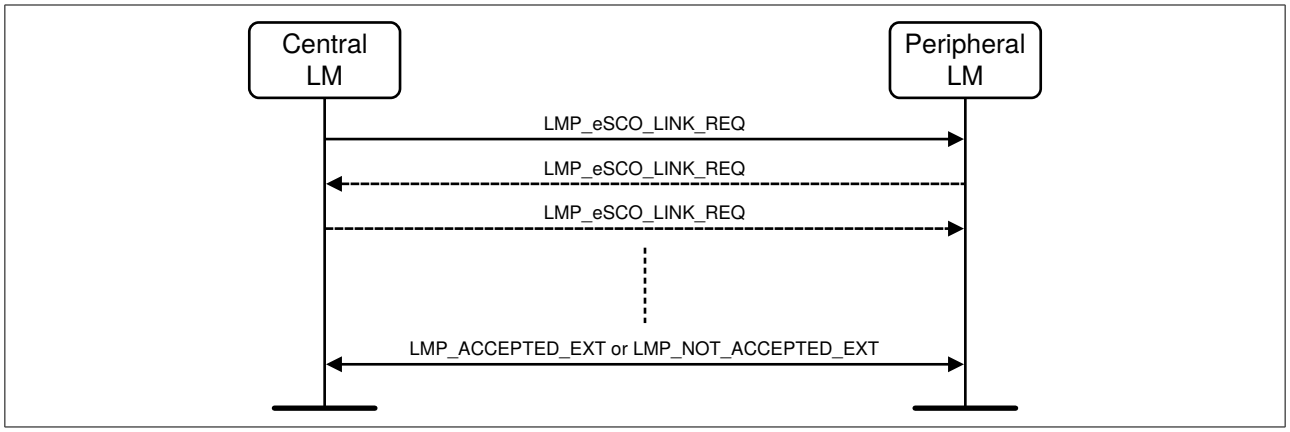
The parameters D_{eSCO}, T_{eSCO}, W_{eSCO}, eSCO_Packet_Type C→P, eSCO_Packet_Type P→C, Packet_Length C→P, Packet_Length P→C are henceforth referred to as the negotiable parameters.

M/O	PDU	Contents
O(31)	LMP_eSCO_LINK_REQ	eSCO_Handle eSCO_LT_ADDR Timing_Control_Flags D_{eSCO} T_{eSCO} W_{eSCO} eSCO_Packet_Type C→P eSCO_Packet_Type P→C Packet_Length C→P Packet_Length P→C Air_Mode Negotiation_State
O(31)	LMP_REMOVE_eSCO_LINK_REQ	eSCO_Handle Error_Code

Table 4.35: PDUs used for managing the eSCO links

4.6.2.1 Central initiates an eSCO link

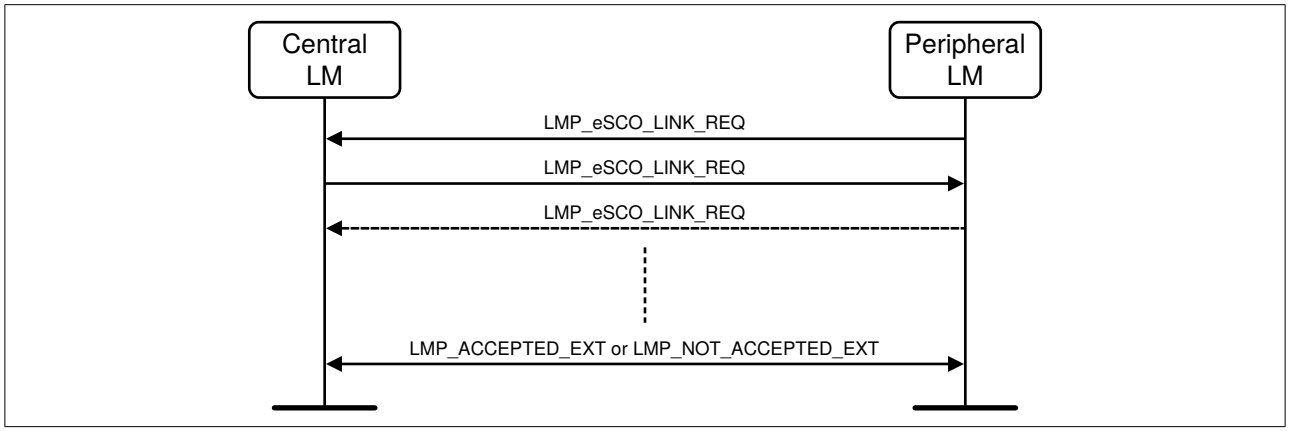
When establishing an eSCO link the Central sends an LMP_eSCO_LINK_REQ PDU specifying all parameters. The Peripheral may accept this with an LMP_ACCEPTED_EXT PDU, reject it with an LMP_NOT_ACCEPTED_EXT PDU, or respond with its own LMP_eSCO_LINK_REQ specifying alternatives for some or all parameters. The Peripheral shall not negotiate the eSCO_Handle or eSCO_LT_ADDR parameters. The negotiation of parameters continues until the Central or Peripheral either accepts the latest parameters with an LMP_ACCEPTED_EXT PDU, or terminates the negotiation with an LMP_NOT_ACCEPTED_EXT PDU. The negotiation shall use the procedures defined in Section 4.6.2.5.



Sequence 96: Central requests an eSCO link

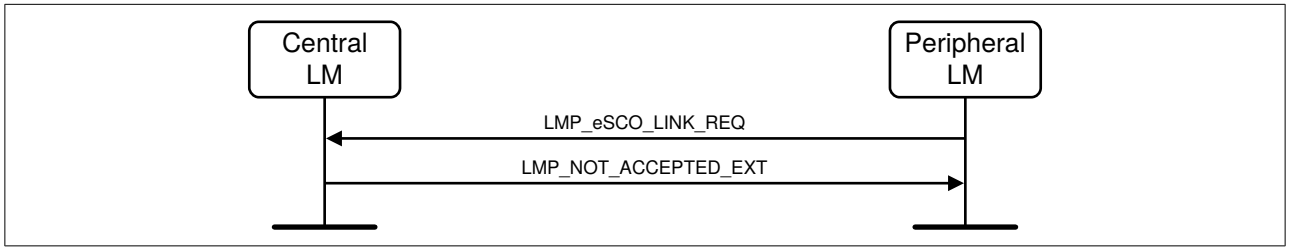
4.6.2.2 Peripheral initiates an eSCO link

When attempting to establish an eSCO link the Peripheral shall send an LMP_eSCO_LINK_REQ PDU specifying all parameters except eSCO_LT_ADDR, which is reserved for future use, and eSCO_Handle, which shall be set to zero. The Central may respond to this with an LMP_eSCO_LINK_REQ PDU, filling in these missing parameters, and potentially changing the other requested parameters. The Peripheral can accept this with an LMP_ACCEPTED_EXT PDU, or respond with a further LMP_eSCO_LINK_REQ PDU specifying alternatives for some or all of the parameters. The negotiation of parameters continues until the Central or Peripheral either accepts the latest parameters with an LMP_ACCEPTED_EXT PDU, or terminates the negotiation with an LMP_NOT_ACCEPTED_EXT PDU.



Sequence 97: Peripheral requests an eSCO link

The Central may reject the request immediately with an LMP_NOT_ACCEPTED_EXT PDU. The negotiation shall use the procedures defined in Section 4.6.2.5.



Sequence 98: Central rejects Peripheral's request for an eSCO link

4.6.2.3 Central or Peripheral requests change of eSCO parameters

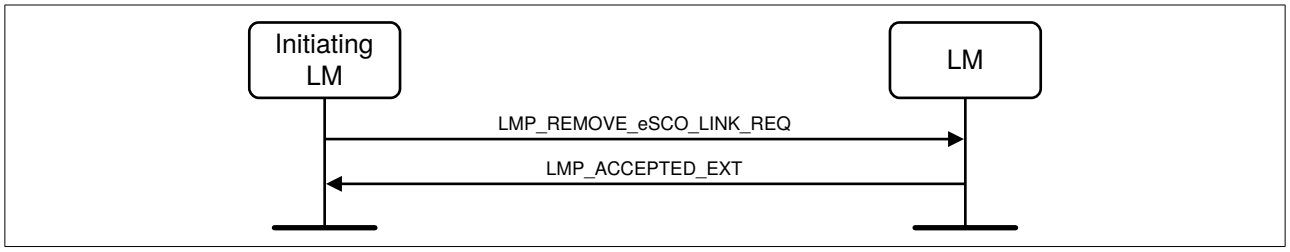
The Central or Peripheral may request a renegotiation of the eSCO parameters. The Central or Peripheral shall send an LMP_eSCO_LINK_REQ PDU with the eSCO handle of the eSCO link the device wishes to renegotiate. The remote device may accept the changed parameters immediately with LMP_ACCEPTED_EXT PDU, or the negotiation may be continued with further LMP_eSCO_LINK_REQ PDUs until the Central or Peripheral accepts the latest parameters with an LMP_ACCEPTED_EXT PDU or terminates the negotiation with an LMP_NOT_ACCEPTED_EXT PDU. In the case of termination with an LMP_NOT_ACCEPTED_EXT PDU, the eSCO link continues on the previously negotiated parameters.

The sequence is the same as in Section 4.6.2.2.

During re-negotiation, the eSCO LT_ADDR and eSCO handle shall not be re-negotiated and shall be set to the originally negotiated values. The negotiation shall use the procedures defined in Section 4.6.2.5.

4.6.2.4 Remove an eSCO link

Either the Central or Peripheral may remove the eSCO link by sending an LMP_REMOVE_eSCO_LINK_REQ PDU including the eSCO handle of the eSCO link to be removed and an Error_Code indicating why the eSCO link is removed. The receiving side shall respond with an LMP_ACCEPTED_EXT PDU. The Peripheral shall shut down its eSCO logical transport before sending its PDU (LMP_REMOVE_eSCO_LINK_REQ for Peripheral initiated removal, LMP_ACCEPTED_EXT for Central initiated). The Central shall not reassign the eSCO LT_ADDR until the end of the removal procedure. If, for some reason, such as the Peripheral being out of range, the procedure cannot be completed, the Central shall not reassign the eSCO LT_ADDR until the primary LT_ADDR is available for reuse (supervision timeout).



Sequence 99: eSCO link removed

4.6.2.5 Rules for the LMP negotiation and renegotiation

Rule 1: the Negotiation_State shall be set to 0 by the initiating LM. After the initial LMP_eSCO_LINK_REQ is sent the Negotiation_State shall not be set to 0.

Rule 2: if the bandwidth (defined as 1600 times the packet length in bytes divided by T_{eSCO} in slots) for either RX or TX or the Air_Mode cannot be accepted the device shall send LMP_NOT_ACCEPTED_EXT with the appropriate Error_Code.

Rule 3: Bandwidth and Air_Mode are not negotiable and shall not be changed for the duration of the negotiation. Once one side has rejected the negotiation (with LMP_NOT_ACCEPTED_EXT) a new negotiation may be started with different bandwidth and Air_Mode parameters.

Rule 4: if the parameters will cause a latency violation (T_{eSCO} + W_{eSCO} + reserved synchronous slots > allowed local latency) the device should propose new parameters that shall not cause a reserved slot violation or latency violation for the device that is sending the parameters. In this case the Negotiation_State shall be set to 3. Otherwise the device shall send LMP_NOT_ACCEPTED_EXT.

Rule 5: once a device has received an LMP_eSCO_LINK_REQ with the Negotiation_State set to 3 (latency violation), the device shall not propose any combination of packet type, T_{eSCO}, and W_{eSCO} that will give an equal or larger latency than the combination that caused the latency violation for the other device.

Rule 6: if the parameters cause both a reserved slot violation and a latency violation or if the parameters are not supported and a latency violation occurs, then the device shall set the Negotiation_State to 3 (latency violation).

Rule 7: if the parameters will cause a reserved slot violation the device should propose new parameters that shall not cause a reserved slot violation. In this case the Negotiation_State shall be set to 2. Otherwise the device shall send LMP_NOT_ACCEPTED_EXT.

Rule 8: If the requested parameters are not supported the device should propose a setting that is supported, and set the Negotiation_State to 4. If it is not possible to find such a parameter set, the device shall send LMP_NOT_ACCEPTED_EXT.

Rule 9: when proposing new parameters for reasons other than a latency violation, reserved slot violation, or configuration not supported, the Negotiation_State shall be set to 1.

4.6.2.6 Negotiation state definitions

Reserved Slot Violation: a reserved slot violation is when the receiving LM cannot setup the requested eSCO logical transport because the eSCO reserved slots would overlap with other regularly scheduled slots (e.g. other synchronous reserved slots or sniff anchor points).

Latency Violation: a latency violation is when the receiving LM cannot setup the requested eSCO logical transport because the latency (W_{eSCO}+T_{eSCO} + reserved synchronous slots) is greater than the maximum allowed latency.

Configuration not supported: The combination of parameters requested is not inside the supported range for the device.

4.7 Test mode

LMP has PDUs to support testing of the Bluetooth radio and Baseband. See [Vol 3] Part D, Section 1 for a detailed description of these test modes.

4.7.1 Activation and deactivation of Test mode

The activation may be carried out locally (via a HW or SW interface), or using the air interface.

- For activation over the air interface, entering the test mode shall be locally enabled for security and type approval reasons. The implementation of this local enabling is not subject to standardization.

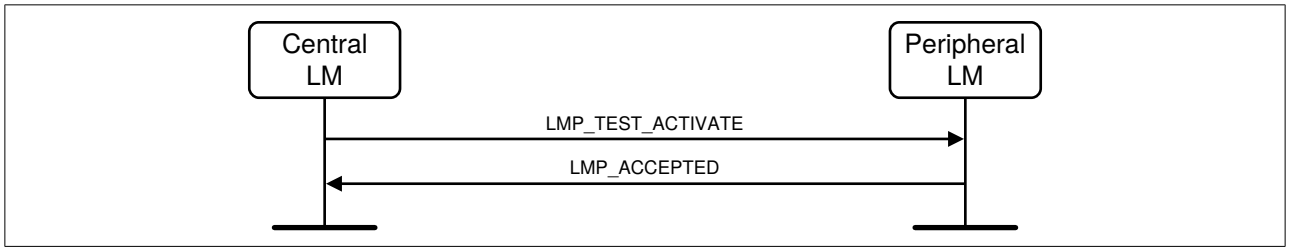
  The tester sends an LMP command that shall force the IUT to enter test mode. The IUT shall terminate all normal operation before entering the test mode.

  The IUT shall return an LMP_ACCEPTED PDU on reception of an activation command. An LMP_NOT_ACCEPTED PDU shall be returned if the IUT is not locally enabled.
- If the activation is performed locally using a HW or SW interface, the IUT shall terminate all normal operation before entering the test mode.

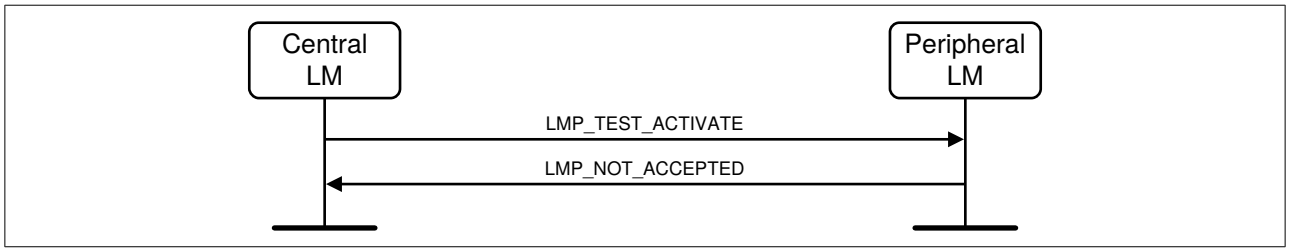
  Until a connection to the tester exists, the device shall perform page scan and inquiry scan. Extended scan activity is recommended.

The test mode is activated by sending an LMP_TEST_ACTIVATE PDU to the implementation under test (IUT). The IUT is always the Peripheral. The LM shall be able to receive this message at any time. If entering test mode is locally enabled in

the IUT, then it shall respond with an LMP_ACCEPTED PDU and test mode is entered. Otherwise the IUT responds with an LMP_NOT_ACCEPTED PDU and the IUT remains in normal operation. The Error_Code in the LMP_NOT_ACCEPTED PDU shall be *LMP PDU Not Allowed* (0x24).



Sequence 100: Activation of test mode successful



Sequence 101: Activation of Test mode fails. Peripheral is not allowed to enter Test mode.

The test mode can be deactivated in two ways. Sending an LMP_TEST_CONTROL PDU with Test_Scenario set to "exit test mode" exits the test mode and the Peripheral returns to normal operation still connected to the Central. Sending an LMP_DETACH PDU to the IUT ends the test mode and the connection.

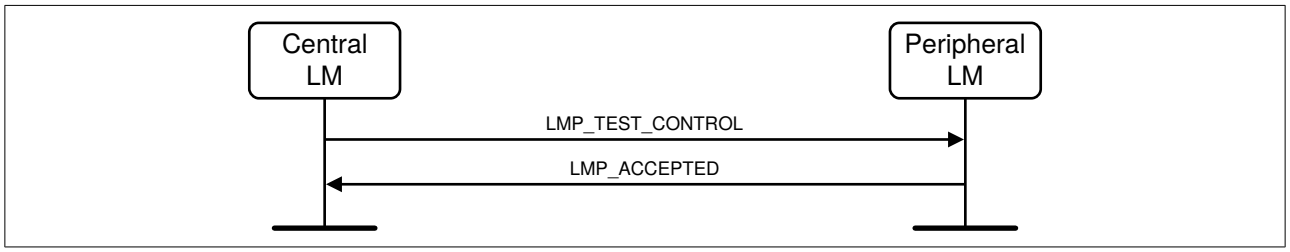
4.7.2 Control of Test mode

Control and configuration is performed using special LMP commands (see Section 4.7.3). These commands shall be rejected if the Bluetooth device is not in test mode. In this case, an LMP_NOT_ACCEPTED shall be returned. The IUT shall return an LMP_ACCEPTED on reception of a control command when in test mode.

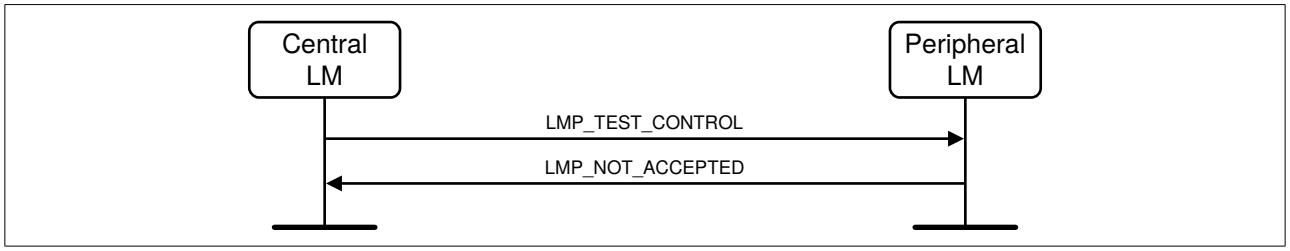
A Bluetooth device in test mode shall ignore all LMP commands not related to control of the test mode. LMP commands dealing with power control and the request for LMP features (LMP_FEATURES_REQ), and adaptive frequency hopping (LMP_SET_AFH, LMP_CHANNEL_CLASSIFICATION_REQ and LMP_CHANNEL_CLASSIFICATION) are allowed in test mode; the normal procedures are also used to test the adaptive power control.

The IUT shall leave the test mode when an LMP_DETACH command is received or an LMP_TEST_CONTROL command is received with Test_Scenario set to 'exit test mode'.

When the IUT has entered test mode, the LMP_TEST_CONTROL PDU can be sent to the IUT to start a specific test. This PDU is acknowledged with an LMP_ACCEPTED PDU. If a device that is not in test mode receives an LMP_TEST_CONTROL PDU, then it responds with an LMP_NOT_ACCEPTED PDU, where the Error_Code shall be *LMP PDU Not Allowed* (0x24).



Sequence 102: Control of Test mode successful



Sequence 103: Control of Test mode rejected since Peripheral is not in Test mode

4.7.3 Summary of Test mode PDUs

Table 4.36 lists all LMP messages used for test mode. To ensure that the contents of the LMP_TEST_CONTROL PDU are suitably whitened (important when sent in transmitter mode), all parameters listed in Table 4.37 are XORed with 0x55 before being sent.

LMP PDU	PDU number	Possible Direction	Contents	Position in Payload
LMP_TEST_ACTIVATE	56	C → P	*none*	
LMP_TEST_CONTROL	57	C → P	Test_Scenario	2
			Hopping_Mode	3
			Tx_Frequency	4
			Rx_Frequency	5
			Power_Mode	6
			Poll_Period	7
			Packet_Type	8
			Test_Data_Length	9-10

LMP PDU	PDU number	Possible Direction	Contents	Position in Payload
LMP_DETACH	7	C → P	*none*	
LMP_ACCEPTED	3	C ← P	*none*	
LMP_NOT_ACCEPTED	4	C ← P	*none*	

Table 4.36: LMP messages used for Test mode

Name	Length (bytes)	Type	Detailed
Test_Scenario	1	uint8	0 Pause Test Mode 1 Transmitter test – 0 pattern 2 Transmitter test – 1 pattern 3 Transmitter test – 1010 pattern 4 Pseudorandom bit sequence 5 Closed Loop Back – ACL packets 6 Closed Loop Back – Synchronous packets 7 ACL packets without whitening 8 Synchronous packets without whitening 9 Transmitter test – 1111 0000 pattern 10–254 Reserved for future use 255 Exit Test Mode The value is XORed with 0x55.
Hopping_Mode	1	uint8	0 RX/TX on single frequency 1 Normal hopping 2–255 Reserved for future use The value is XORed with 0x55.
Tx_Frequency	1	uint8	f = [2402 + k] MHz The value is XORed with 0x55.
Rx_Frequency	1	uint8	f = [2402 + k] MHz The value is XORed with 0x55.
Power_Mode	1	uint8	0 fixed TX output power 1 adaptive power control The value is XORed with 0x55.
Poll_Period	1	uint8	Unit: 1.25 ms The value is XORed with 0x55.

Name	Length (bytes)	Type	Detailed
Packet_Type	1	uint8	Bits 3-0 numbering as in packet header, see [Vol 2] Part B, Section 6.4.2 Bits 7-4 0: ACL/SCO 1: eSCO 2: Enhanced Data Rate ACL 3: Enhanced Data Rate eSCO 4-15: Reserved for future use The value is XORed with 0x55.
Test_Data_Length	2	uint16	This is equal to the length of user data in [Vol 2] Part B, Section 6.5, in bytes, excluding the payload header and CRC if present in the relevant type of packet. The value is XORed with 0x5555.

Table 4.37: Parameters used in LMP_TEST_CONTROL PDU

The control PDU is used for both transmitter and loop back tests. The following restrictions apply for the parameter settings:

Parameter	Restrictions Transmitter Test	Restrictions Loopback Test
Tx_Frequency	0 ≤ k ≤ 78	0 ≤ k ≤ 78
Rx_Frequency	same as Tx_Frequency	0 ≤ k ≤ 78
Poll_Period	*none*	not applicable (set to 0)
Test_Data_Length	Depends on packet type. See [Vol 2] Part B, Table 6.8 and [Vol 2] Part B, Table 6.9	For ACL and SCO packets: not applicable (set to 0) For eSCO packets: see [Vol 2] Part B, Table 6.8

Table 4.38: Restrictions on the parameters in the LMP_TEST_CONTROL PDU

5 SUMMARY

5.1 PDU summary

Where the "Possible direction" column in Table 5.1 shows "B", the PDU is sent on the APB-C logical link. All other PDUs are sent on the ACL-C logical link and only in the direction(s) indicated.

Table 5.1: Coding of the different LM PDUs

Note 1. Parameters coincide with their namesakes in LMP_SCO_LINK_REQ and LMP_REMOVE_SCO_LINK_REQ apart from the following:

1. eSCO_LT_ADDR - the eSCO connection will be active on an additional LT_ADDR that needs to be defined. The Central is not allowed to re-assign an active eSCO link to a different LT_ADDR.
2. D_{eSCO}, T_{eSCO} - as per LMP_SCO_LINK_REQ but with a greater flexibility in values (e.g. no longer fixed with respect to HV1, HV2, and HV3 packet choice).
3. W_{eSCO} - the eSCO retransmission window size (in slots)
4. packet type and packet length may be prescribed differently in Central-to-Peripheral or Peripheral-to-Central directions for asynchronous eSCO links
5. packet length (in bytes) - eSCO packet types no longer have fixed length
6. negotiation state – this is used to better enable the negotiation of the negotiable parameters: D_{eSCO}, T_{eSCO}, W_{eSCO}, eSCO_Packet_Type C→P, eSCO_Packet_Type P→C, Packet_Length C→P, Packet_Length P→C. When responding to an eSCO link request with a new suggestion for these parameters, this flag may be set to 1 to indicate that the last received negotiable parameters are possible, but the new parameters specified in the response eSCO link request would be preferable, to 2 to indicate that the last received negotiable parameters are not possible as they cause a reserved slot violation or to 3 to indicate that the last received negotiable parameters would cause a latency violation. The flag is set to zero in the initiating LMP_eSCO_LINK_REQ.

Note: The following opcodes were previously used: 22, 25 to 30. All other opcodes not listed in Table 5.1 are reserved for future use.

5.2 Parameter definitions

Where no mandatory range is given, the mandatory range consists of all valid values that are not reserved for future use.

Name	Length (bytes)	Type	Unit	Detailed
Access_Scheme	1	uint4		0: polling technique 1-15: reserved for future use
AFH_Channel_Classification	10	uint2 [40]		The n^{th} (numbering from 0) element defines the classification of channels *2n* and *2n+1*, other than the 39^{th} element which just contains the classification of channel 78. The value of each element indicates: 0 = unknown 1 = good 2 = reserved for future use 3 = bad
AFH_Channel_Map	10	uint1 [80]		If *AFH_Mode* is not 1 (enabled), the contents of this parameter are reserved for future use. Otherwise: The n^{th} (numbering from 0) element (in the range 0 to 78) contains the value for channel *n*. Element 79 is reserved for future use. The value of each element indicates: 0: channel *n* is unused 1: channel *n* is used
AFH_Instant	4	uint32	slots	Bits 27:1 of the Central's clock value at the time of switching hop sequences. Only even values are valid.
AFH_Max_Interval	2	uint16	slots	Range is 0x0640 to 0xBB80 slots (1 to 30 s) Only even values are valid
AFH_Min_Interval	2	uint16	slots	Range is 0x0640 to 0xBB80 slots (1 to 30 s) Only even values are valid

Name	Length (bytes)	Type	Unit	Detailed
AFH_Mode	1	uint8		0: disabled 1: enabled 2-255: reserved for future use
AFH_Reporting_Mode	1	uint8		0: disabled 1: enabled 2-255: reserved for future use
Air_Mode	1	uint8		0: μ-law log 1: A-law log 2: CVSD 3: transparent data 4-255: reserved for future use
Authentication_Rsp	4	multiple bytes		
Authentication_-Requirements	1	uint8		0x00: MITM Protection Not Required – No Bonding 0x01: MITM Protection Required – No Bonding 0x02: MITM Protection Not Required – Dedicated Bonding 0x03: MITM Protection Required – Dedicated Bonding 0x04: MITM Protection Not Required – General Bonding 0x05: MITM Protection Required – General Bonding 0x06 to 0xFF: reserved for future use
BD_ADDR	6	multiple bytes		BD_ADDR of the sending device
Clk_Adj_Clk	4	uint32	slot pairs	CLK[27:2] for the moment that the PDU is transmitted.
Clk_Adj_ID	1	uint8		Clk_Adj_ID is chosen by the Central as a handle to identify a Coarse Clock Adjustment event.
Clk_Adj_Instant	4	uint32	slots	CLK_{old}[27:1] at the time of the coarse clock adjustment, based on the value of time_base_offset before the adjustment is made. Only even values are valid.

Name	Length (bytes)	Type	Unit	Detailed
Clk_Adj_Mode	1	uint8		0: Before Instant 1: After Instant 2-255: reserved for future use
Clk_Adj_Offset	2	sint16	µs	The offset between the old and new slot boundaries. Valid range is –624 to +624.
Clk_Adj_Period	1	uint8	slots	Indicates to the Central that adding an integer multiple of this value to Clk_Adj_Slots gives an equally acceptable adjustment. The value of Clk_Adj_Period shall be zero or an even number greater than Clk_Adj_Slots. Only even values are valid.
Clk_Adj_Slots	1	uint8	slots	The difference between the clocks at the adjustment instant (i.e. $CLK_{new}[27:1]$ - $CLK_{old}[27:1]$).
Clock_Offset	2	uint15	1.25 ms	($CLKN_{16\text{-}2\ Peripheral}$ - $CLKN_{16\text{-}2\ Central}$) *mod* 2^{15}
Commitment_Value	16	uint128		
Company_Identifier	2	uint16		see Assigned Numbers
Confirmation_Value	16	uint128		

Name	Length (bytes)	Type	Unit	Detailed
Data_Rate	1	uint8		When in Basic Rate mode: bit 0 = 0: use FEC bit 0 = 1: do not use FEC bits 1-2=0: No packet-size preference available bits 1-2=1: use 1-slot packets bits 1-2=2: use 3-slot packets bits 1-2=3: use 5-slot packets When in Enhanced Data Rate mode: bits 3-4=0: use DM1 packets bits 3-4=1: use 2 Mb/s packets bits 3-4=2: use 3 Mb/s packets bits 3-4=3: reserved for future use bits 5-6=0: No packet-size preference available bits 5-6=1: use 1-slot packets bits 5-6=2: use 3-slot packets bits 5-6=3: use 5-slot packets bit 7: reserved for future use
D_{eSCO}	1	uint8	slots	Only even values less than T_{eSCO} are valid
Drift	1	uint8	ppm	
D_{SAM}	1	uint8	slots	Only even values less than T_{SAM} are valid
D_{SCO}	1	uint8	slots	Only even values less than T_{SCO} are valid
D_{Sniff}	2	uint16	slots	Only even values less than T_{Sniff} are valid
Encap_Data	16	Multiple bytes		MSBs zero padded when data is less than 16 bytes. Little-endian format
Encap_Major_Type	1	uint8		See Table 5.4
Encap_Minor_Type	1	uint8		See Table 5.4
Encap_Payload_Length	1	uint8		See Table 5.4

Name	Length (bytes)	Type	Unit	Detailed
Encryption_Mode	1	uint8		0: no encryption 1: encryption 2: previously used 3-255: reserved for future use
Error_Code	1	uint8		See [Vol 1] Part F
Escape_Opcode	1	uint8		Identifies which Escape_Opcode is being acknowledged: range 124-127
eSCO_Handle	1	uint8		
eSCO_LT_ADDR	1	uint3		Logical transport address for the eSCO logical transport. Valid range is 1-7.
eSCO_Packet_Type	1	uint8		0x00 (C → P): POLL 0x00 (P → C): NULL 0x07: EV3 0x0C: EV4 0x0D: EV5 0x26: 2-EV3 0x2C: 2-EV5 0x37: 3-EV3 0x3D: 3-EV5 Other values are reserved for future use
Extended_Features	8	uint1 [64]		The n^{th} (numbering from 0) element represents feature number 64P + *n* in Tables 3.2 onwards, where P is the relevant features page number.
Extended_Opcode	1	uint8		Which Extended_Opcode is being acknowledged
Features	8	uint1 [64]		The n^{th} (numbering from 0) element represents feature number *n* in Table 3.2
Features_Page	1	uint8		Identifies which page of extended features is being requested. 0 means standard features 1-255 other feature pages
Hold_Instant	4	uint32	slots	Bits 27:1 of the Central's clock value. Only even values are valid

Name	Length (bytes)	Type	Unit	Detailed
Hold_Time	2	uint16	slots	Only even values less than or equal to (*supervisionTO* × 0.999) are valid. Mandatory range 0x0014 to 0x8000.
IO_Capabilities	1	uint8		0: Display only 1: Display YesNo 2: KeyboardOnly 3: NoInputNoOutput 4-255: reserved for future use
Jitter	1	uint8	µs	
Key	16	multiple bytes		
Key_Size	1	uint8	byte	
Key_Size_Mask	2	uint1 [16]		Supported broadcast encryption key sizes: first element is support for length 1, and so on. The bit shall be one if the key size is supported.
Max_Slots	1	uint8	slots	
Max_Sniff_Subrate	1	uint8	subrate	Valid range: 1-255
Max_Supported_Page	1	uint8		Highest page of extended features which contains a non-zero bit for the originating device. Range 0-255
Min_Sniff_Mode_Timeout	2	uint16	slots	Only even values are valid
Name_Fragment	14	utf8s{14z}		UTF-8 characters.
Name_Length	1	uint8	bytes	
Name_Offset	1	uint8	bytes	
N_{BC}	1	uint8		Minimum number of times that an APB broadcast packet should be sent.

Name	Length (bytes)	Type	Unit	Detailed
Negotiation_State	1	uint8		0: Initiate negotiation 1: the latest received set of negotiable parameters were possible but these parameters are preferred. 2: the latest received set of negotiable parameters would cause a reserved slot violation. 3: the latest received set of negotiable parameters would cause a latency violation. 4: the latest received set of negotiable parameters are not supported. Other values are reserved for future use
Nonce_Value	16	Multiple bytes		Little-endian Format
Notification_Type	1	uint8		0=passkey entry started 1=passkey digit entered 2=passkey digit erased 3=passkey cleared 4=passkey entry completed 5-255: reserved for future use
N_{Poll}	1	uint8		
N_{SAM_SM}	1	uint8	submaps	Number of submaps in the SAM slot map; range 0 to 48
OOB_Auth_Data	1	uint8		0: No OOB Authentication Data received 1: OOB Authentication Data received 2-255: reserved for future use
Opcode	1	uint8		

Name	Length (bytes)	Type	Unit	Detailed
Packet_Length	2	uint16	bytes	Length of the eSCO payload 0 for POLL/NULL 1-30 for EV3 1-120 for EV4 1-180 for EV5 1-60 for 2-EV3 1-360 for 2-EV5 1-90 for 3-EV3 1-540 for 3-EV5 Other values are invalid
Packet_Type_Table	1	uint8		0: 1 Mb/s only 1: 2/3 Mb/s 2-255: reserved for future use
Paging_Scheme	1	uint8		0: mandatory scheme 1-255: reserved for future use
Paging_Scheme_Settings	1	uint8		For mandatory scheme: 0: R0 1: R1 2: R2 3-255: reserved for future use
Poll_Interval	2	uint16	slots	Only even values are valid. Mandatory range 0x0006 to 0x1000.
Power_Adj_Req	1	uint8		0: decrement power one step 1: increment power one step 2: increase to maximum power 3-255: reserved for future use

Name	Length (bytes)	Type	Unit	Detailed
Power_Adj_Rsp	1	uint2 [4]		element 0: GFSK element 1: π/4-DQPSK element 2: 8DPSK element 3: reserved for future use Each 2-bit value is defined as follows 0: not supported 1: changed one step, (not min or max) 2: max power 3: min power
Random_Number	16	multiple bytes		
Reserved	1	uint8		Reserved for future use
SAM_Index	1	uint8		Index of the SAM slot map. Mandatory values 0, 1, 2, and 0xFF.
SAM_Instant	4	uint32	slots	CLK[27:1] at the instant the SAM slot map is to be activated. Only even values are valid.
SAM_Submaps	12	uint2 [48]		This parameter contains 48 2-bit fields. Only the first N_{SAM_SM} fields are significant; the remainder are reserved for future use. The n^{th} (numbering from 0) such field defines the submap type of the n^{th} submap in the map. The meanings of the possible values are: 0 = Each slot is individually available or unavailable as configured. Slots may have different availabilities for transmission and reception 1 = All slots are available for transmission and reception 2 = All slots are unavailable for transmission and reception 3 = reserved for future use

Name	Length (bytes)	Type	Unit	Detailed
SAM_Type0_Submap	14	uint2 [56]		This parameter contains 56 2-bit fields. The n^{th} (numbering from 0) such field defines the slot type of the n^{th} slot. The meanings of the possible values are: 0 = The slot is not available for either transmission or reception 1 = The slot is available for transmission but not reception 2 = The slot is available for reception but not transmission 3 = The slot is available for both transmission and reception
SCO_Handle	1	uint8		
SCO_Packet	1	uint8		0: HV1 1: HV2 2: HV3 3-255: reserved for future use
Slot_Offset	2	uint16	µs	Valid range is 0 to 1249
Sniff_Attempt	2	uint16	received slots	Number of receive slots. Mandatory range 1 to T_{sniff} ÷2
Sniff_Subrating_Instant	4	uint32	slots	Bits 27:1 of the Central's clock value Only even values are valid
Sniff_Timeout	2	uint16	received slots	Number of receive slots. Mandatory range 0 to 0x0028.
Subversion	2	uint16		Defined by each company
Supervision_Timeout	2	uint16	slots	Mandatory values 0 and 0x0190 to 0xFFFF. 0 means an infinite timeout
Switch_Instant	4	uint32	slots	Bits 27:1 of the Central's clock value Only even values are valid
T_{eSCO}	1	uint8	slots	Valid range is 4 – 254 slots Only even values are valid

Name	Length (bytes)	Type	Unit	Detailed
Timing_Control_Flags	1	uint8		bit 0 is ignored by the recipient bit 1 = 0: use initialization 1 bit 1 = 1: use initialization 2 bit 2 is ignored by the recipient bits 3-7: reserved for future use
T_{SAM_SM}	1	uint8	slots	Length of each SAM submap. Range 2 to 56. Only even values are valid
T_{sco}	1	uint8	slots	Only even values are valid. Mandatory values 2 and 6.
T_{Sniff}	2	uint16	slots	Only even values less than or equal to (*supervisionTO* × 0.999) are valid. Mandatory values: valid values in the range 0x0006 to 0x0540.
Update_Mode	1	uint8		0: Existing SAM slot maps containing any type 0 submaps are invalidated 1: The defined type 0 submap takes effect immediately 2:The defined type 0 submap takes effect at the start of the next sub-interval All other values are reserved for future use.
Version	1	uint8		See Assigned Numbers
W_{eSCO}	1	uint8	slots	Number of slots in the retransmission window Valid range is 0 – 254 slots Only even values are valid

Table 5.2: Parameters in LM PDUs

If a parameter is described as "only even values are valid" and a device receives an LMP PDU with an odd value for this parameter field, the PDU should be rejected with an error code of *Invalid LMP Parameters* (0x1E).

Where a parameter is described as bits N:M of some other value V, the parameter value in the PDU shall be V shifted right by M bits. Where the space available for the parameter is greater than that needed (N-M+1 bits), the parameter value still occupies the entire space and the remaining bits shall be zero.

For example, if a 16 bit parameter is equal to 0xDEAD and bits 10:6 are stored in a uint8, the resulting parameter will be 0x1A.

The recipient shall accept any of the values for the eSCO parameter listed in Table 5.3 and may accept any other value listed for the parameter in Table 5.2.

	Single Slot Packets	**3-Slot Packets**
Packet type and T_{eSCO}	EV3: 6 2-EV3: 6-12 (even) 3-EV3: 6-18 (even)	EV4: 16 EV5: 16 2-EV5: 16 3-EV5: 16
W_{eSCO}	0, 2, and 4	0 and 6
Packet_Length (in each direction)	10 × T_{eSCO} ÷ 2	10 × T_{eSCO} ÷ 2
Air_Mode	At least one of A-law, μ-law, CVSD, transparent	transparent

Table 5.3: Mandatory parameter ranges for eSCO packet types

5.3 LMP encapsulated

Name	**Major Type**	**Minor Type**	**Payload Length**	**Detailed**
P-192 Public Key	1	1	48	X, Y format Bytes 23-0: X co-ordinate Bytes 47-24: Y co-ordinate Little-endian Format
P-256 Public Key	1	2	64	X, Y format Bytes 31-0: X co-ordinate Bytes 63-32: Y co-ordinate Little-endian Format

Table 5.4: LMP encapsulated

All other combinations of major and minor type are reserved for future use.

5.4 Default values

Devices shall use these values before anything else has been negotiated:

Parameter	**Value**
AFH_Mode	disabled
AFH_Reporting_Mode	disabled

Parameter	Value
Drift	250
Jitter	10
Max_Slots	1
Poll_Interval	40

Table 5.5: Device default values

Appendix A Changes to parameter names

Previous versions of this specification used different names for some of the parameters listed in Section 5.2. Table A.1 shows the previous and current names where a name has been changed; Table A.2 shows those names that have not changed.

Previous name	Current name
access scheme	Access_Scheme
AFH_channel_classification	AFH_Channel_Classification
AFH_channel_map	AFH_Channel_Map
AFH_instant	AFH_Instant
AFH_max_interval	AFH_Max_Interval
AFH_min_interval	AFH_Min_Interval
AFH_mode	AFH_Mode
AFH_reporting_mode	AFH_Reporting_Mode
air mode	Air_Mode
authentication response	Authentication_Rsp
clk_adj_clk	Clk_Adj_Clk
clk_adj_id	Clk_Adj_ID
clk_adj_instant	Clk_Adj_Instant
clk_adj_mode	Clk_Adj_Mode
clk_adj_period	Clk_Adj_Period
clk_adj_slots	Clk_Adj_Slots
clk_adj_us	Clk_Adj_Offset
clock offset	Clock_Offset
Commitment value	Commitment_Value
CompId	Company_Identifier
Confirmation value	Confirmation_Value
data rate	Data_Rate
drift	Drift
D_{sniff}	D_{Sniff}
encapsulated data	Encap_Data
encapsulated major type	Encap_Major_Type
encapsulated minor type	Encap_Minor_Type

Previous name	Current name
encapsulated payload length	Encap_Payload_Length
encryption mode	Encryption_Mode
error code	Error_Code
escape op code	Escape_Opcode
eSCO handle	eSCO_Handle
eSCO LT_ADDR	eSCO_LT_ADDR
eSCO packet type	eSCO_Packet_Type
extended features	Extended_Features
extended op code	Extended_Opcode
features	Features
features page	Features_Page
for future use	Reserved
hold instant	Hold_Instant
hold time	Hold_Time
hopping mode	Hopping_Mode
jitter	Jitter
key	Key
key size	Key_Size
key size mask	Key_Size_Mask
length of test data	Test_Data_Length
max slots	Max_Slots
max supported page	Max_Supported_Page
max_sniff_subrate	Max_Sniff_Subrate
min_sniff_mode_timeout	Min_Sniff_Mode_Timeout
name fragment	Name_Fragment
name length	Name_Length
name offset	Name_Offset
negotiation state	Negotiation_State
Nonce Value	Nonce_Value
Notification Type	Notification_Type
N_{poll}	N_{Poll}
N_{SAM-SM}	N_{SAM_SM}
OOB Authentication Data	OOB_Auth_Data

Previous name	Current name
op code	Opcode
packet length	Packet_Length
packet type	Packet_Type
packet type table	Packet_Type_Table
paging scheme	Paging_Scheme
paging scheme settings	Paging_Scheme_Settings
poll interval	Poll_Interval
poll period	Poll_Period
power_adjustment_request	Power_Adj_Req
power_adjustment_response	Power_Adj_Rsp
power control mode	Power_Mode
random number	Random_Number
RX frequency	RX_Frequency
SAM_Type0-Submap	SAM_Type0_Submap
SCO handle	SCO_Handle
SCO packet	SCO_Packet
slot offset	Slot_Offset
sniff attempt	Sniff_Attempt
sniff timeout	Sniff_Timeout
sniff_subrating_instant	Sniff_Subrating_Instant
SubVersNr	Subversion
supervision timeout	Supervision_Timeout
switch instant	Switch_Instant
test scenario	Test_Scenario
timing control flags	Timing_Control_Flags
T_{SAM-SM}	T_{SAM_SM}
T_{sniff}	T_{Sniff}
TX frequency	TX_Frequency
Update Mode	Update_Mode
VersNr	Version

Host Controller Interface Functional Specification is located in [Vol 4] Part E

MESSAGE SEQUENCE CHARTS

Examples of interactions between Host Controller Interface commands and events and Link Manager Protocol Data Units are represented in the form of message sequence charts. These charts show typical interactions and do not indicate all possible protocol behavior.

CONTENTS

1 INTRODUCTION

This Part shows typical interactions between Host Controller Interface (HCI) commands and events and Link Manager (LM) Protocol Data Units (PDU) on the BR/EDR Controller. It provides message sequence charts (MSCs) for a range of common Link Manager procedures and the associated Host commands.

This Part illustrates only the most useful scenarios, it does not cover all possible alternatives. Furthermore, the message sequence charts do not consider errors over the air interface or Host interface. In all message sequence charts it is assumed that all events are not masked, so the Controller will not filter out any events.

The sequence of messages in these message sequence charts is for illustrative purposes. The messages may be sent in a different order where allowed by the Link Manager or HCI. If any of these charts differ with text in the Baseband, Link Manager, or HCI Parts, the text in those Parts overrides these charts.

1.1 Notation

The notation used in the message sequence charts (MSCs) consists of ovals, elongated hexagons, boxes, lines, and arrows. The vertical lines terminated on the top by a shadow box and at the bottom by solid oval indicate a protocol entity that resides in a device. MSCs describe interactions between these entities and states those entities may be in.

The following symbols represent interactions and states:

Oval	Defines the context for the message sequence chart.
Hexagon	Indicates a condition needed to start the transactions below this hexagon. The location and width of the Hexagon indicates which entity or entities make this decision.
Box	Replaces a group of transactions. May indicate a user action, or a procedure in the Baseband.
Dashed Box	Optional group of transactions.
Solid Arrow	Represents a message, signal or transaction. Can be used to show LMP and HCI traffic. Some Baseband packet traffic is also shown. These are prefixed by BB followed by either the type of packet, or an indication that there is an ACK signal in a packet.
Dashed Arrow	Represents an optional message, signal or transaction. Can be used to show LMP and HCI traffic.

1.2 Flow of control

Some message sequences are split into several charts. In these charts, numbers indicate normal or required ordering and letters represent alternative paths. For example, Step 4 is after Step 3, and Step 5a could be executed instead of Step 5b.

1.3 Example MSC

The protocol entities represented in the example shown in Figure 1.1 illustrate the interactions of two devices named A and B. Each device includes a Host and a LM entity in this example. Other MSCs in this Part may show the interactions of more than two devices.

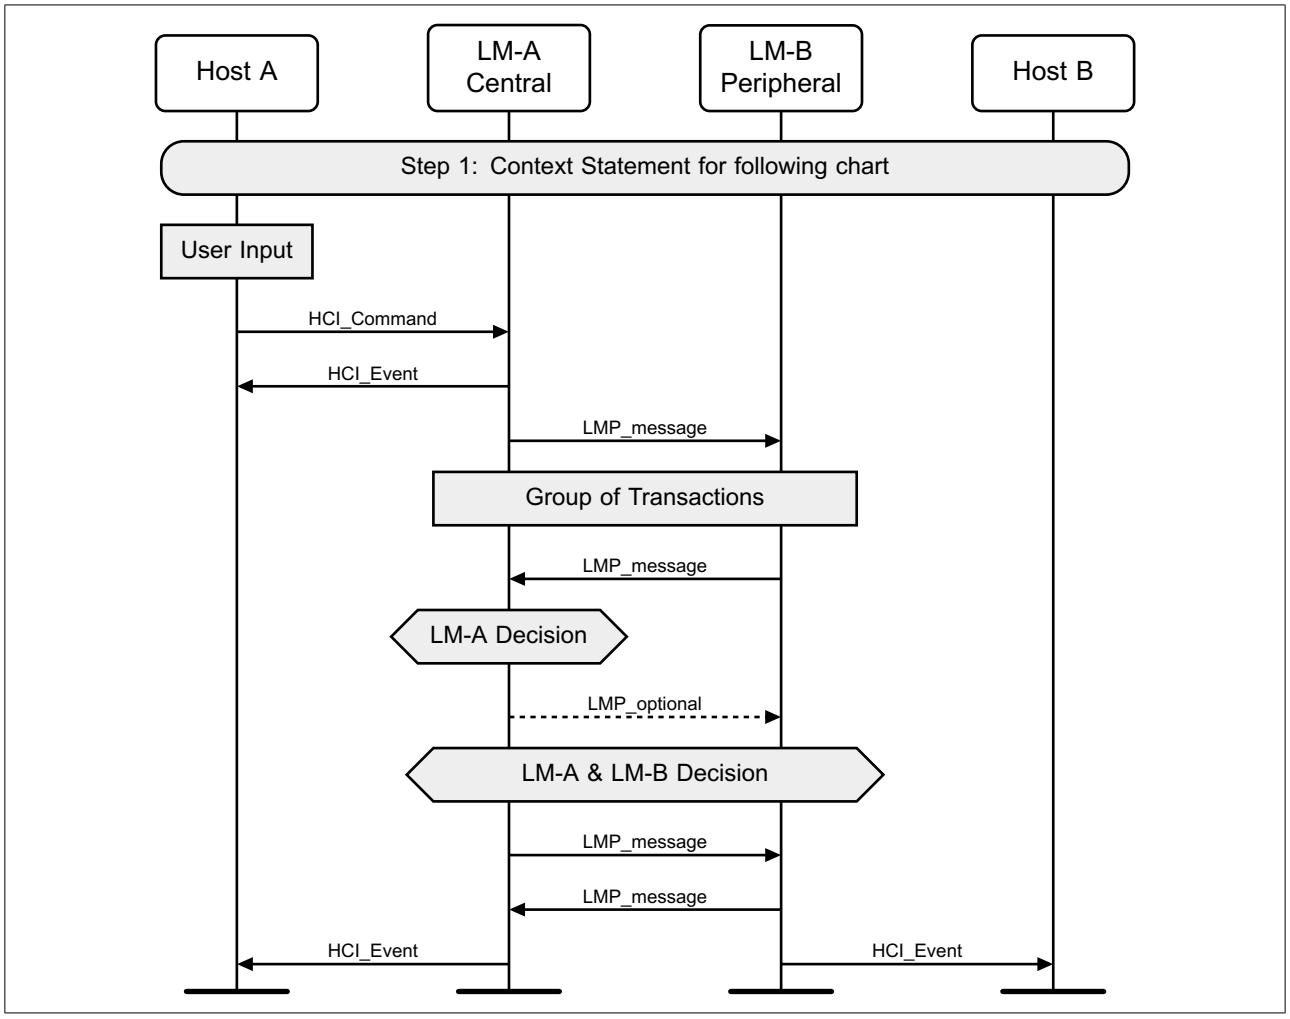

Figure 1.1: Example MSC

1.4 Forward compatibility

Many of the message sequences in this Part use HCI commands or events that have enhanced or extended variants that were added to the specification later than the

relevant sequence. Such variants can be related commands or events with different names (e.g., HCI_Flush and HCI_Enhanced_Flush commands) or commands or events with multiple versions (e.g., HCI_Encryption_Change event). In some instances (for example, see [Vol 4] Part E, Section 3.1.1), a Host is required to use the new variant rather than the one shown in the MSC. Even when this is not a requirement, Host implementers may prefer to use the newer variants.

In these circumstances, the MSCs have not been rewritten to use newer features but have been left unchanged. In general, the new commands and events will directly replace the old ones, but this is not always the case and readers should not assume it.

2 SERVICES WITHOUT CONNECTION REQUEST

2.1 Remote Name Request

The service Remote Name Request is used to find out the name of the remote device without requiring an explicit ACL connection.

Step 1: The Host sends an HCI_Set_Event_Mask with the bit of Remote Host Supported Features Notification event (bit 60) set and an HCI_Remote_Name_Request command expecting that its local device will automatically try to connect to the remote device. (See Figure 2.1.)

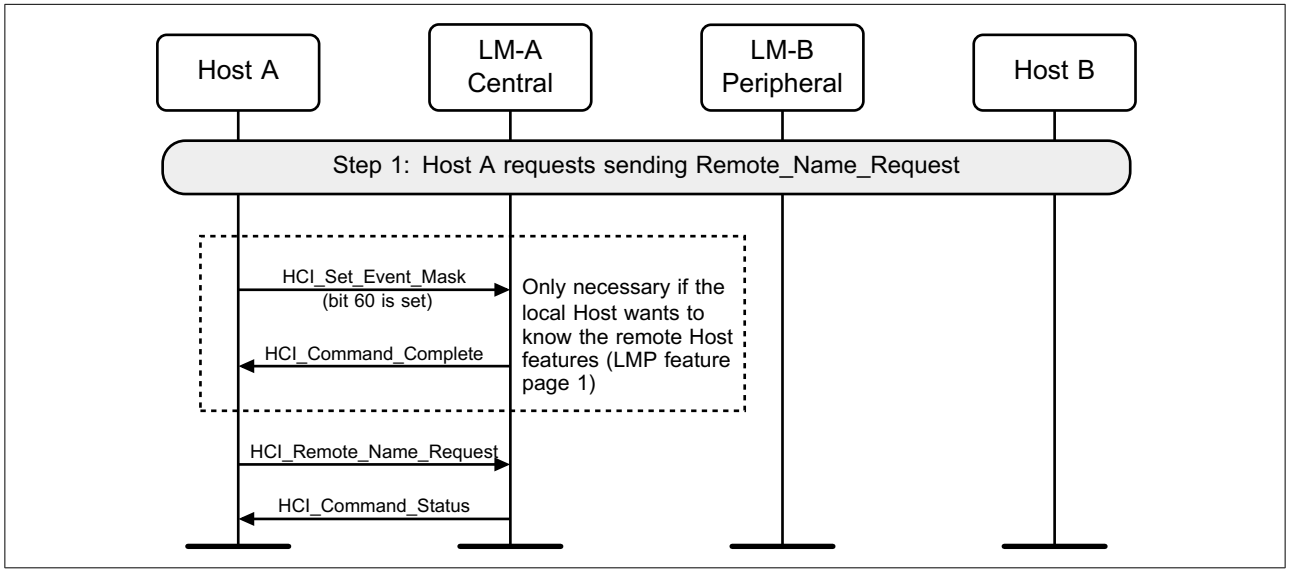

Figure 2.1: Remote name request

Step 2a: If an ACL connection does not exist device A pages device B. After the Baseband Paging procedure, the local device attempts to get the remote device's extended features, send an HCI_Remote_Host_Supported_Features_Notification event, get the remote name, disconnect, and return the name of the remote device to the Host. (See Figure 2.2.)

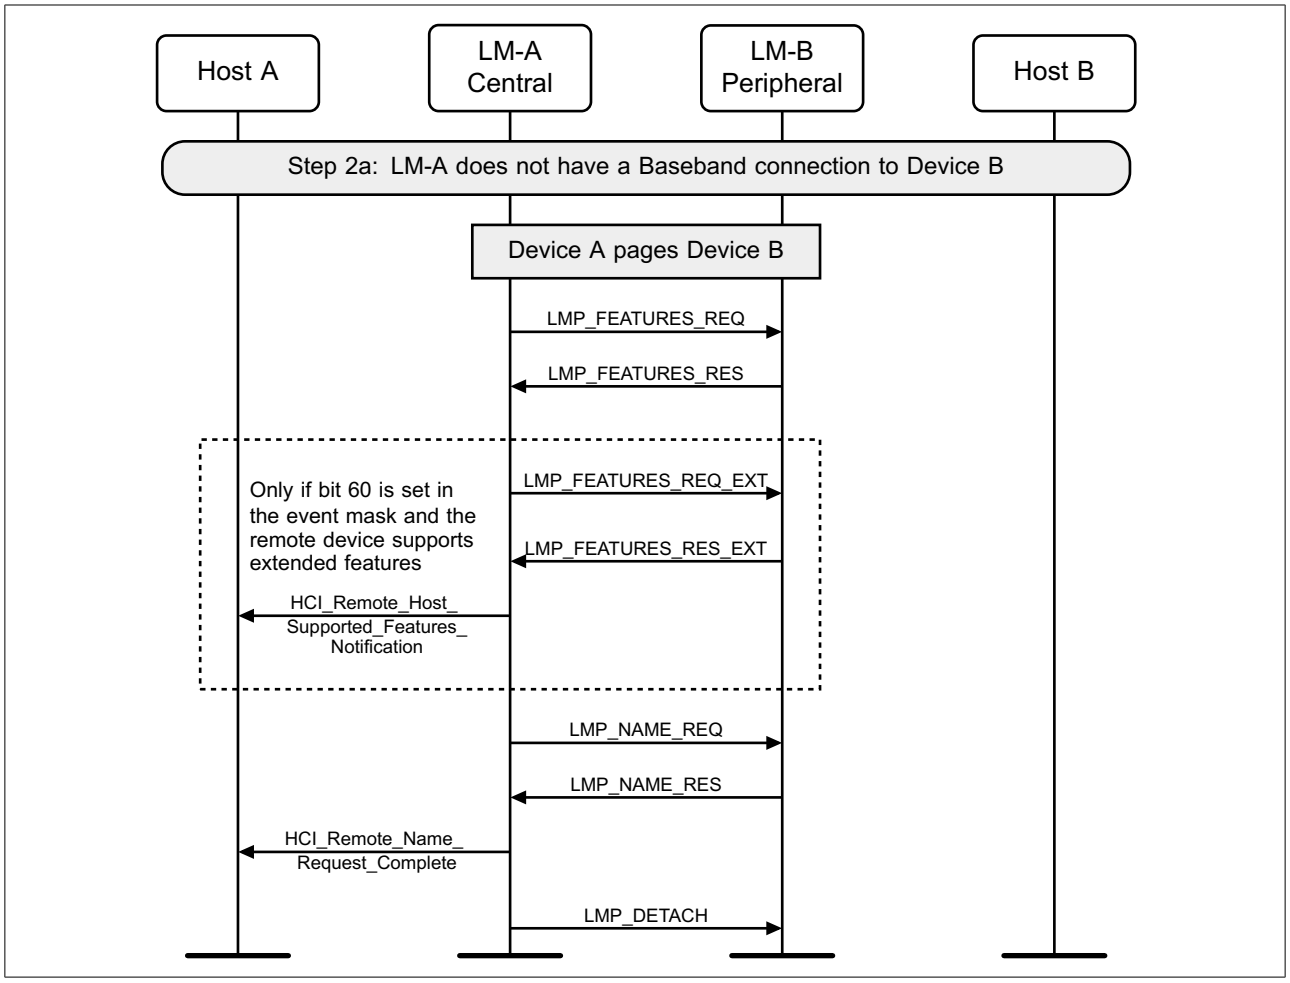

Figure 2.2: Remote name request if no current Baseband connection

Step 2b: If an ACL connection exists when the request is made, then the Remote Name Request procedure will be executed like an optional service. No Paging and no ACL disconnect is done. (See Figure 2.3.)

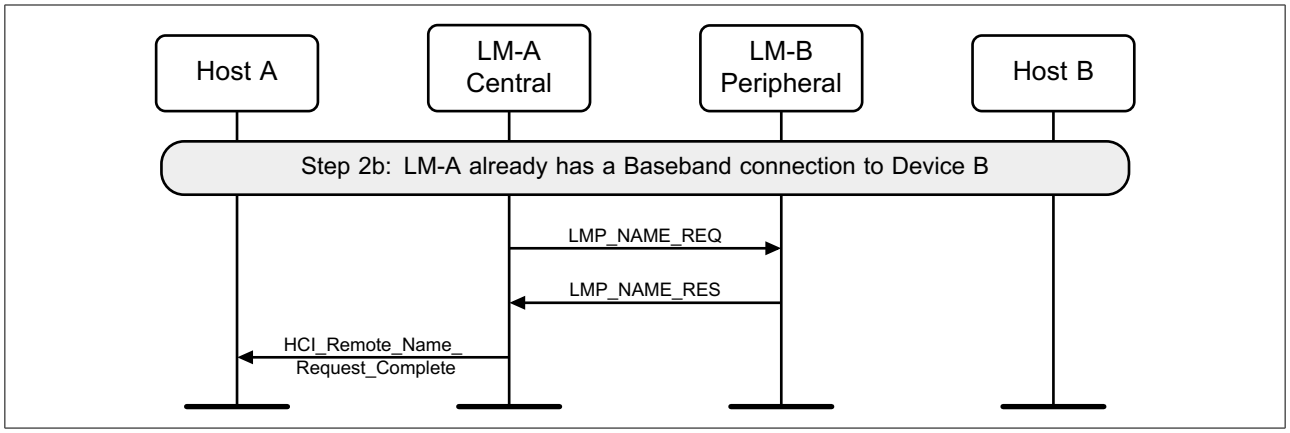

Figure 2.3: Remote name request with Baseband connection

2.2 One-time inquiry

Inquiry is used to detect and collect nearby devices.

Step 1: The Host sends an HCI_Inquiry command. (See Figure 2.4.)

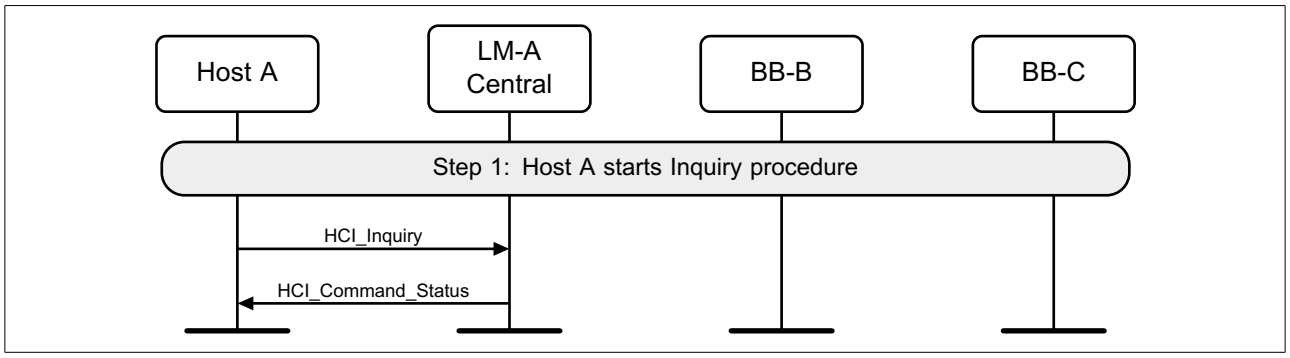

Figure 2.4: Host A starts inquiry procedure

Step 2: The Controller will start the Baseband Inquiry procedure with the specified Inquiry Access Code and Inquiry Length. When inquiry responses are received, the Controller extracts the required information and returns the information related to

the found devices using one or more HCI_Inquiry_Result events to the Host. (See Figure 2.5.)

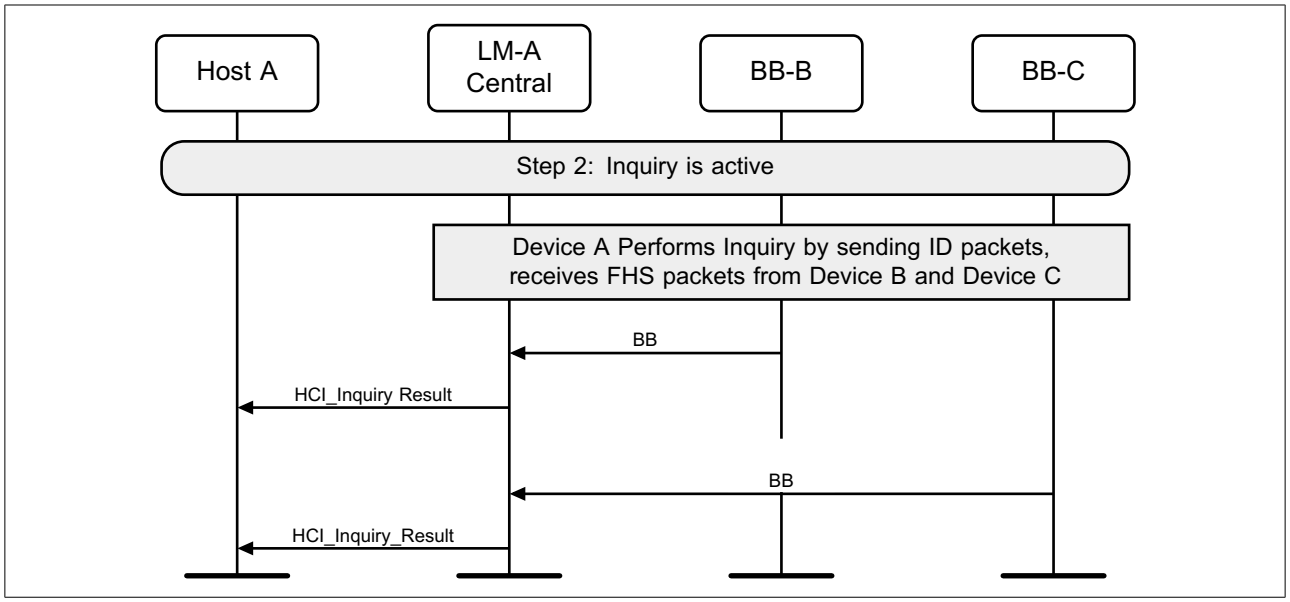

Figure 2.5: LM-A performs inquiry and reports result

Step 3a: If the Host wishes to terminate an Inquiry, the HCI_Inquiry_Cancel command is used to immediately stop the inquiry procedure. (See Figure 2.6.)

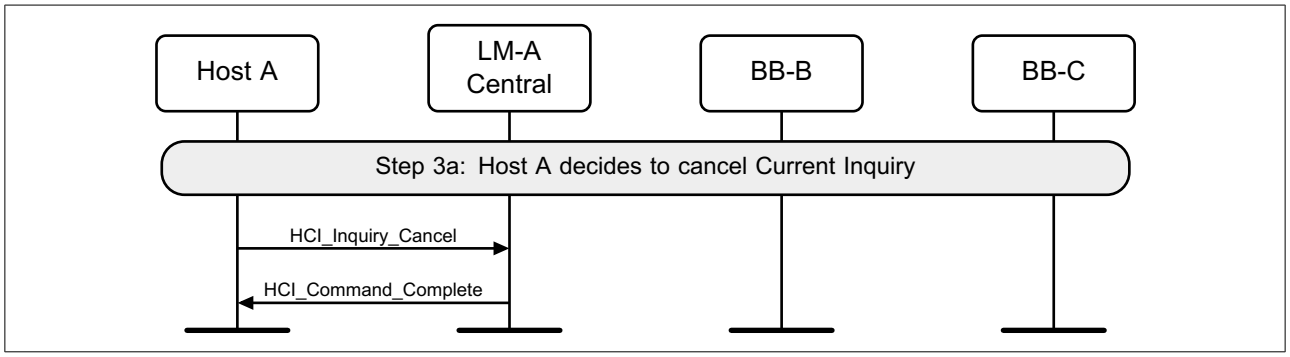

Figure 2.6: Host A cancels inquiry

Step 3b: If the Inquiry procedure is completed due to the number of results obtained, or the Inquiry Length has expired, an HCI_Inquiry_Complete event is returned to the Host. (See Figure 2.7.)

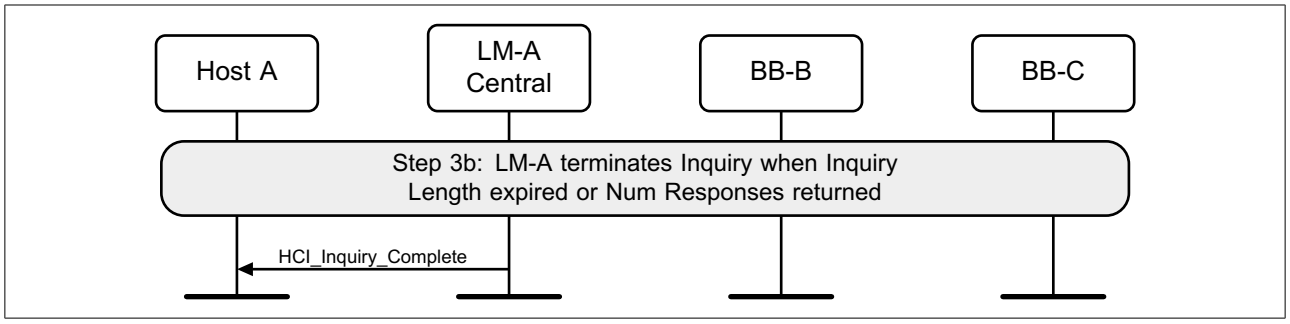

Figure 2.7: LM-A terminates current inquiry

2.3 Periodic inquiry

Periodic inquiry is used when the inquiry procedure is to be repeated periodically.

Step 1: The Hosts sends an HCI_Periodic_Inquiry_Mode command. (See Figure 2.8.)

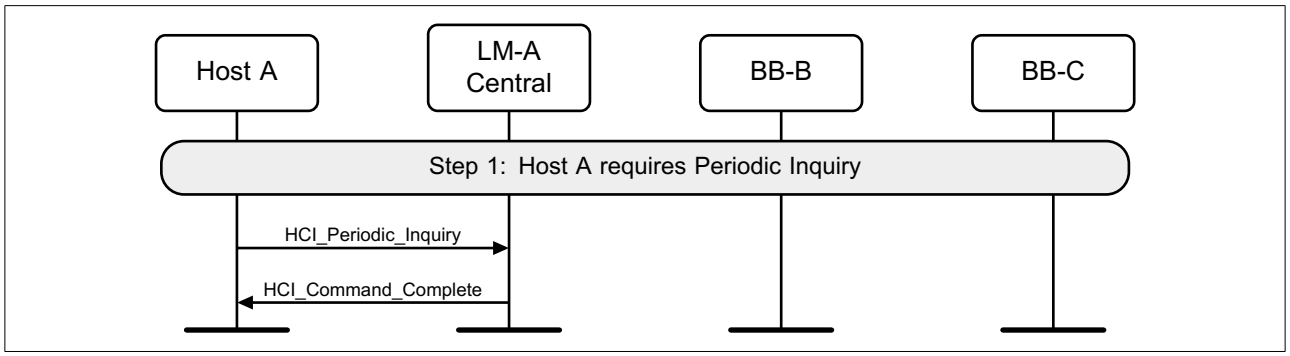

Figure 2.8: Host A starts periodic inquiry

Step 2: The Controller will start a periodic Inquiry. In the inquiry cycle, one or several HCI_Inquiry_Result events will be returned. (See Figure 2.9.)

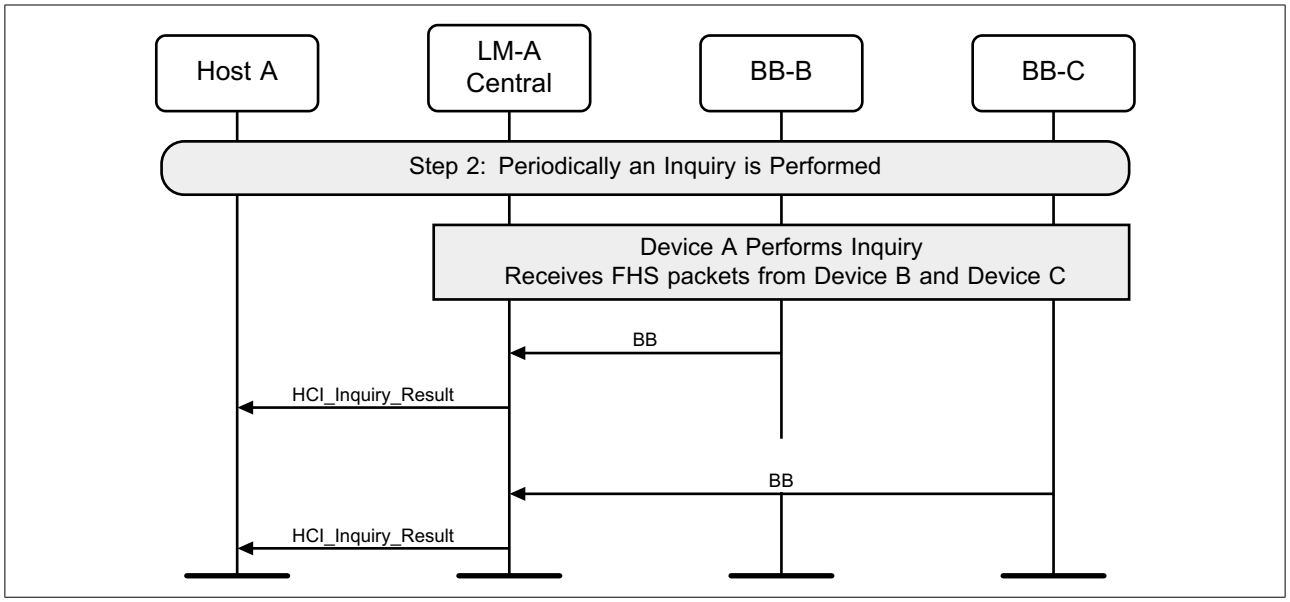

Figure 2.9: LM-A periodically performs an inquiry and reports result

Step 3: An HCI_Inquiry_Complete event will be returned to the Host when the current periodic inquiry has finished. (See Figure 2.10.)

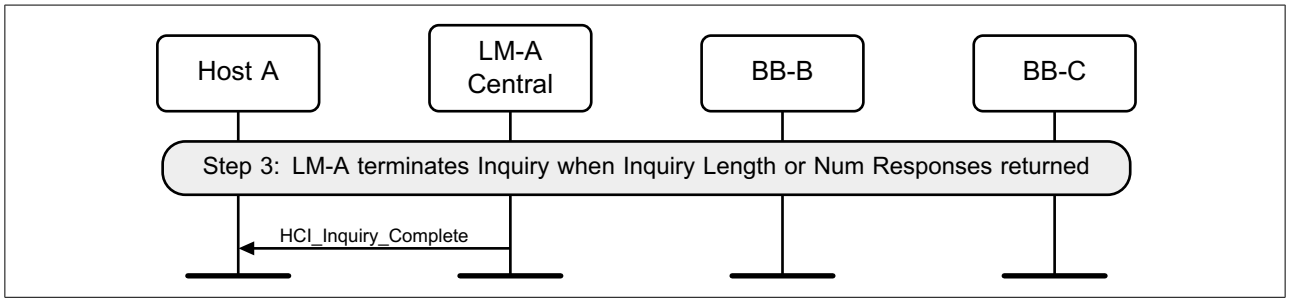

Figure 2.10: LM-A terminates current inquiry

Step 4: The periodic Inquiry can be stopped using the HCI_Exit_Periodic_Inquiry_Mode command. (See Figure 2.11.)

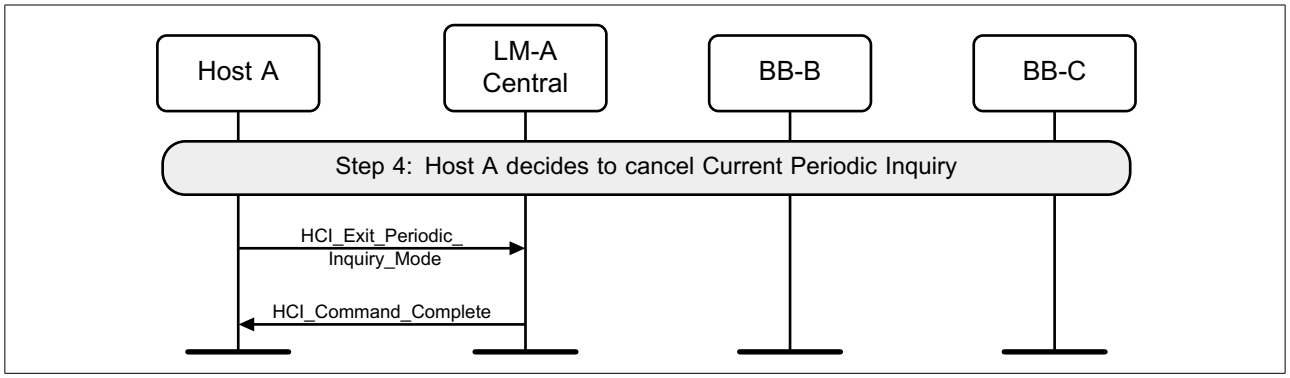

Figure 2.11: Host A decides to exit periodic inquiry

3 ACL CONNECTION ESTABLISHMENT AND DETACHMENT

A flow diagram of the establishment and detachment of a connection between two devices is shown in Figure 3.1. The process is illustrated in 9 distinct steps. A number of these steps may be optionally performed, such as authentication and encryption. Some steps are required, such as the Connection Request and Setup Complete steps. The steps in the overview diagram directly relate to the steps in the following message sequence charts.

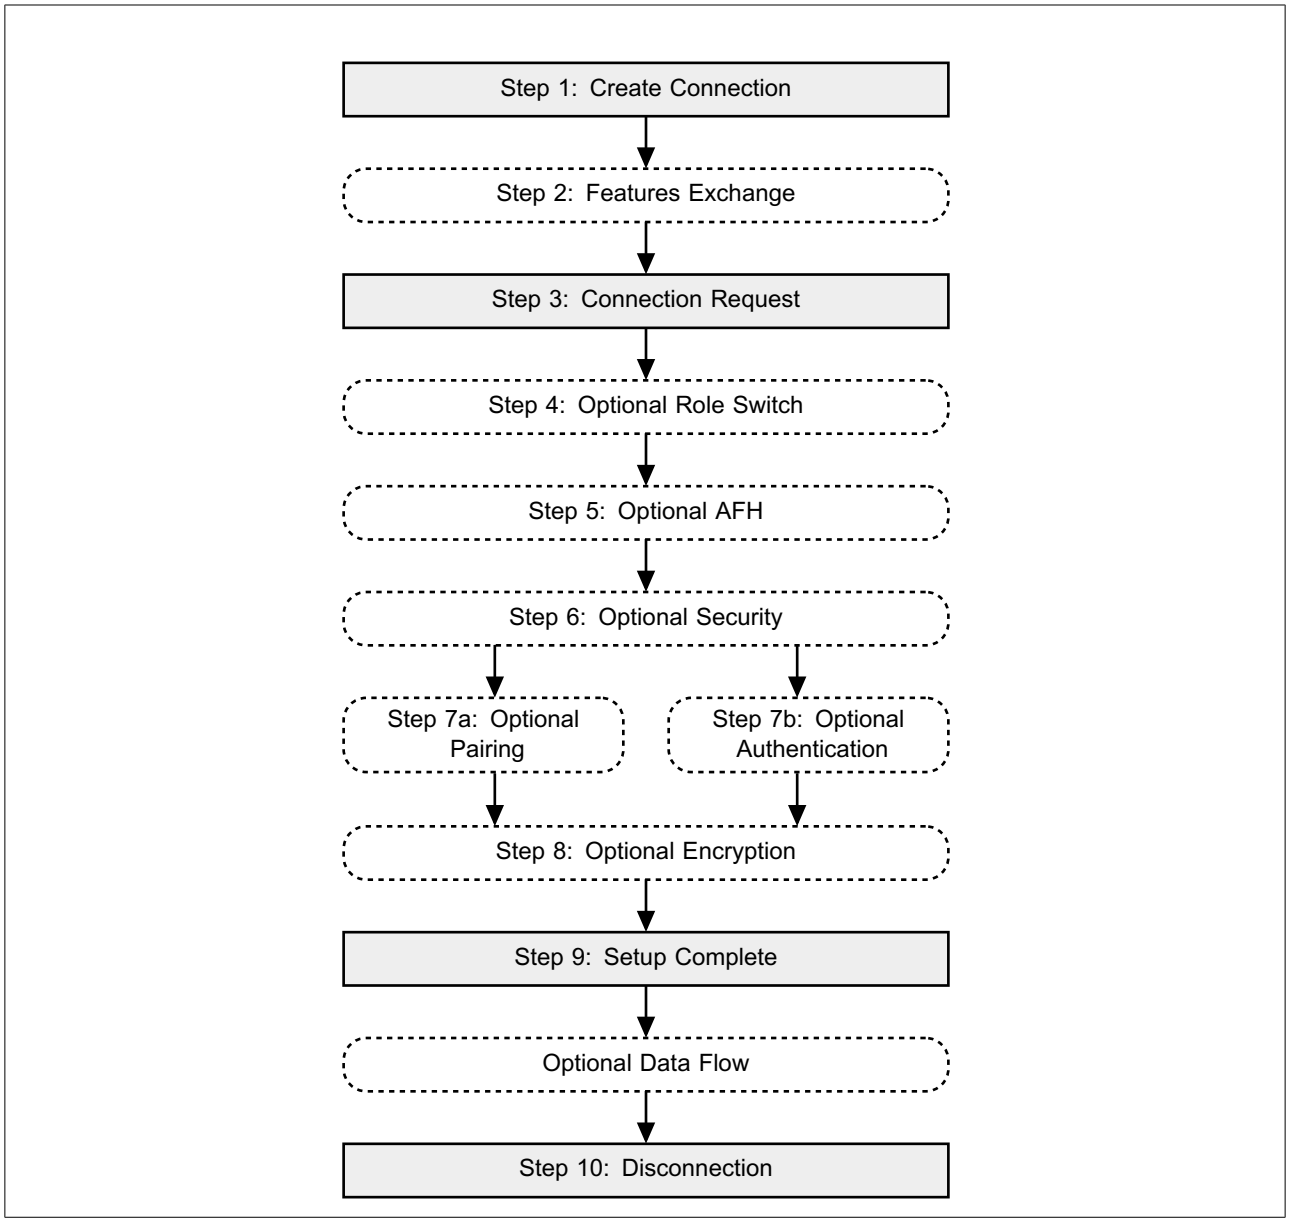

Figure 3.1: Overview diagram for connection setup

3.1 Connection setup

Step 1: The Host sends an HCI_Create_Connection command to the Controller. The Controller then performs a Baseband Paging procedure with the specified BD_ADDR. (See Figure 3.2.)

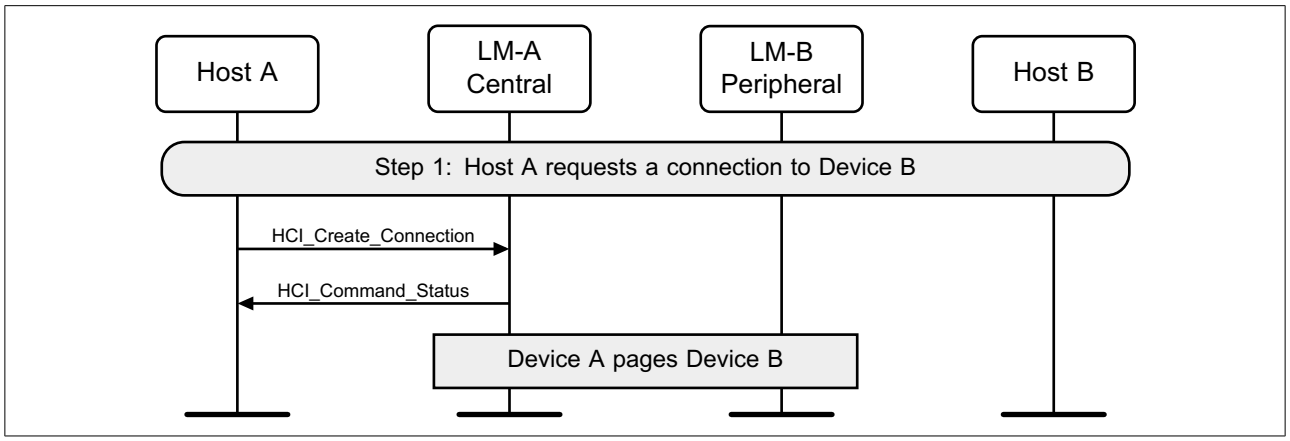

Figure 3.2: Host A requests connection with device B

Step 2: Optionally, the LM may decide to exchange features.

(See Figure 3.3.)

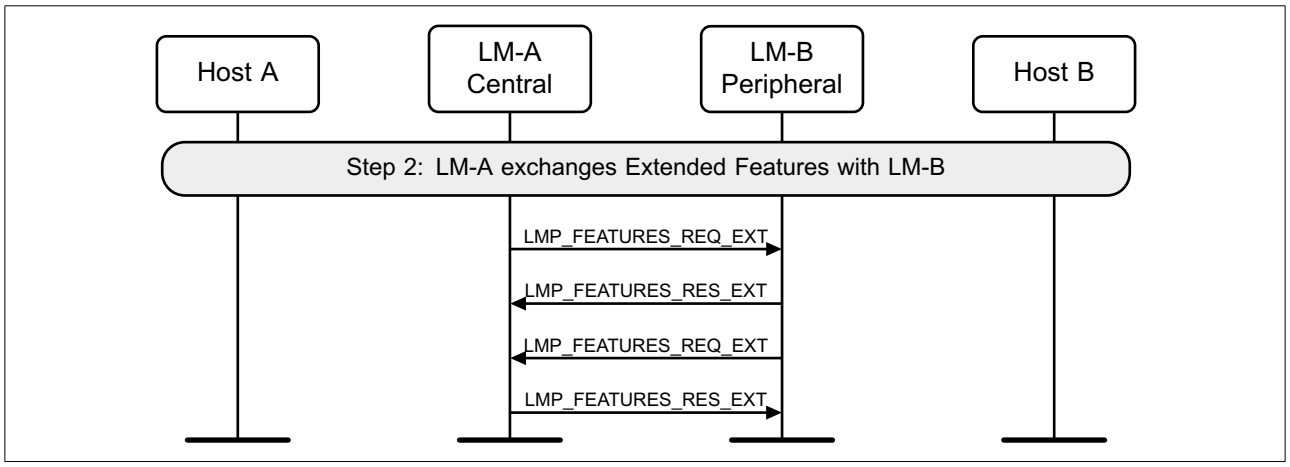

Figure 3.3: LM-A and LM-B exchange features

Step 3: The LM on the Central will request an LMP_HOST_CONNECTION_REQ PDU. The LM on the Peripheral will then confirm that a connection is OK, and if so, what role is preferred. (See Figure 3.4)

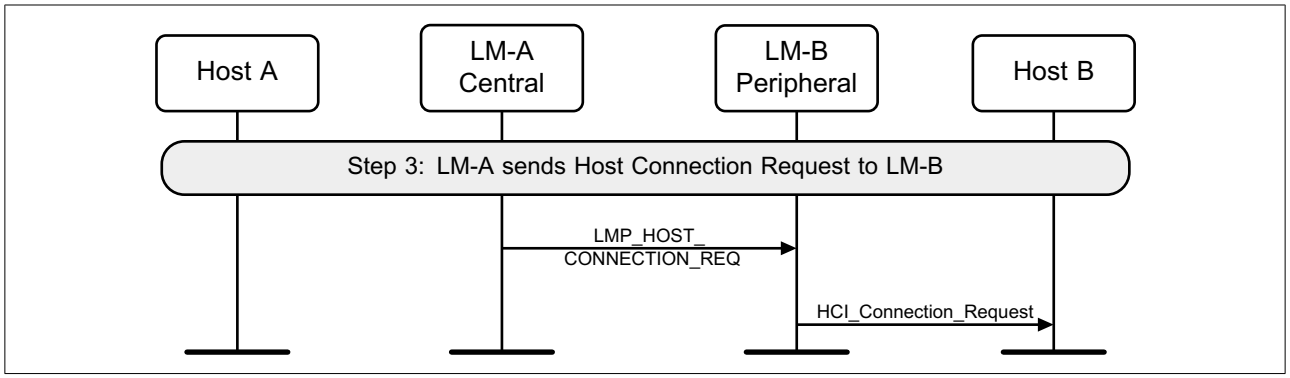

Figure 3.4: LM-A requests Host connection

Step 4a: The remote Host rejects this connection, and the link is terminated. (See Figure 3.5.)

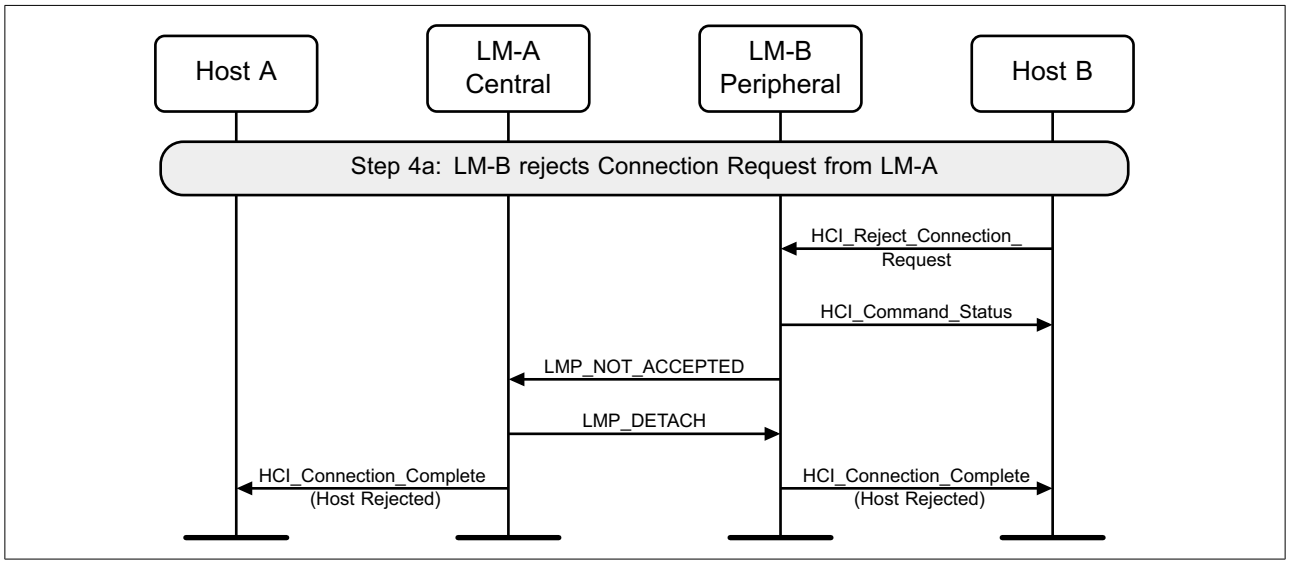

Figure 3.5: Device B rejects connection request

Step 4b: The remote Host accepts this connection. (See Figure 3.6.)

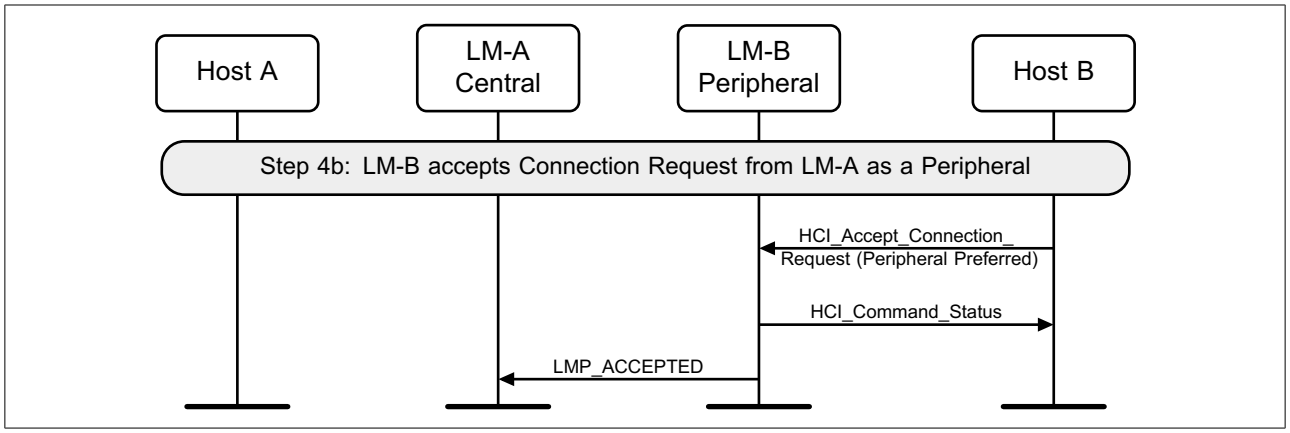

Figure 3.6: Device B accepts connection request

Step 4c: The remote Host accepts this connection but with the preference of being a Central. This will cause a role switch to occur before the LMP_ACCEPTED for the LMP_HOST_CONNECTION_REQ PDU is sent. (See Figure 3.7.)

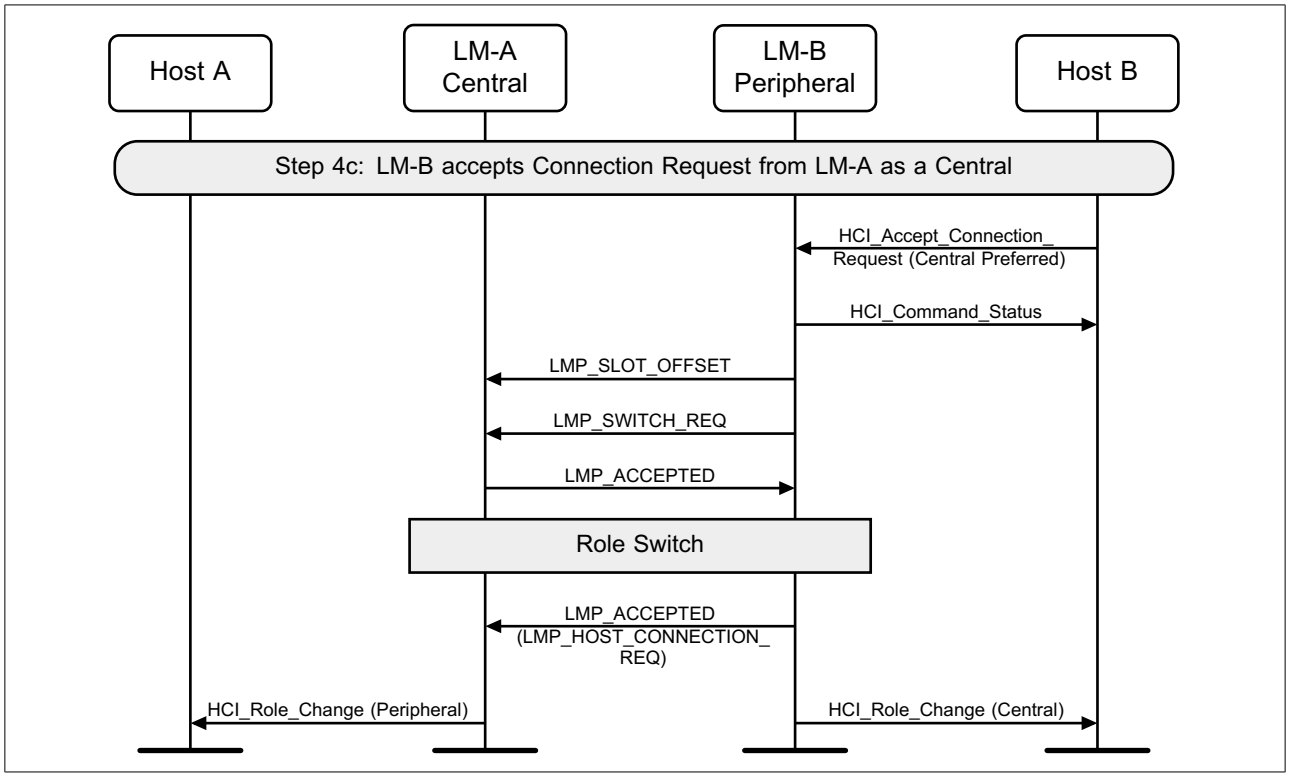

Figure 3.7: Device B accepts connection requests as Central

Step 5: After the features have been exchanged and AFH support is determined to be available, the Central may at any time send an LMP_SET_AFH and LMP_CHANNEL_CLASSIFICATION_REQ PDU. (See Figure 3.8.)

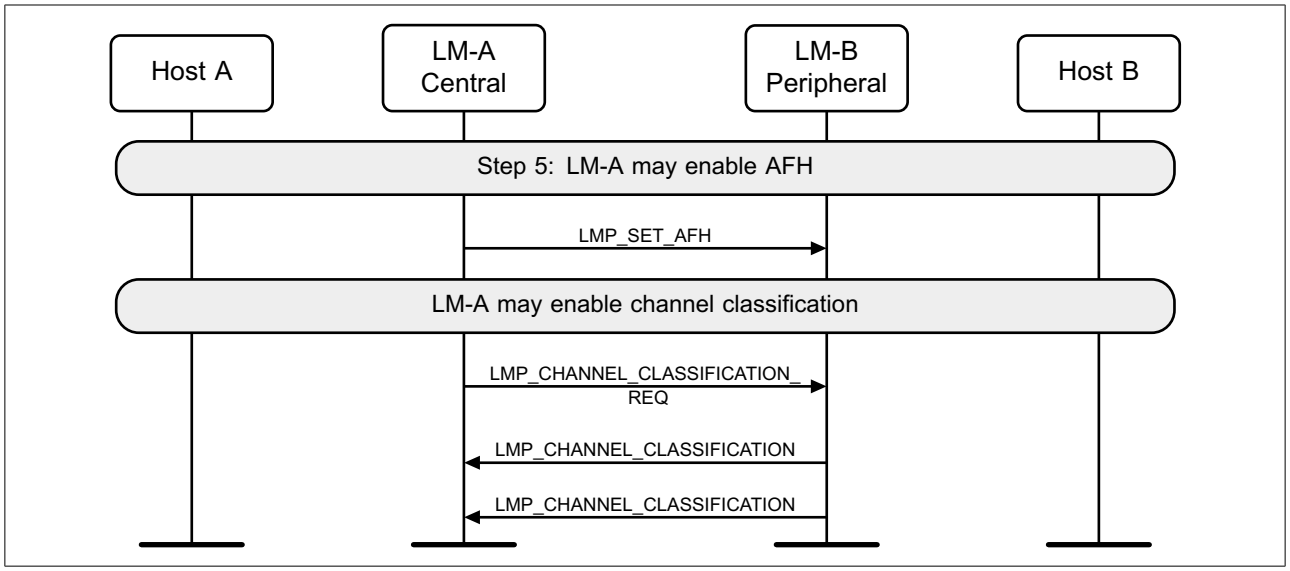

Figure 3.8: LM-A starts Adaptive Frequency Hopping

Step 6: The LM will request if authentication is required. It does this by requesting the Link Key for this connection from the Host. (See Figure 3.9.)

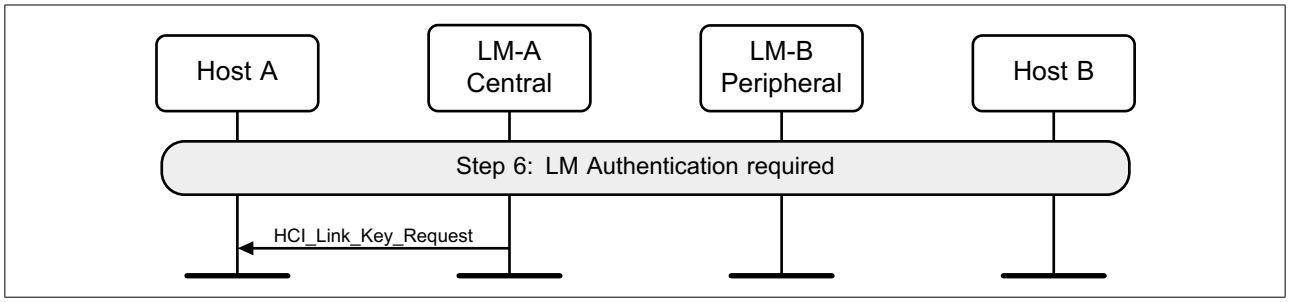

Figure 3.9: Authentication initiated

Step 7a: If authentication is required by the higher layers and the devices to be connected do not have a common link key, a pairing procedure will be used. The LM will have requested a link key from the Host for this connection. If there is a negative reply, then a PIN code will be requested. This PIN code will be requested on both sides of the connection, and authentication performed based on this PIN code. The last step is for the new link key for this connection to be passed to the Host so that it may store it for future connections. (See Figure 3.10.)

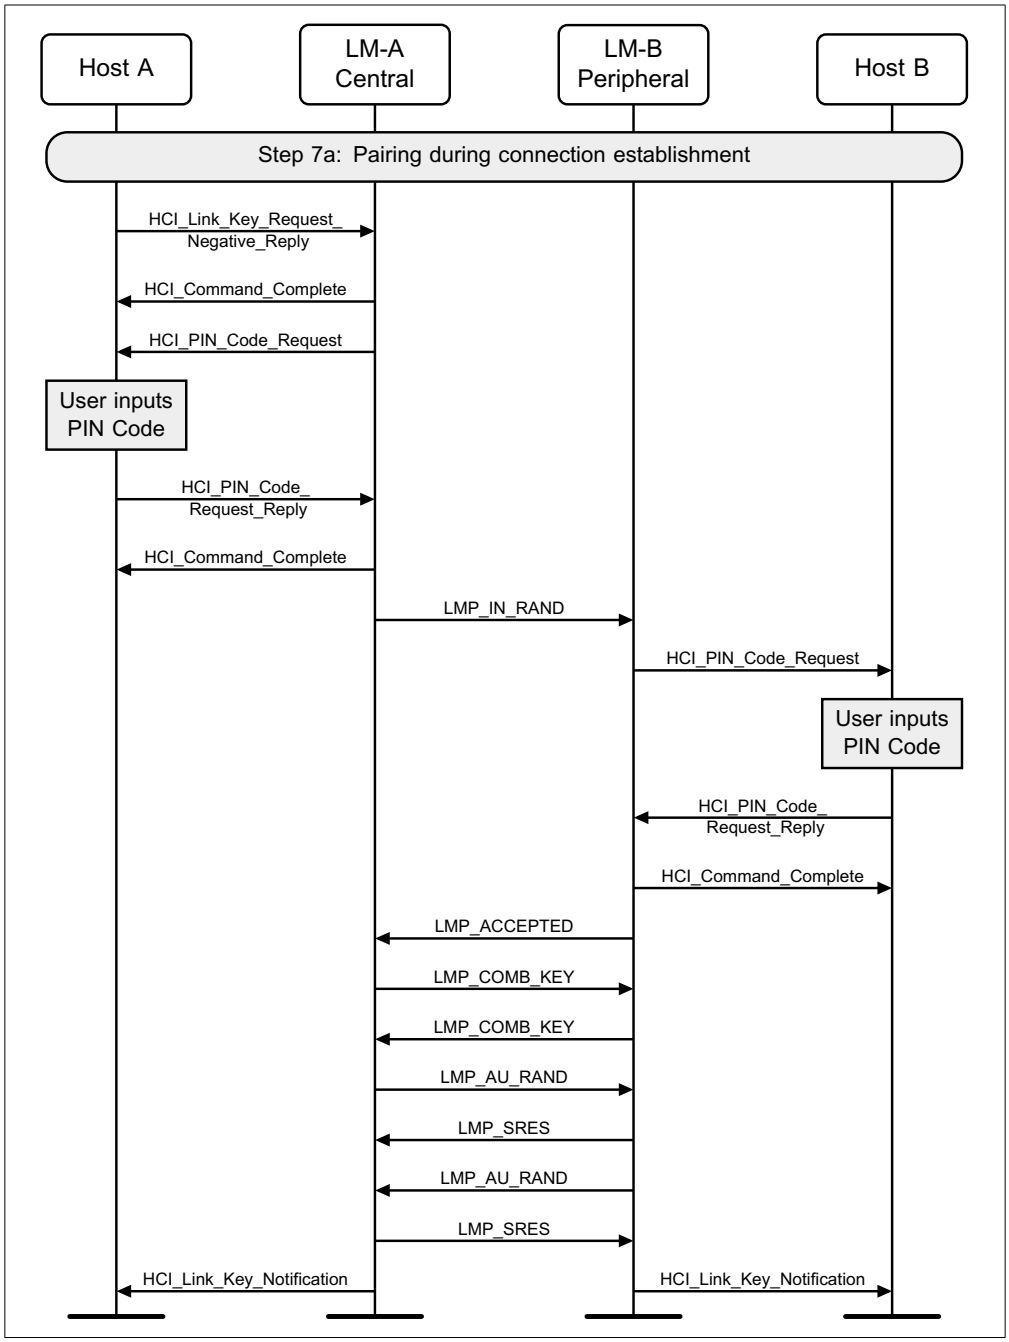

Figure 3.10: Pairing during connection setup

Step 7b: If a common link key exists between the devices, then pairing is not needed. The LM will have asked for a link key from the Host for this connection. If this is a positive reply, then the link key is used for authentication. If the configuration parameter Authentication_Enable is set, then the authentication procedure is executed. This MSC only shows the case when Authentication_Enable is set on both sides. (See Figure 3.11.)

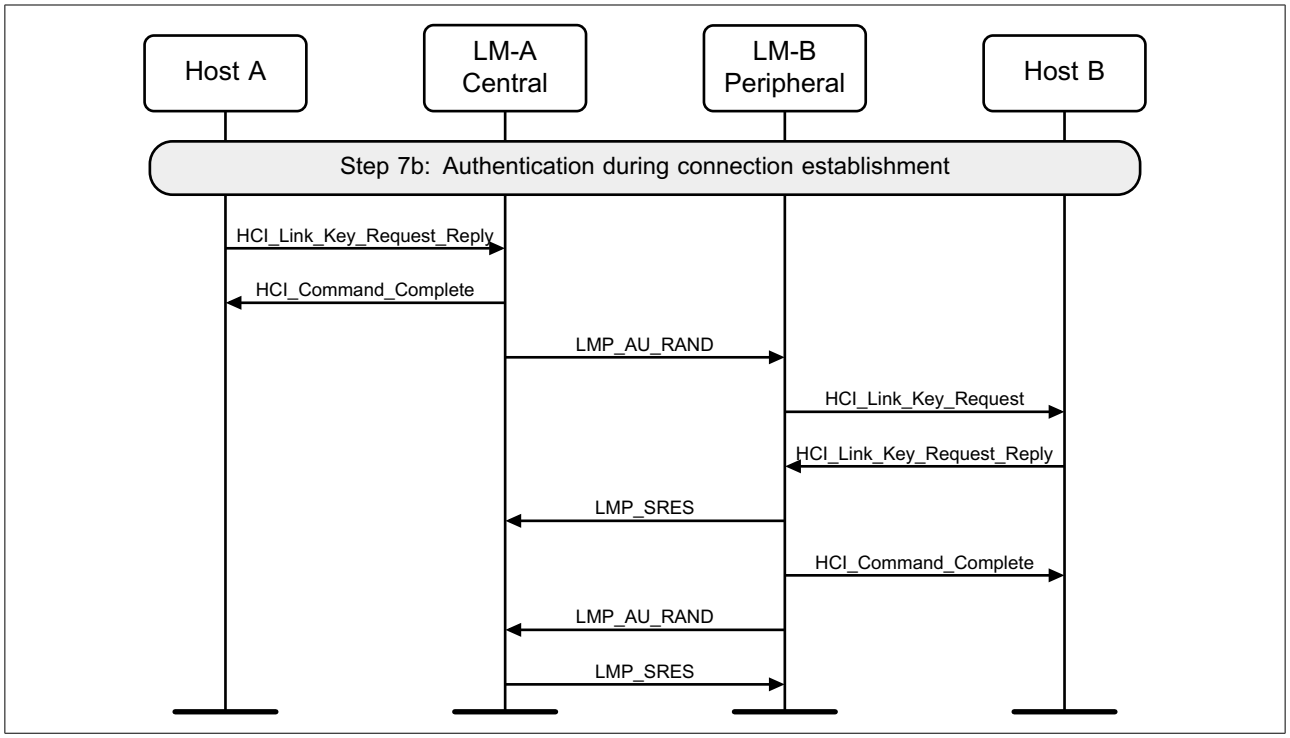

Figure 3.11: Authentication during connection setup

Step 8: Once the pairing or authentication procedure is successful, the encryption procedure may be started. This MSC only shows the set up of an encrypted point-to-point connection. (See Figure 3.12.)

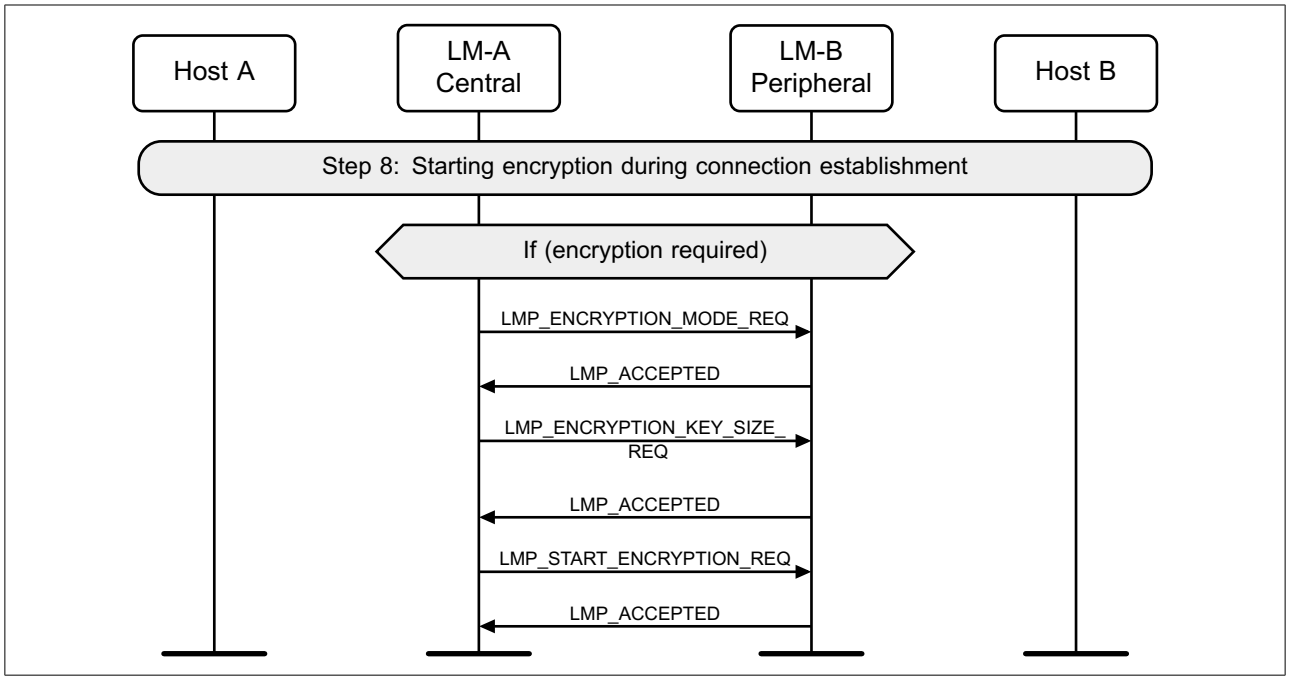

Figure 3.12: Starting encryption during connection setup

Step 9: The LMs indicate that the connection is setup by sending LMP_SETUP_COMPLETE PDU. This will cause the Host to be notified of the new Connection_Handle, and this connection may be used to send higher layer data such as L2CAP information. (See Figure 3.13.)

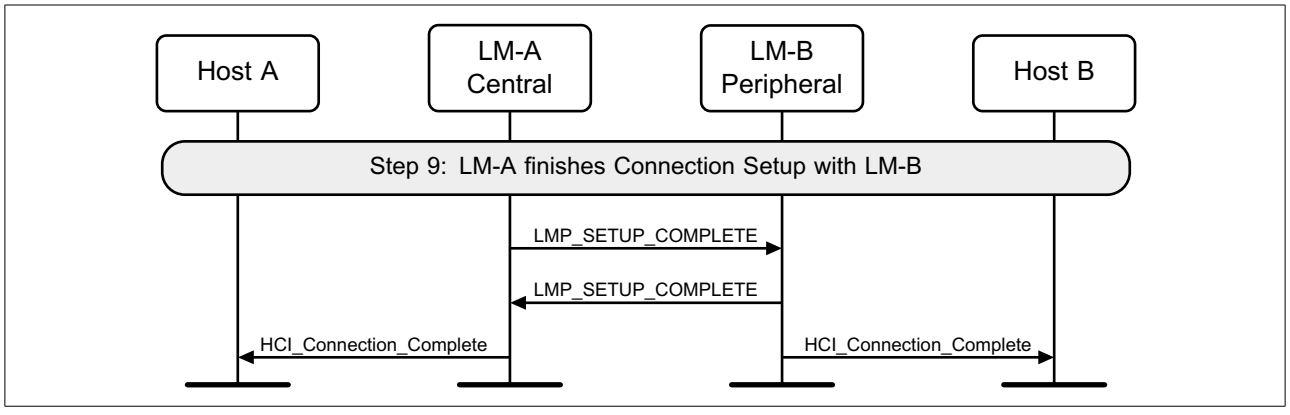

Figure 3.13: LM-A and LM-B finishes connection setup

Step 10: Once the connection is no longer needed, either device may terminate the connection using the HCI_Disconnect command and LMP_DETACH message PDU. The disconnection procedure is one-sided and does not need an explicit acknowledgment from the remote LM. The use of ARQ Acknowledgment from the Baseband indicates that the remote LM has received the LMP_DETACH PDU. (See Figure 3.14.)

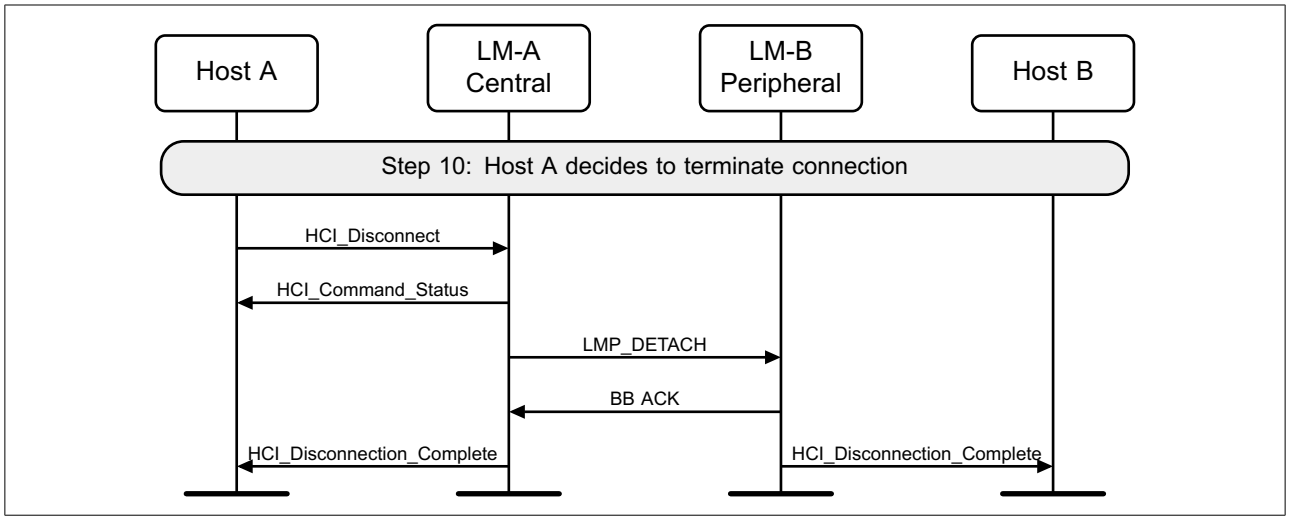

Figure 3.14: Host A decides to disconnect

4 OPTIONAL ACTIVITIES AFTER ACL CONNECTION ESTABLISHMENT

4.1 Authentication requested

Step 1: Authentication can be explicitly executed at any time after a connection has been established. If no Link Key is available then the Link Key is required from the Host. (See Figure 4.1.)

Note: If the Controller or LM and the Host do not have the Link Key, the devices will need to pair using a procedure such as that in Section 3.1 Step 7a or that in Section 4.2.

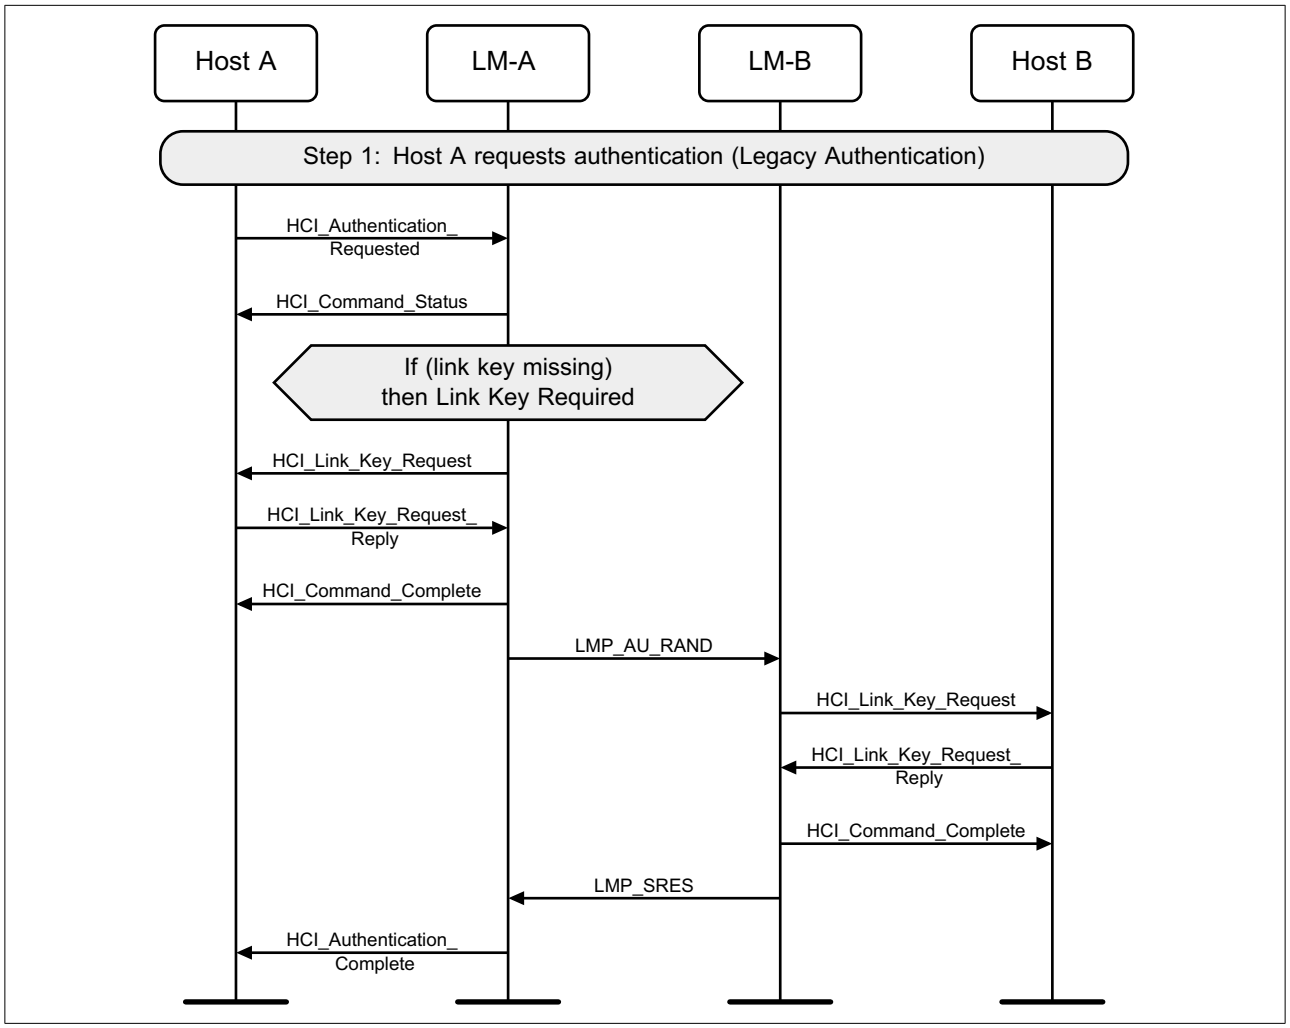

Figure 4.1: Authentication requested (legacy authentication)

When both devices support Secure Connections, Secure Authentication is used.

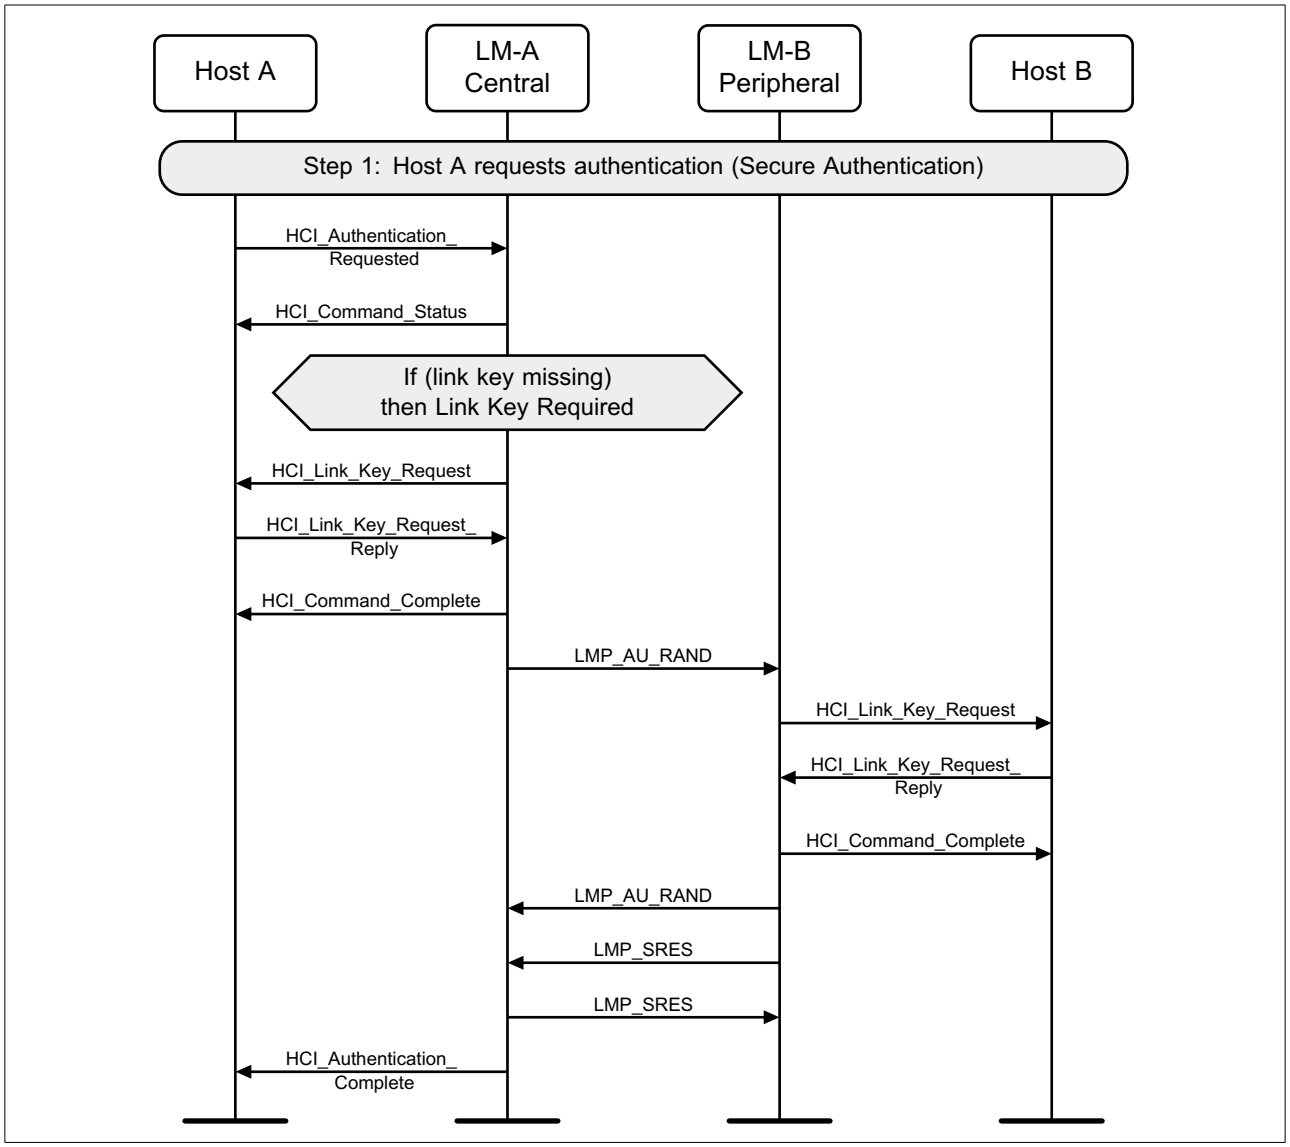

Figure 4.2: Authentication requested (secure authentication)

4.2 Secure Simple Pairing message sequence charts

A flow diagram of Secure Simple Pairing between two devices is shown in Figure 4.3. The process is illustrated in 11 distinct steps. A number of these steps have a number of different options.

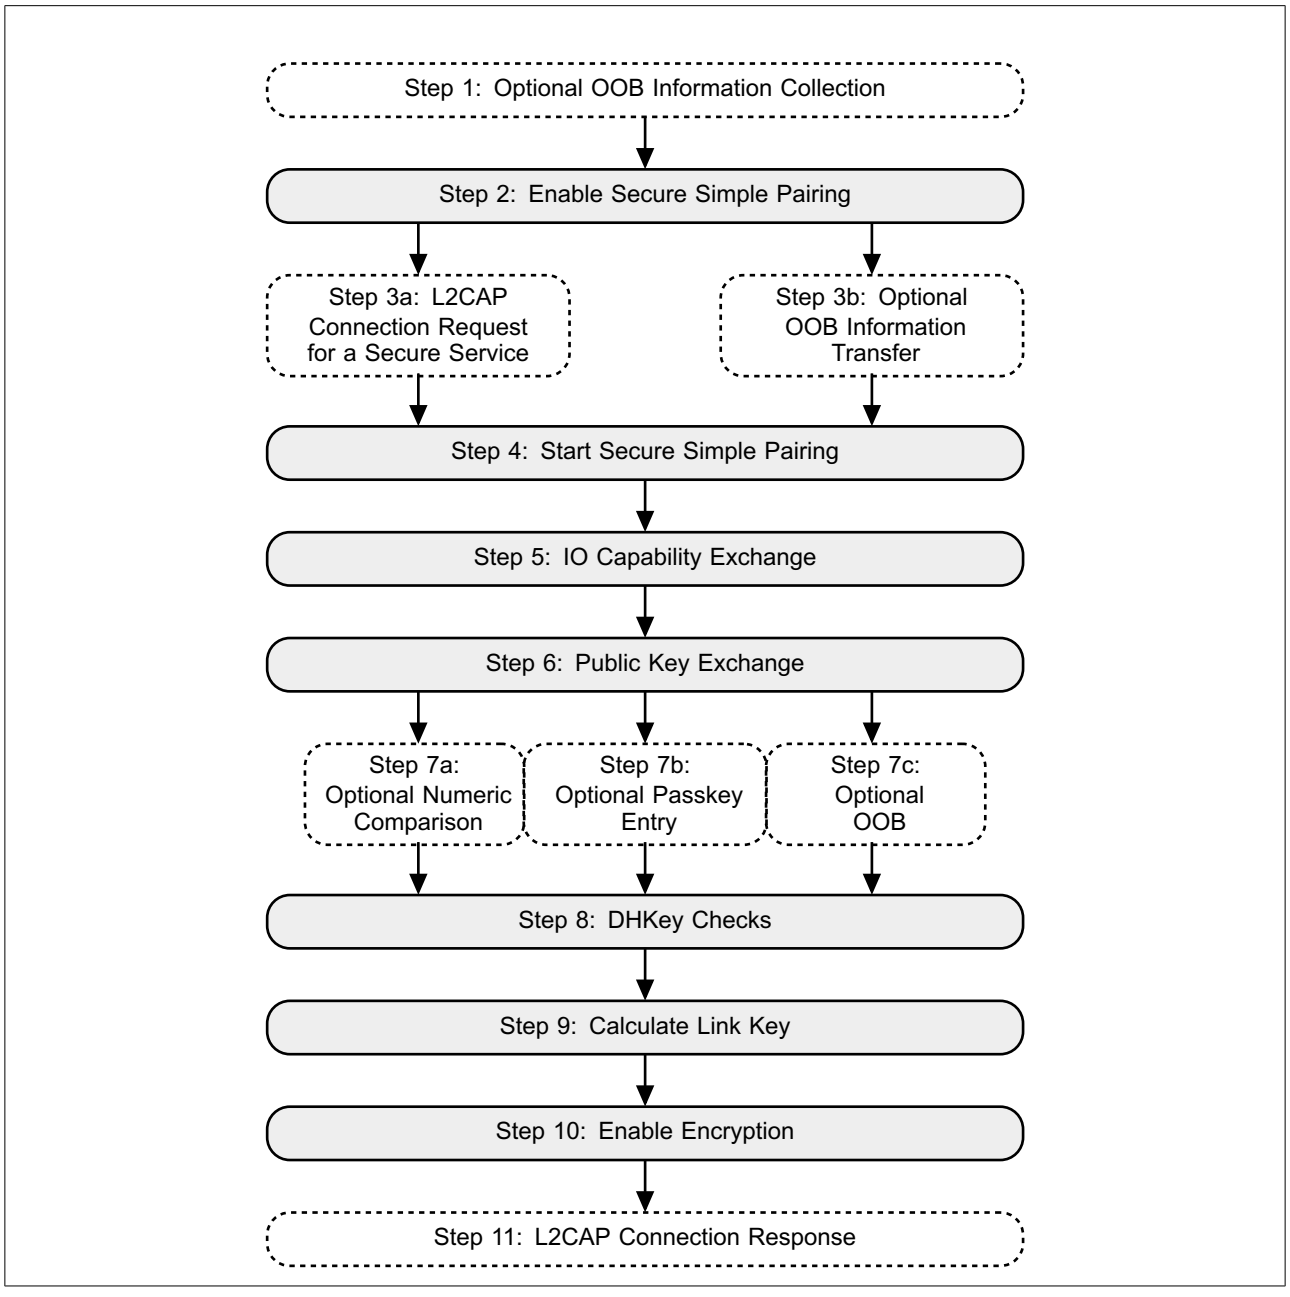

Figure 4.3: Secure Simple Pairing - flow diagram

4.2.1 Optional OOB information collection

If a device supports OOB information exchange, then the Host should request the C and R values from the Controller that need to be sent by OOB. It is then assumed that the Host transfers this information to the OOB system. This could occur a long time before, for example at the factory for a passive tag.

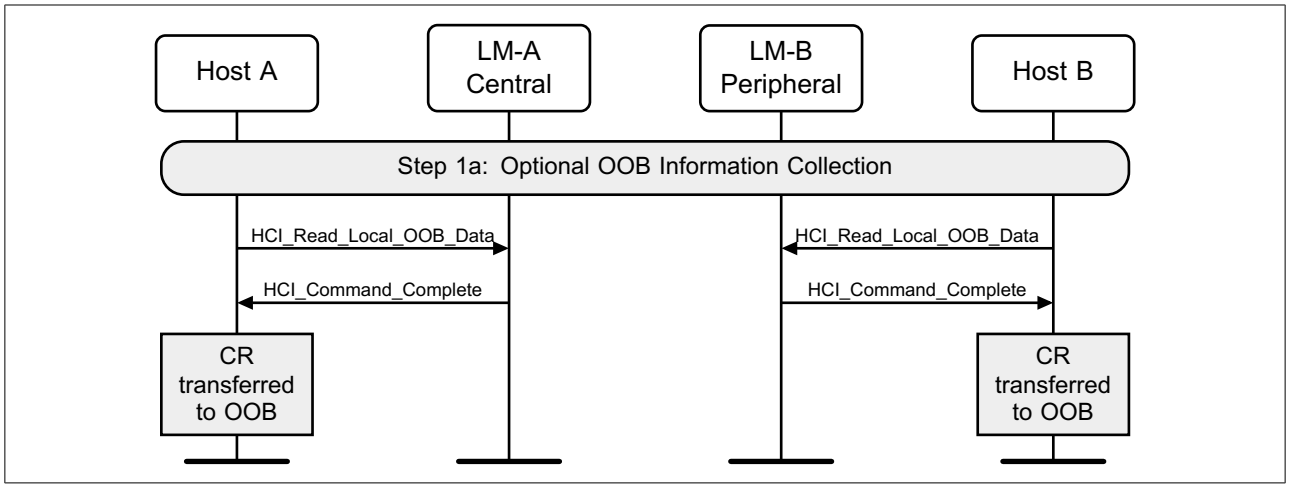

Figure 4.4: Optional OOB information collection (P-192 only)

When the Controller and Host support Secure Connections, the HCI_Read_Local_OOB_Extended_Data command is used instead of HCI_Read_Local_OOB_Data.

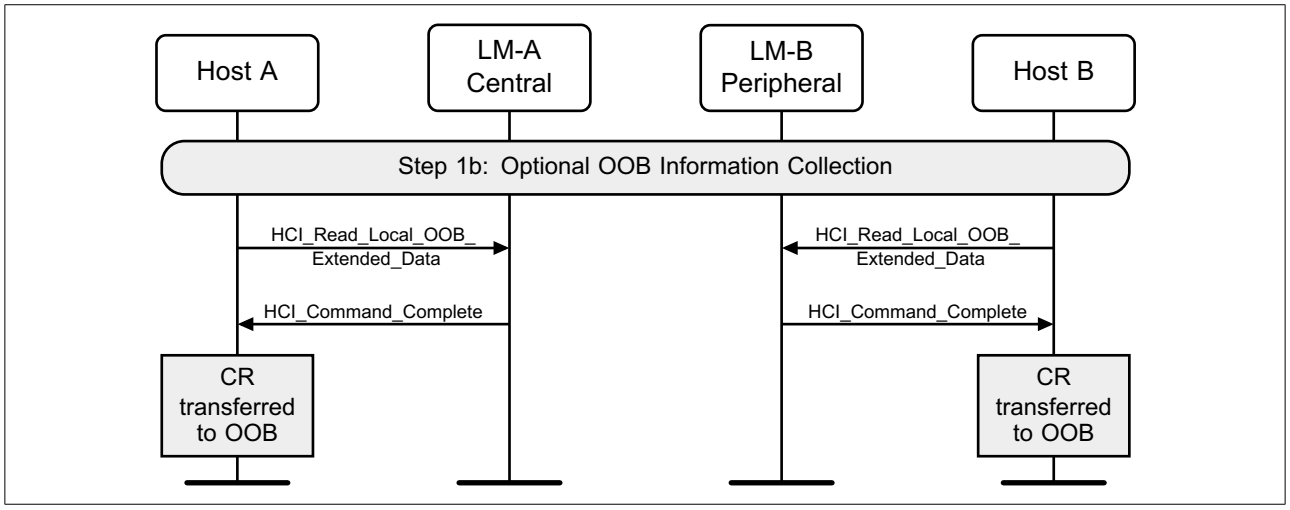

Figure 4.5: Optional OOB information collection (P-192 and P-256)

4.2.2 Enable Secure Simple Pairing and Secure Connections

To enable Secure Simple Pairing, a device must use the HCI_Write_Simple_Pairing_Mode command. This must be done before any connections that use Secure Simple Pairing are created.

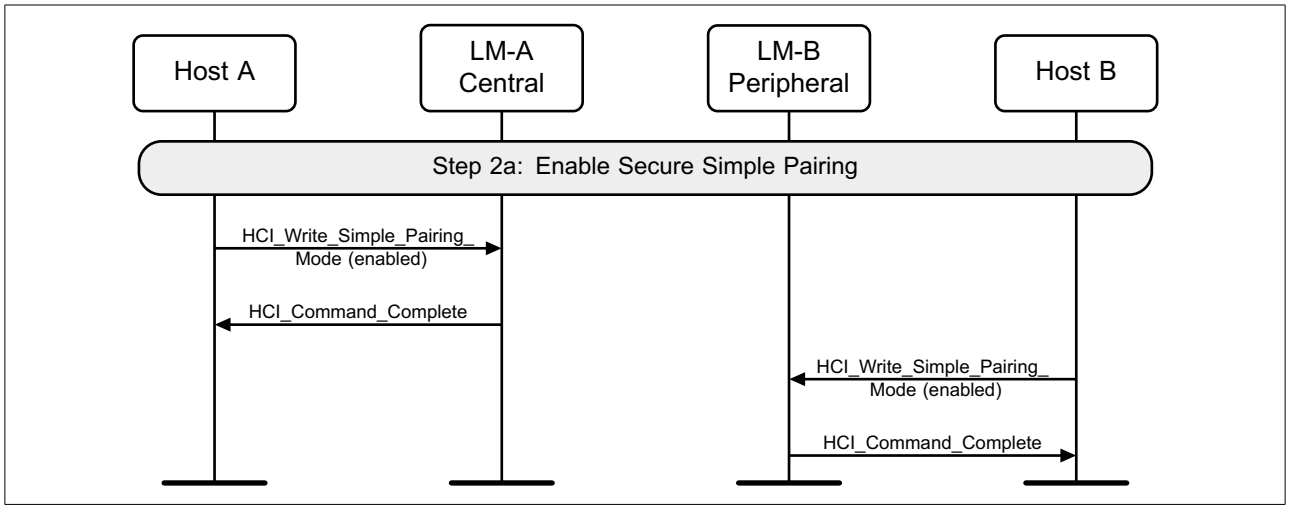

Figure 4.6: Enable Secure Simple Pairing

To configure the Controller to use Secure Connections HCI commands and events, a device must use the HCI_Write_Secure_Connections_Host_Support command. This must be done when no ACL connections are present.

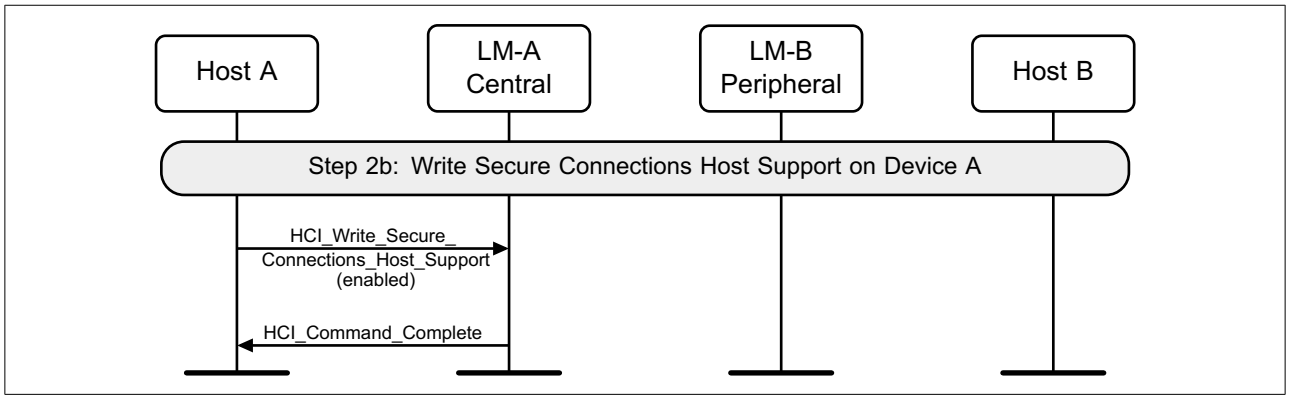

Figure 4.7: Enable Secure Connections Host Support

To configure the Controller to enforce a maximum interval between packets containing a MIC (when AES-CCM encryption is used), a device must use the HCI_Write_Authenticated_Payload_Timeout command.

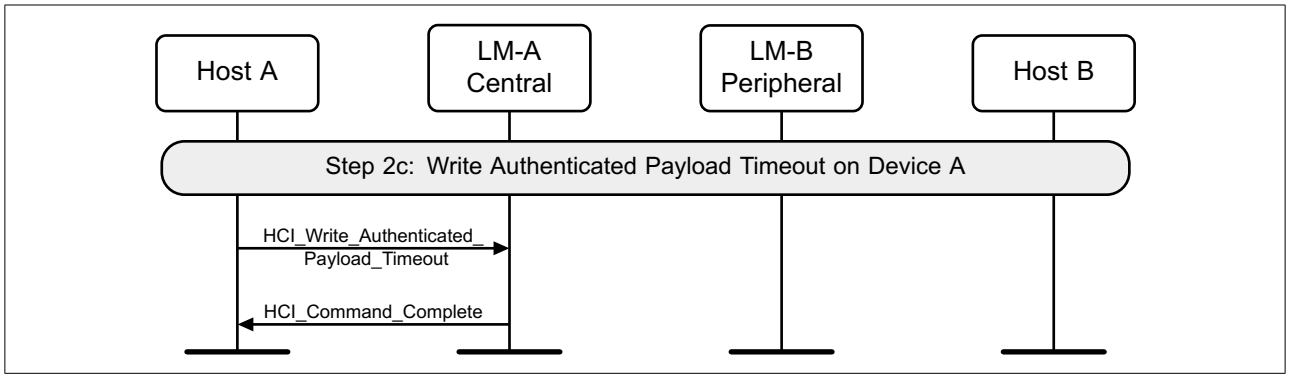

Figure 4.8: Set Authenticated_Payload_Timeout

4.2.3 Connection establishment

Secure Simple Pairing, once it is enabled, is triggered by one of two possible actions. It could be triggered by an L2CAP connection request to a service that requires security, or it could be triggered by an OOB transfer of information.

4.2.4 L2CAP connection request for a secure service

Once a connection has been established between two devices, if a device requests an L2CAP connection to a service that requires authentication and encryption, then the device will start Secure Simple Pairing.

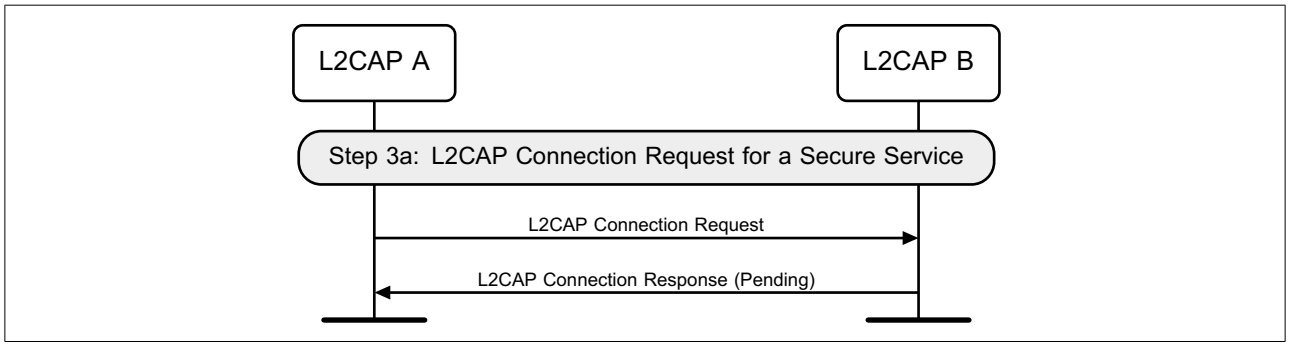

Figure 4.9: L2CAP connection request for a secure service

4.2.5 Optional OOB information transfer

Even if a Bluetooth connection has not been established between two devices, an OOB transfer can occur that transfers the Bluetooth Device Address of the device, and other OOB information for authentication. If an OOB transfer occurs, then the Host can start Secure Simple Pairing.

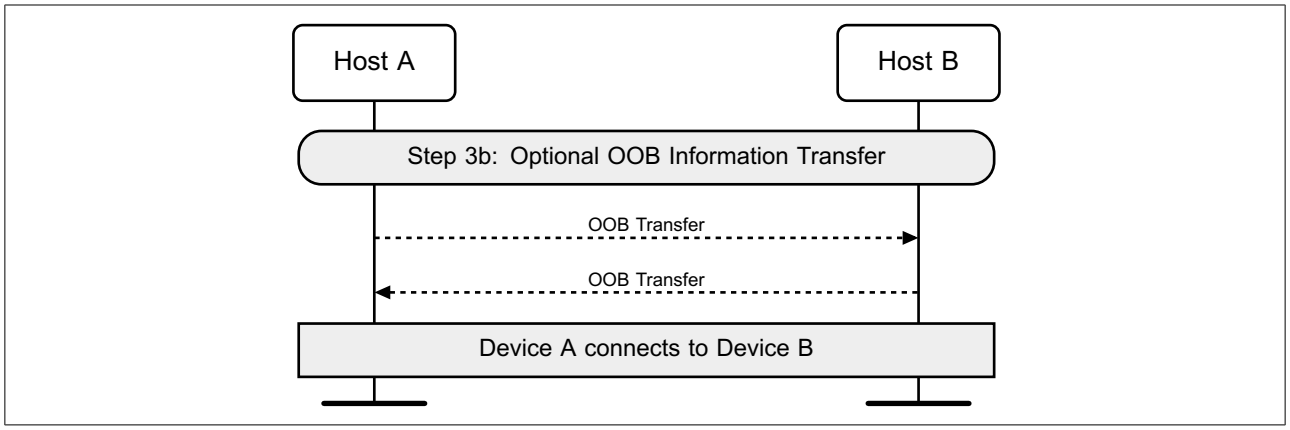

Figure 4.10: Optional OOB information transfer

4.2.6 Start Secure Simple Pairing

Once the Host has determined that Secure Simple Pairing should start, it issues an HCI_Authentication_Requested command to the Controller. This will cause the Controller to generate a request for a link key. If the Host has a link key for this connection, then pairing is not required, and the link key can be used immediately once it has been authenticated. Secure Simple Pairing will only be used if an

HCI_Link_Key_Request_Negative_Reply command is sent from the Host to the Controller on the initiating side.

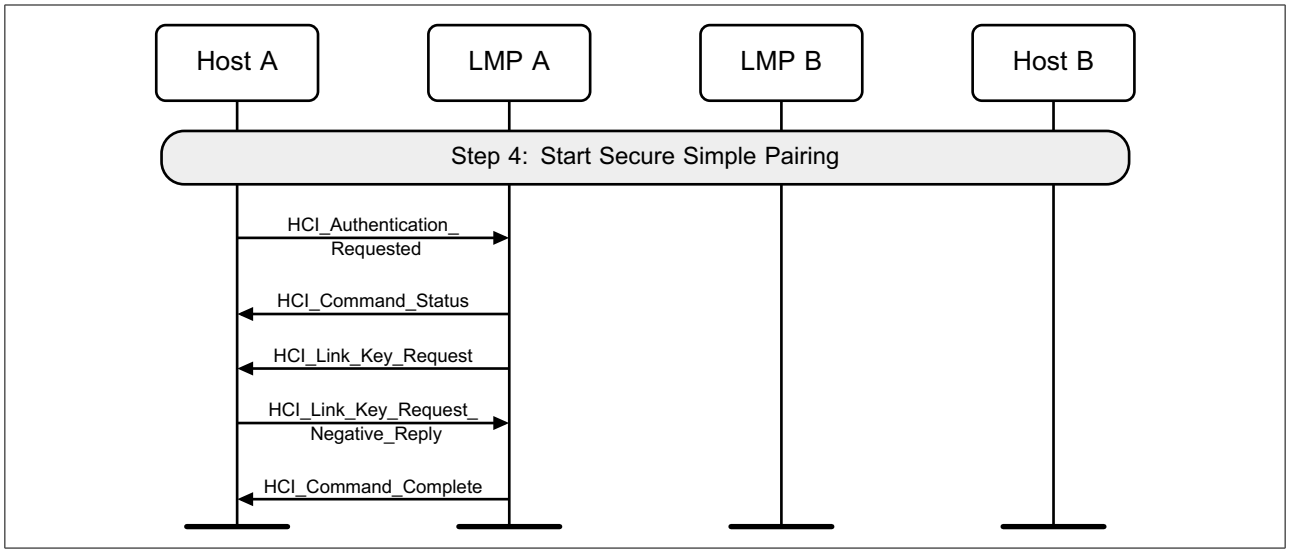

Figure 4.11: Start Secure Simple Pairing

4.2.7 IO capability exchange

To be able to determine the correct authentication algorithm to use, the input / output capabilities of the two devices are exchanged.

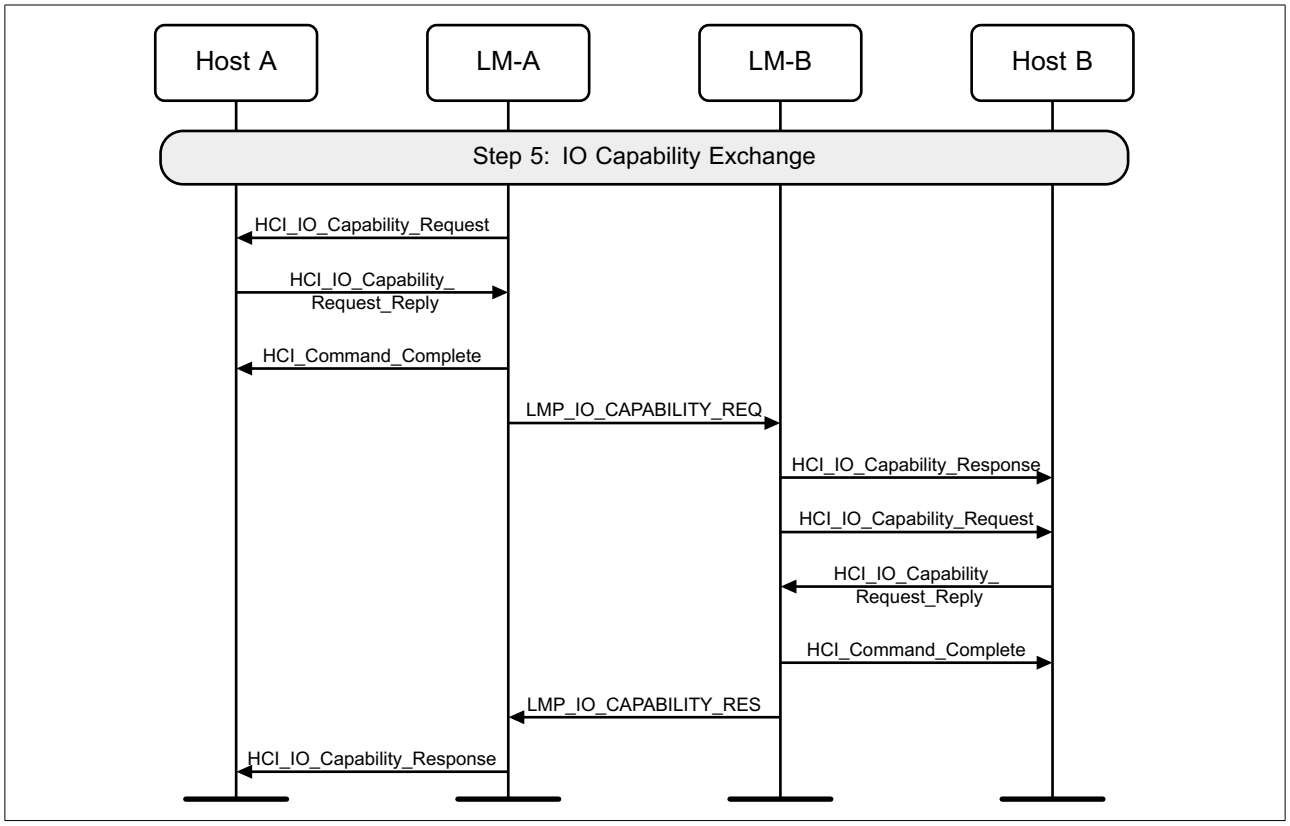

Figure 4.12: IO capability exchange

4.2.8 Public key exchange

Next the public keys are exchanged between the two devices. Once a device has received the public key of the peer device, it can start to calculate the Diffie Hellman

Key (DHKey). This may take a long time, and should be started early, so that user interaction can hide the calculation time. The DHKey is not required until step 8.

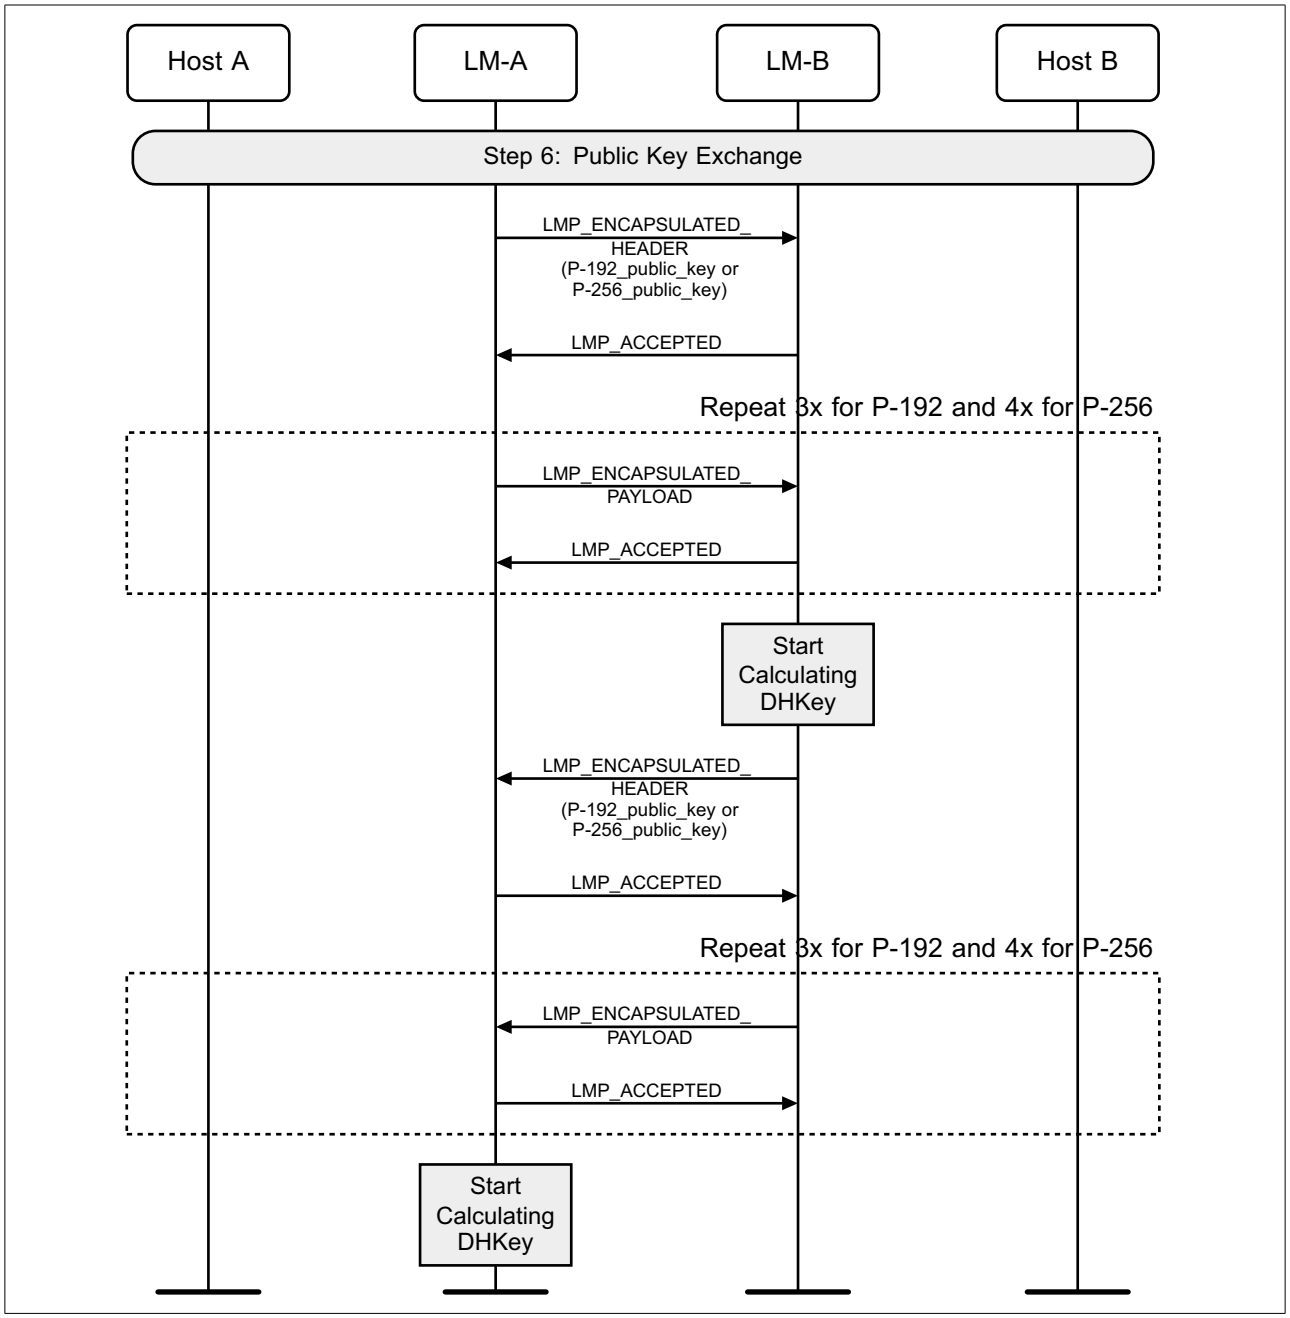

Figure 4.13: Public key exchange

4.2.9 Authentication

A device can be authenticated by using one of three algorithms. The choice of algorithm is determined by the combination of the IO capabilities of the two devices.

4.2.10 Numeric Comparison

The numeric comparison step will be done when both devices have output capabilities, or if one of the devices has no input or output capabilities. If both devices have output capabilities, this step requires the displaying of a user confirmation value. This value should be displayed until the end of step 8. If one or both devices do not have output capabilities, the same protocol is used but the Hosts will skip the step asking for the user confirmation. The sequence for Just Works is identical to that of Numeric Comparison with the exception that the Host will not show the numbers to the user.

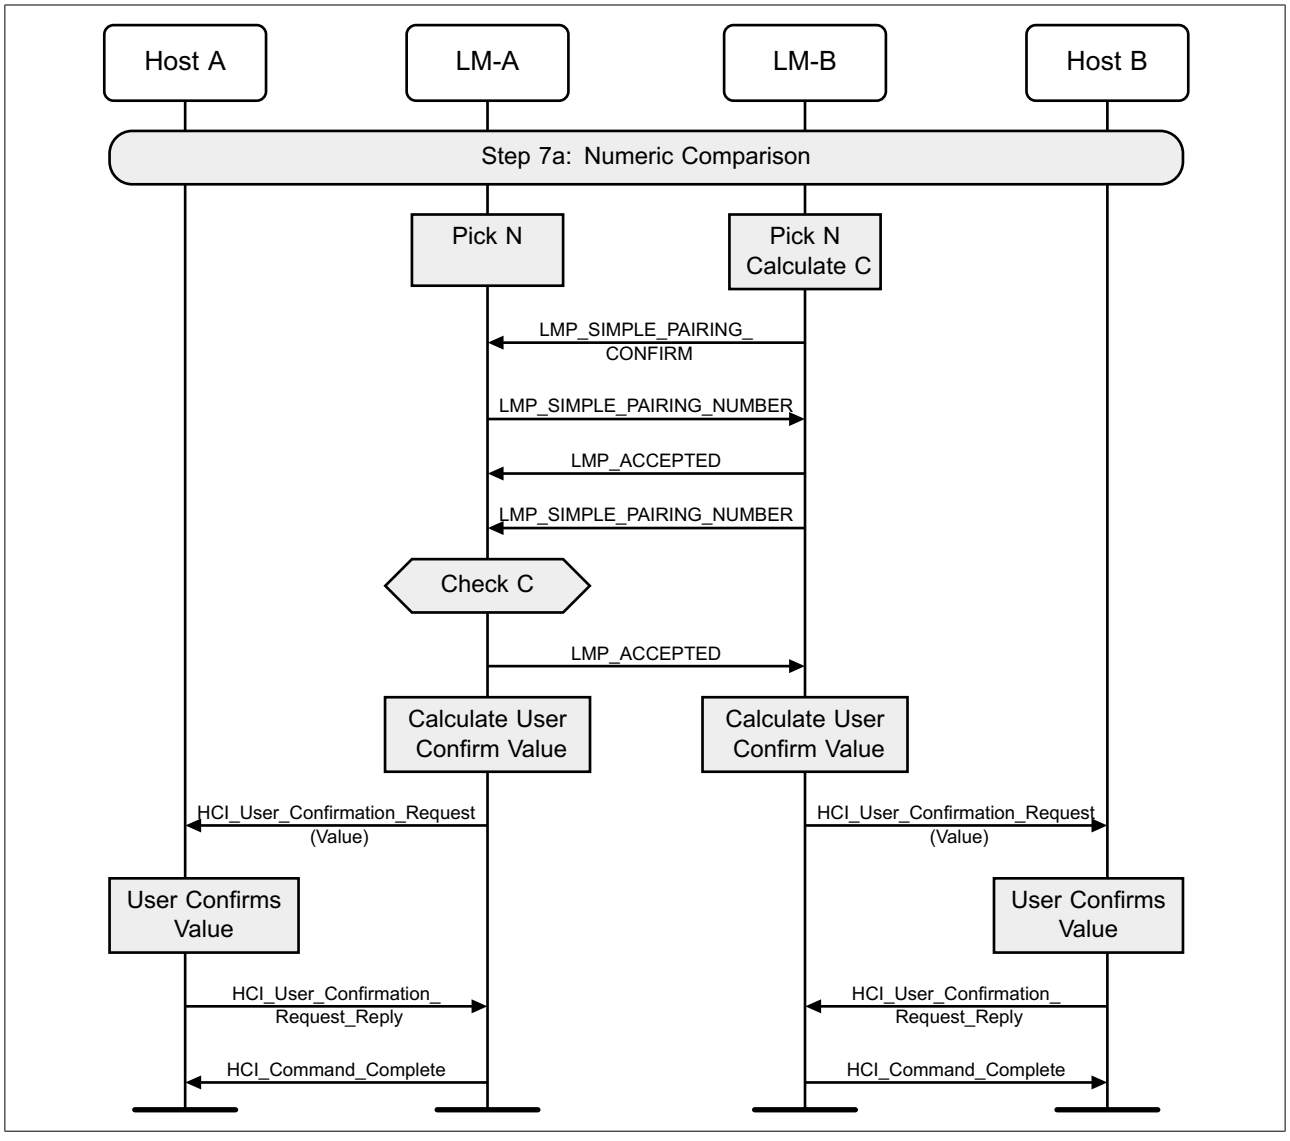

Figure 4.14: Numeric Comparison authentication

4.2.11 Numeric Comparison failure on initiating side

If the numeric comparison fails on the initiating side due to the user indicating that the confirmation values do not match, Secure Simple Pairing is terminated.

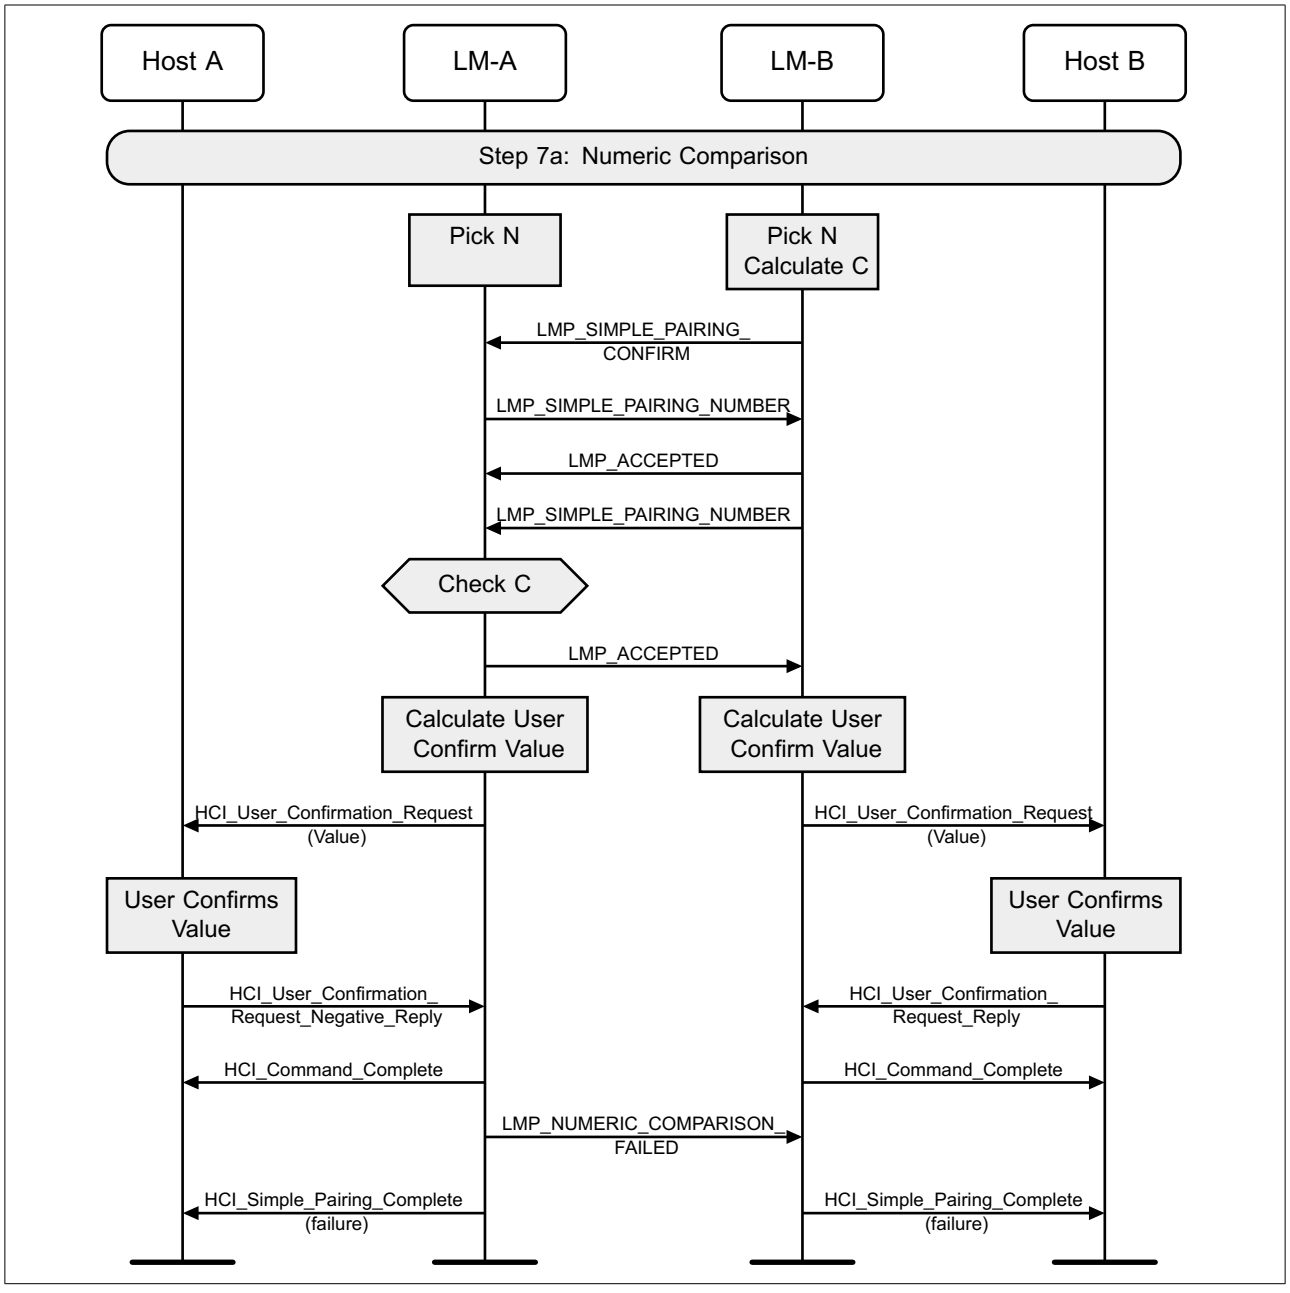

Figure 4.15: Numeric Comparison authentication (failure on initiating side)

4.2.12 Numeric Comparison failure on responding side

If the numeric comparison fails on the responding side due to the user indicating that the confirmation values do not match, Secure Simple Pairing is terminated.

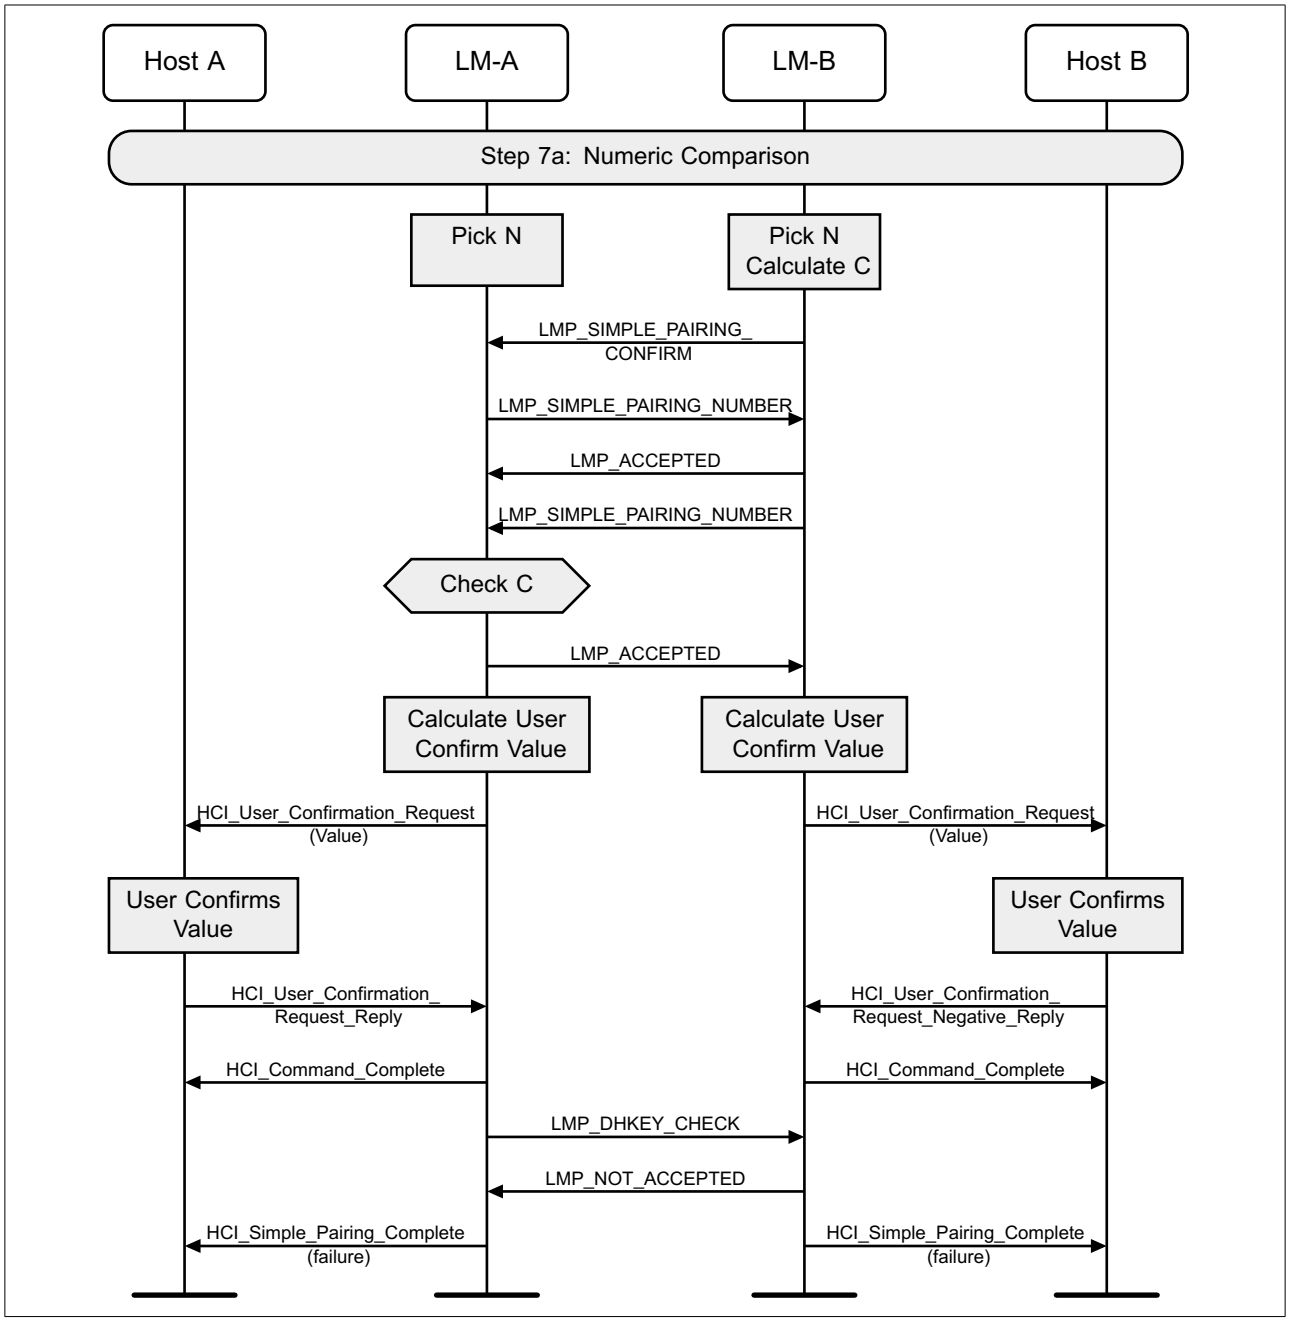

Figure 4.16: Numeric Comparison failure on responding side

4.2.13 Passkey Entry

The Passkey Entry step is used in two cases: when one device has numeric input only and the other device has either a display or numeric input capability or when both

devices only have numeric input capability. In this step, one device display a number to be entered by the other device or the user enters a number on both devices. This number should be displayed until the end of step 8. Key press notification messages are shown during the user input phase.

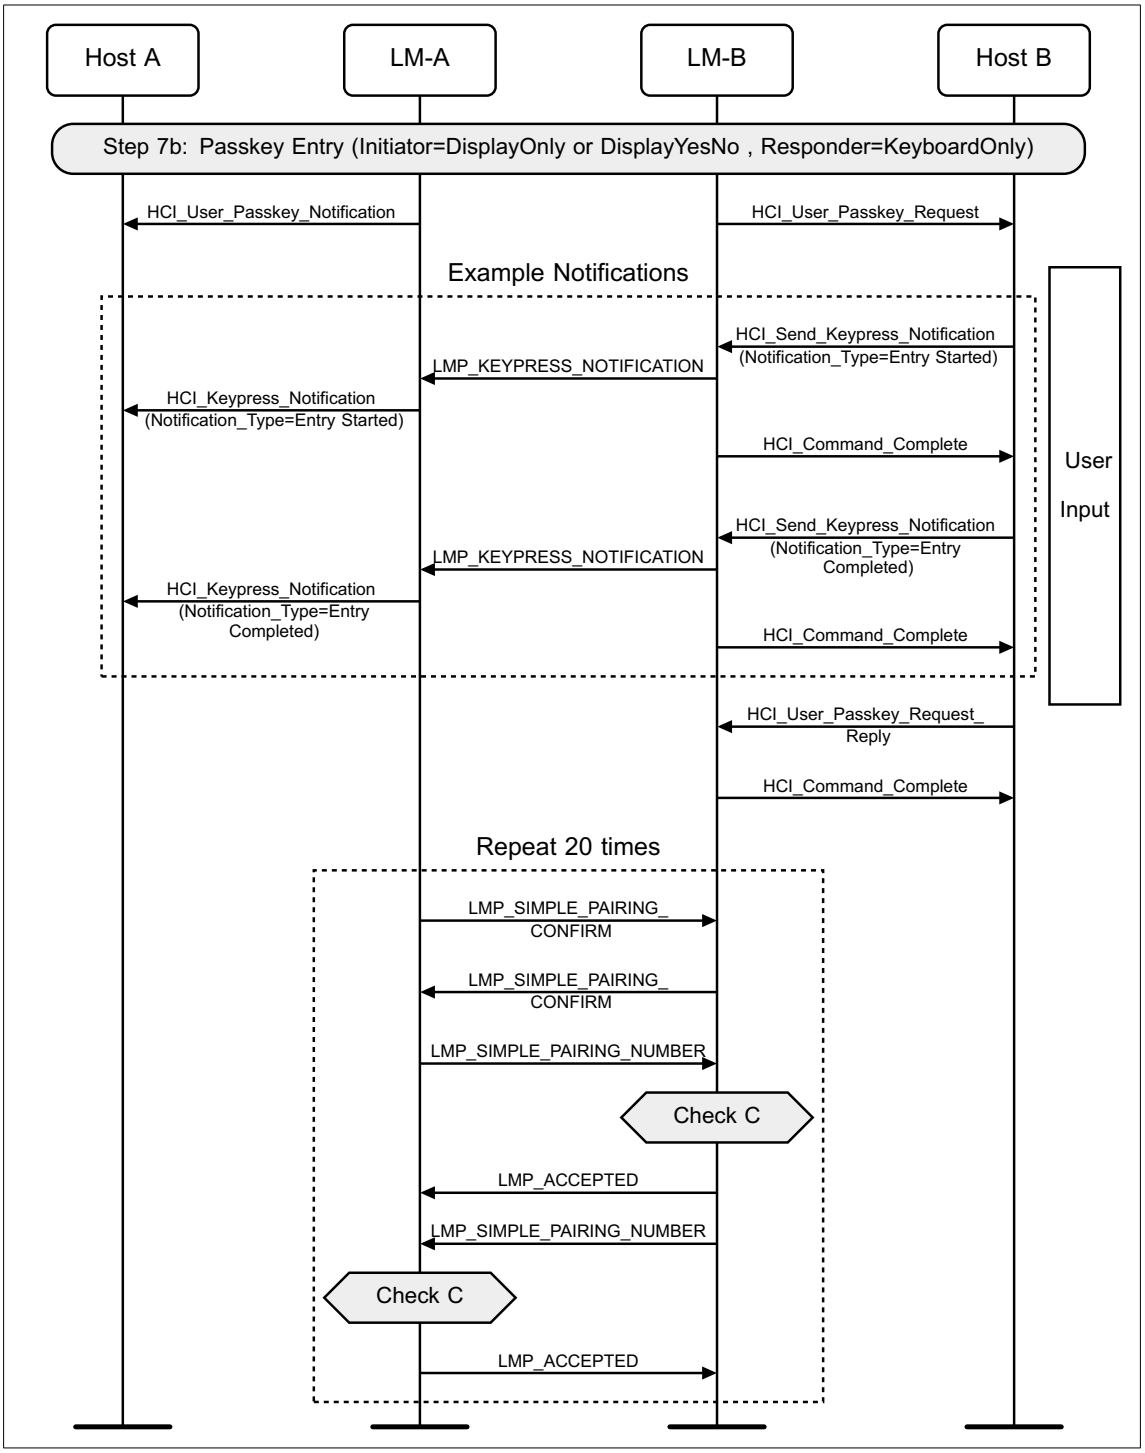

Figure 4.17: Passkey Entry authentication

4.2.14 Passkey Entry failure on responding side

If the Passkey Entry fails on the responding side, Secure Simple Pairing is terminated.

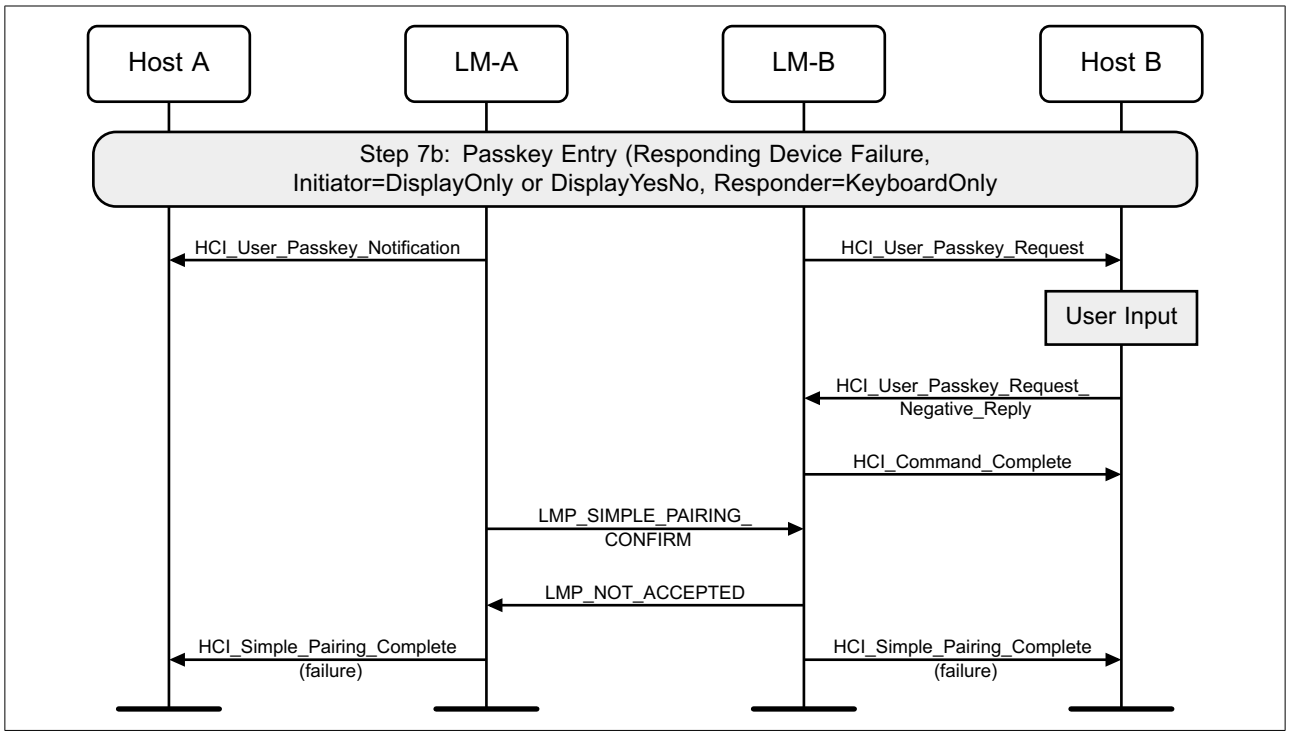

Figure 4.18: Passkey Entry failure on responding side

4.2.15 Passkey Entry failure on initiator side

If the Passkey Entry fails on the initiating side, Secure Simple Pairing is terminated. This is only possible if the initiating LM side sends an HCI_User_Passkey_Request event.

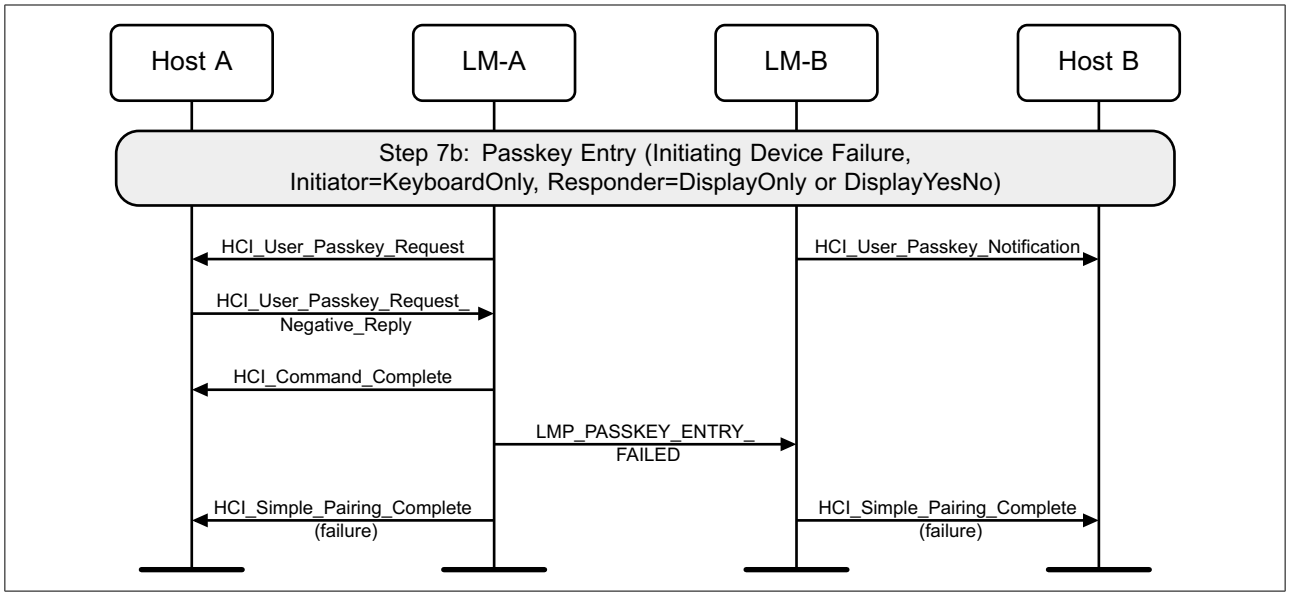

Figure 4.19: Passkey Entry failure on initiating side

4.2.16 Out of Band

The OOB authentication will only be done when both devices have some OOB information to use. This step requires no user interaction.

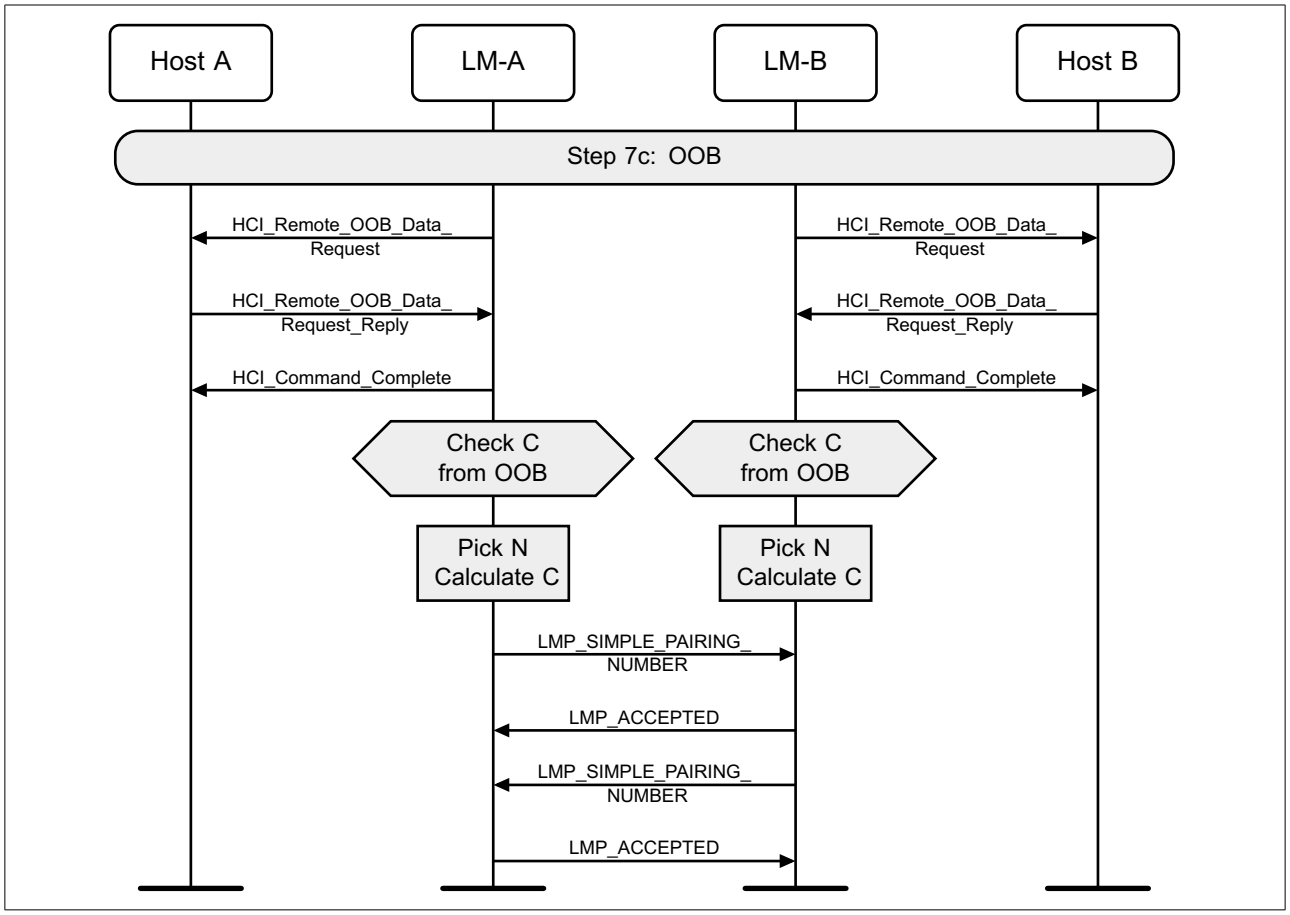

Figure 4.20: OOB authentication (P-192)

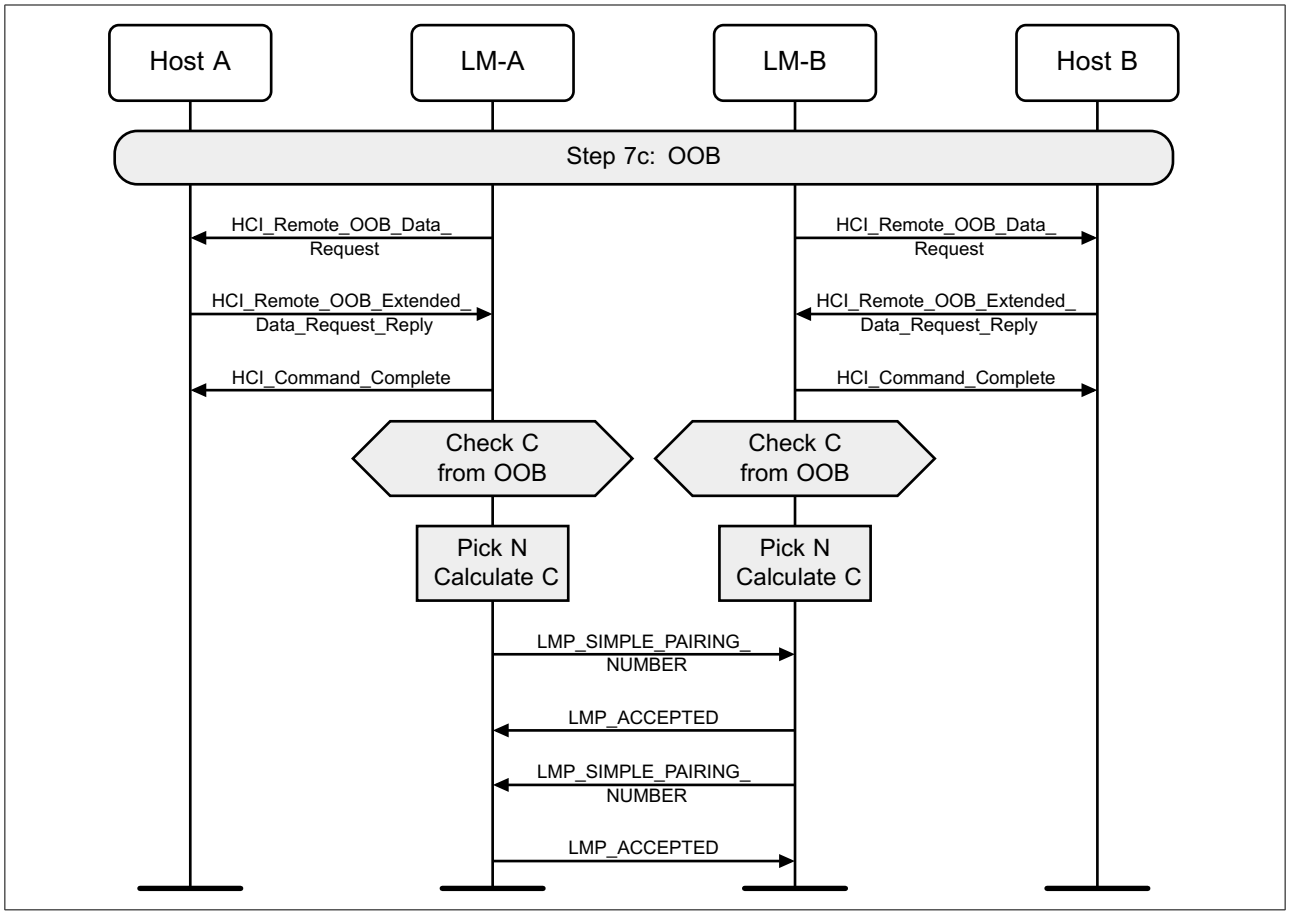

Figure 4.21: OOB authentication (P-256)

4.2.17 OOB failure on initiator side

If the initiating side does not have OOB information, Secure Simple Pairing is terminated.

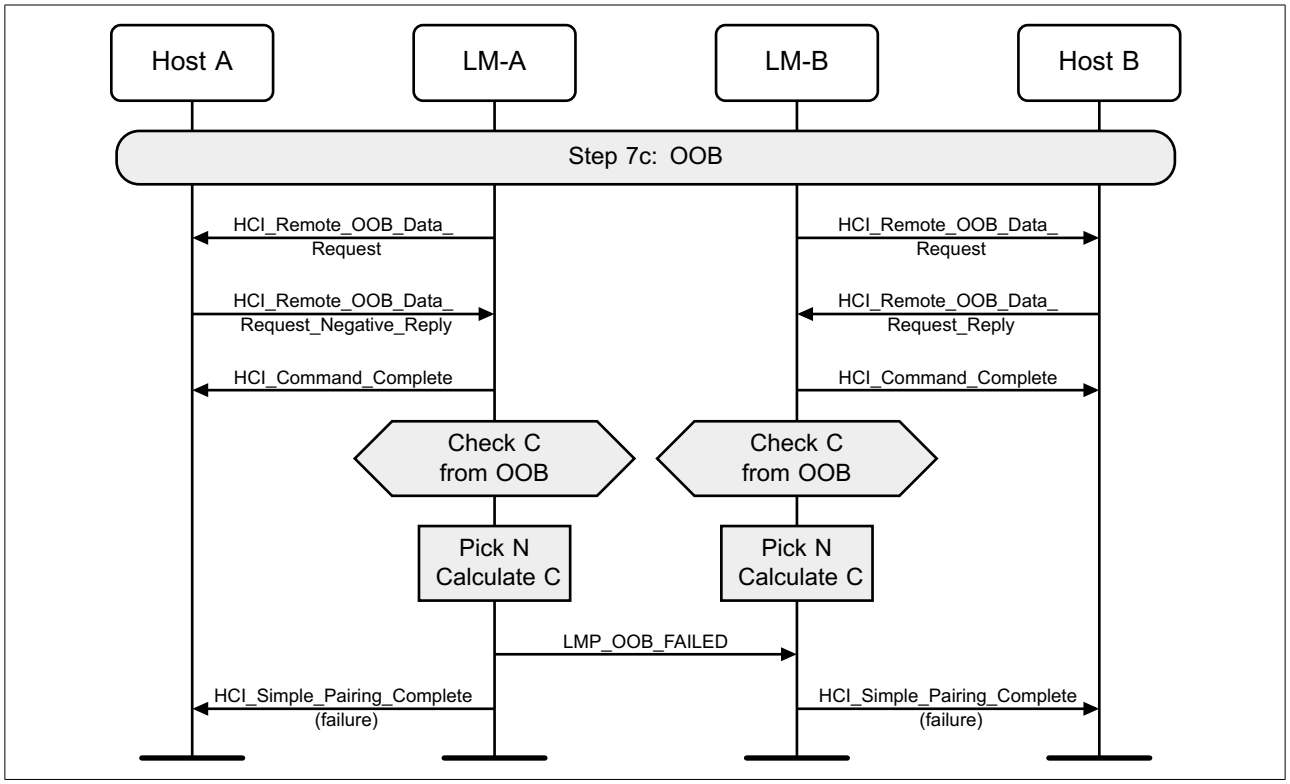

Figure 4.22: OOB authentication failure on initiating side

4.2.18 DHKey checks

Once the devices have been authenticated, and the DHKey calculation has completed, the DHKey value generated is checked. If this succeeds, then both devices would have

finished displaying information to the user about the process, and therefore a message is sent from the Controller to the Host to notify it to stop displaying this information.

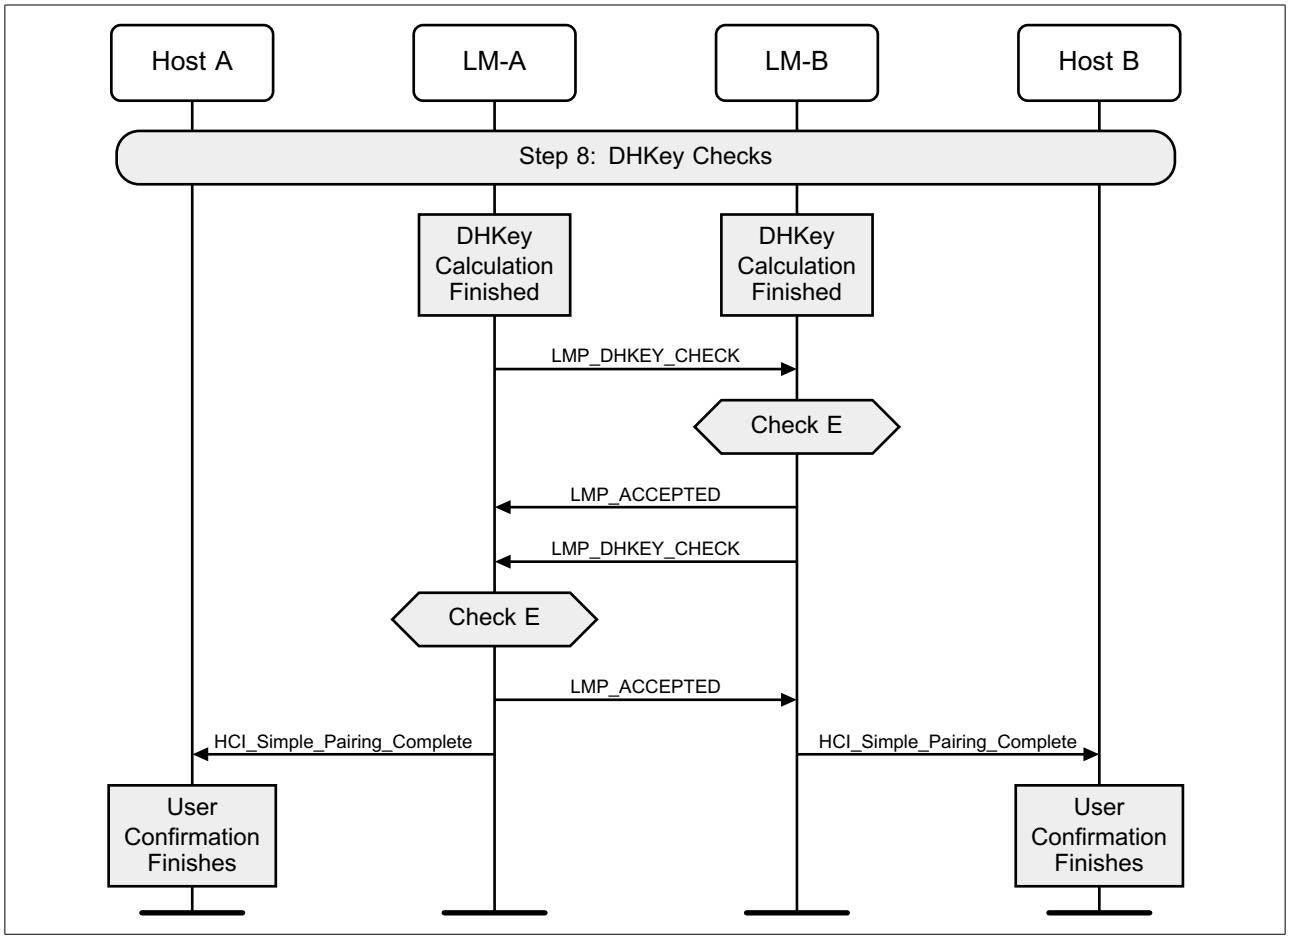

Figure 4.23: DHKey checks

4.2.19 Calculate link key

Once Secure Simple Pairing is complete, the link key can be calculated from the DHKey and used as input to a standard mutual authentication. Once this is complete, an HCI_Link_Key_Notification event will be generated.

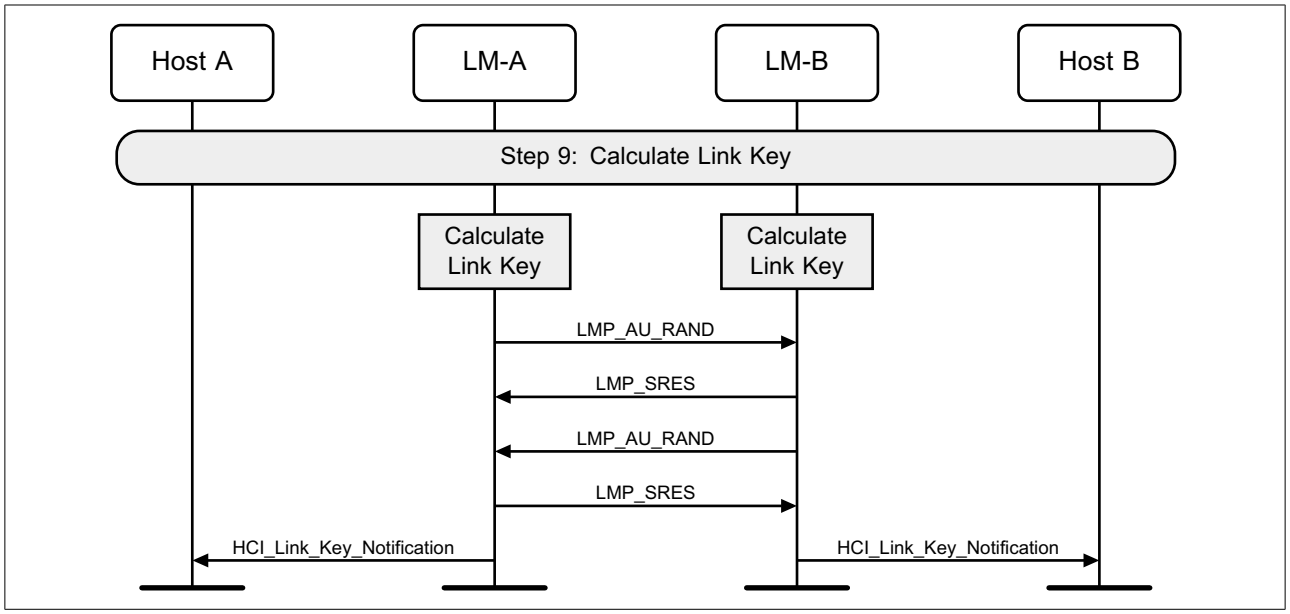

Figure 4.24: Calculate link key

4.2.20 Enable encryption

Once the link key has been notified to the Host, the HCI_Authentication_Requested command will complete with an HCI_Authentication_Complete event. The Host can then turn on encryption using the standard methods.

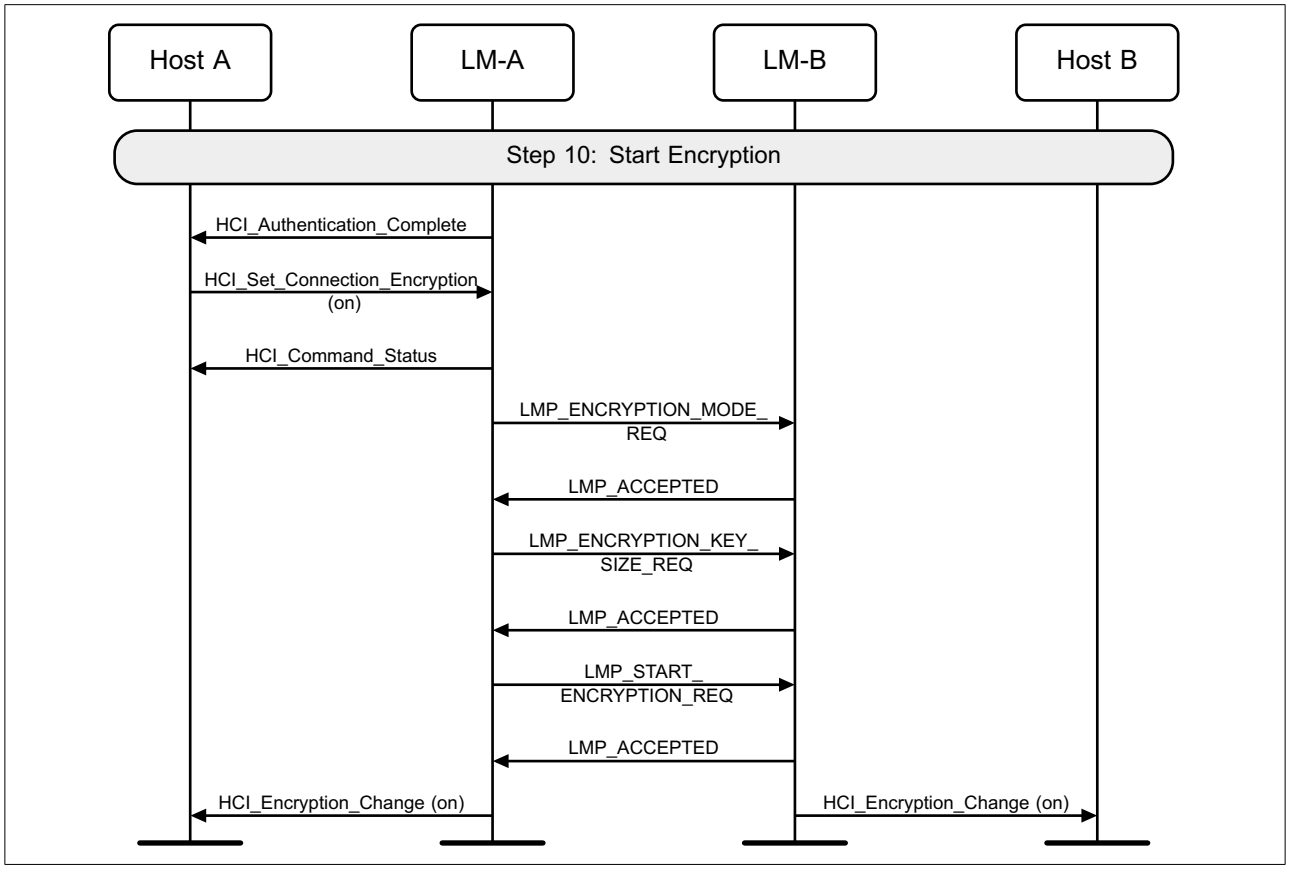

Figure 4.25: Start encryption

4.2.21 L2CAP connection response

If this Secure Simple Pairing was triggered by an L2CAP Connection Request, then only after all of the above steps have completed can the L2CAP Connection Response message be sent.

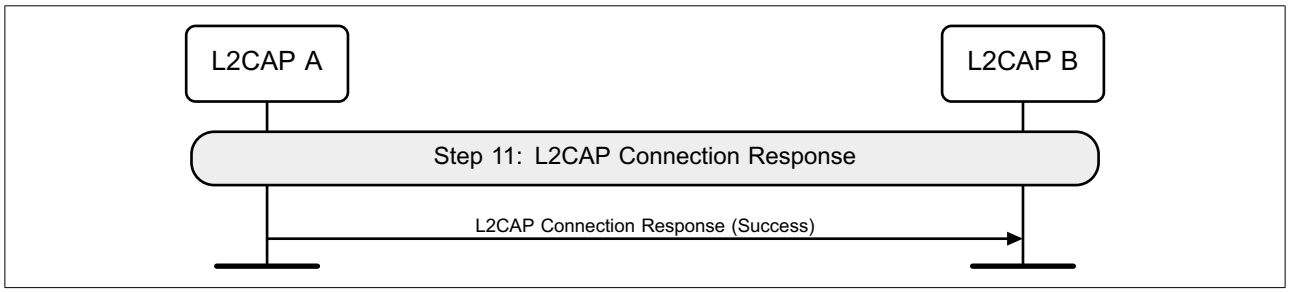

Figure 4.26: L2CAP Connection Response

4.2.22 LMP ping

When the Authenticated Payload Timeout has nearly expired, the Link Manager will force the remote device to send a packet containing a MIC by sending the LMP_PING_REQ PDU.

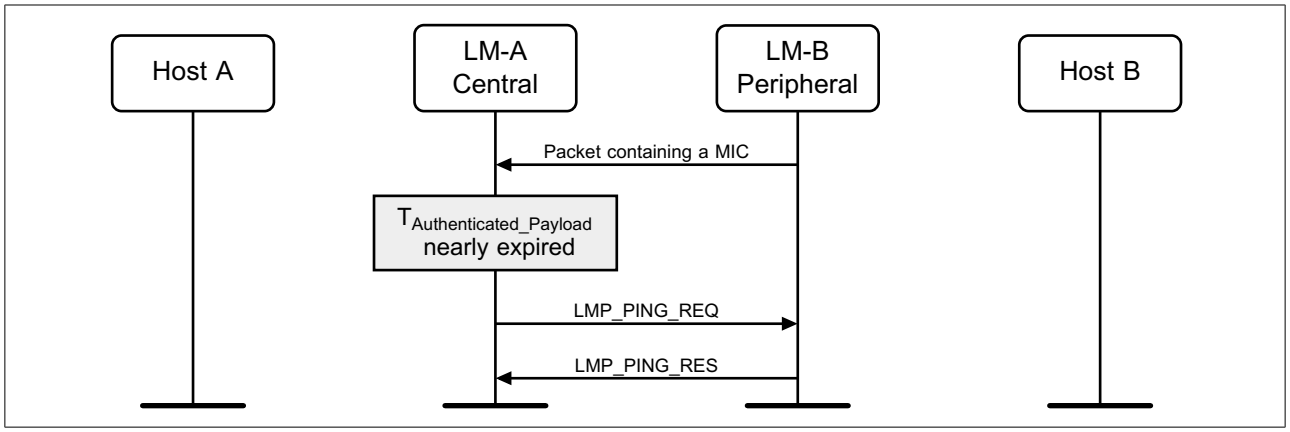

Figure 4.27: Successful ping

When a packet with a MIC has not been received within the Authenticated Payload Timeout, the Host is notified that the timer has expired.

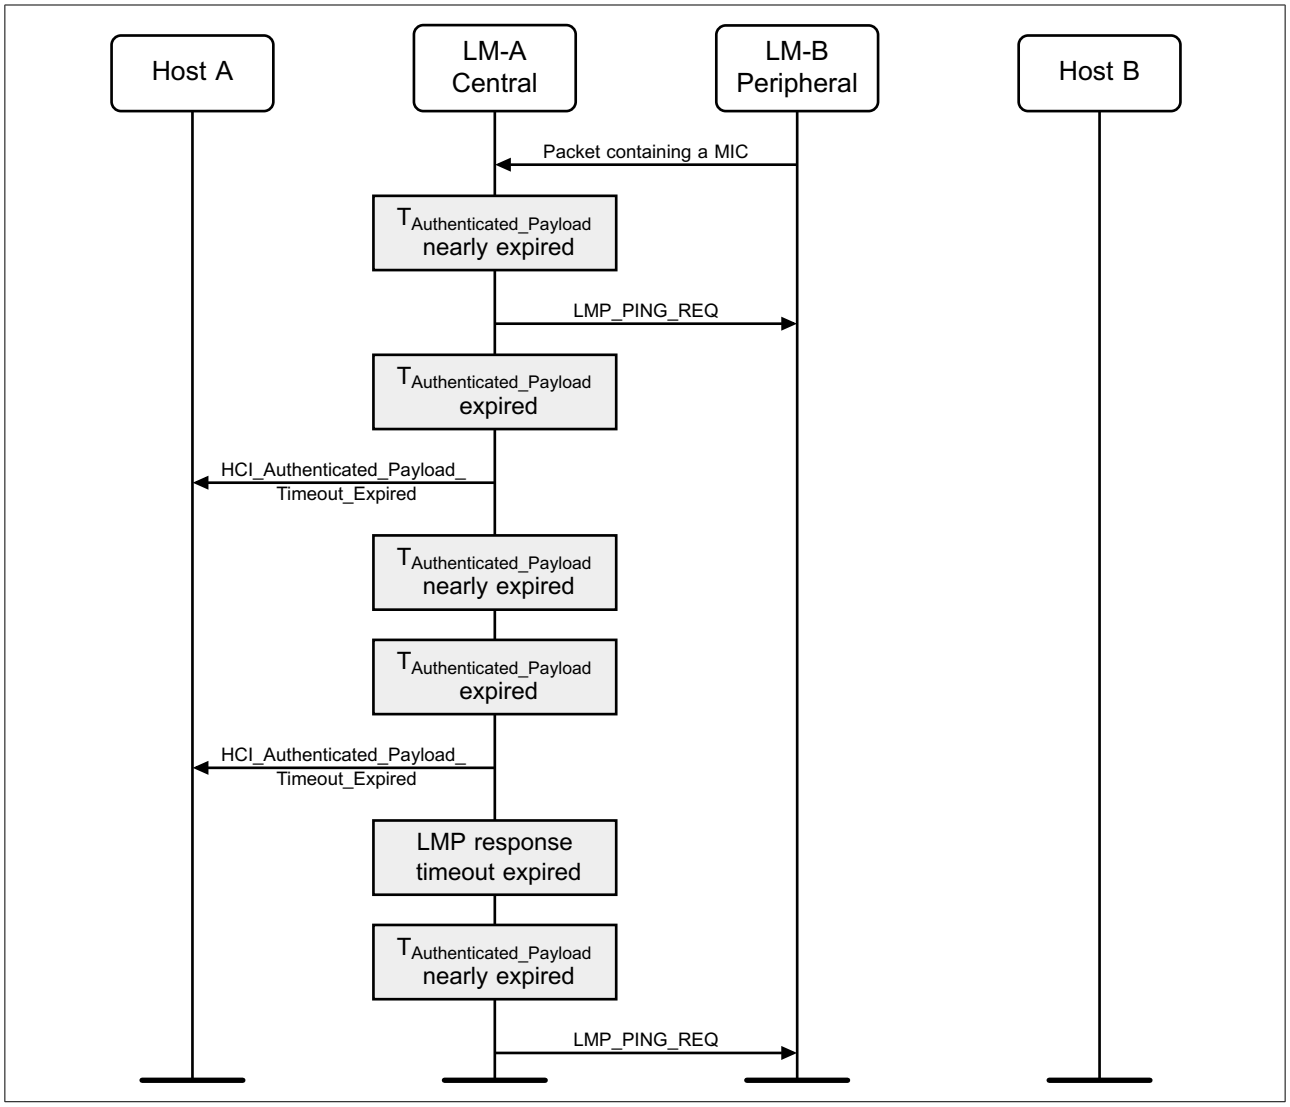

Figure 4.28: Unsuccessful ping

4.3 Link Supervision Timeout Changed event

When enabled by the Host, the Peripheral generates an HCI_Link_Supervision_Timeout_Changed event after the LMP_SUPERVISION_TIMEOUT PDU is received.

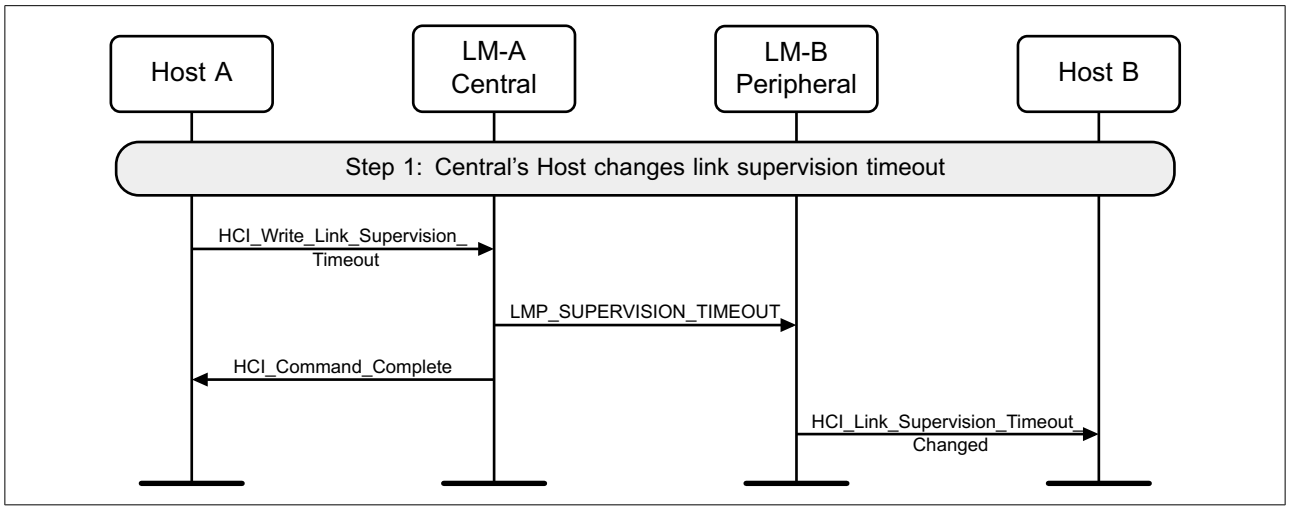

Figure 4.29: Link supervision timeout event

4.4 Set Connection Encryption

Step 1: The Host may at any time turn on encryption using the HCI_Set_Connection_Encryption command. This command can be originated from either the Central or Peripheral sides. Only the Central side is shown in Figure 4.30. If this command is sent from a Peripheral, the only difference is that the LMP_ENCRYPTION_MODE_REQ PDU will be sent from the Peripheral. The LMP_ENCRYPTION_KEY_SIZE_REQ and LMP_START_ENCRYPTION_REQ PDUs will always be requested from the Central. (See Figure 4.30.)

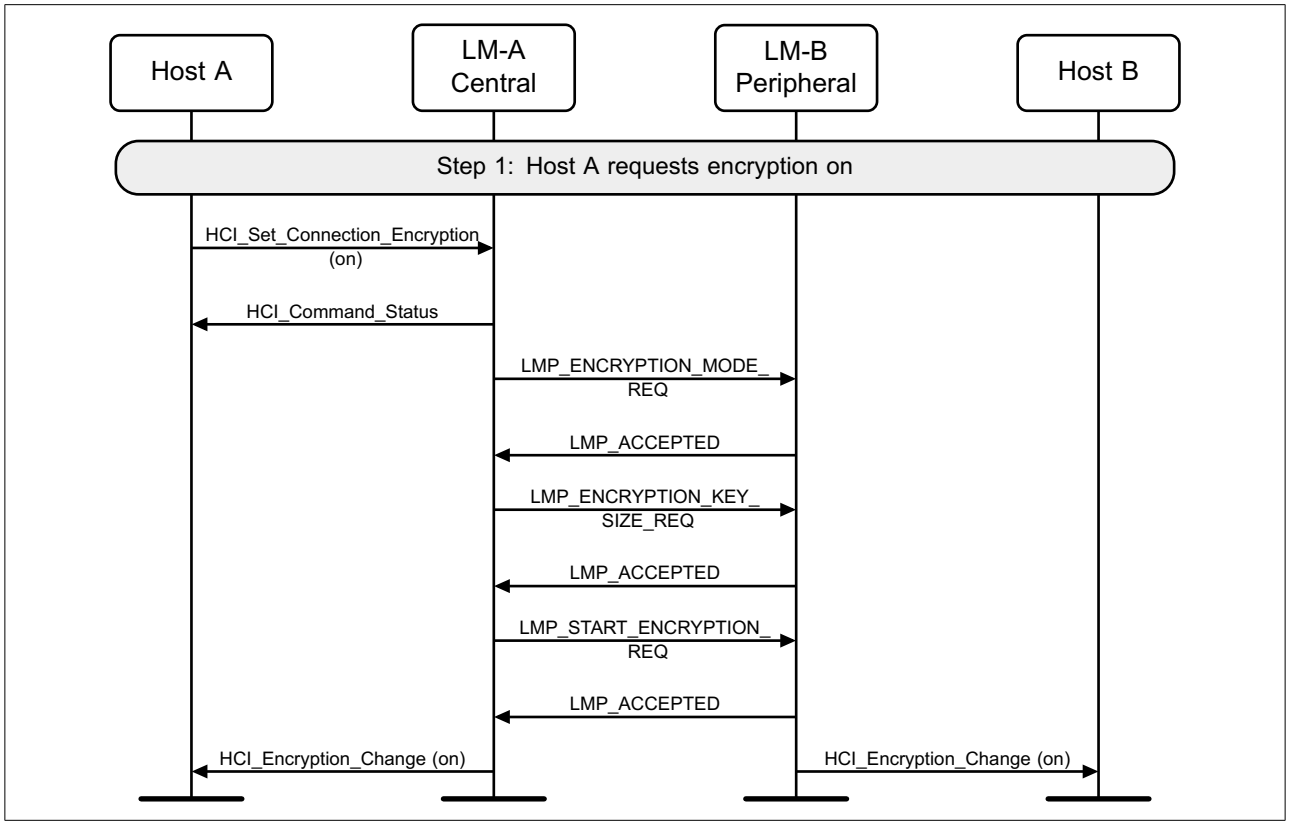

Figure 4.30: Encryption requested

Step 2: To terminate the use of encryption, the HCI_Set_Connection_Encryption command is used. (See Figure 4.31.)

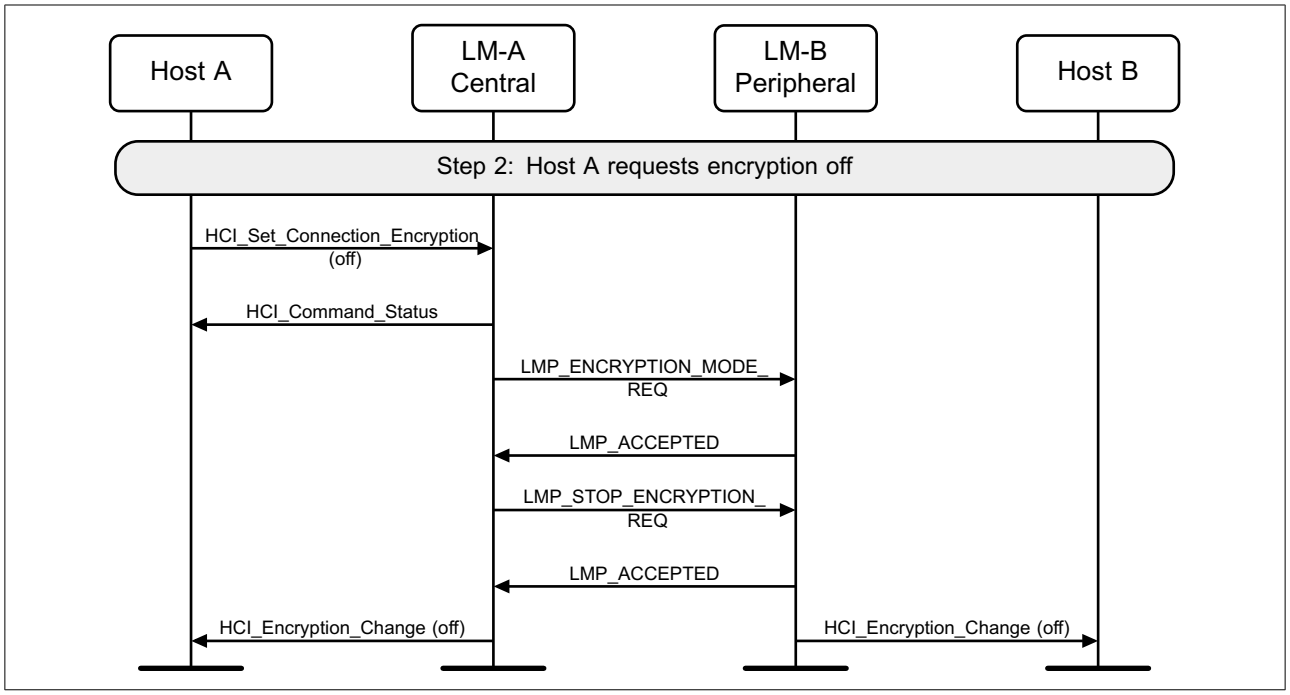

Figure 4.31: Encryption off requested

4.5 Change connection link key

Step 1: The Central's Host (Host A) may change the connection link key using the HCI_Change_Connection_Link_Key command. A new link key will be generated and the Hosts will be notified of this new link key. (See Figure 4.32.)

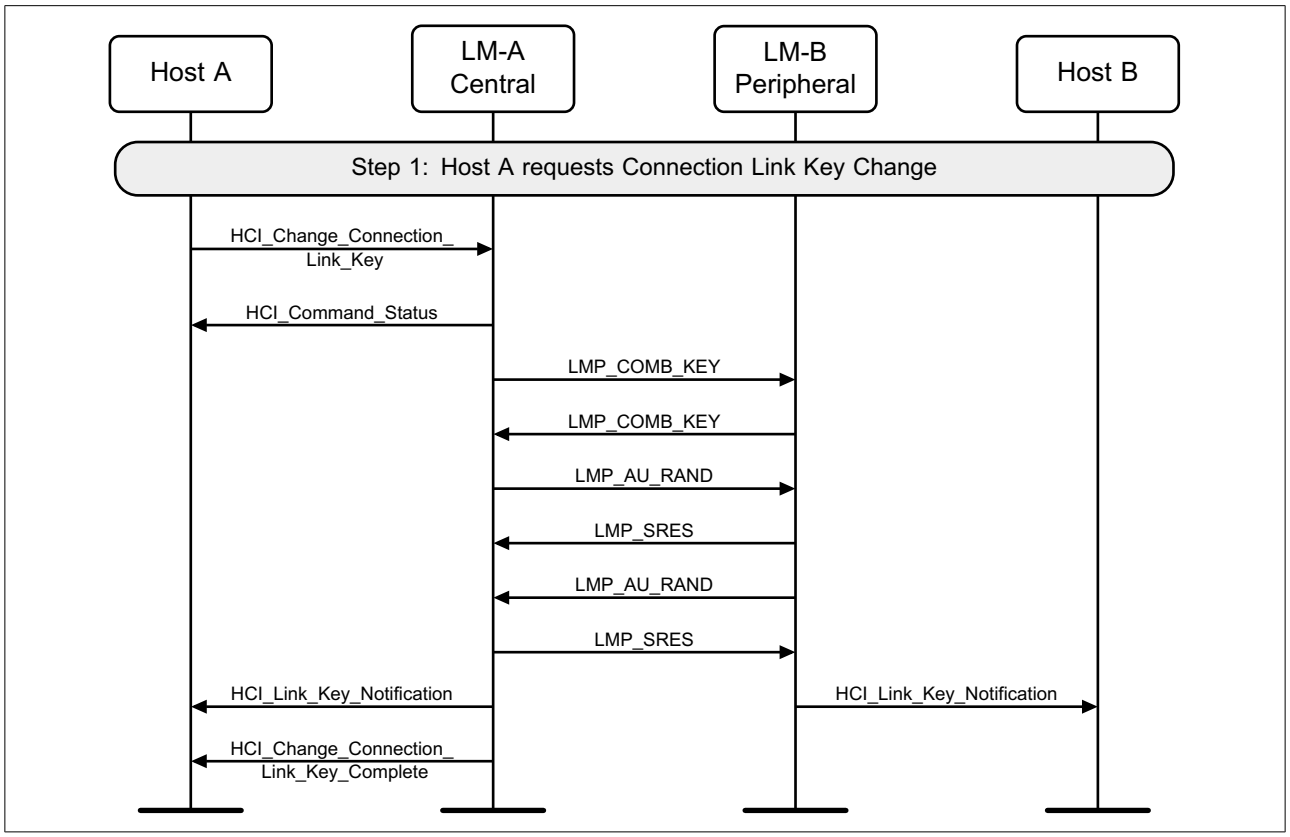

Figure 4.32: Change connection link key

4.6 Change connection link key with encryption pause and resume

Step 1: The Central's Host (Host A) may change the connection link key using the HCI_Change_Connection_Link_Key command. A new link key will be generated and the Hosts will be notified of this new link key. Encryption will then be paused and

resumed, immediately using this new link key to generate a new encryption key. (See Figure 4.33.)

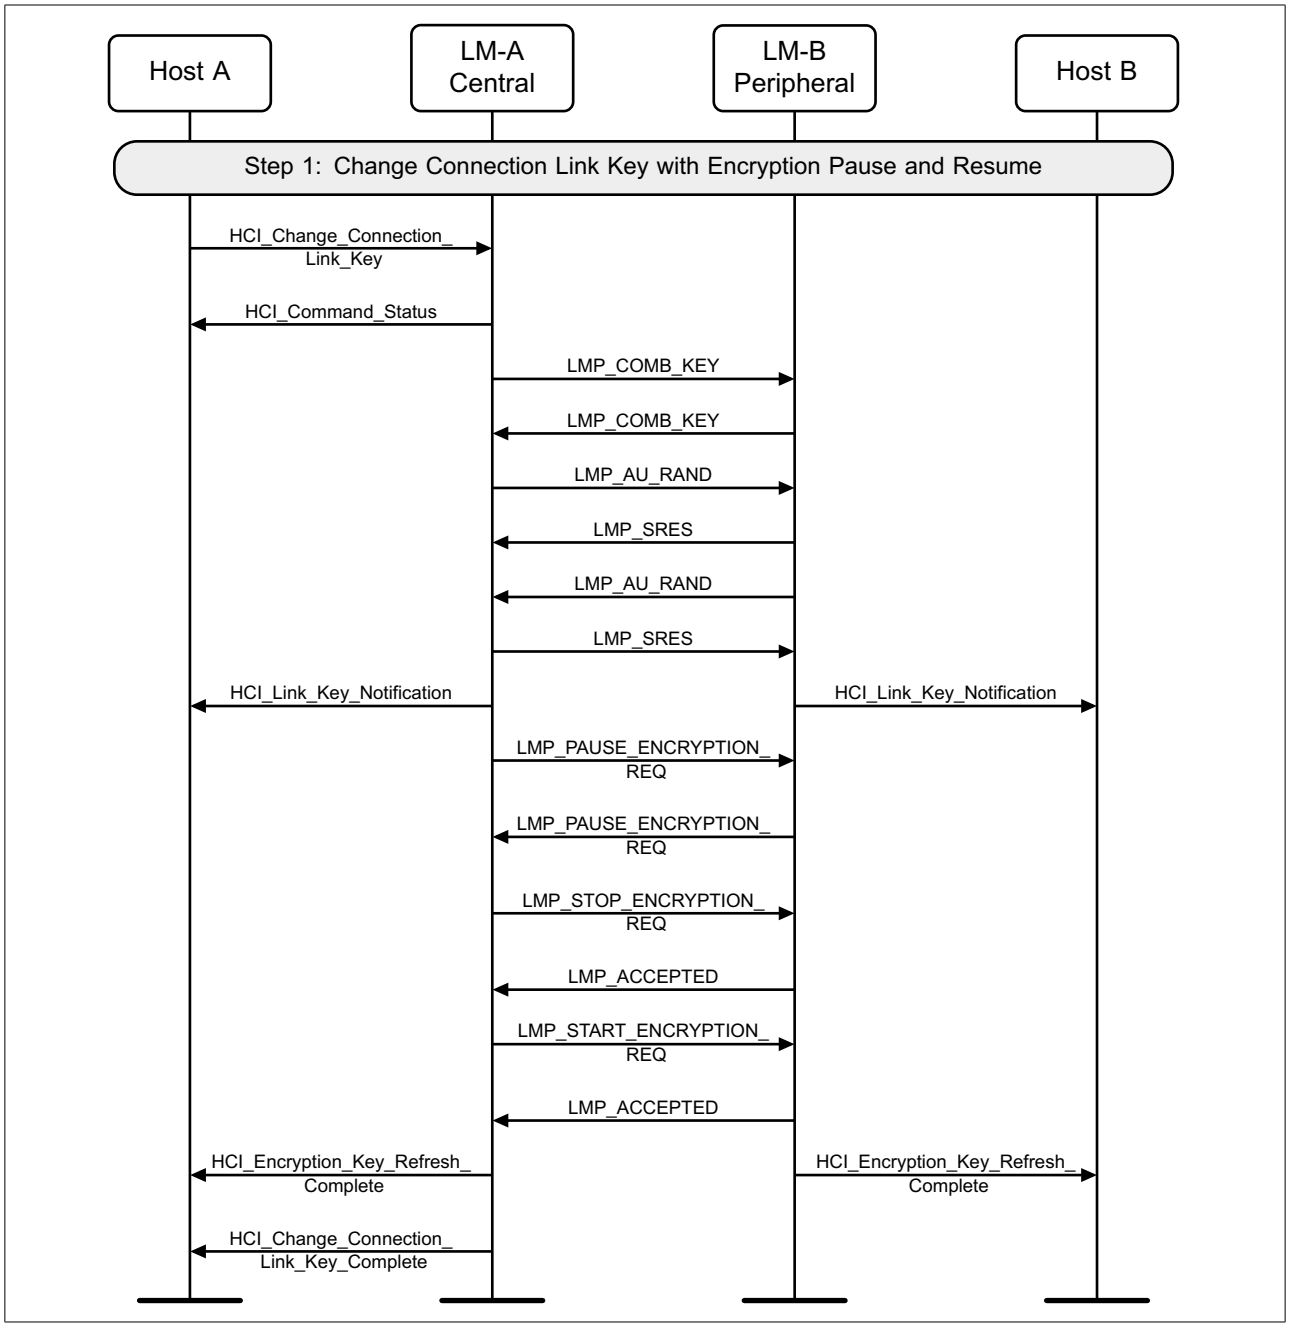

Figure 4.33: Change connection link key with encryption pause and resume

4.7 Temporary Link Key

Step 1: The Host changes to a Temporary Link Key from a Semi-permanent Link Key using the HCI_Link_Key_Selection command when at least one device does not support Encryption Pause and Resume. (See Figure 4.34.)

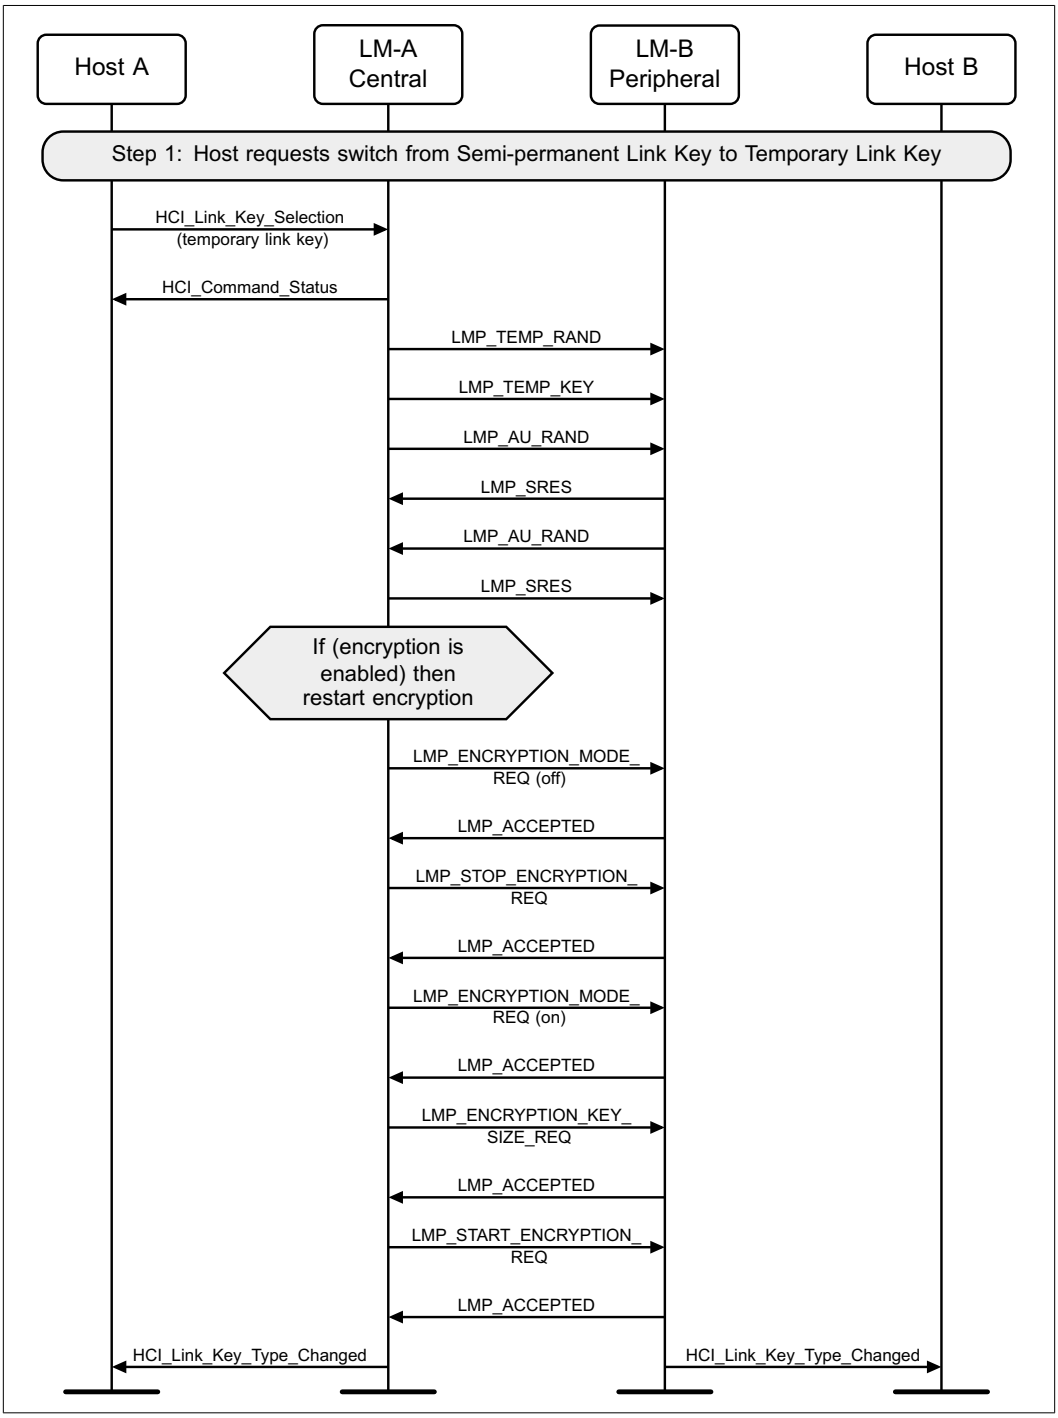

Figure 4.34: Change to temporary link key

Step 2: The Host changes to a Semi-permanent Link Key from a Temporary Link Key using the HCI_Link_Key_Selection command. (See Figure 4.35.)

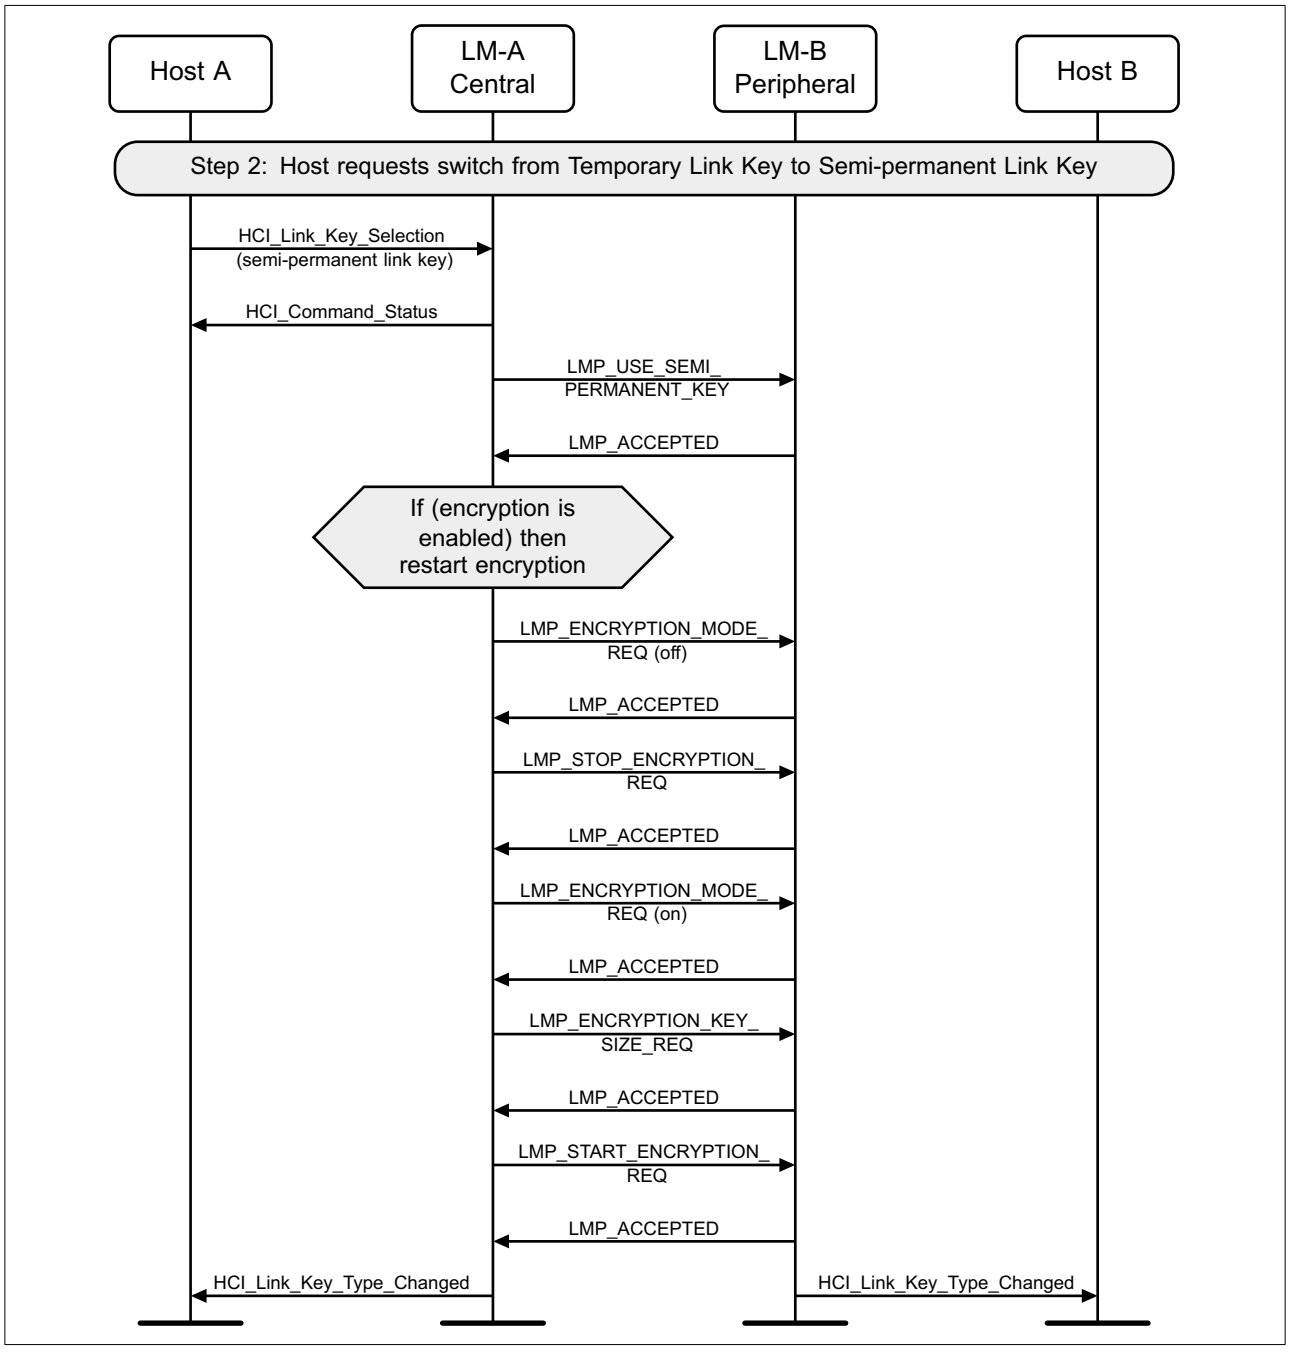

Figure 4.35: Change to semi-permanent link key

4.8 Read remote supported features

Using the HCI_Read_Remote_Supported_Features command the supported LMP Features of a remote device can be read. (See Figure 4.36.)

If the remote supported features have been obtained previously then the Controller may return them without sending any LMP PDUs.

Step 1: The Host requests the supported features of a remote device.

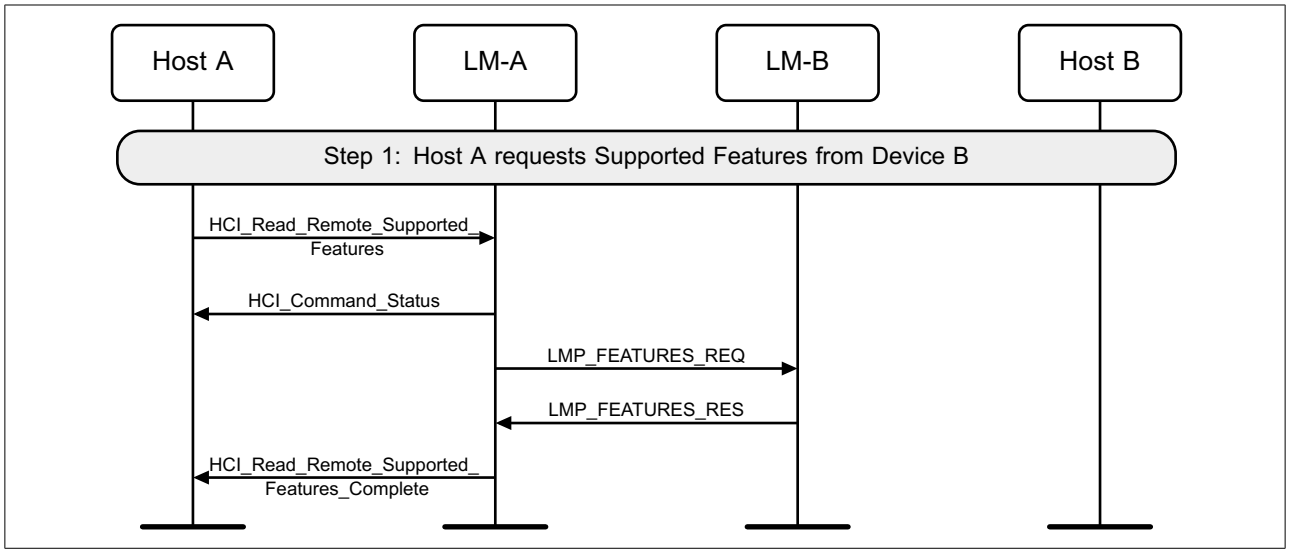

Figure 4.36: Read remote supported features

4.9 Read remote extended features

Using the HCI_Read_Remote_Extended_Features command the extended LMP features of a remote device can be read. (See Figure 4.37.)

If the remote extended features have been obtained previously then the Controller may return them without sending any LMP PDUs.

Step 1: The Host requests the extended features of a remote device.

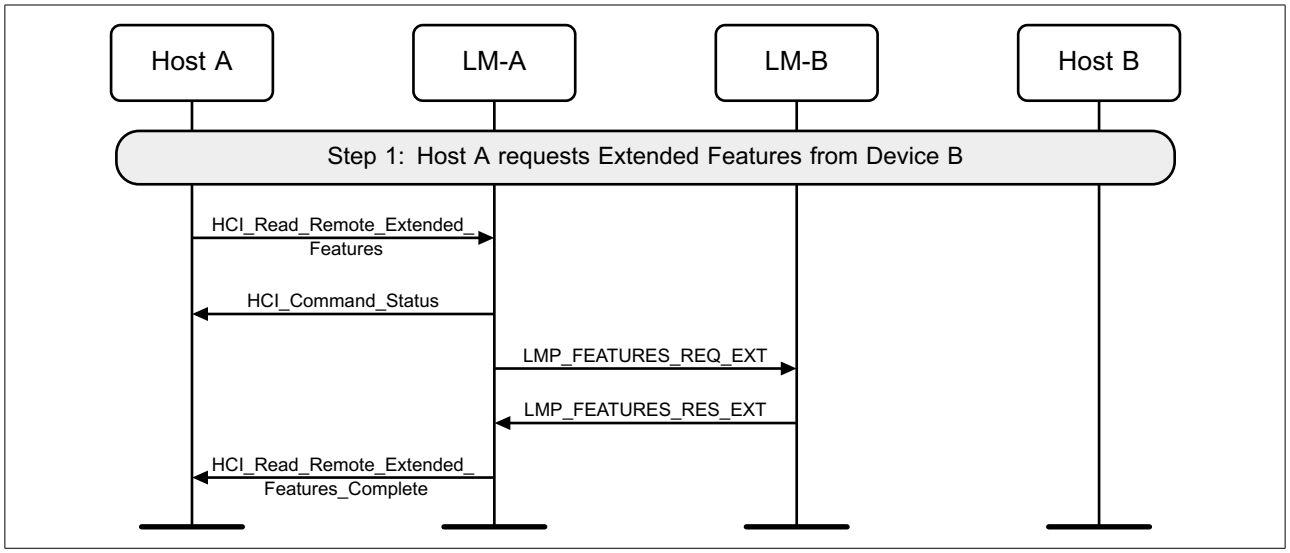

Figure 4.37: Read remote extended features

4.10 Read clock offset

Using the HCI_Read_Clock_Offset command the device acting as the Central can read the Clock Offset of a Peripheral (see Figure 4.38). The Clock Offset can be used to speed up the paging procedure in a later connection attempt.

Step 1: The Host requests the clock offset of a remote device.

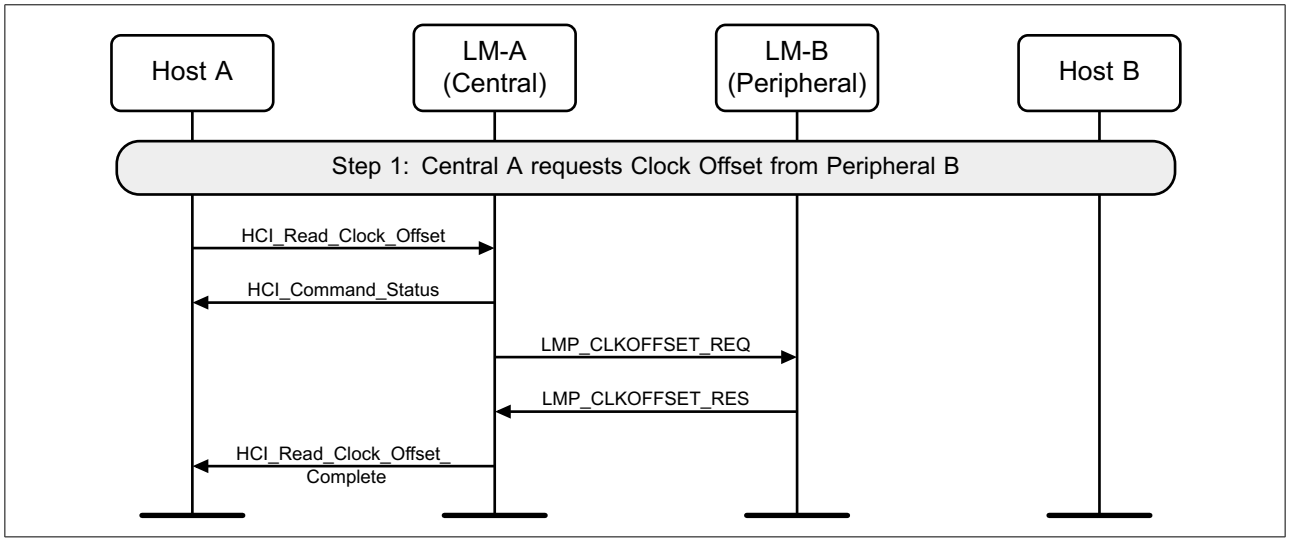

Figure 4.38: Read clock offset (Central)

If the command is requested from the Peripheral, the Controller will directly return an HCI_Command_Status event and an HCI_Read_Clock_Offset_Complete event without sending any LMP PDUs (see Figure 4.39).

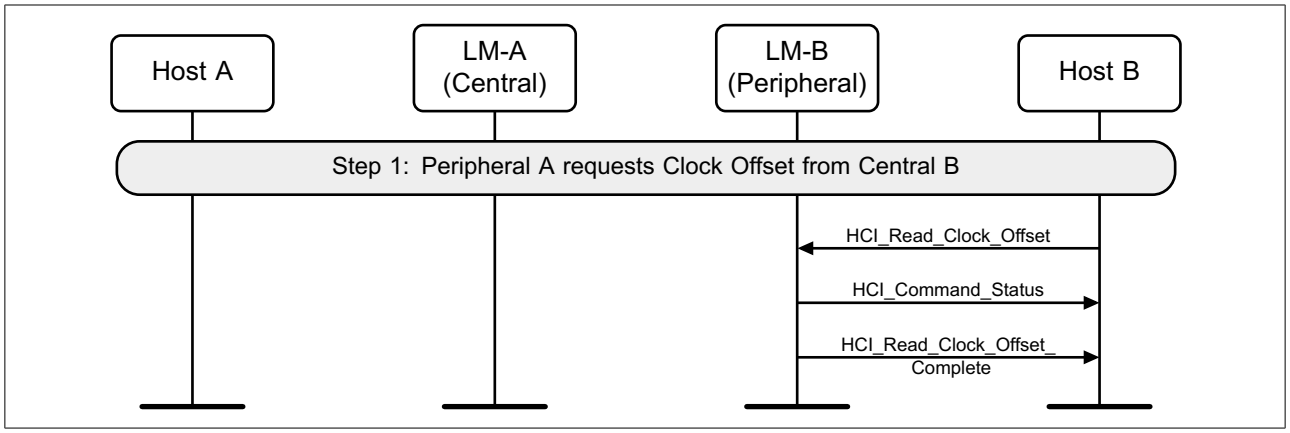

Figure 4.39: Read clock offset (Peripheral)

4.11 Role switch on an encrypted link using encryption pause and resume

The HCI_Switch_Role command can be used to explicitly switch the current Central / Peripheral role of the local device with the specified device. The Central's Host (A) requests a role switch with a Peripheral. This will first pause encryption, and then send the switch request, and the Peripheral will respond with the slot offset and accepted. The role switch is performed by doing the TDD switch and piconet switch.

Encryption is resumed, and finally an HCI_Role_Change event is sent on both sides. (See Figure 4.40.)

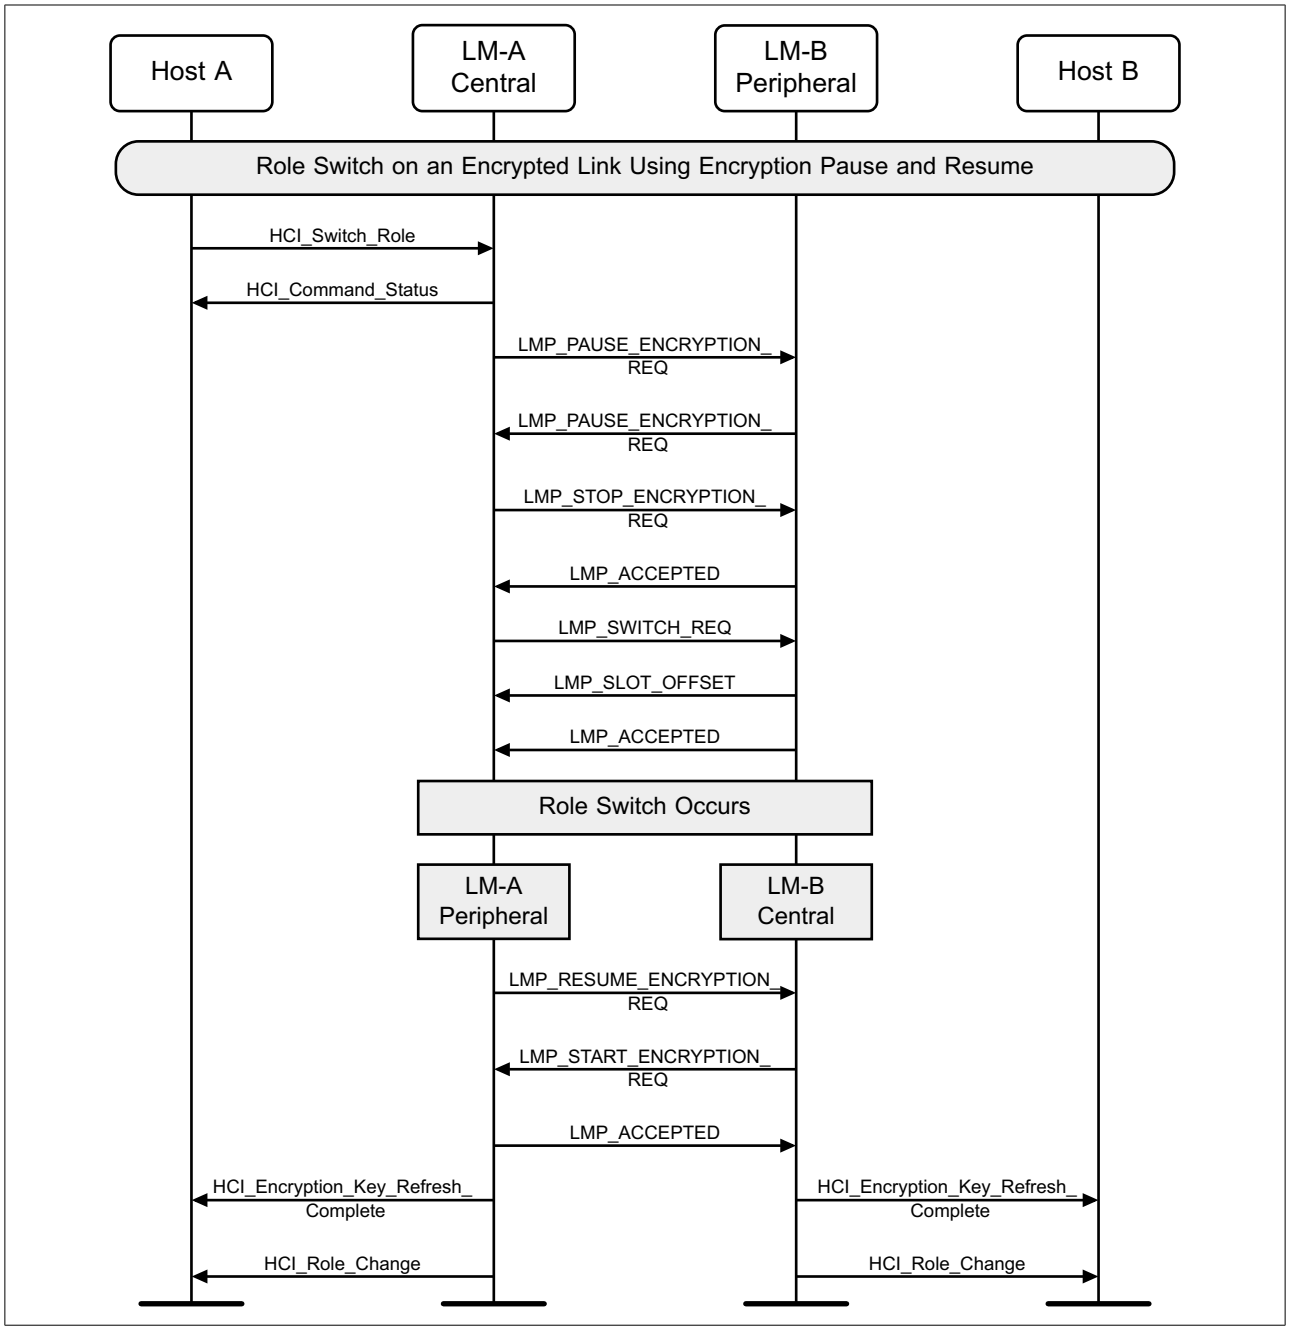

Figure 4.40: Role switch on an encrypted link using encryption pause and resume

4.12 Refreshing encryption keys

The HCI_Refresh_Encryption_Key command may be used by the Central's Host to explicitly pause and resuming encryption to refresh the encryption key. After encryption is resumed an HCI_Encryption_Key_Refresh_Complete event is sent on both sides. (See Figure 4.41).

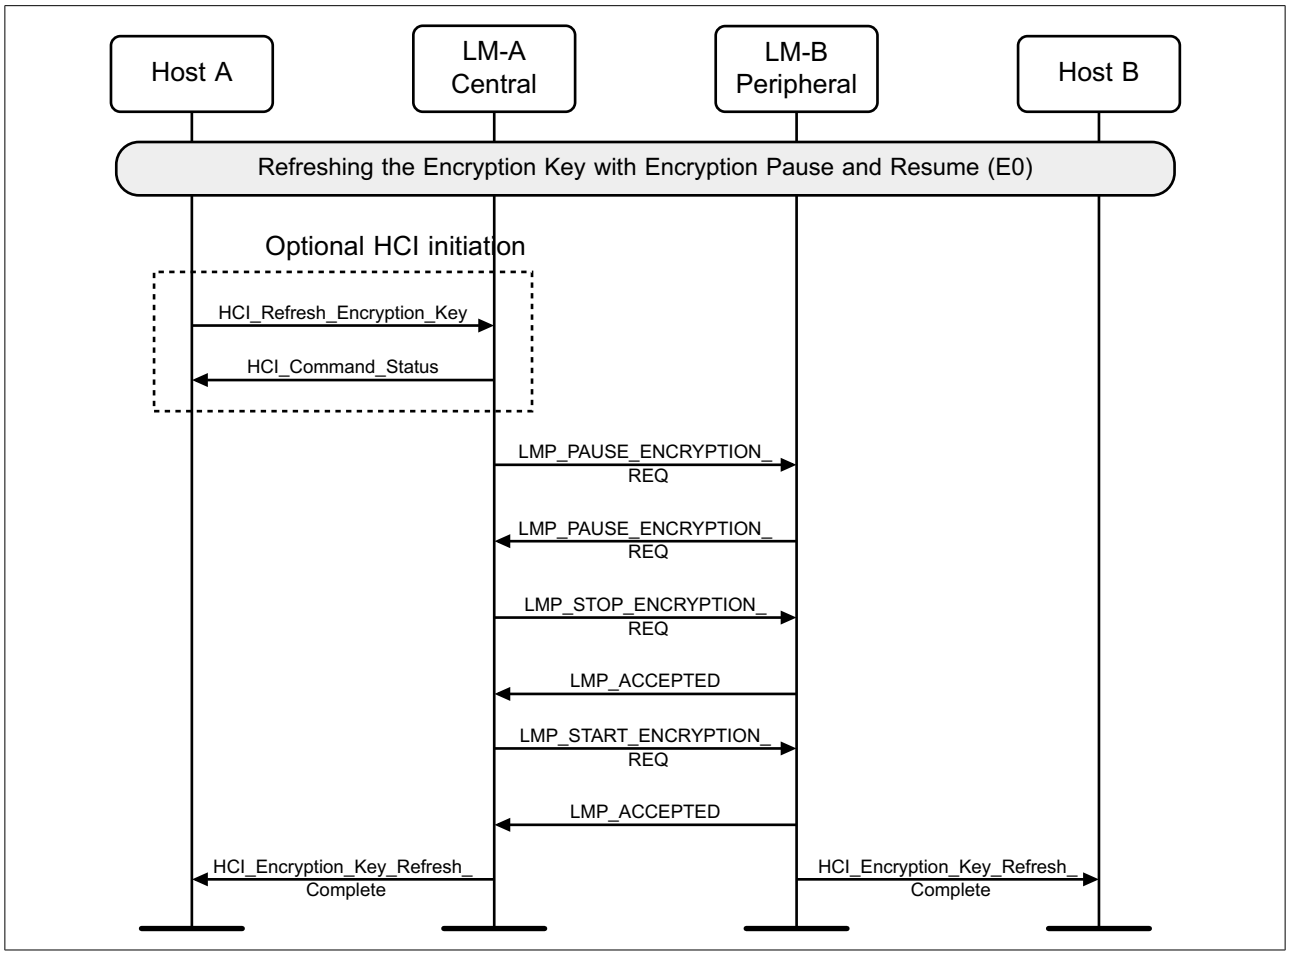

Figure 4.41: Refreshing encryption keys (E0)

When both devices support Secure Connections, the encryption key refresh sequence is performed as follows.

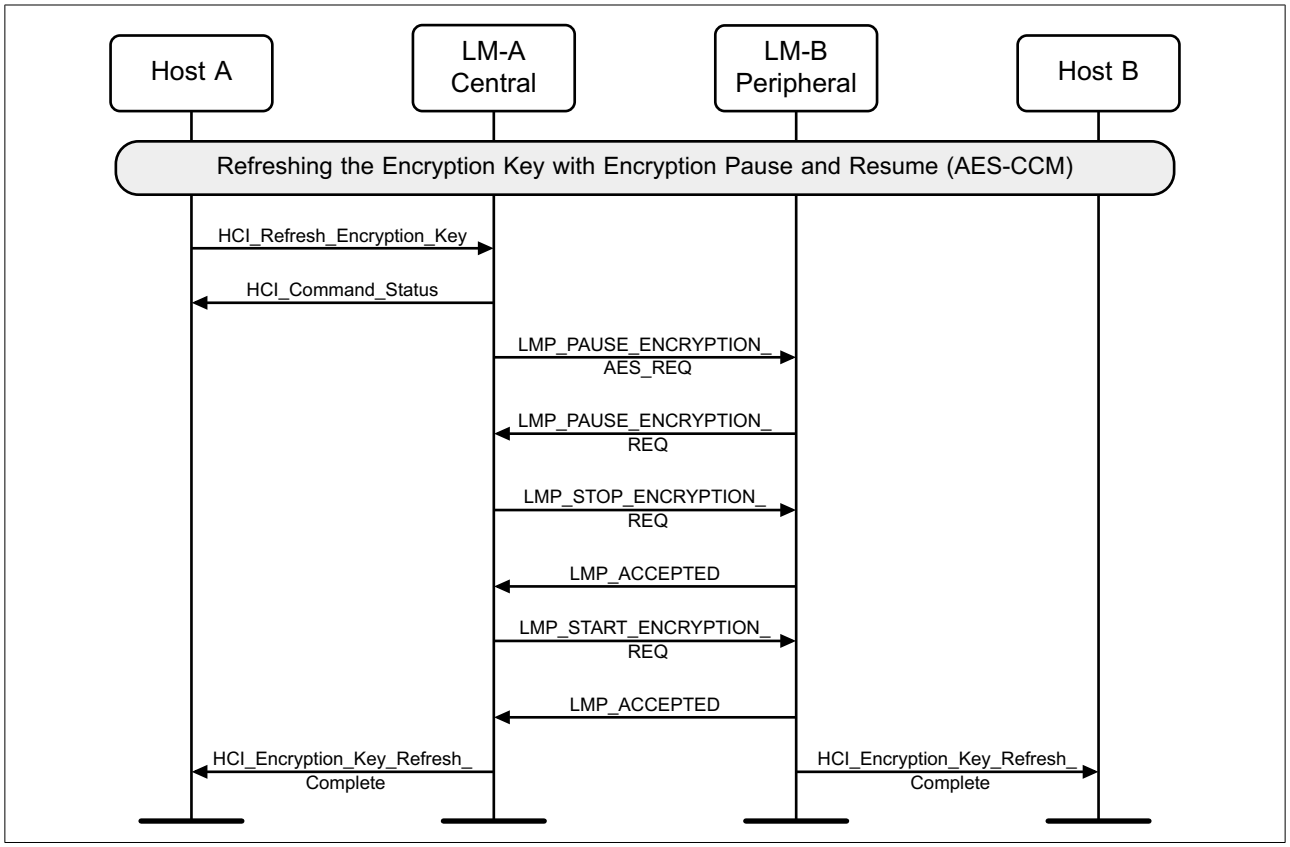

Figure 4.42: Refreshing encryption keys (AES-CCM)

4.13 Read remote version information

Using the HCI_Read_Remote_Version_Information command the version information of a remote device can be read. (See Figure 4.43.)

If the remote version information has been obtained previously then the Controller may return them without sending any LMP PDUs.

Step 1: The Host requests the version information of a remote device.

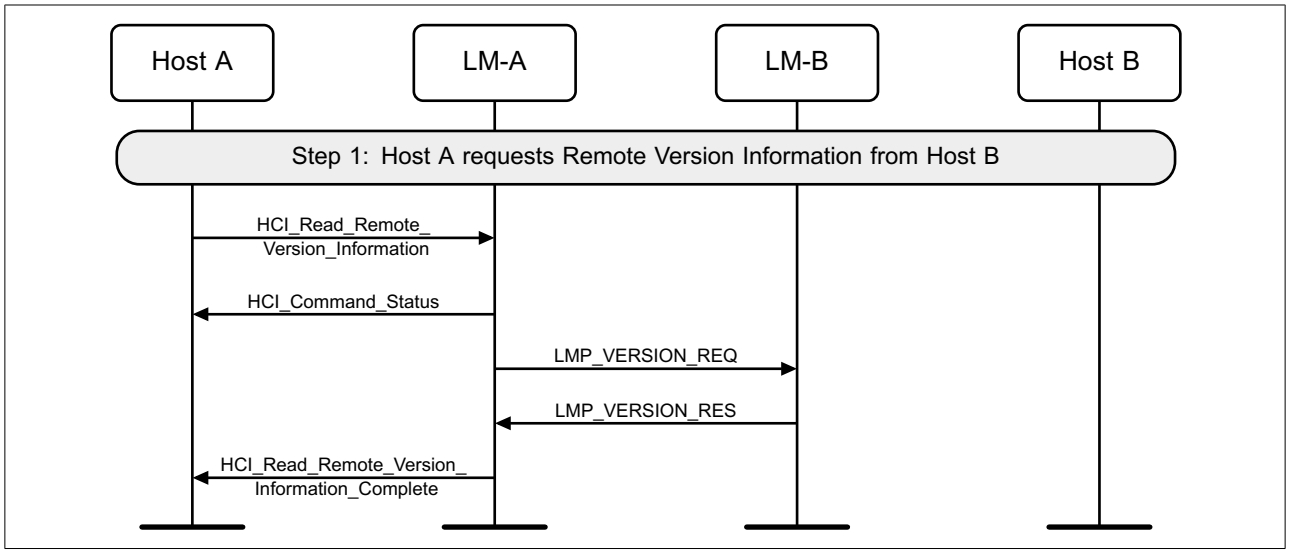

Figure 4.43: Read remote version information

4.14 QoS setup

Using the HCI_Flow_Specification command the Quality of Service (QoS) and Flow Specification requirements of a connection can be notified to a Controller. The Controller may then change the quality of service parameters with a remote device. (See Figure 4.44.)

Step 1: The Host sends QoS parameters to a remote device.

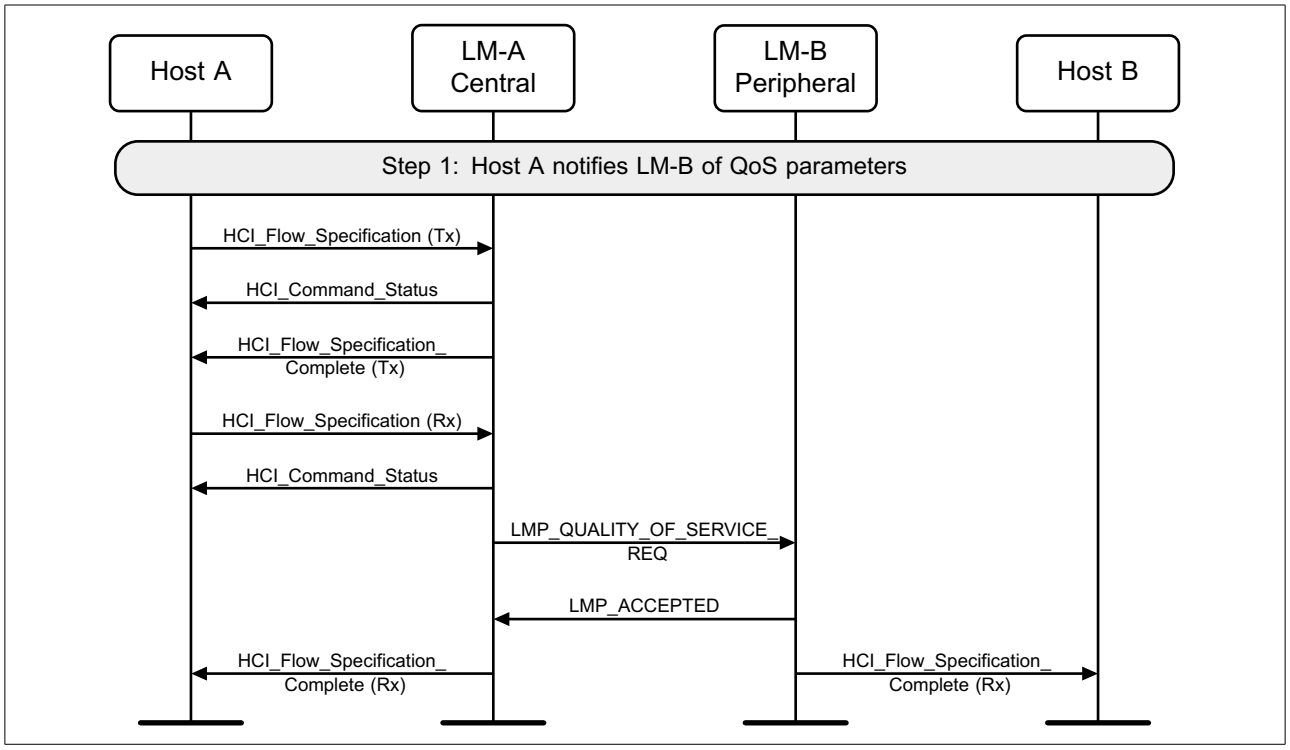

Figure 4.44: QoS flow specification

4.15 Switch role

The HCI_Switch_Role command can be used to explicitly switch the current Central / Peripheral role of the local device with the specified device.

Step 1a: The Central's Host (A) requests a role switch with a Peripheral. This will send the switch request, and the Peripheral will respond with the slot offset and accepted. (See Figure 4.45.)

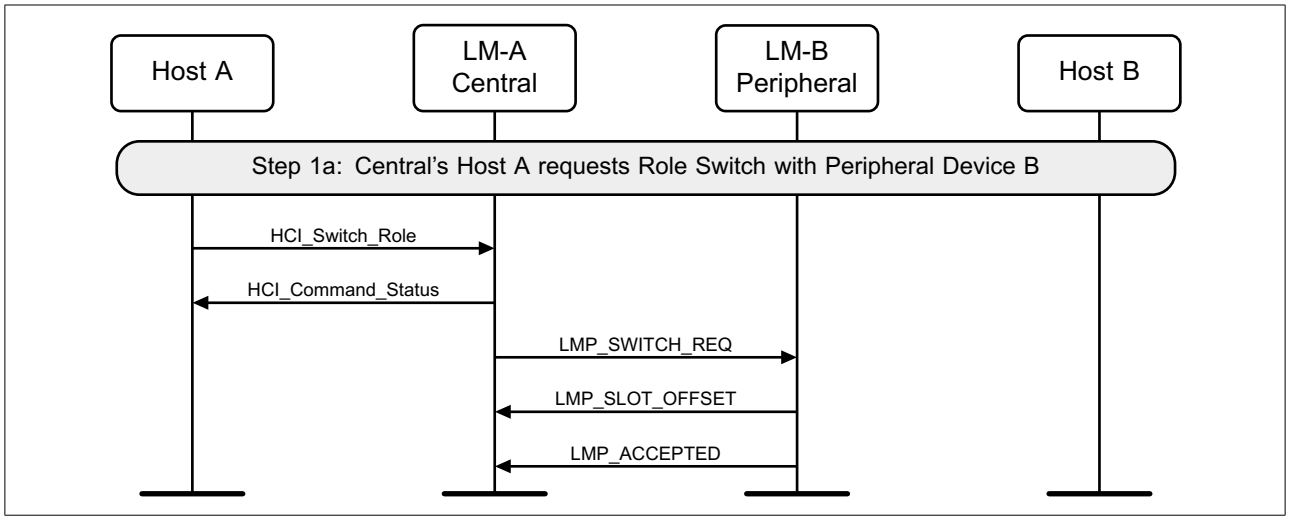

Figure 4.45: Central requests role switch

Step 1b: The Peripheral's Host (B) requests a role switch with a Central. This will send the slot offset and the switch request, and the Central will respond with a LMP_ACCEPTED PDU. (See Figure 4.46.)

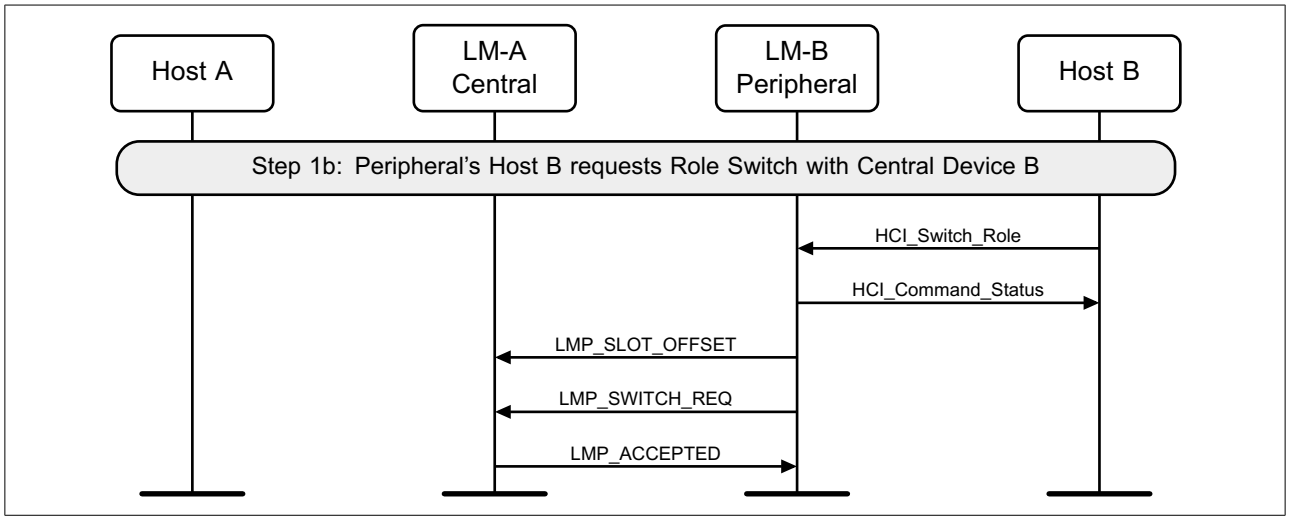

Figure 4.46: Peripheral requests role switch

Step 2: The role switch is performed by doing the TDD switch and piconet switch. Finally an HCI_Role_Change event is sent on both sides. (See Figure 4.47.)

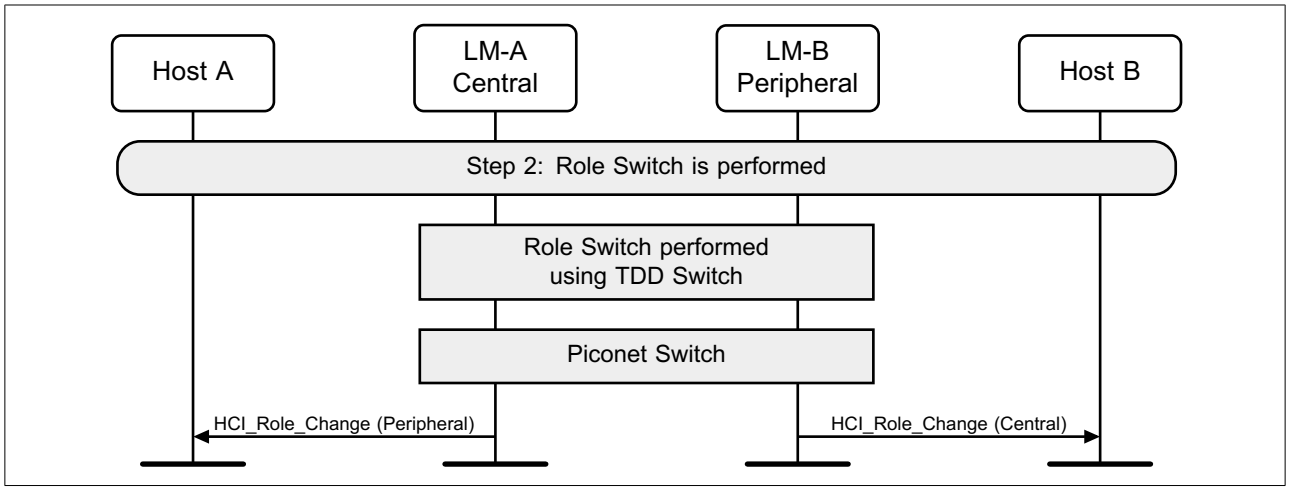

Figure 4.47: Role switch is performed

4.16 [This section is no longer used]

4.17 [This section is no longer used]

4.18 Slot availability mask

Step 1: The setup of SAM may be triggered by the Link Manager for MWS coexistence or topology management purposes. SAM setup may be triggered by HCI commands

as shown in Figure 4.48 or by the real-time signals (e.g. MWS_PATTERN_Index, FRAME_SYNC, etc.) from the Coexistence Logical Interface (see [Vol 7] Part A).

Piconet Clock Adjustment may be performed to create more available slot pairs per MWS frame.

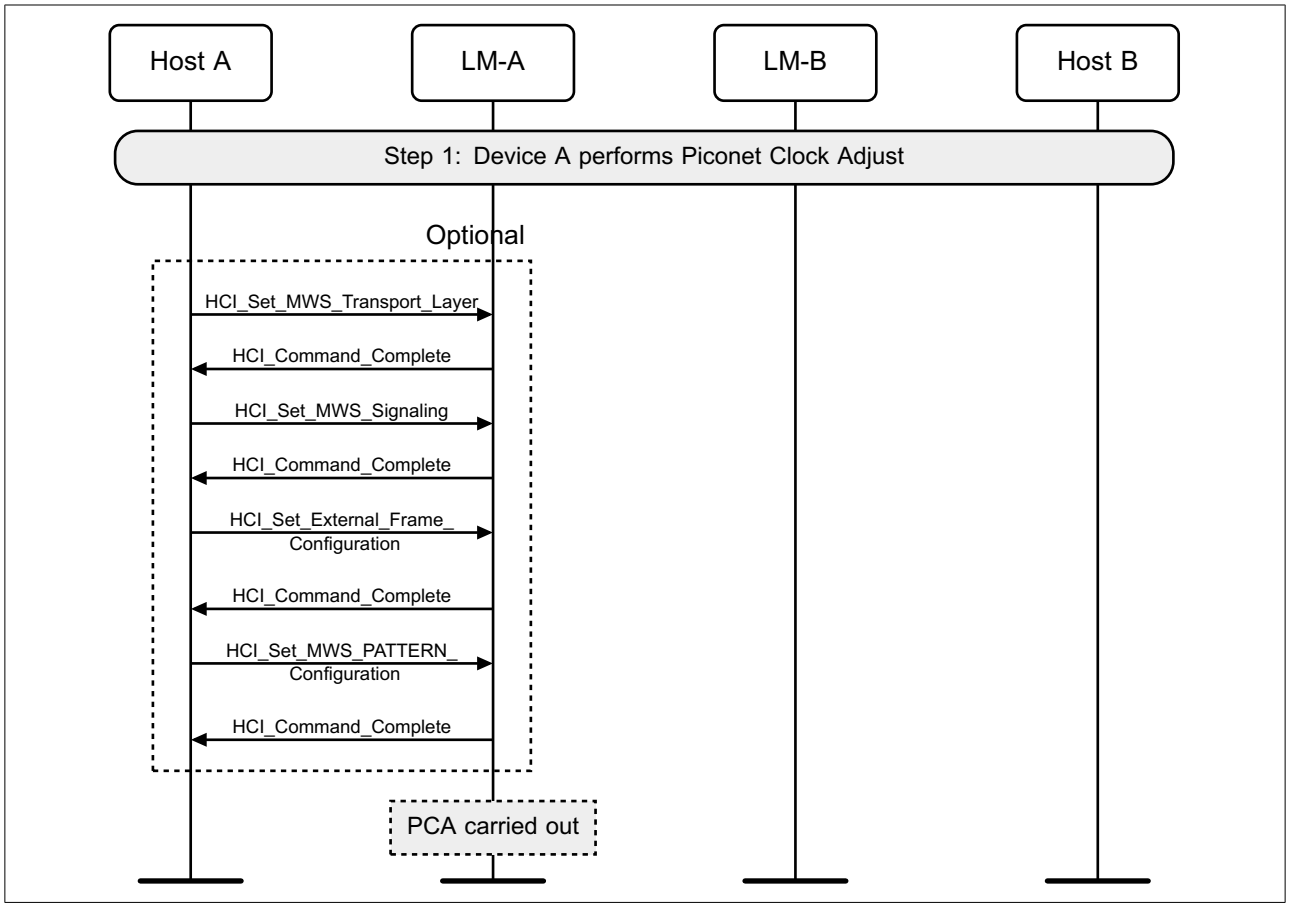

Figure 4.48: SAM configuration setup on device A

Step 2: The Link Manager on device A sends the SAM configuration to device B and then selects a SAM map (see Figure 4.49).

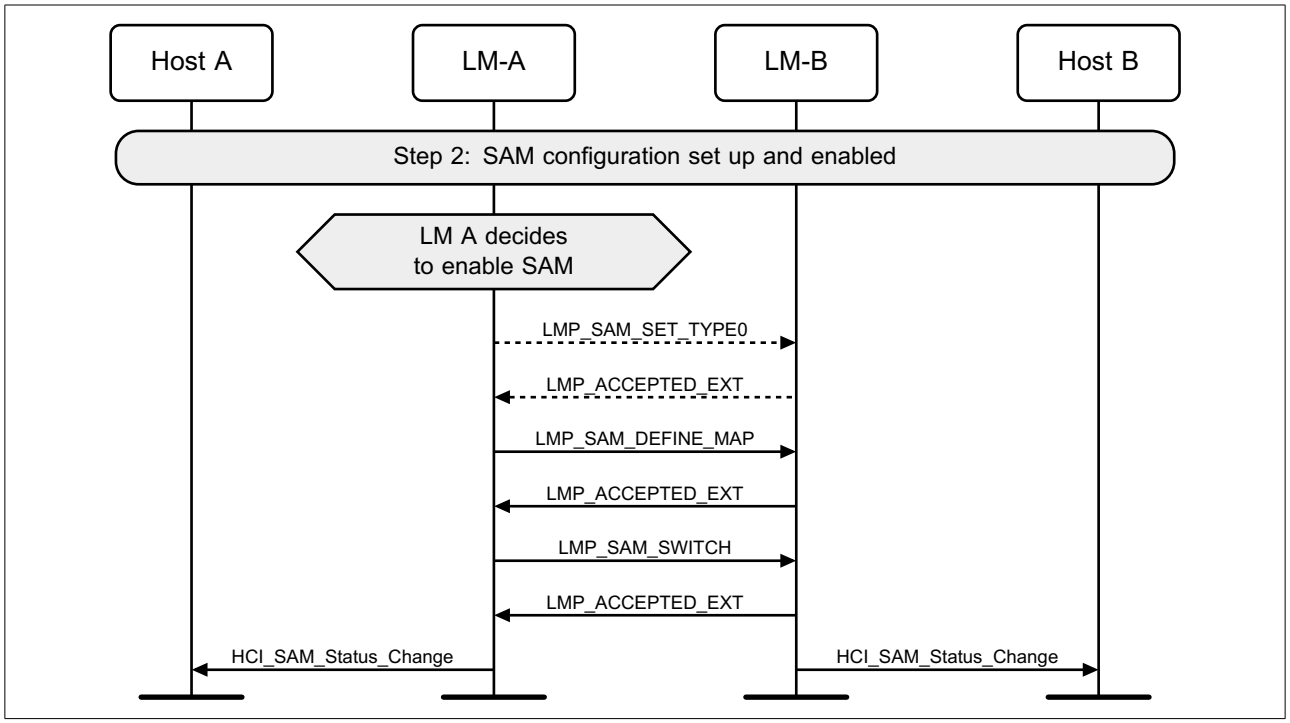

Figure 4.49: SAM configuration transmitted to device B

Step 3: Device A receives a new configuration (possibly over HCI), sends it to device B, and switches to using it (see Figure 4.50).

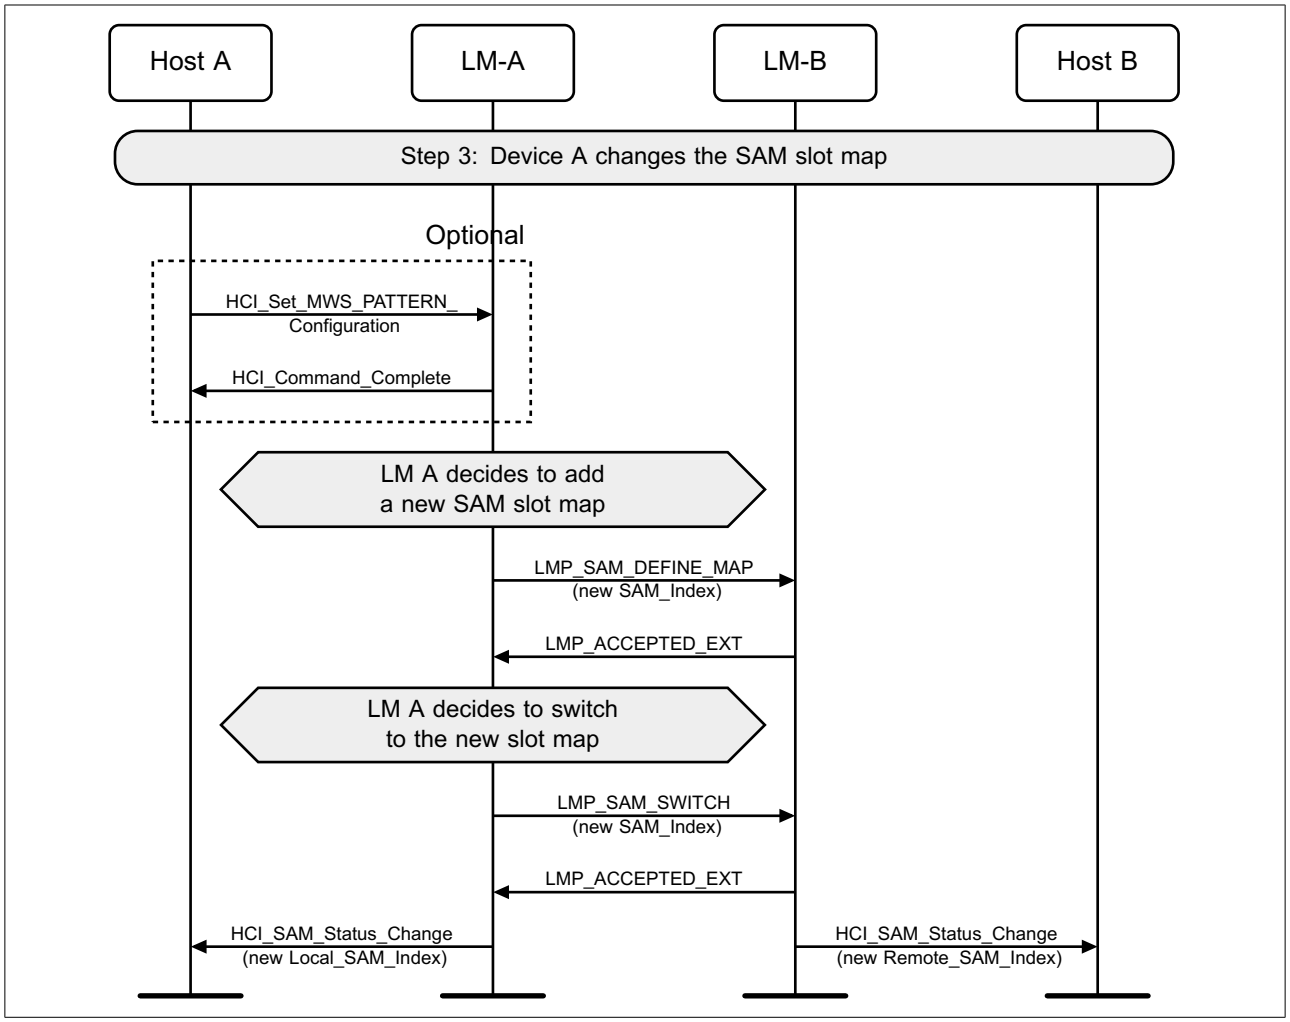

Figure 4.50: SAM configuration change

4.19 LMP transaction collision

The Link Managers of both the Central and Peripheral may initiate the same LMP transaction at the same time.

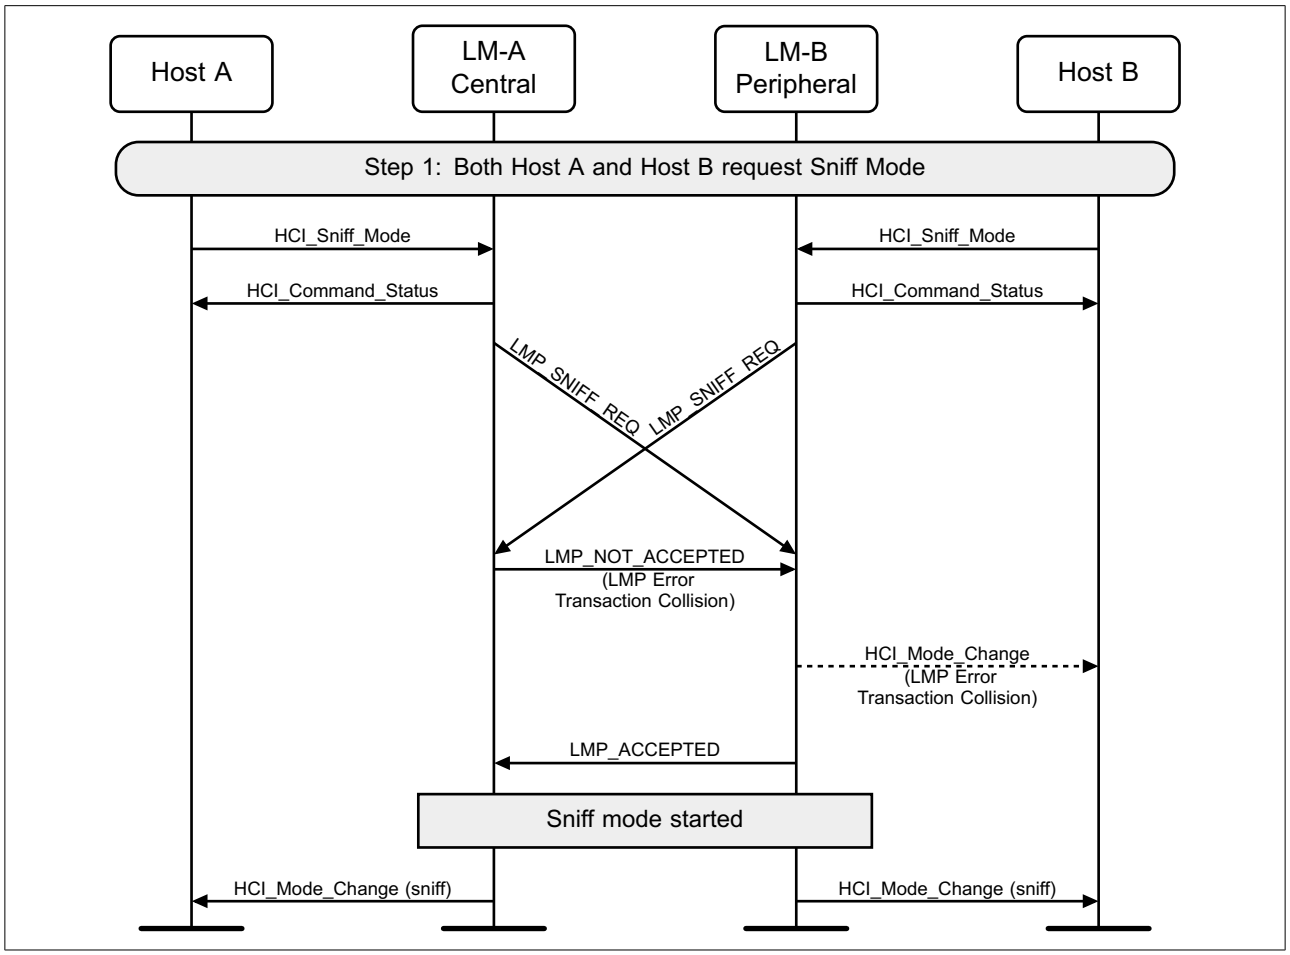

Figure 4.51: LMP transaction collision

5 SYNCHRONOUS CONNECTION ESTABLISHMENT AND DETACHMENT

5.1 Synchronous connection setup

Using the HCI_Setup_Synchronous_Connection command, a Host can add a synchronous logical channel to the link. A synchronous logical link can be provided by creating a SCO or an eSCO logical transport.

Note: An ACL connection must be established before a synchronous connection can be created.

Step 1a: Central requests a synchronous connection with a device. (See Figure 5.1.)

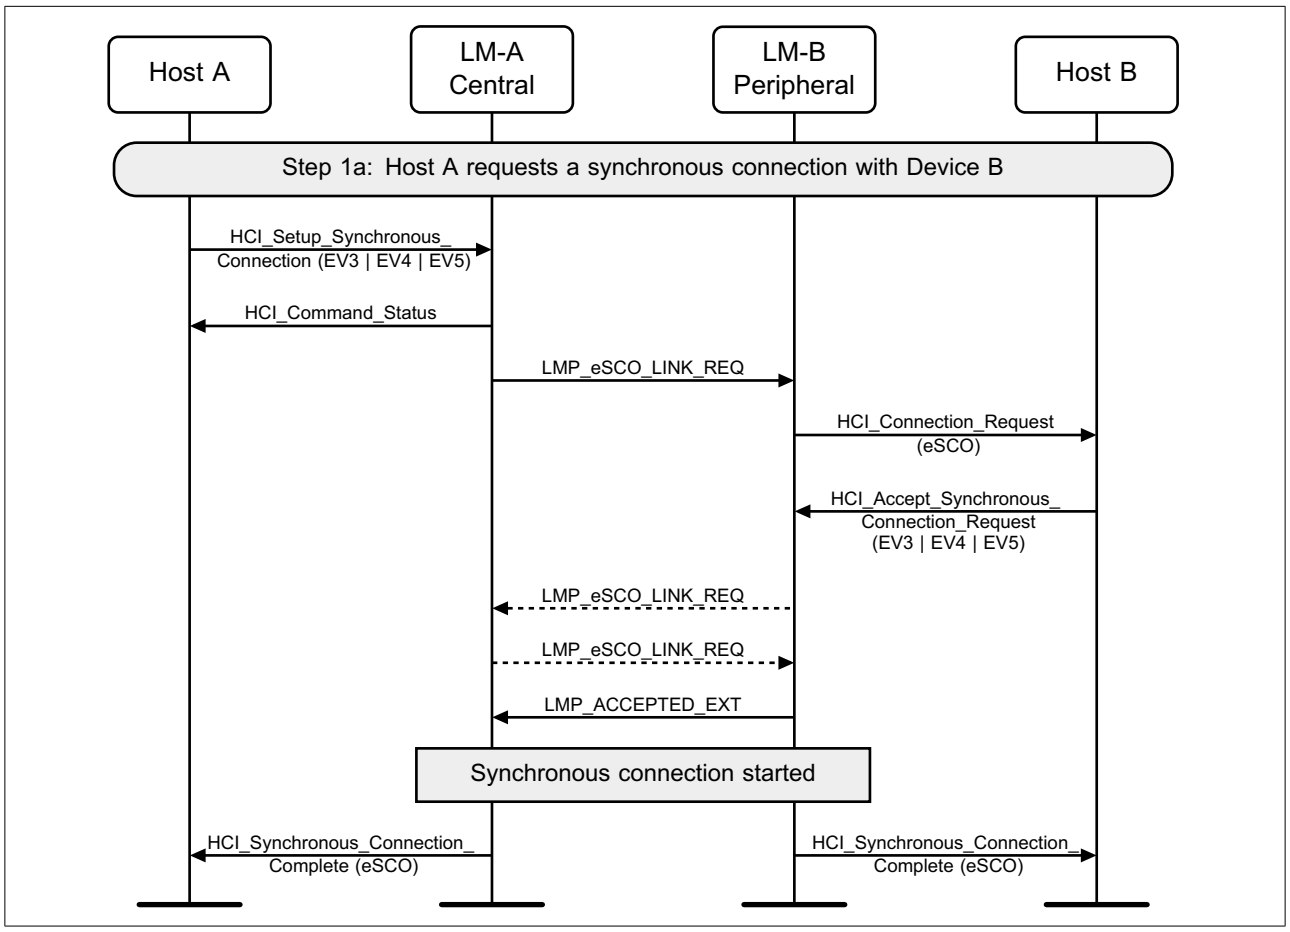

Figure 5.1: Central requests synchronous EV3, EV4, or EV5 connection

Step 1b: Peripheral requests a synchronous connection with a device. (See Figure 5.2.)

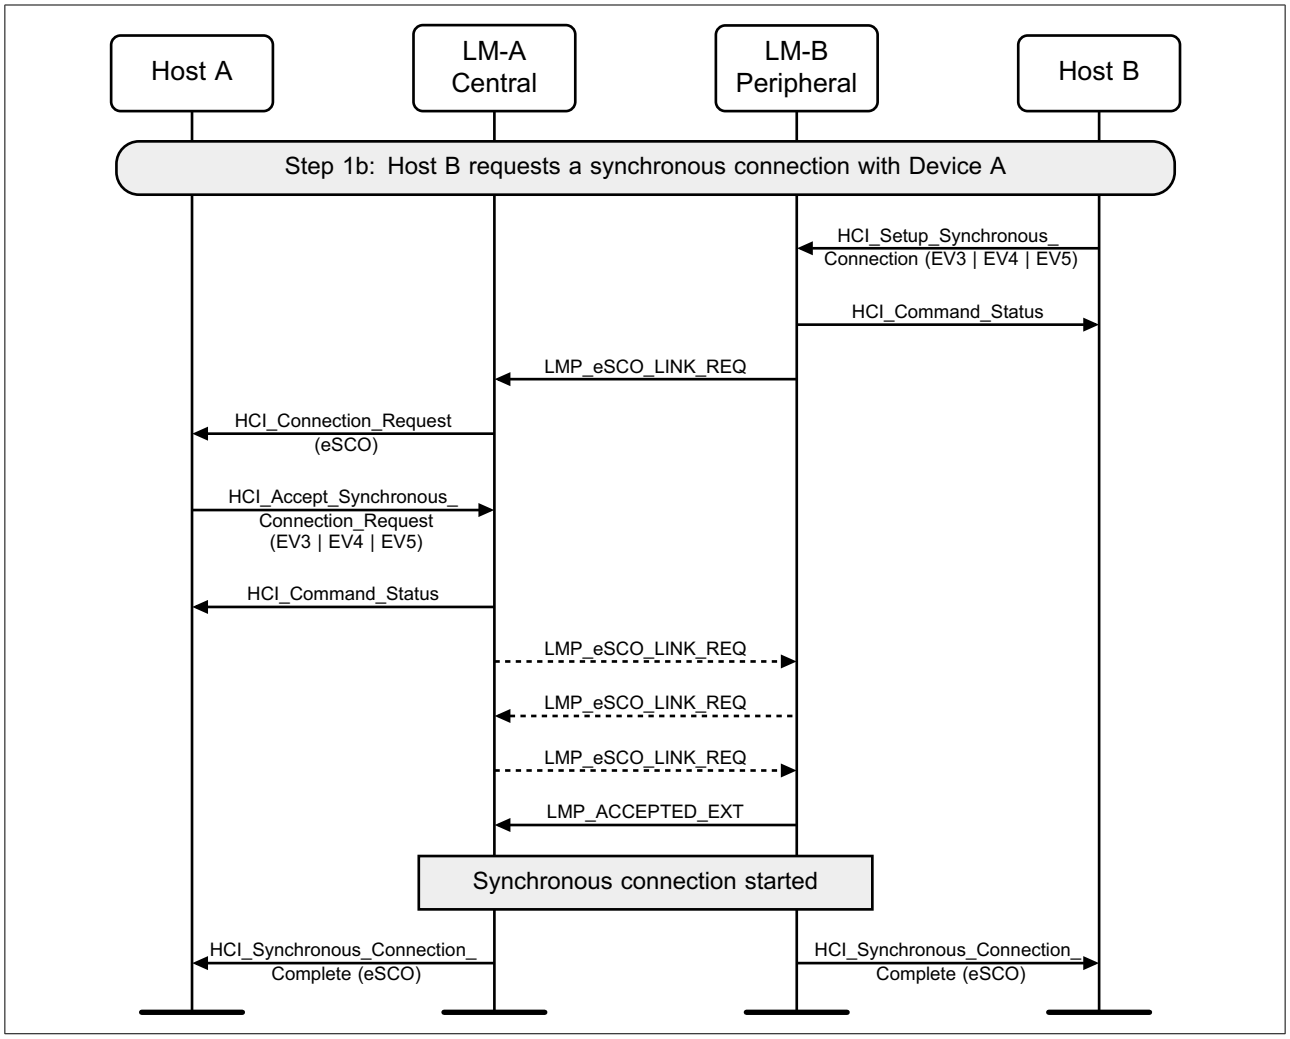

Figure 5.2: Peripheral requests synchronous EV3, EV4, or EV5 connection

Step 1c: Central requests a SCO connection with a device. (See Figure 5.3.)

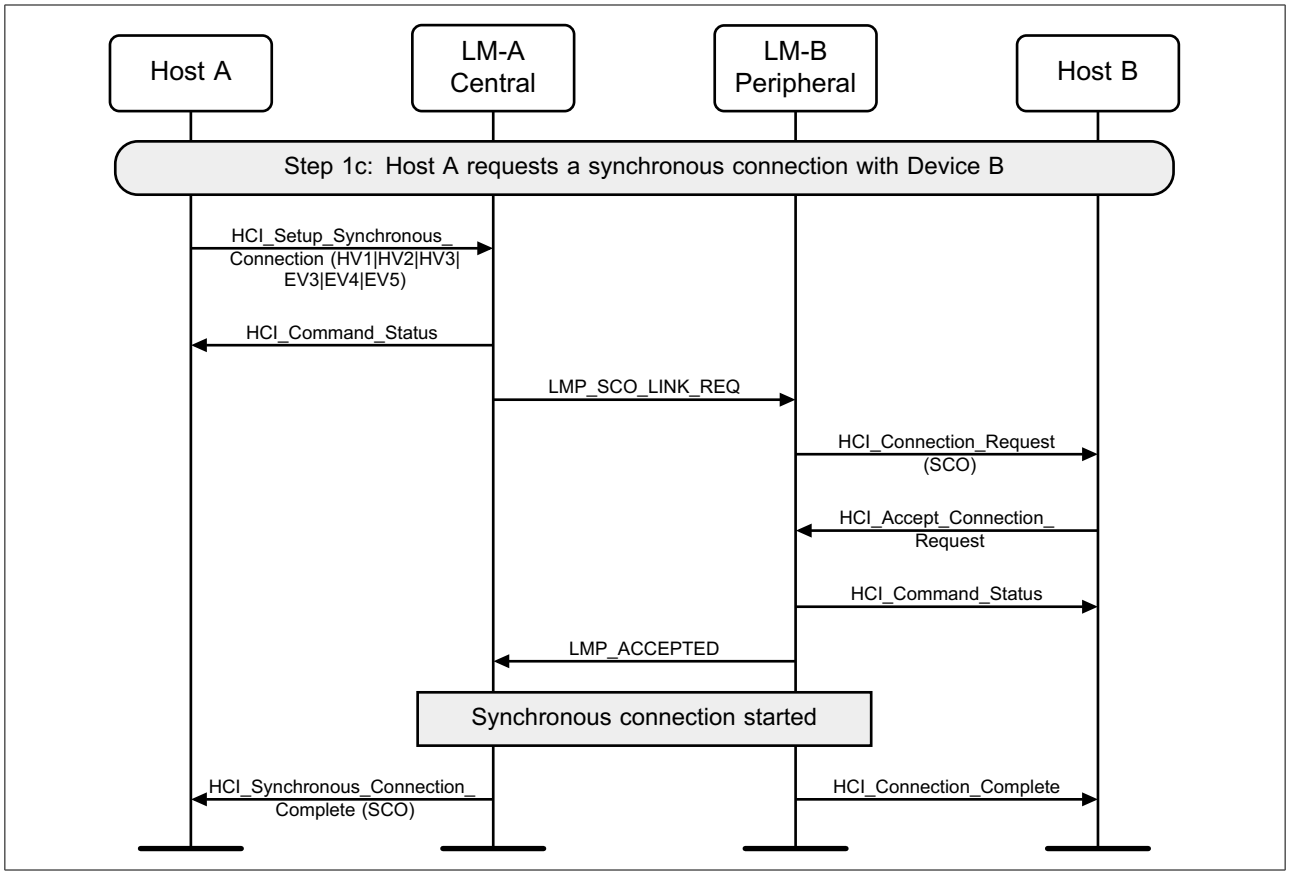

Figure 5.3: Central requests synchronous connection using SCO

Step 1d: Central requests a SCO connection with a device. (See Figure 5.4.)

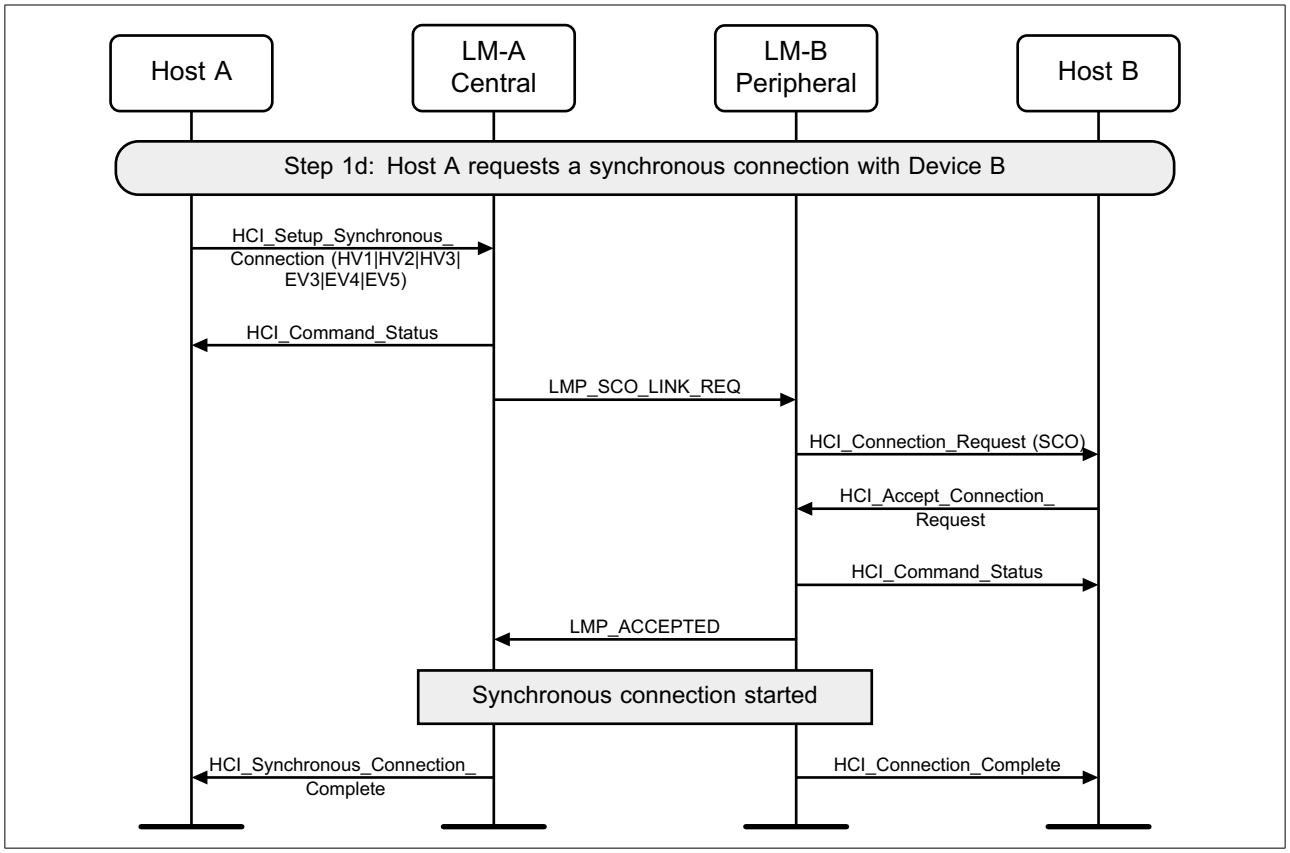

Figure 5.4: Central requests synchronous connection with legacy Peripheral

Step 1e: Host device requests a SCO connection with a device. (See Figure 5.5.)

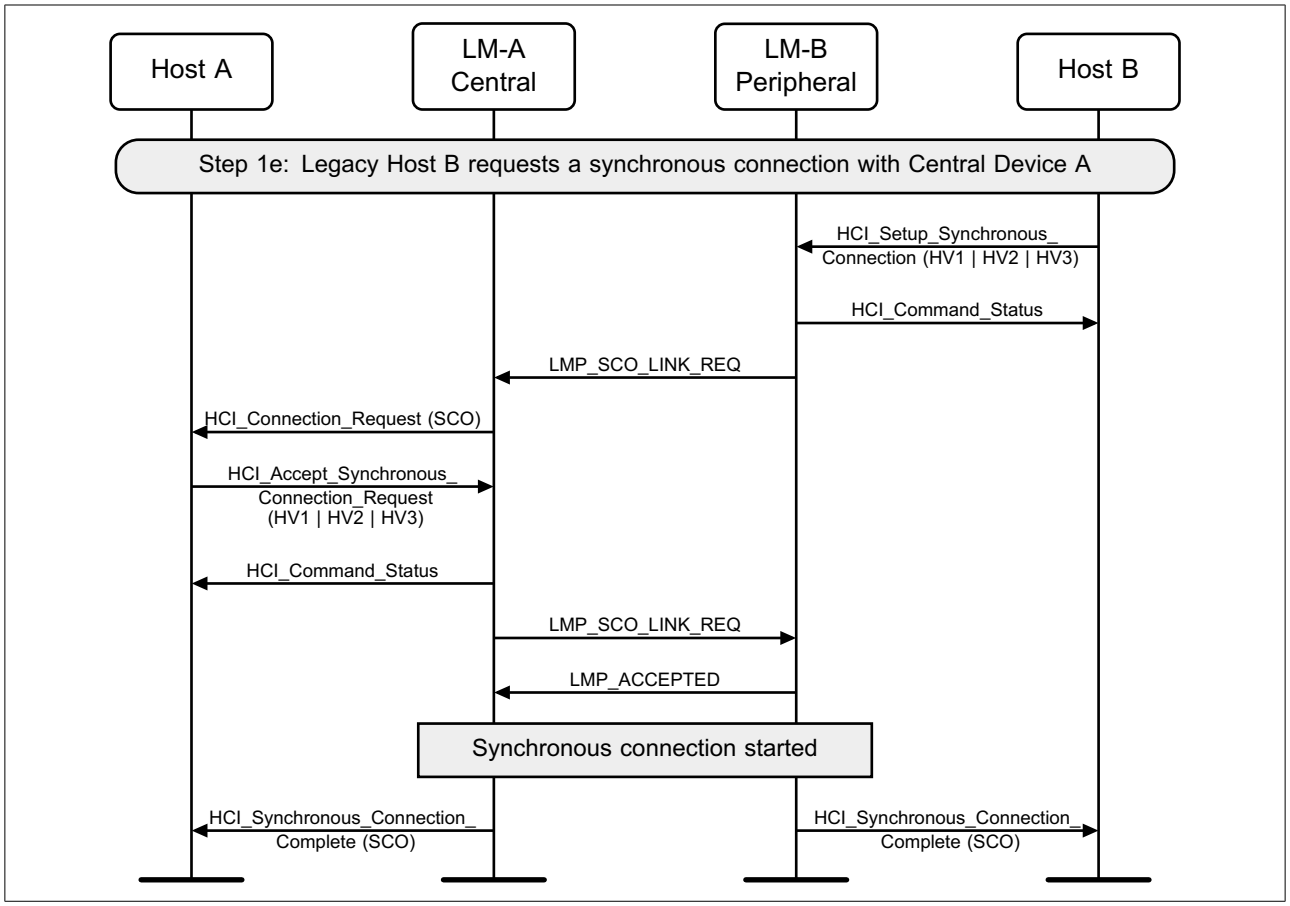

Figure 5.5: Any device that supports only SCO connections requests a synchronous connection with a device

Step 2a: Central renegotiates eSCO connection (see Figure 5.6.)

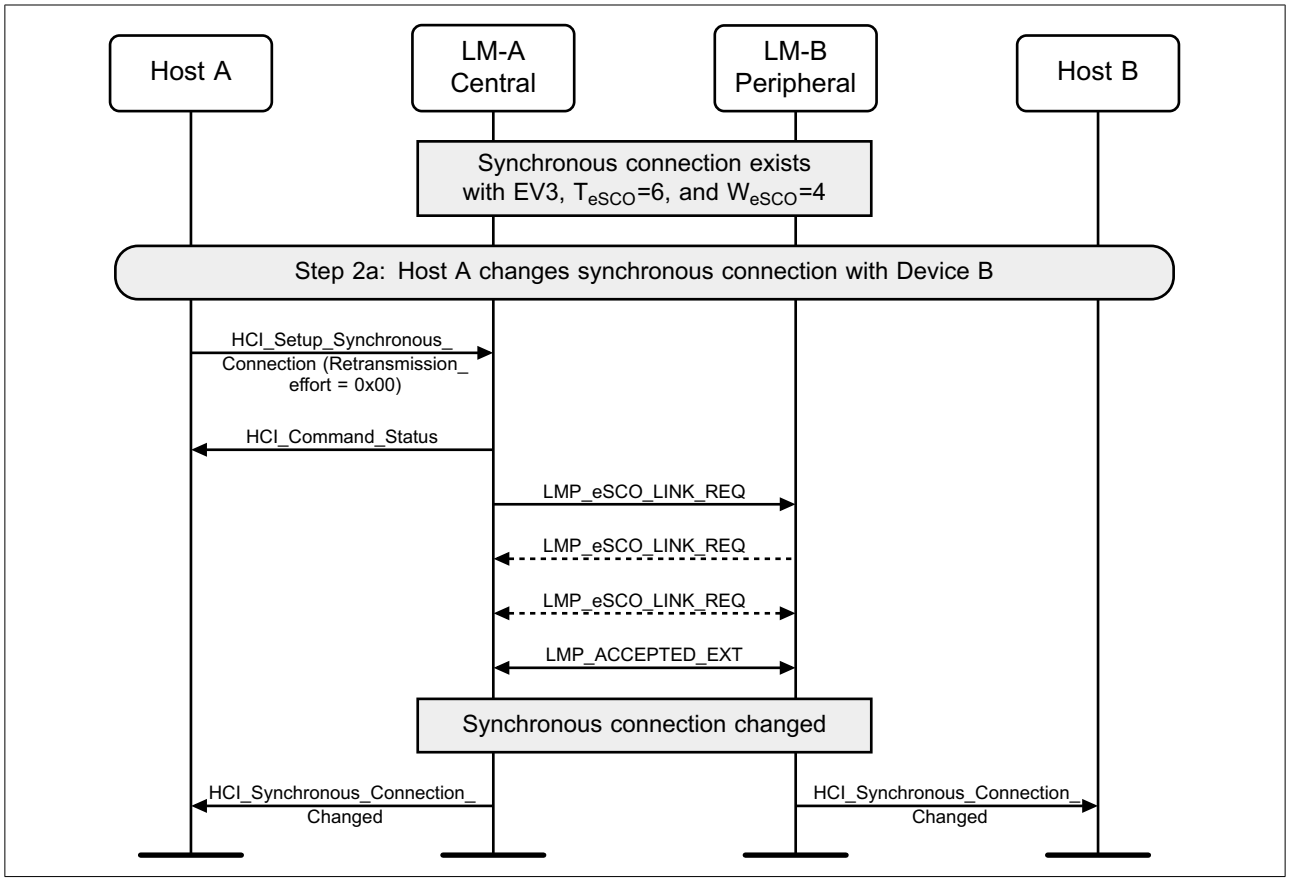

Figure 5.6: Central renegotiates eSCO connection

Step 2b: Peripheral renegotiates eSCO connection (see Figure 5.7.)

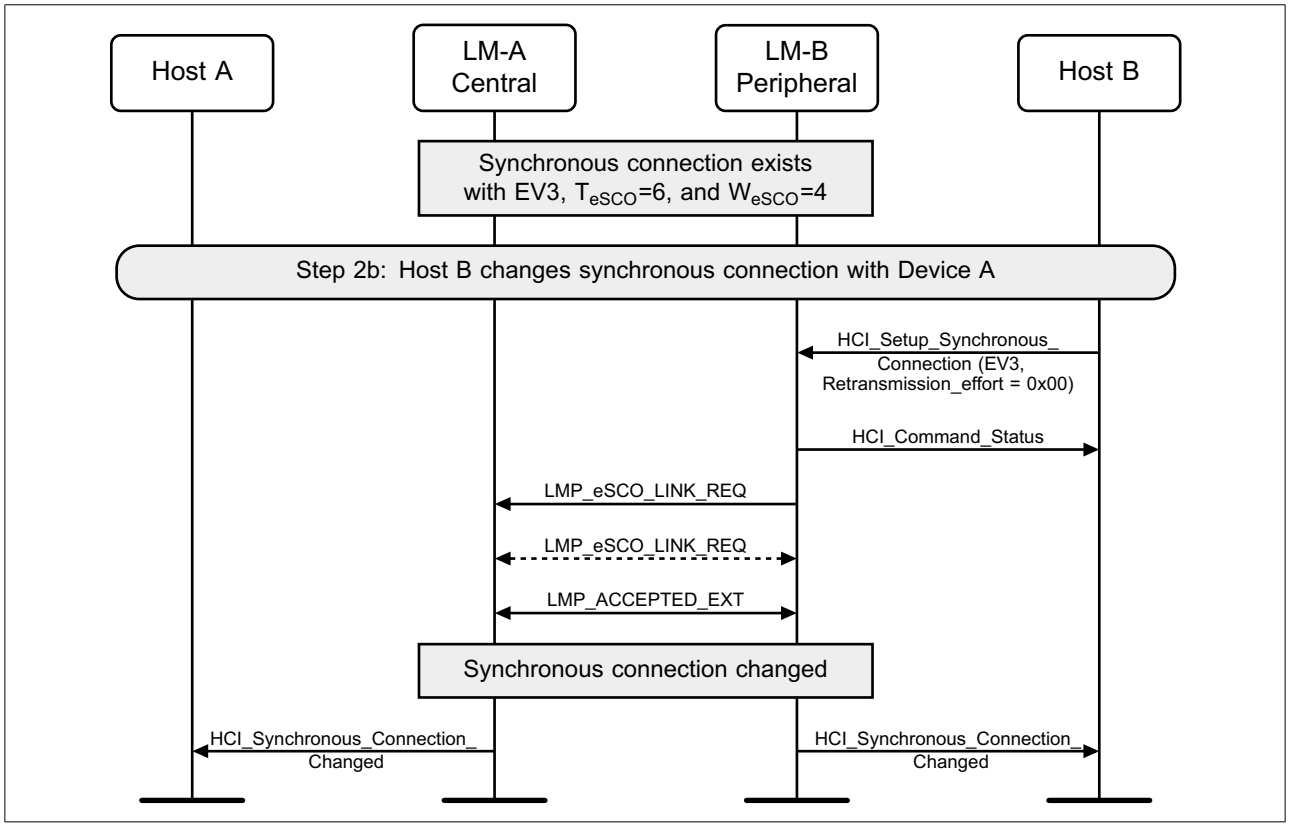

Figure 5.7: Peripheral renegotiates eSCO connection

Step 3a: eSCO disconnection. (See Figure 5.8.)

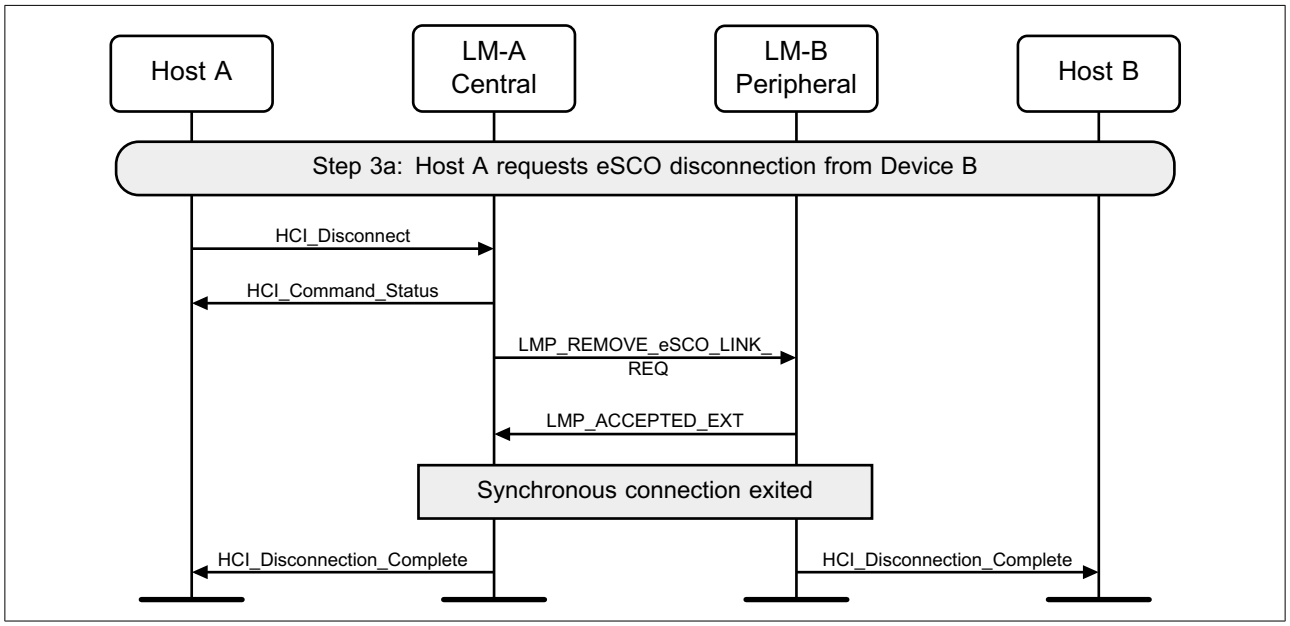

Figure 5.8: Synchronous disconnection of eSCO connection

Step 3b: SCO disconnection. (See Figure 5.9.)

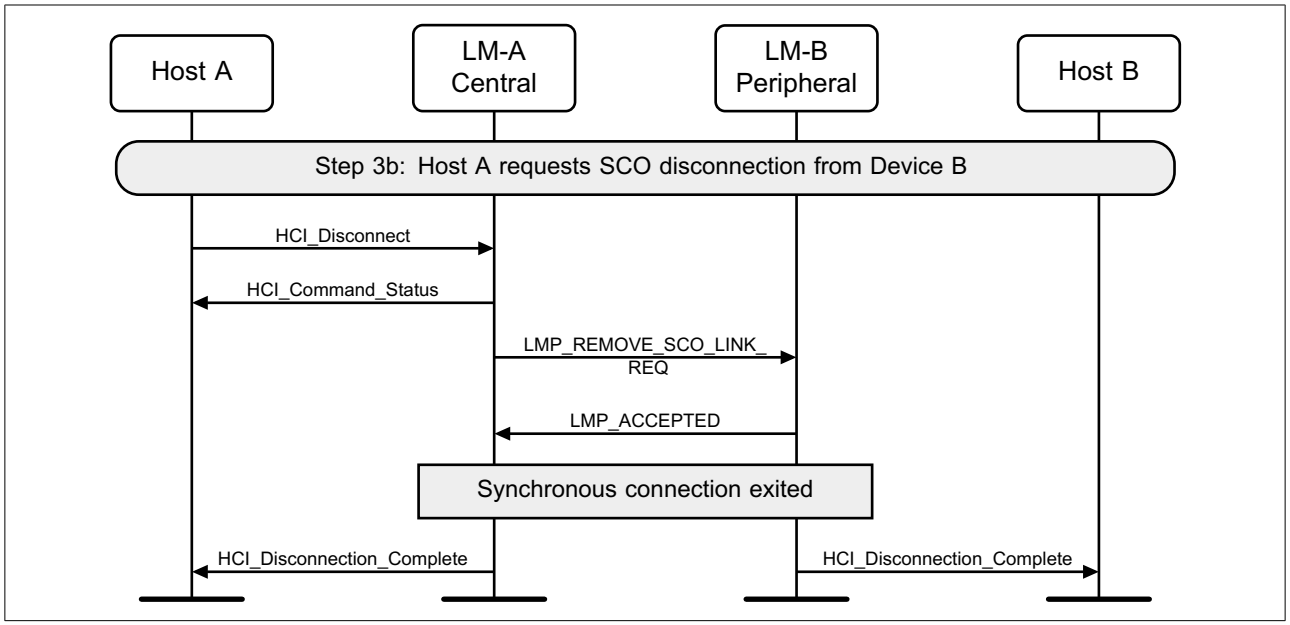

Figure 5.9: Synchronous disconnection of SCO connection

5.2 Synchronous connection setup with enhanced synchronous commands

Using the HCI_Enhanced_Setup_Synchronous_Connection command, a Host can add a synchronous logical channel to the link. A synchronous logical link can be provided by creating a SCO or an eSCO logical transport.

Note: An ACL connection must be established before a synchronous connection can be created.

Step 1a: Central requests a synchronous connection with a Peripheral.

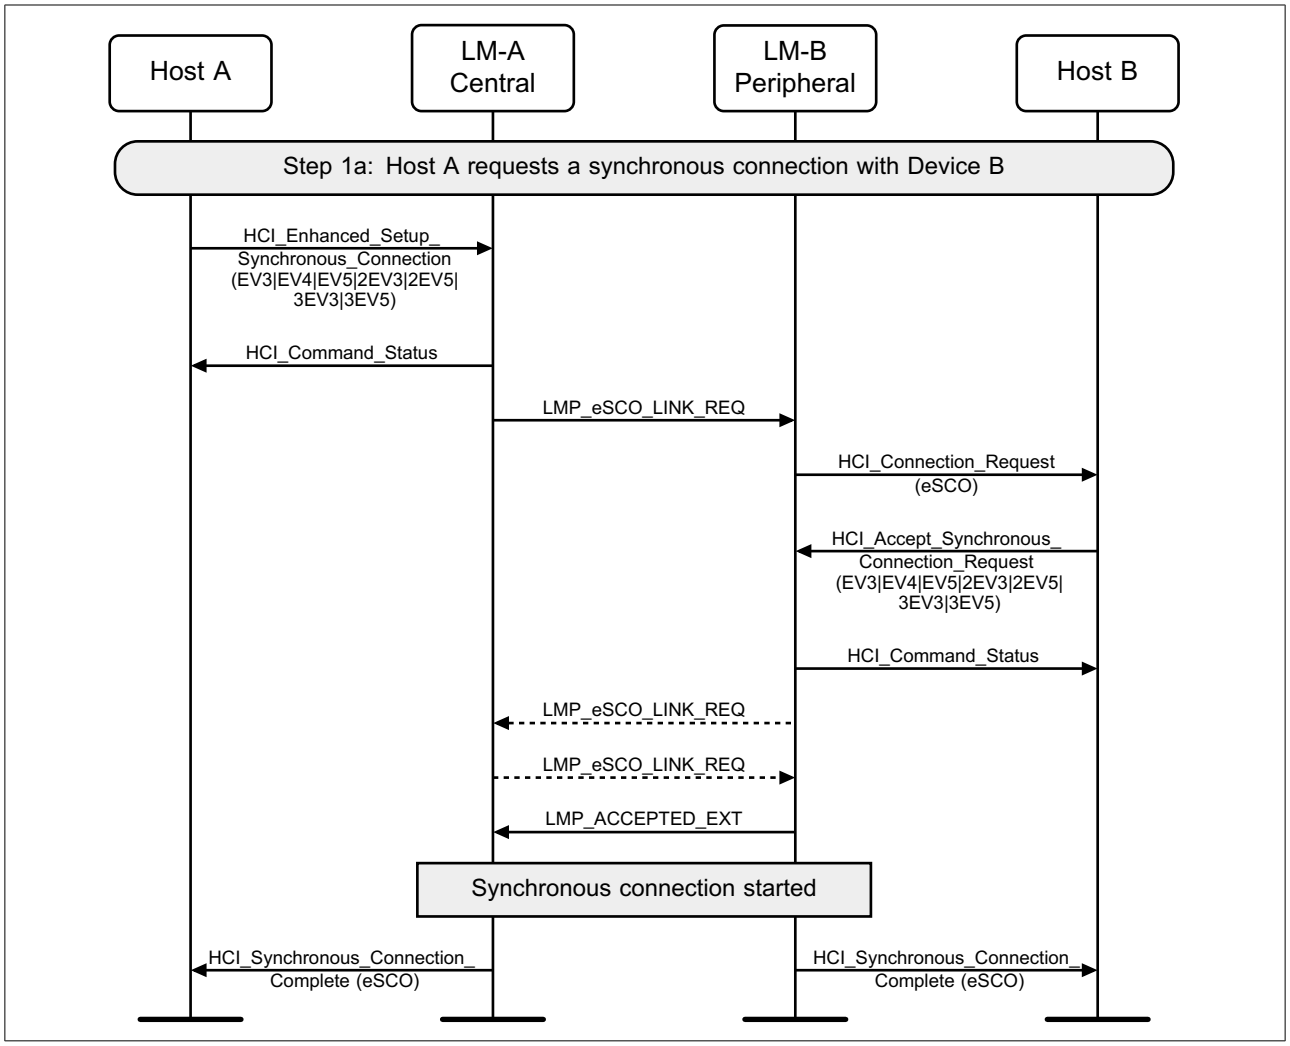

Figure 5.10: Central requests synchronous connection (EV3, EV4, EV5, 2-EV3, 2-EV5, 3-EV3, or 3-EV5)

Step 1b: Peripheral requests a synchronous connection with a Central.

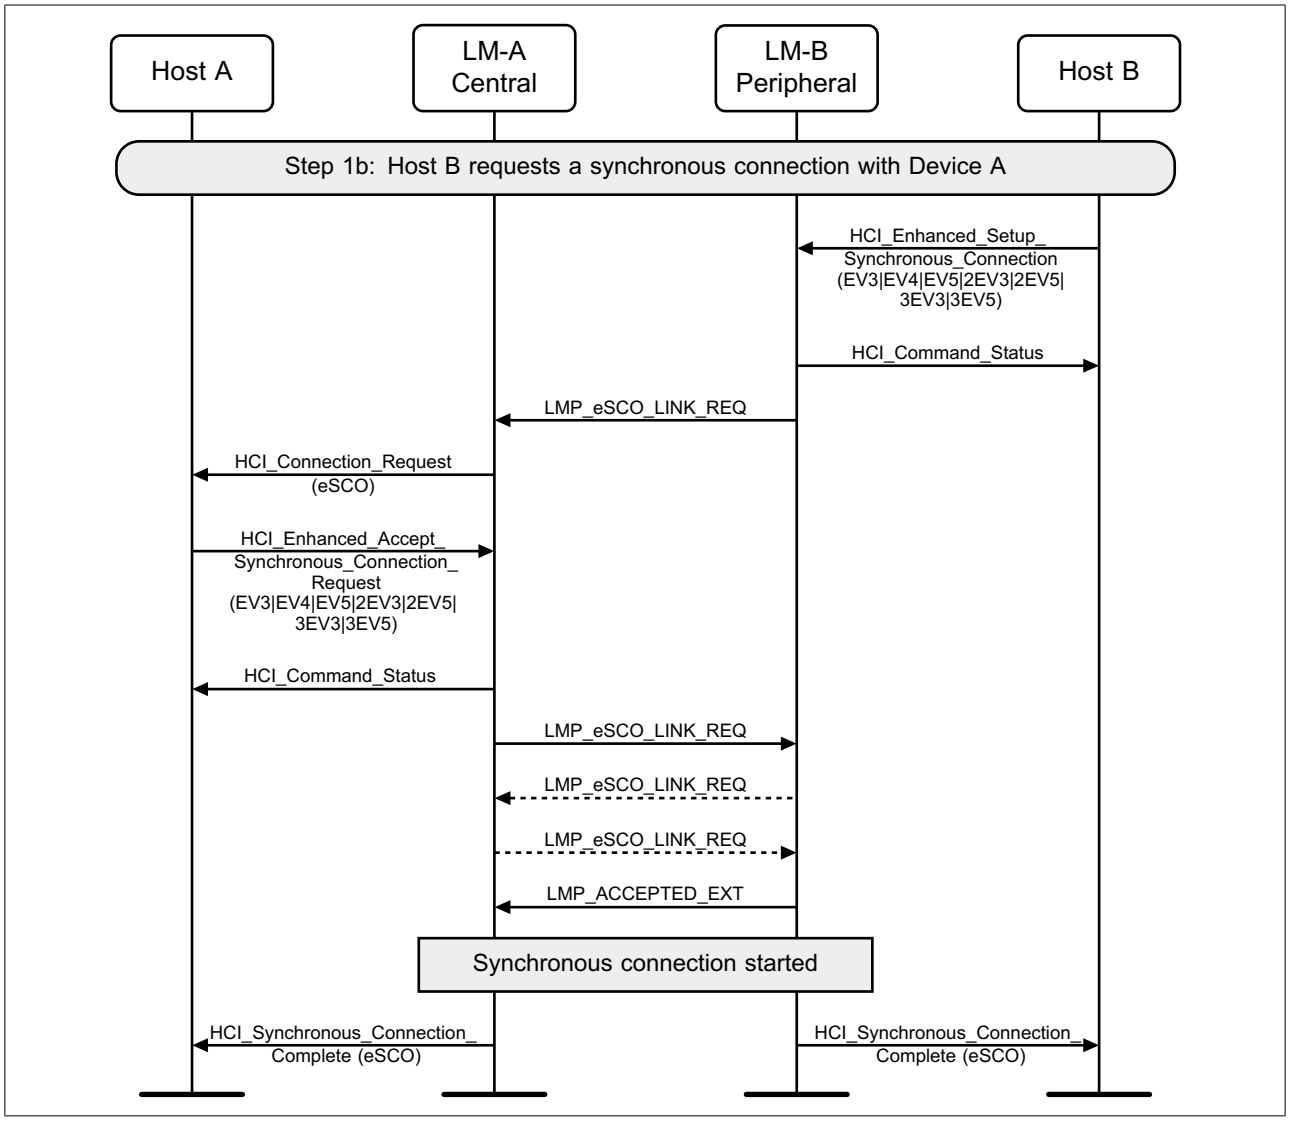

Figure 5.11: Peripheral requests synchronous connection (EV3, EV4, EV5, 2-EV3, 2-EV5, 3-EV3, or 3-EV5)

Step 1c : Central requests a SCO connection with a Peripheral.

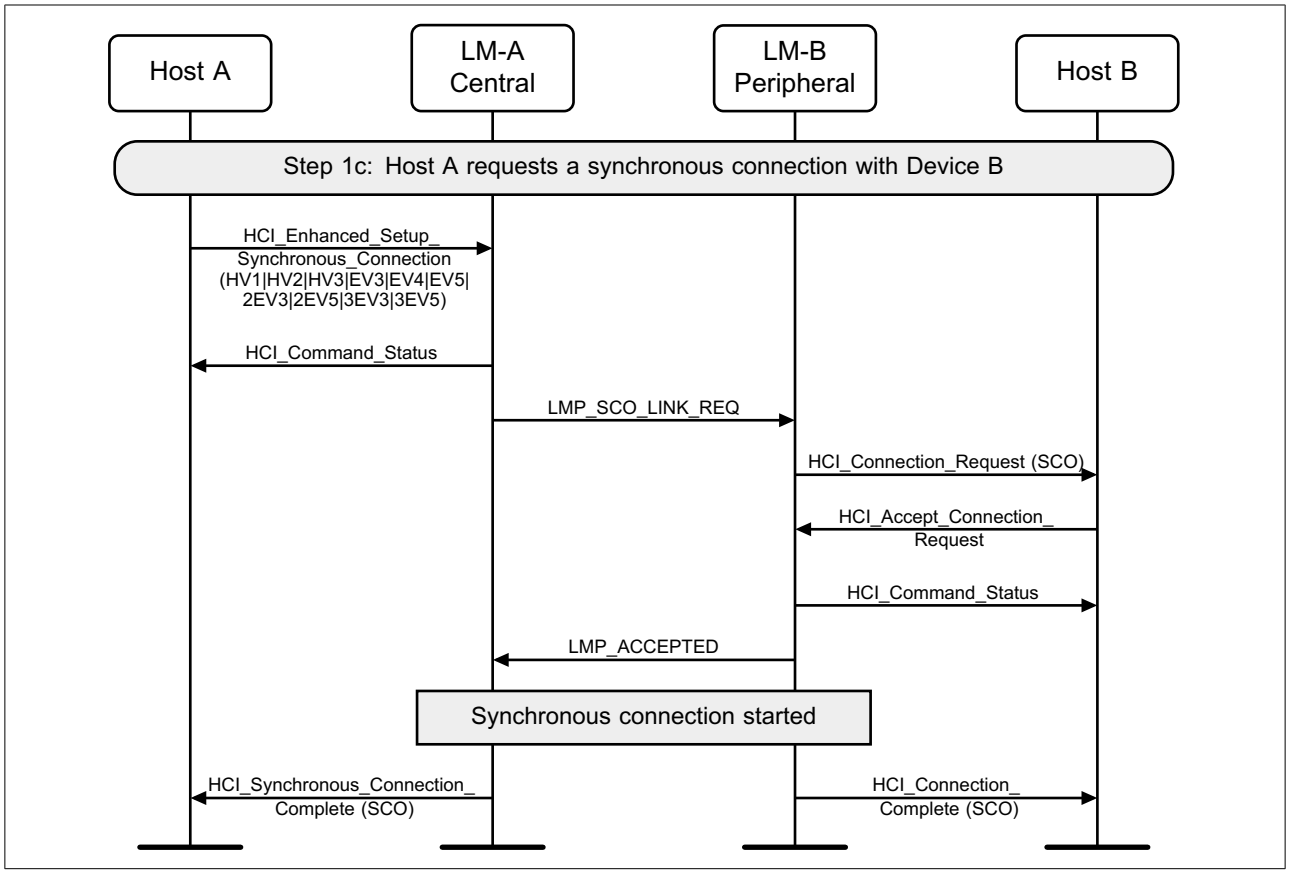

Figure 5.12: Central requests synchronous connection (HV1, HV2, HV3, EV3, EV4, EV5, 2EV3, 2EV5, 3EV3, or 3EV5)

Step 1d : Peripheral requests a SCO connection with a Central.

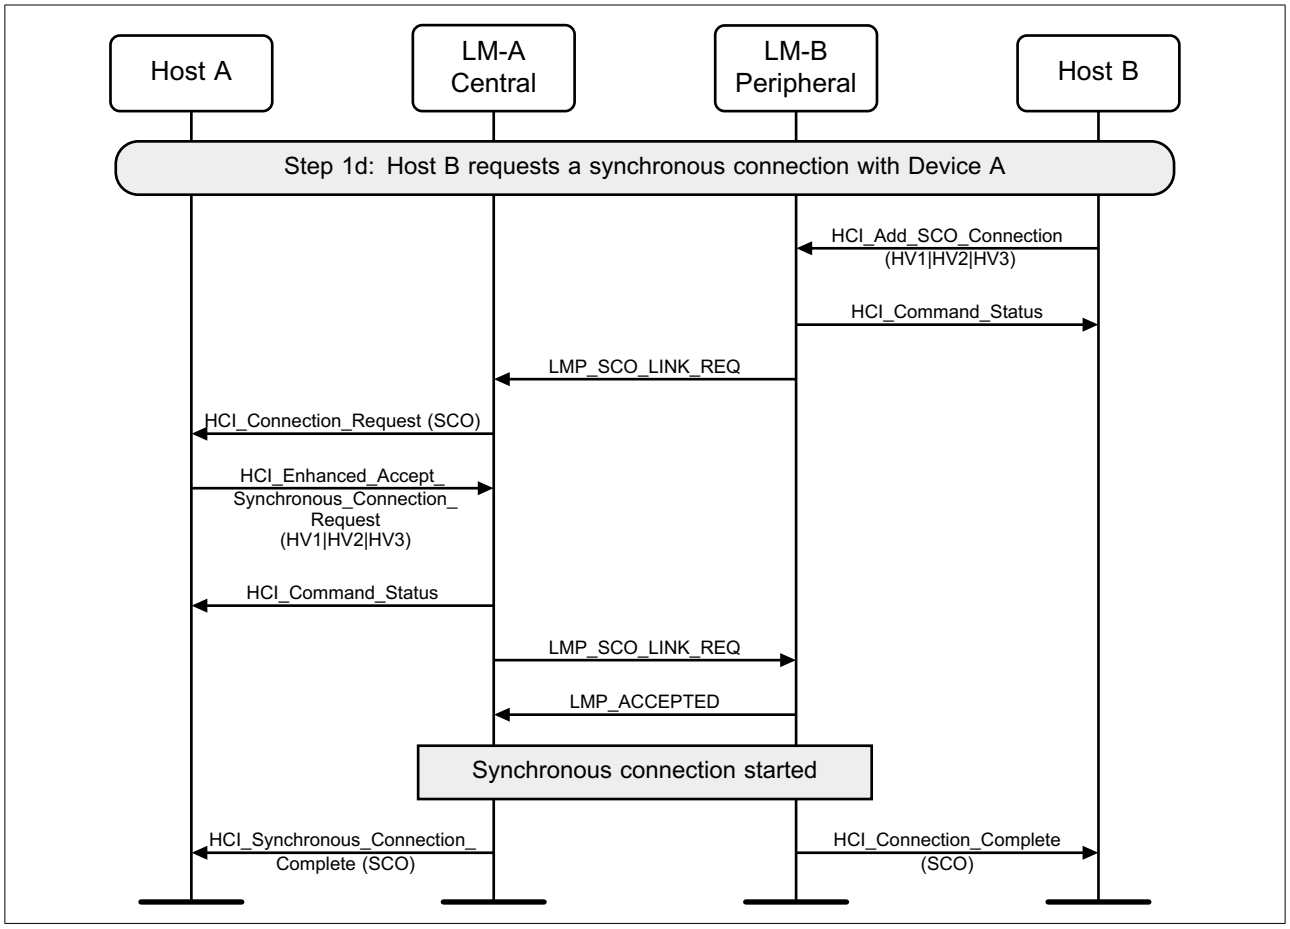

Figure 5.13: Peripheral requests synchronous connection (HV1, HV2, or HV3)

Step 2a: Central renegotiates eSCO connection.

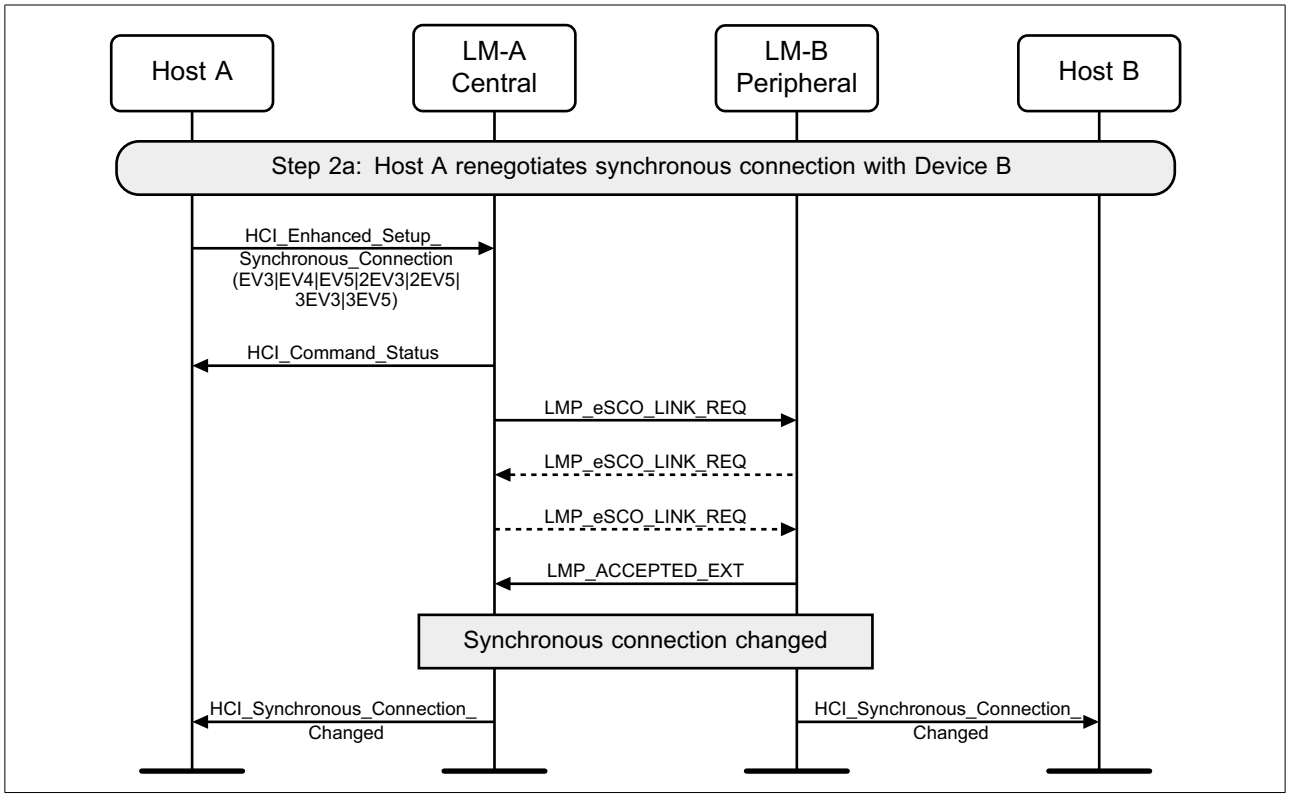

Figure 5.14: Central renegotiates synchronous connection parameter change

Step 2b: Peripheral renegotiates eSCO connection.

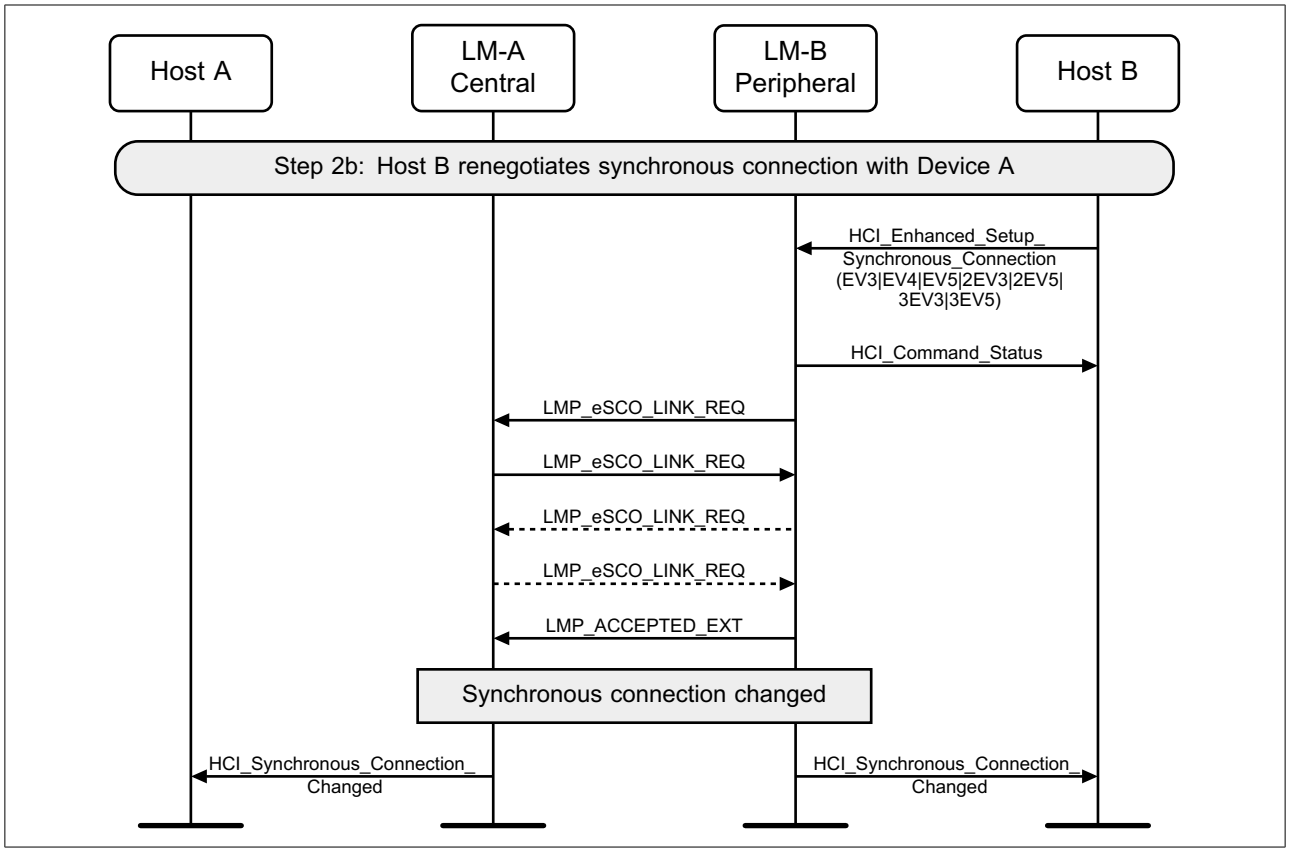

Figure 5.15: Peripheral renegotiates synchronous connection parameter change

6 SNIFF AND HOLD MODES

Entry into Sniff mode or Hold mode requires an established ACL connection.

6.1 Sniff mode

The HCI_Sniff_Mode command is used to enter Sniff mode. The HCI_Exit_Sniff_Mode command is used to exit Sniff mode.

Step 1: Host requests to enter Sniff mode. Multiple LMP_SNIFF_REQ PDUs may be sent as the parameters for Sniff mode are negotiated. (See Figure 6.1.)

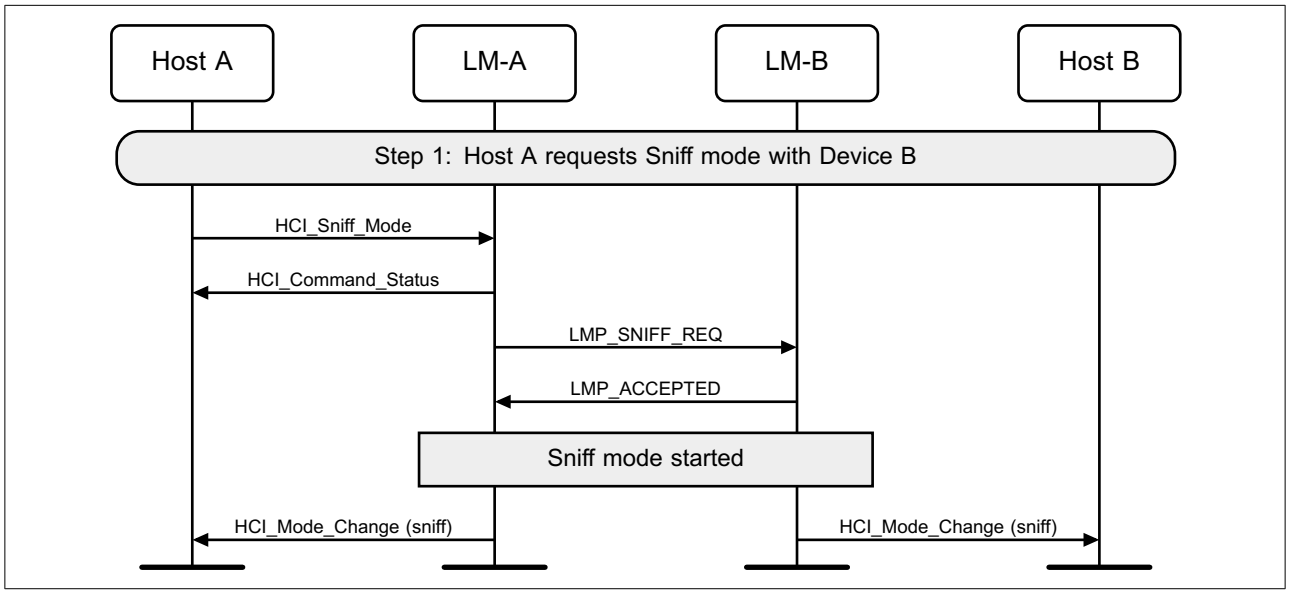

Figure 6.1: Sniff mode request

Step 2: Host requests to exit Sniff mode. (See Figure 6.2.)

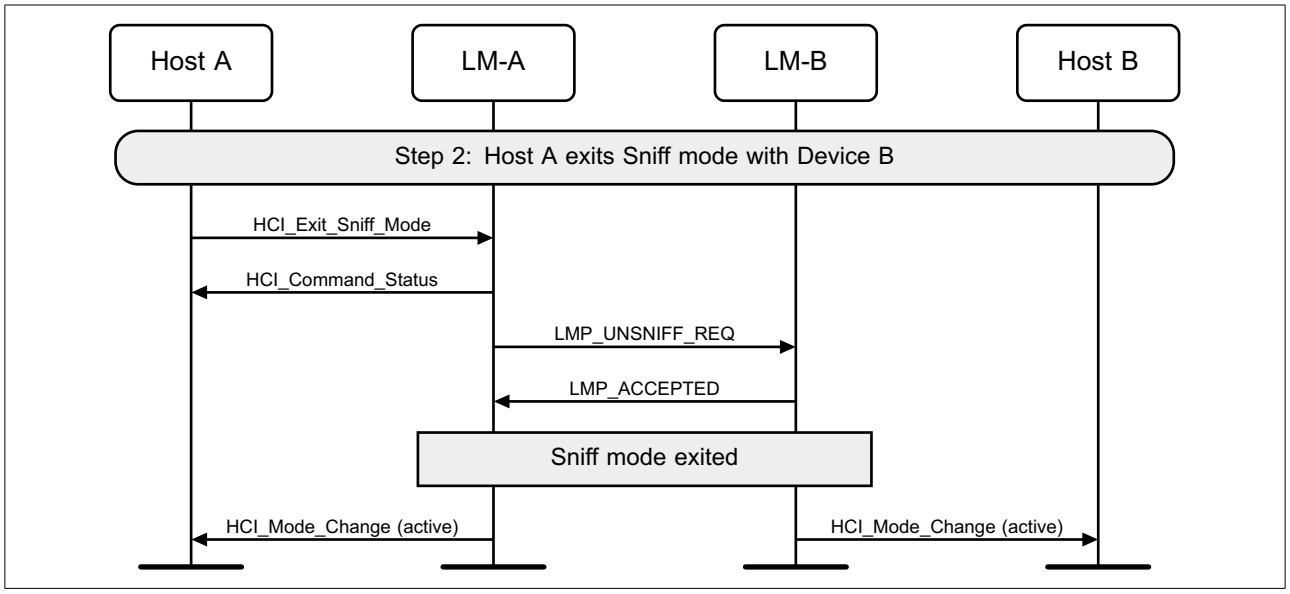

Figure 6.2: Exit Sniff mode request

6.2 Hold mode

The HCI_Hold_Mode command can be used to place a device into Hold mode. The Controller may do this by either negotiating the Hold mode parameters or forcing Hold mode. Hold mode will automatically end after the negotiated length of time.

Step 1a: A Host requests Hold mode. (See Figure 6.3.)

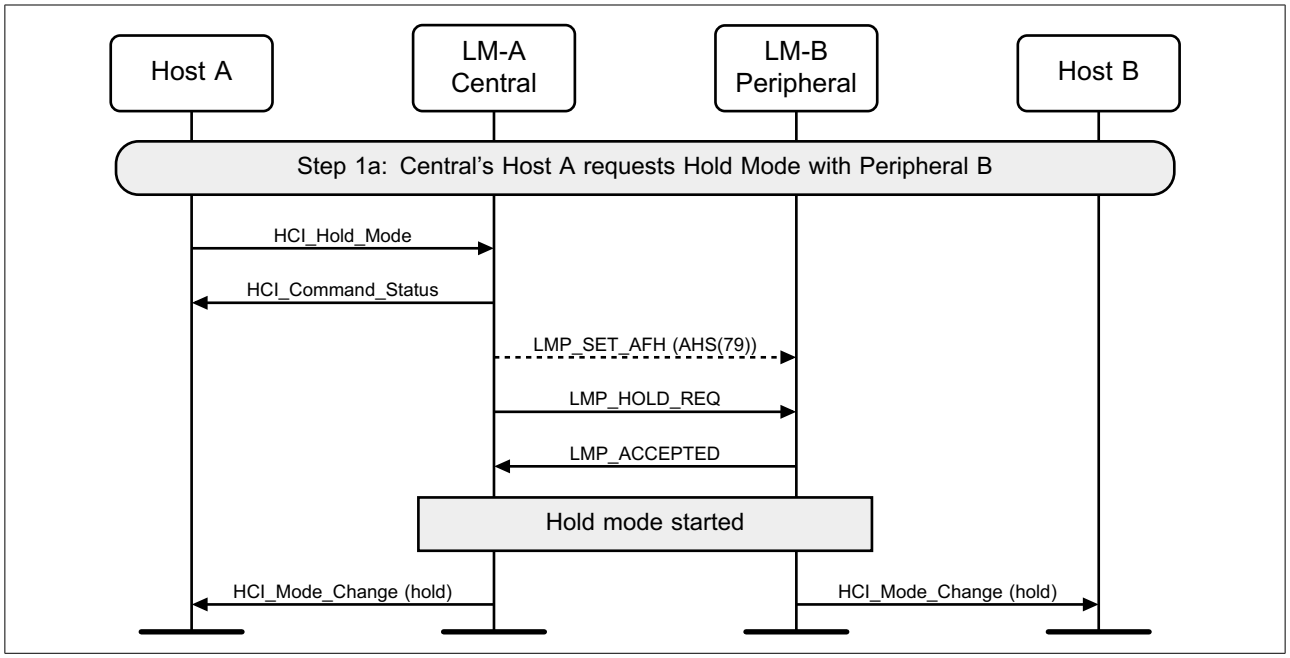

Figure 6.3: Hold request

Step 1b: A Host may force Hold mode. (See Figure 6.4.)

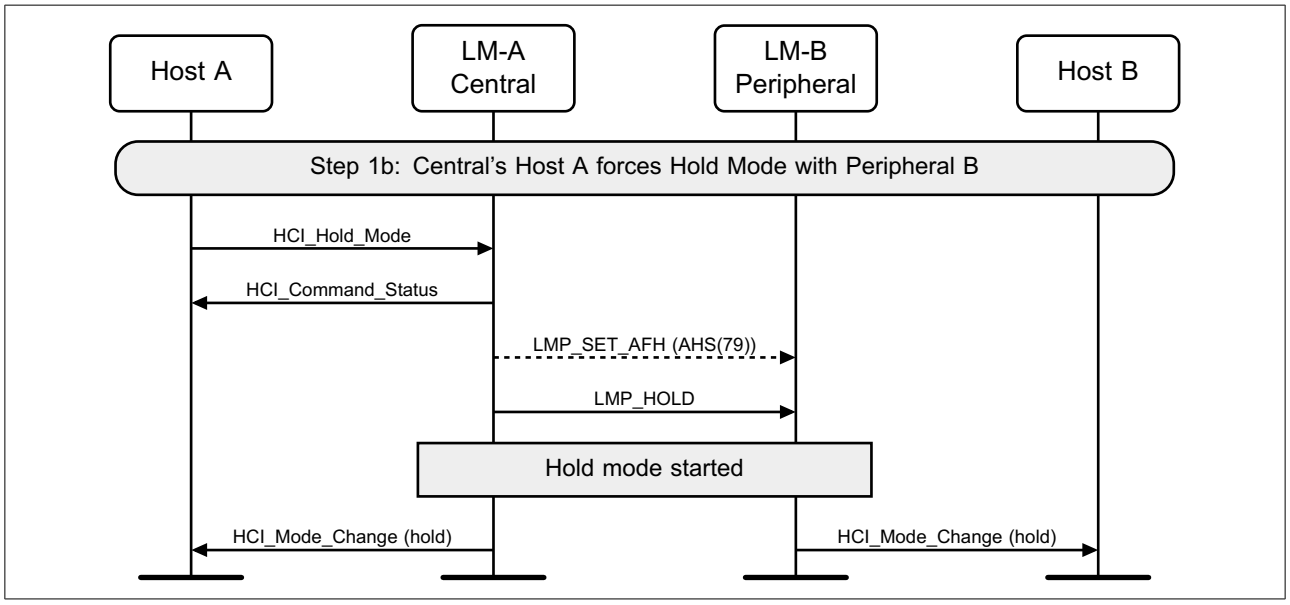

Figure 6.4: Central forces Hold mode

Step 1c: A Peripheral requests Hold mode. (See Figure 6.5.)

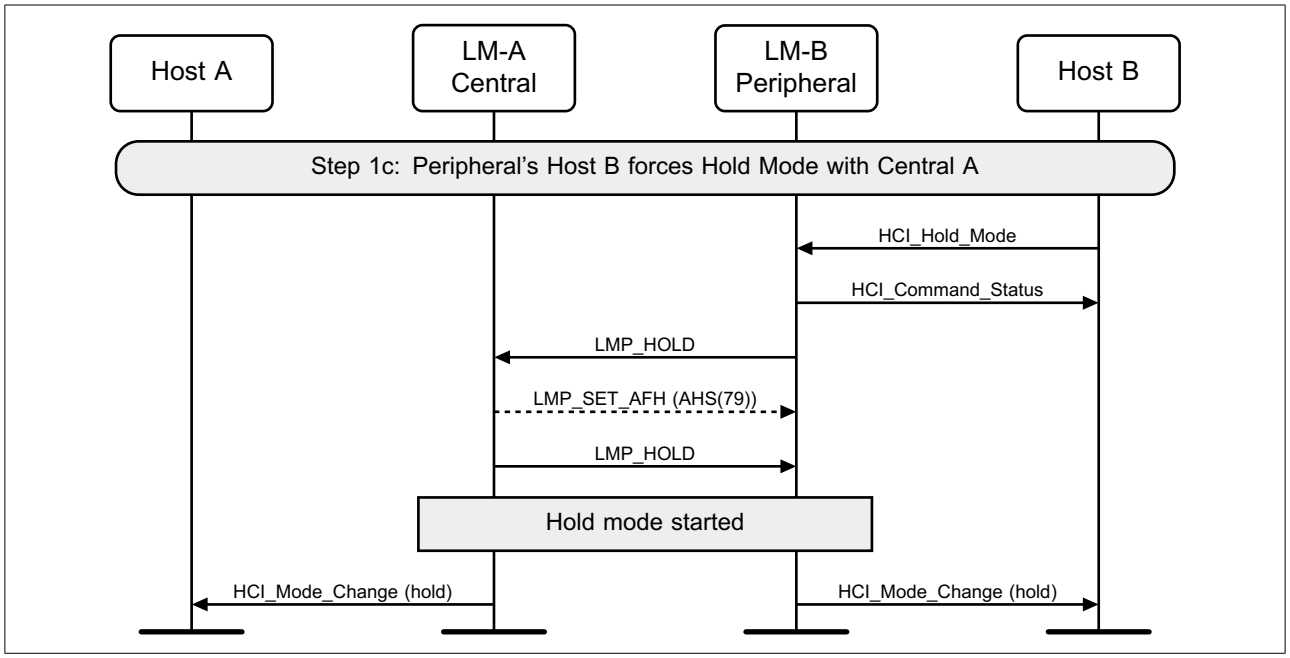

Figure 6.5: Peripheral forces Hold mode

Step 2: When Hold mode completes the Hosts are notified using the HCI_Mode_Change event. (See Figure 6.6.)

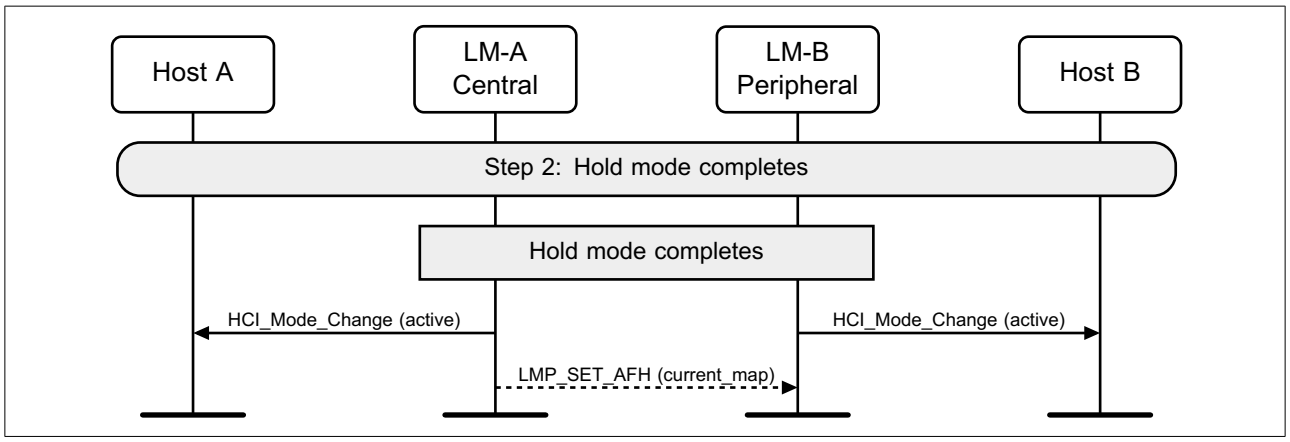

Figure 6.6: Hold mode completes

6.3 [This section is no longer used]

7 BUFFER MANAGEMENT, FLOW CONTROL

Buffer management is very important for resource limited devices.
This can be achieved on the Host Controller interface using the HCI_Read_Buffer_Size command, and the HCI_Number_Of_Completed_Packets event, and the HCI_Set_Controller_To_Host_Flow_Control, HCI_Host_Buffer_Size and HCI_Host_Number_Of_Completed_Packets commands.

Step 1: During initialization, the Host reads the buffer sizes available in the Controller. When an HCI Data packet has been transferred to the remote device, and a Baseband acknowledgment has been received for this data, then an HCI_Number_Of_Completed_Packets event will be generated. (See Figure 7.1.)

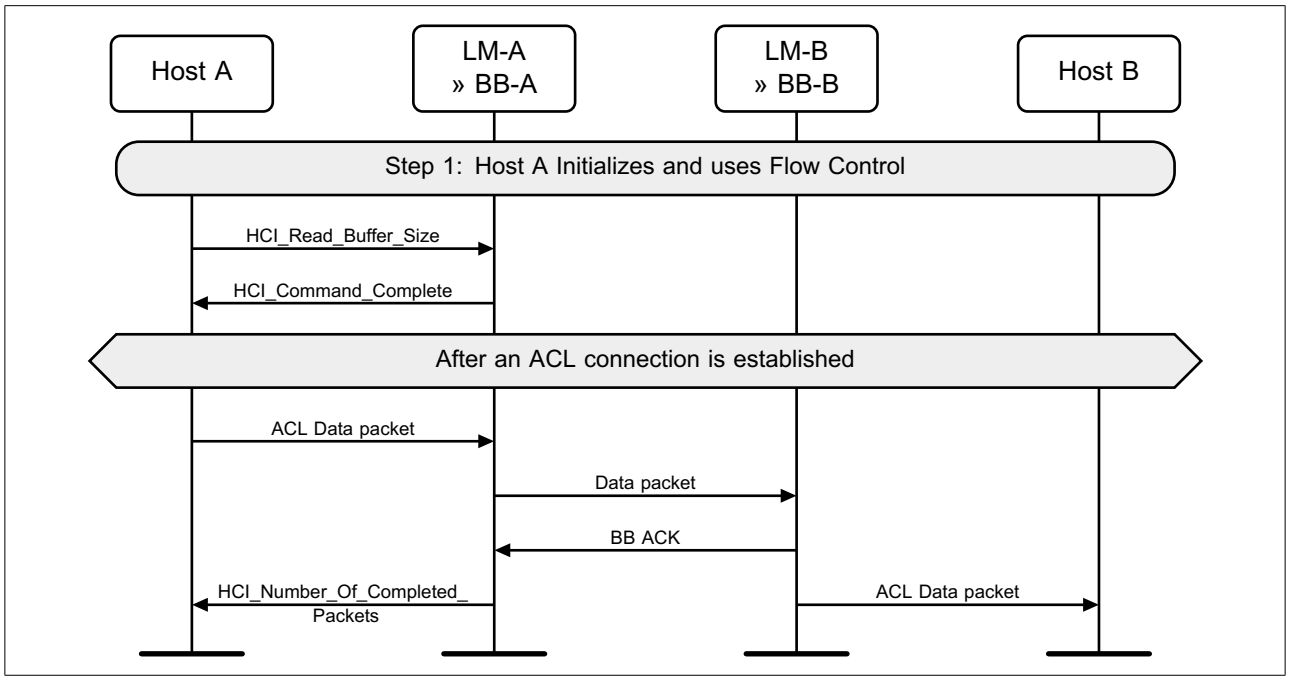

Figure 7.1: Host to Controller flow control

Step 2: During initialization, the Host may notify the Controller that Host flow control is being used and the Host buffer sizes available. When a data packet has been received from a remote device, an HCI Data packet is sent to the Host from the Controller and the Host acknowledges its receipt by sending an HCI_Host_Number_Of_Completed_Packets command. (See Figure 7.2.)

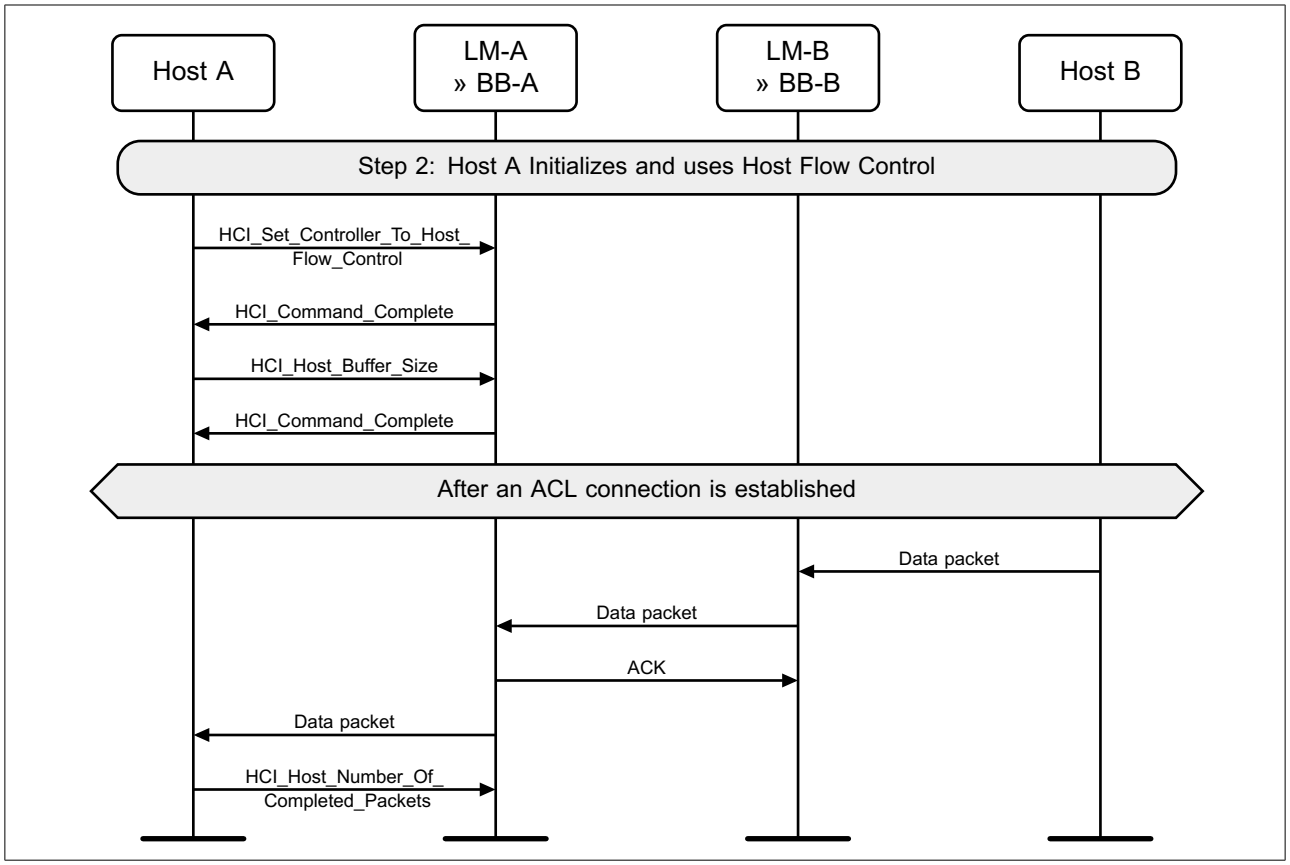

Figure 7.2: Controller to Host flow control

8 LOOPBACK MODE

The loopback modes are used for testing of a device only.

8.1 Local Loopback mode

The Local Loopback mode is used to loopback received HCI commands, and HCI ACL Data and HCI Synchronous Data packets sent from the Host to the Controller.

Step 1: The Host enters Local Loopback mode. Four HCI_Connection_Complete events are generated and then an HCI_Command_Complete event. (See Figure 8.1.)

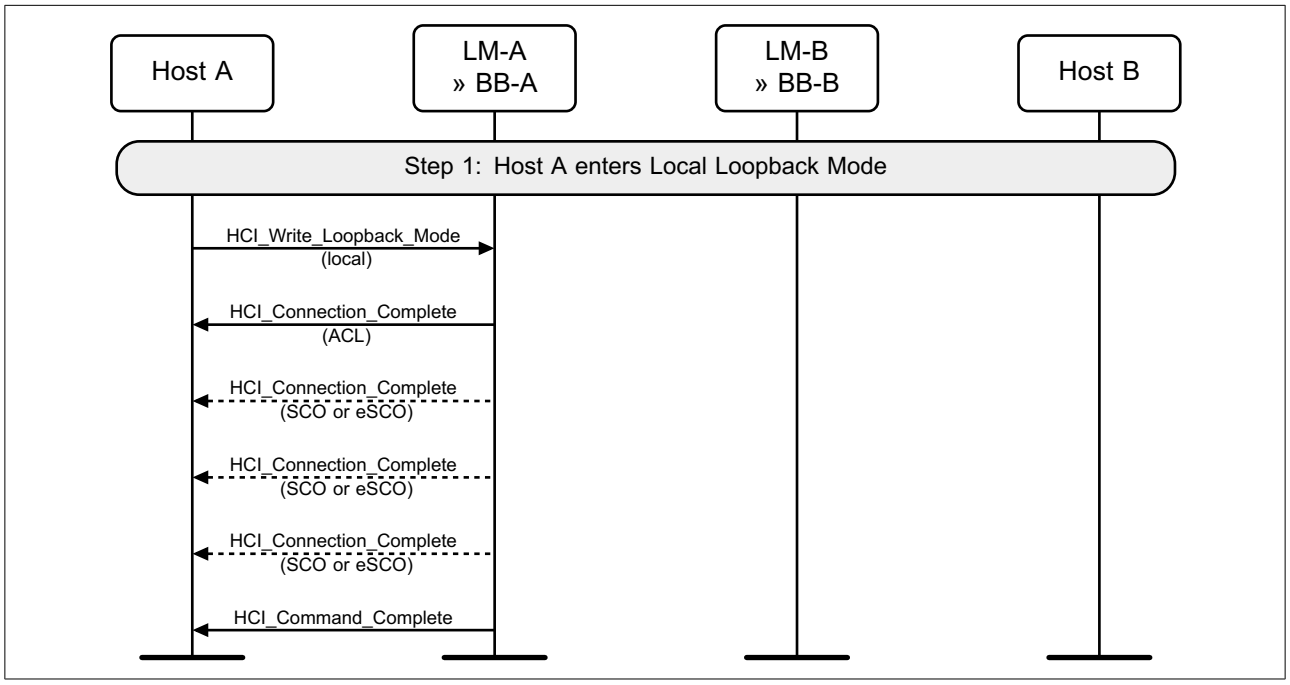

Figure 8.1: Entering Local Loopback mode

Step 2a: The Host sending HCI Data packet will receive the exact same data back in HCI Data packets from the Controller. (See Figure 8.2.)

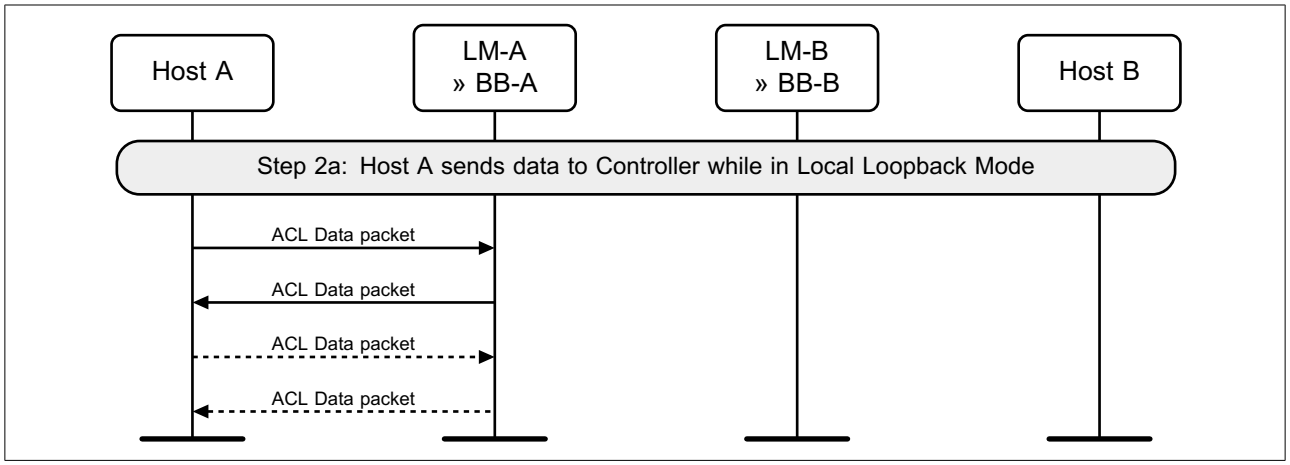

Figure 8.2: Looping back data in Local Loopback mode

Step 2b: The Host sending most HCI Command packets to the Controller will receive an HCI_Loopback_Command event with the contents of the HCI Command packet in the payload. (See Figure 8.3.)

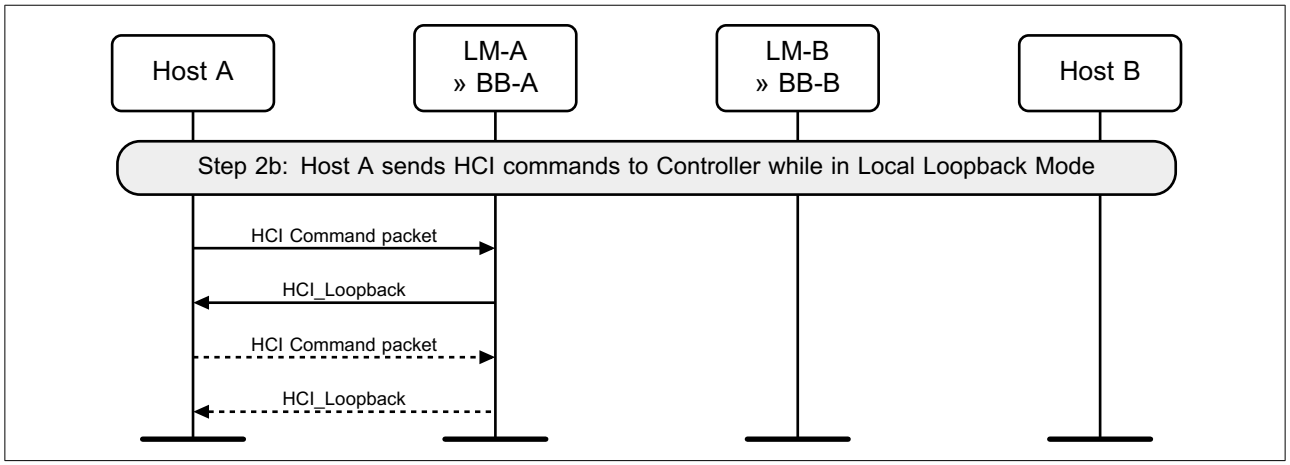

Figure 8.3: Looping back commands in Local Loopback mode

Step 3: The Host exits Local Loopback mode. Multiple HCI_Disconnection_Complete events are generated before the HCI_Command_Complete event. (See Figure 8.4.)

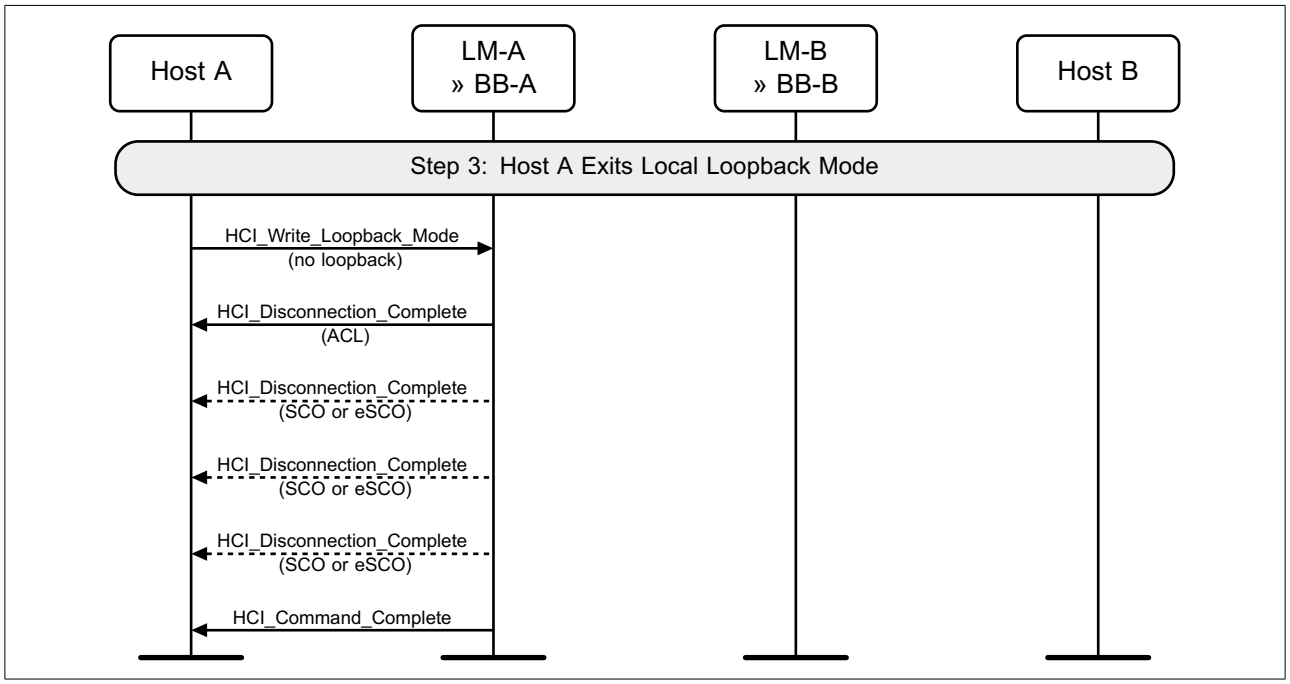

Figure 8.4: Exiting Local Loopback mode

8.2 Remote Loopback mode

The Remote Loopback mode is used to loopback data to a remote device over the air.

Step 1: The local device first enables remote loopback. The remote Host then sets up a connection to the local device. (See Figure 8.5.)

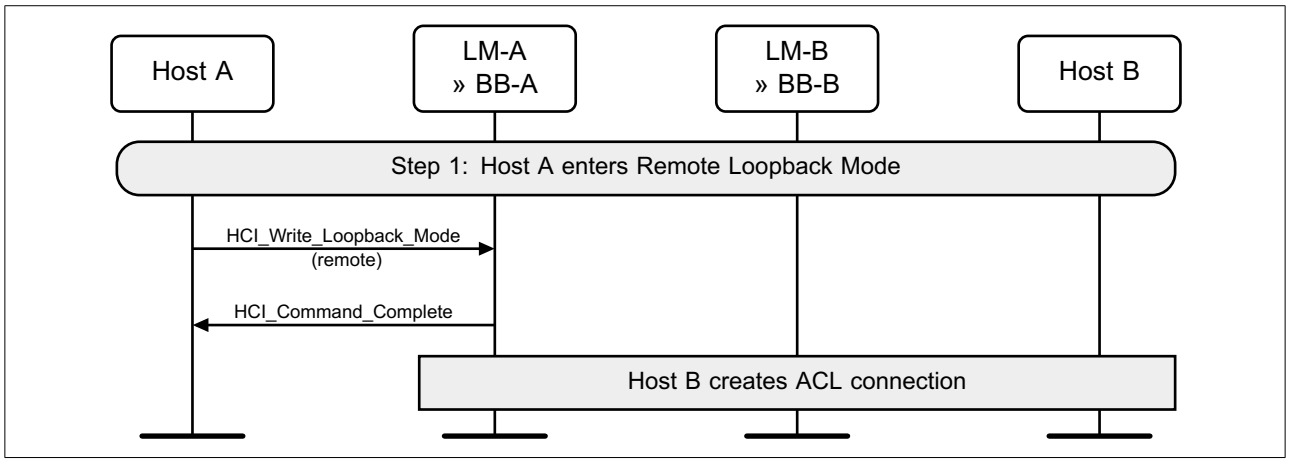

Figure 8.5: Entering Remote Loopback mode

Step 2: Any data received from the remote Host will be looped back in the Controller of the local device. (See Figure 8.6.)

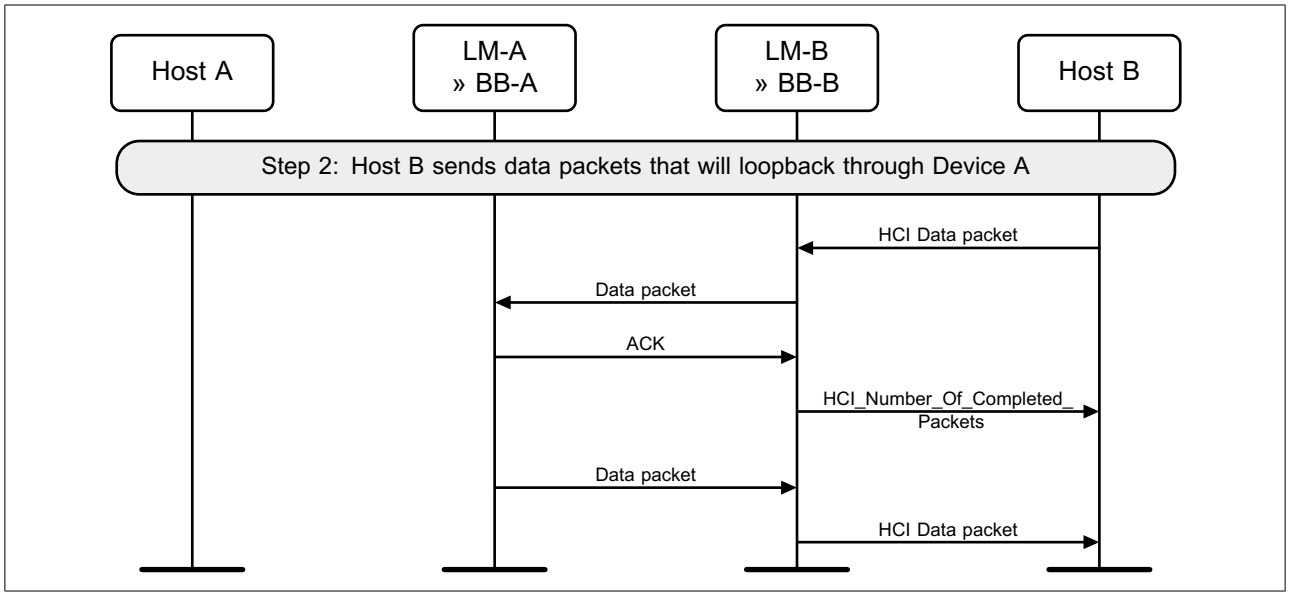

Figure 8.6: Looping back data in Remote Loopback mode

Step 3: The local Host exits Remote Loopback mode. Any connections can then be disconnected by the remote device. (See Figure 8.7.)

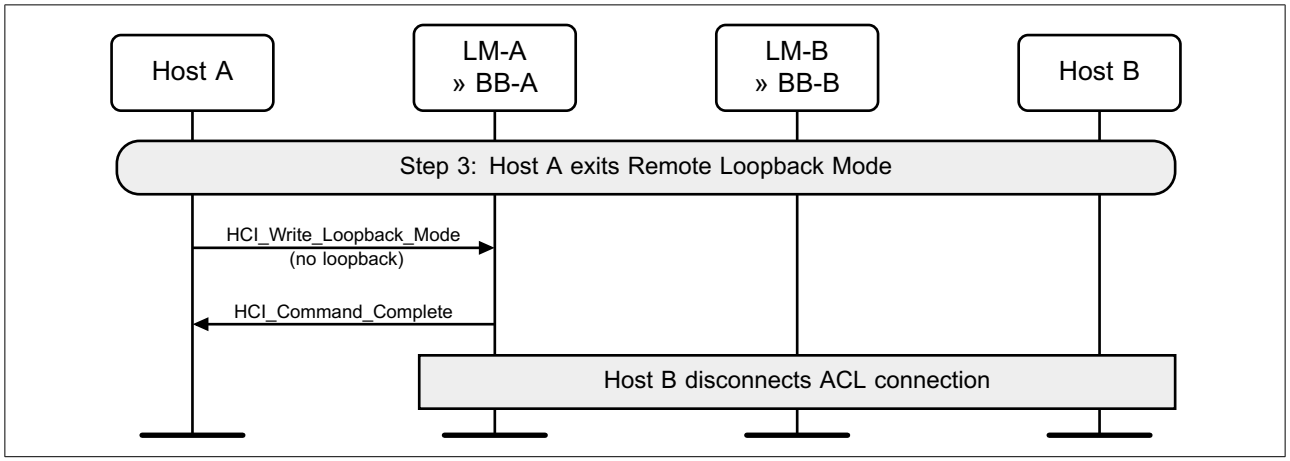

Figure 8.7: Exiting Remote Loopback mode

9 CONNECTIONLESS PERIPHERAL BROADCAST SERVICES

Figure 9.1 illustrates the Truncated Page procedure.

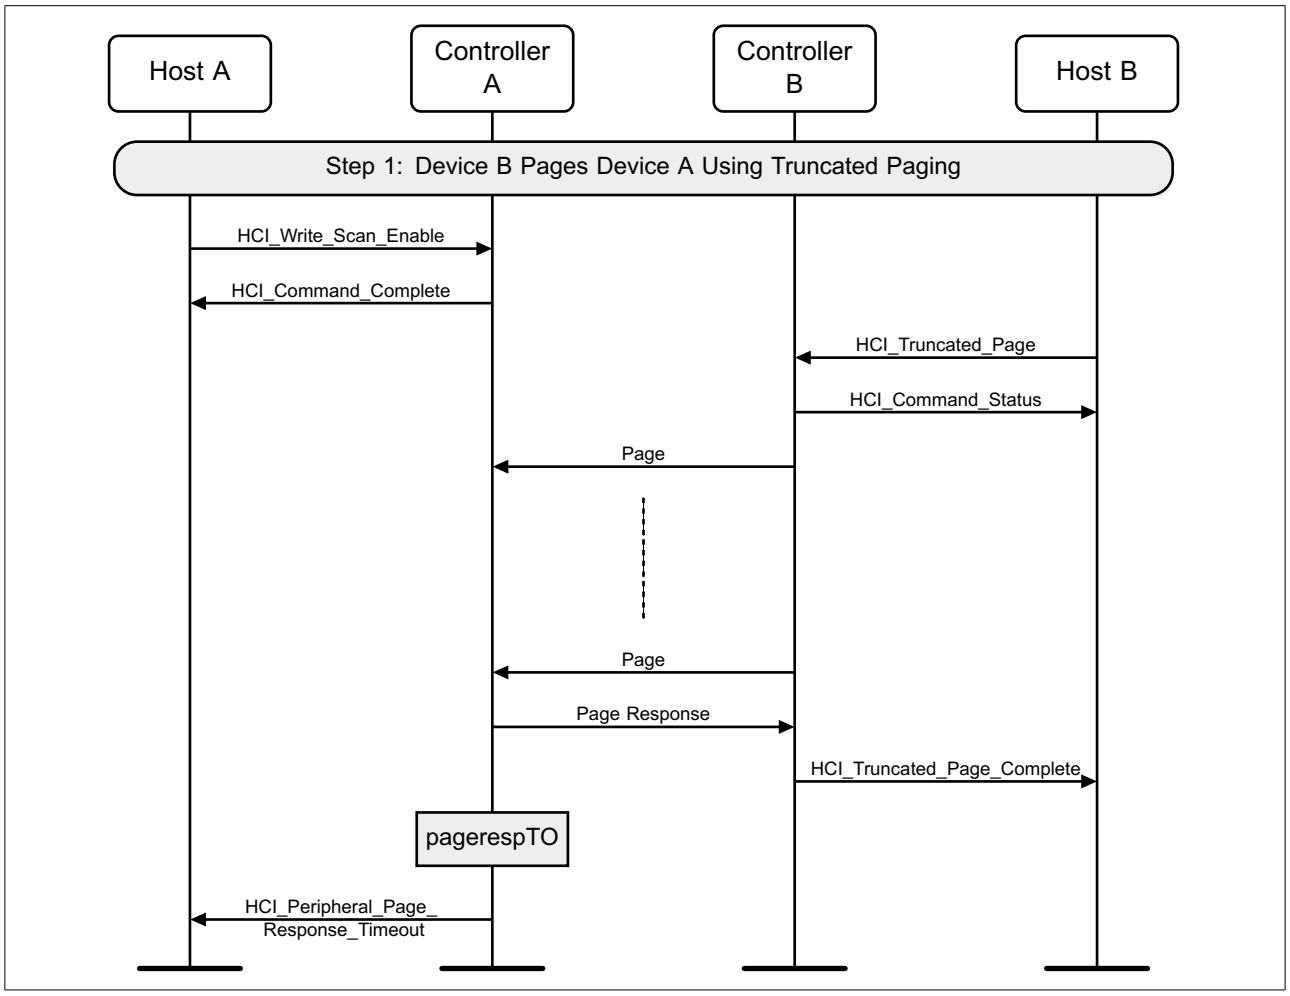

Figure 9.1: Truncated paging

Figure 9.2 illustrates how Device A starts transmitting Connectionless Peripheral Broadcast packets to Device B.

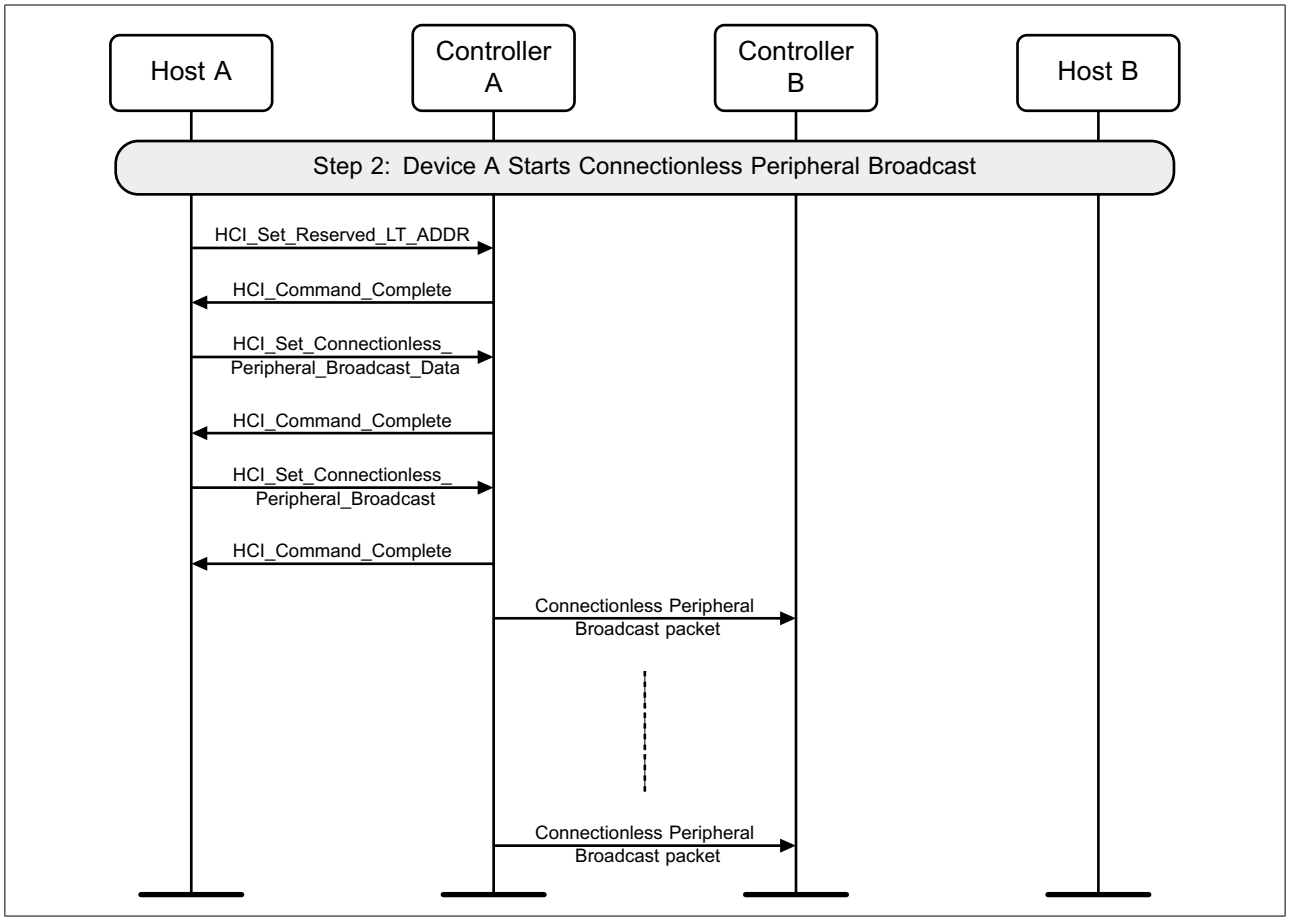

Figure 9.2: Connectionless Peripheral Broadcast transmitter start

Figure 9.3 shows the Synchronization Train feature. Device A is the Connectionless Peripheral Broadcast Transmitter. Device B is the Connectionless Peripheral Broadcast Receiver.

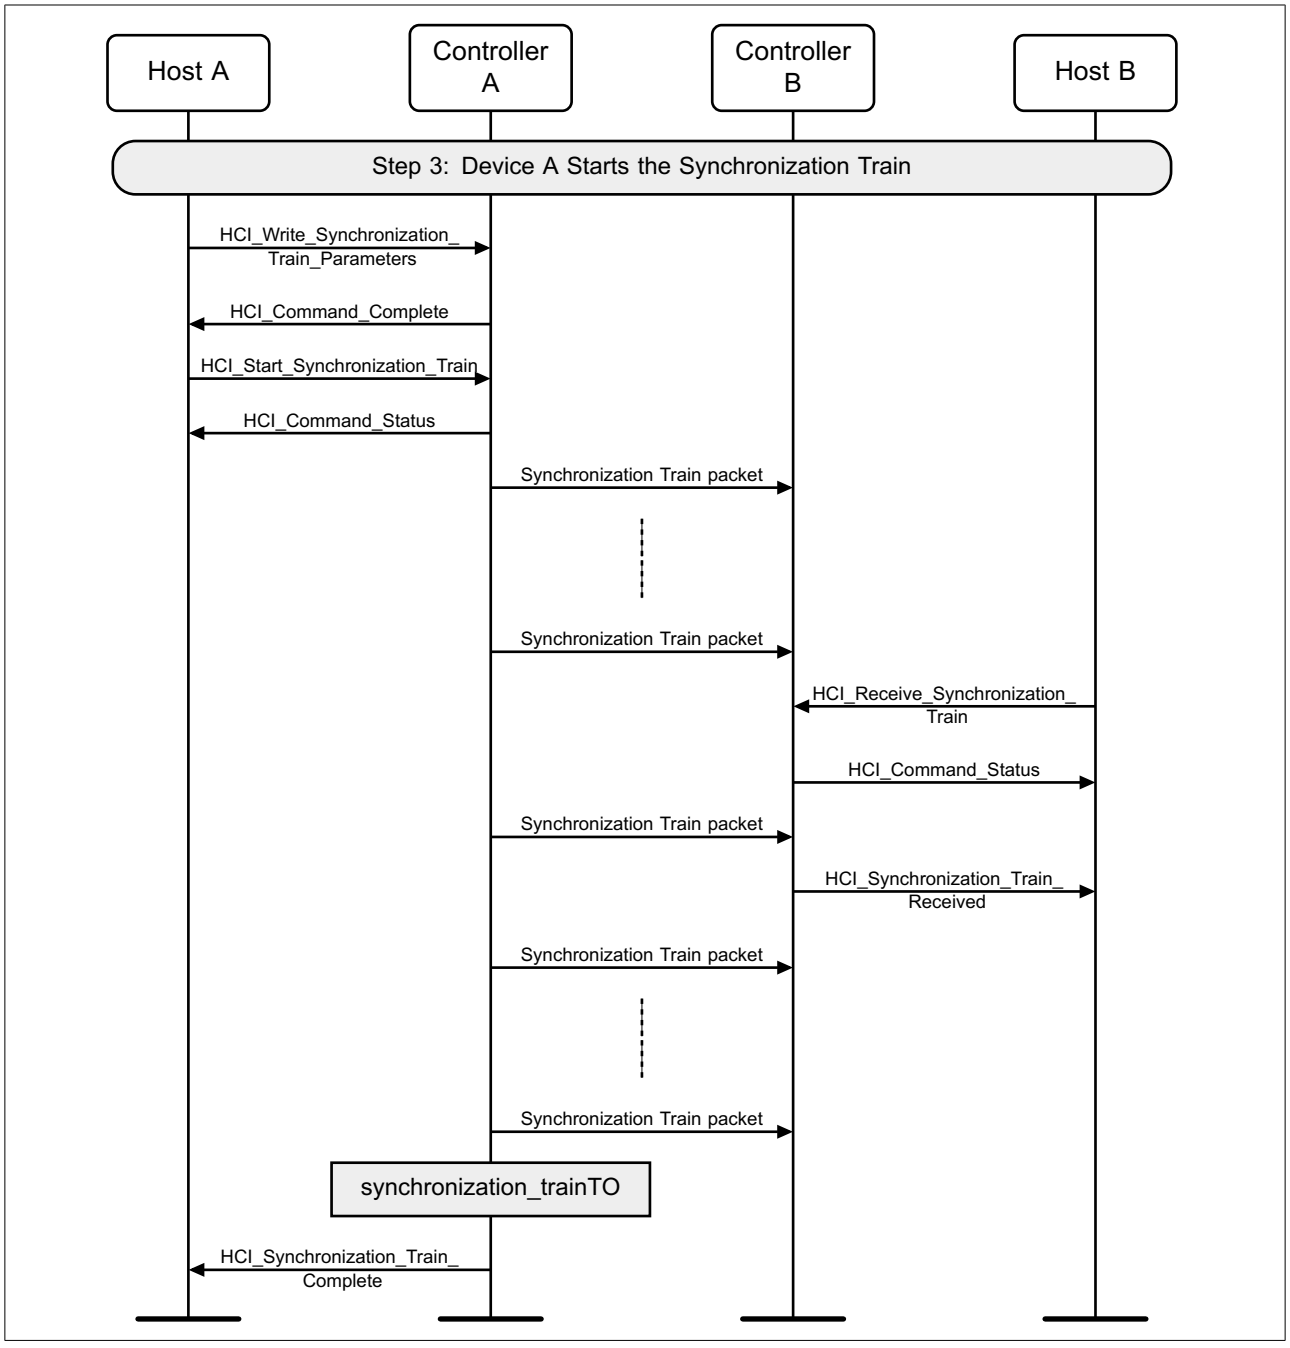

Figure 9.3: Synchronization Train

Figure 9.4 illustrates how Device B starts receiving Connectionless Peripheral Broadcast packets from Device A.

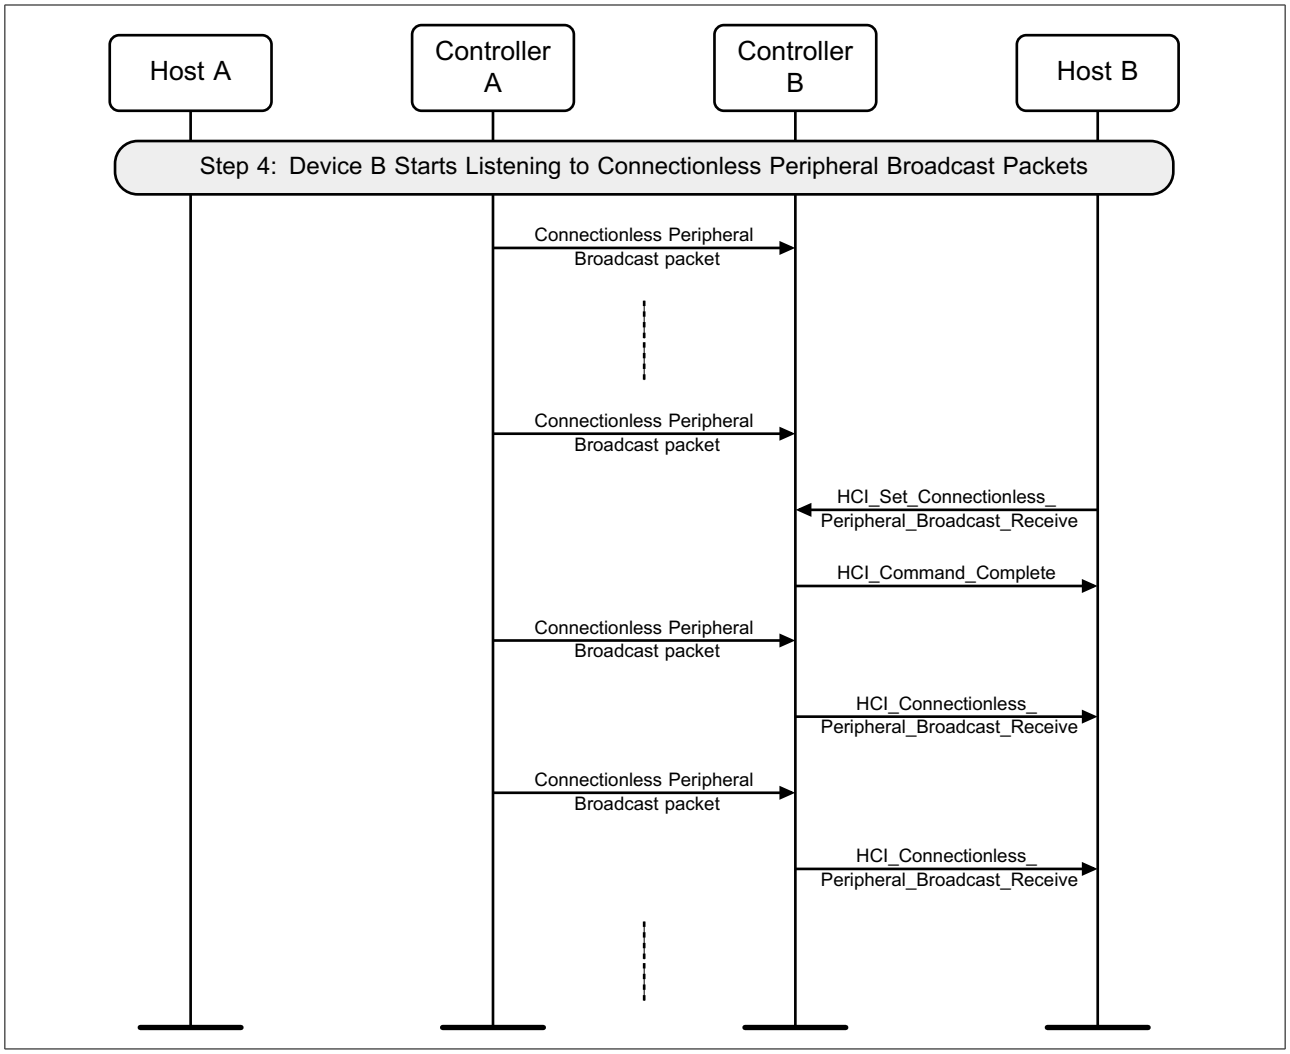

Figure 9.4: Connectionless Peripheral Broadcast receiver start

SAMPLE DATA

Sample data for various parts of the Baseband specification. All sample data are provided for reference purpose only; they are intended as a complement to the definitions provided elsewhere in the specification. They can be used to check the behavior of an implementation and avoid misunderstandings.

CONTENTS

1 ENCRYPTION SAMPLE DATA

1.1 E0 encryption sample data

This section contains four sets of sample data for the encryption process.

With respect to the functional description of the E_0 encryption algorithm in the Bluetooth Baseband specification, the contents of registers and resulting concurrent values are listed as well. This by no means excludes different implementations (as far as they produce the same encryption stream) but is intended to describe the functional behavior.

1.1.1 Generating K_session from K_enc

where K_session(x) = g2(x)(K_enc(x) *mod* g1(x)).

Note: All polynomials are in hexadecimal notation.

'L' is the effective key length in bytes.

The notation 'p: [m]' implies that deg(p(x)) = m.

1.1.3 Second set of sample data

```
Initial values for the key, BD_ADDR and clock

K_session[0]  = 00  K_session[1]  = 00  K_session[2]  = 00  K_session[3]  = 00
K_session[4]  = 00  K_session[5]  = 00  K_session[6]  = 00  K_session[7]  = 00
K_session[8]  = 00  K_session[9]  = 00  K_session[10] = 00  K_session[11] = 00
K_session[12] = 00  K_session[13] = 00  K_session[14] = 00  K_session[15] = 00

BD_ADDR_C[0] = 00  BD_ADDR_C[1] = 00  BD_ADDR_C[2] = 00
BD_ADDR_C[3] = 00  BD_ADDR_C[4] = 00  BD_ADDR_C[5] = 00

CL[0] = 00  CL[1] = 00  CL[2] = 00  CL[3] = 03

The corresponding values of CLK are 0x600_0000 and 0xE00_0000.

Sample Data

1.1.5 Fourth set of samples

```
Initial values for the key, BD_ADDR and clock

K_session[0]  = 21  K_session[1]  = 87  K_session[2]  = F0  K_session[3]  = 4A
K_session[4]  = BA  K_session[5]  = 90  K_session[6]  = 31  K_session[7]  = D0
K_session[8]  = 78  K_session[9]  = 0D  K_session[10] = 4C  K_session[11] = 53
K_session[12] = E0  K_session[13] = 15  K_session[14] = 3A  K_session[15] = 63

BD_ADDR_C[0] = 2C  BD_ADDR_C[1] = 7F  BD_ADDR_C[2] = 94
BD_ADDR_C[3] = 56  BD_ADDR_C[4] = 0F  BD_ADDR_C[5] = 1B

CL[0] = 5F  CL[1] = 1A  CL[2] = 00  CL[3] = 02

The corresponding values of CLK are 0x400_34BE and 0xC00_34BE.
```

```

Sample Data

1.2 AES-CCM encryption sample data

All values below are hexadecimal and follow notation of AES-CCM: MSbyte to LSbyte & msbit to lsbit.

1.2.1 Sample data 1 (DM1, Central → Peripheral)

```
Payload byte length: 00
K: 89678967 89678967 45234523 45234523
Payload counter: 0000bc614e
Zero-length ACL-U Continuation: 0
Direction: 0
Initialization vector: 66778899 aabbccdd
LT_ADDR: 1
Packet Type: 3
LLID: 2
Payload:

B0: 494e61bc 0000ddcc bbaa9988 77660000

2 FREQUENCY HOPPING SAMPLE DATA

The section contains three sets of sample data showing the basic and adapted hopping schemes for different combinations of addresses and initial clock values.

2.1 First set

```
Hop sequence {k} for Page Scan and Inquiry Scan substates:
CLKN start:   0x0000000
UAP / LAP:    0x00000000
#ticks:       0000 | 1000 | 2000 | 3000 | 4000 | 5000 | 6000 | 7000 |

4 HEC AND PACKET HEADER SAMPLE DATA

This section contains examples of HECs computed for sample UAP and packet header contents (Data). The resulting 54 bit packet headers are shown in the rightmost column. The UAP, Data and HEC values are in hexadecimal notation, while the header is in octal notation. The header is transmitted from left to right over the air.

UAP	Data	HEC	Header (octal)
00	123	e1	770007 007070 000777
47	123	06	770007 007007 700000
00	124	32	007007 007007 007700
47	124	d5	007007 007070 707077
00	125	5a	707007 007007 077070
47	125	bd	707007 007070 777707
00	126	e2	077007 007007 000777
47	126	05	077007 007070 700000
00	127	8a	777007 007007 070007
47	127	6d	777007 007070 770770
00	11b	9e	770770 007007 777007
47	11b	79	770770 007070 077770
00	11c	4d	007770 007070 770070
47	11c	aa	007770 007007 070707
00	11d	25	707770 007070 700700
47	11d	c2	707770 007007 000077
00	11e	9d	077770 007070 777007
47	11e	7a	077770 007007 077770
00	11f	f5	777770 007070 707777
47	11f	12	777770 007007 007000

5 CRC SAMPLE DATA

This section shows the CRC computed for a sample 10 byte payload and a UAP of 0x47.

```
Data:
-----

data[0] = 0x4e
data[1] = 0x01
data[2] = 0x02
data[3] = 0x03
data[4] = 0x04
data[5] = 0x05
data[6] = 0x06
data[7] = 0x07
data[8] = 0x08
data[9] = 0x09

UAP = 0x47

==> CRC = 6d d2

Codeword (hexadecimal notation):
--------------------------------

4e 01 02 03 04 05 06 07 08 09 6d d2

NB: Over the air each byte in the codeword
    is sent with the LSB first.
```

6 COMPLETE SAMPLE PACKETS

6.1 Example of DH1 packet

```
Packet header: (MSB...LSB)
--------------------------
LT_ADDR = 011
TYPE = 0100 (DH1)
FLOW = 0
ARQN = 1
SEQN = 0

Payload: (MSB...LSB)
--------------------
payload length: 5 bytes
logical channel = 10 (UA/I, Start L2CAP message)
flow = 1
data byte 1 = 00000001
data byte 2 = 00000010
data byte 3 = 00000011
data byte 4 = 00000100
data byte 5 = 00000101

HEC and CRC initialization: (MSB...LSB)
---------------------------------------
uap = 01000111

NO WHITENING USED

AIR DATA (LSB...MSB)

Packet header (incl HEC):
-------------------------
111111000
000000111000
000111000
000111111000000000000000
```

Sample Data

```
Payload (incl payload header and CRC):
------------------------------------------------------------
01110100
10000000
01000000
11000000
00100000
10100000
1110110000110110
```

6.2 Example of DM1 packet

```
Packet header: (MSB...LSB)
--------------------------
LT_ADDR = 011
TYPE = 0011 (DM1)
FLOW = 0
ARQN = 1
SEQN = 0

Payload: (MSB...LSB)
--------------------
payload length: 5 bytes
logical channel = 10 (UA/I, Start L2CAP message)
flow = 1
data byte 1 = 00000001
data byte 2 = 00000010
data byte 3 = 00000011
data byte 4 = 00000100
data byte 5 = 00000101

HEC and CRC initialization: (MSB...LSB)
---------------------------------------
uap = 01000111

NO WHITENING USED

AIR DATA (LSB...MSB)

Packet header (incl HEC):
-------------------------
111111000
111111000000
000111000
111000000111111111111000

Payload (incl payload header, FEC23, CRC and 6 padded zeros):
```

Sample Data

```
------------------------------------------------------------
0111010010 11001
0000000100 01011
0000110000 11110
0000100000 00111
1010000011 01100
1011000011 00010
0110000000 10001
```

7 SECURE SIMPLE PAIRING SAMPLE DATA

This section provides sample data for the Secure Simple Pairing cryptographic functions (f1, f2, f3, g and the ECDH calculations).

7.1 Elliptic curve sample data

In each data set, the bytes are ordered from least significant on the right to most significant on the left.

7.1.1 P-192 sample data

7.1.1.1 P-192 data set 1

9 FEC SAMPLE DATA

```
================================================

Rate 2/3 FEC -- (15,10) Shortened Hamming Code

================================================

Data is in hexadecimal notation, the codewords are in binary notation.
The codeword bits are sent from left to right over the air interface.
The space in the codeword indicates the start of parity bits.

Data:            Codeword:

0x001         1000000000 11010
0x002         0100000000 01101
0x004         0010000000 11100
0x008         0001000000 01110
0x010         0000100000 00111
0x020         0000010000 11001
0x040         0000001000 10110
0x080         0000000100 01011
0x100         0000000010 11111
0x200         0000000001 10101
```

10 ENCRYPTION KEY SAMPLE DATA

For Section 10.1 to Section 10.5, the hexadecimal sample data is written with the least significant byte at the leftmost position and the most significant byte at the rightmost position. Within each byte, the *least significant bit* (LSB) is at the rightmost position and the *most significant bit* (MSB) is at the leftmost position Thus, a line reading:

aco: 48afcdd4bd40fef76693b113

means aco[0]=0x48, ac[1]=0xAF, ..., aco[11]=0x13. The LSB of aco[11] is 1 and the MSB of aco[11] is 0.

Key [i]: denotes the ith sub-key in Ar or A'r;

round r: denotes the input to the rth round;

added ->: denotes the input to round 3 in A'r after adding original input (of round 1).

10.1 Four tests of E1

11 CONNECTIONLESS PERIPHERAL BROADCAST SAMPLE DATA

This section contains an example of the DM3 packet used for the synchronization train (see [Vol 2] Part B, Section 8.11.2).

```
Packet header: (MSB...LSB)
--------------------------
LT_ADDR = 0
TYPE = 1010 (DM3)
FLOW = 0
ARQN = 0
SEQN = 0

Payload:
--------
logical channel = 10 (binary) (L2CAP start or no fragmentation)
payload length = 28 bytes
flow = 0
current CLK = 0x2345678
next Connectionless Peripheral Broadcast instant = 0x23457a0
AFH channel map = all channels used except 16 and 42 to 47
Central BD_ADDR = NAP 0xACDE, UAP 0x48, LAP 0x610316
Connectionless Peripheral Broadcast interval = 564 slots
Connectionless Peripheral Broadcast LT_ADDR = 1
service data = 0x69

AIR DATA

Packet header (including HEC, in transmitted bit order):
--------------------------------------------------------
000000000
000111000111
000
000
000
111111111000000000000111

Payload
-------
```

Sample Data

The data forming the payload consists of the following 32 octets (given in hexadecimal) in the order transmitted:

```
e2 00
78 56 34 02
d0 2b 1a 01
ff ff fe ff ff 03 ff ff ff 7f
16 03 61 48 de ac
34 02
01
69
f2 85
```

The bit sequence transmitted (including FEC) will therefore begin:

```
0100011100 01001
0000000001 10101
1110011010 11011
```

and end:

```

1000010000 00011
```

BR/EDR Controller
Part H

SECURITY SPECIFICATION

This Part describes the security system which may be used at the Link Layer. The Encryption, Authentication, and Key Generation schemes are specified. The requirements for the supporting process of random number generation are also specified.

CONTENTS

1 SECURITY OVERVIEW

Bluetooth wireless technology provides peer-to-peer communications over short distances. In order to provide usage protection and information confidentiality, the system provides security measures both at the application layer and the Link Layer. These measures are designed to be appropriate for a peer environment.

This means that in each device, the authentication and encryption routines are implemented in the same way.

In this Part, the term "random number" includes pseudo-random numbers, subject to the requirements in Section 2.

The security mechanisms used in BR/EDR have evolved over the course of multiple versions of the specification in three phases: legacy, Secure Simple Pairing, and Secure Connections. The encryption, authentication and key generation algorithms associated with each is shown in Table 1.1.

Security Mechanism	Legacy	Secure Simple Pairing	Secure Connections
Encryption	E0	E0	AES-CCM
Authentication	SAFER+	SAFER+	HMAC-SHA256
Key Generation	SAFER+	P-192 ECDH HMAC-SHA-256	P-256 ECDH HMAC-SHA-256

Table 1.1: Security algorithms

The legacy encryption, authentication and key generation algorithms are described in Section 3 to 6. The algorithms used for Secure Simple Pairing and Secure Connections are described in Section 7 to 9.

Four different entities are used for maintaining security at the Link Layer: a Bluetooth Device Address, two secret keys, and a random number that shall be regenerated for each new transaction. The four entities and their sizes are summarized in Table 1.2.

Entity	Size
BD_ADDR	48 bits
Private user key, authentication	128 bits
Private user key, encryption configurable length (byte-wise)	8 to 128 bits
RAND	128 bits

Table 1.2: Entities used in authentication and encryption procedures

The Bluetooth Device Address (BD_ADDR) is the 48-bit address. The BD_ADDR can be obtained via user interactions, or, automatically, via an inquiry routine by a device.

The secret keys are derived during initialization and are never disclosed. The encryption key is derived from the authentication key during the authentication process. For the authentication algorithm, the size of the key used is always 128 bits. For the encryption algorithm, the key size may vary between 1 and 16 octets (8 - 128 bits).

The encryption key is entirely different from the authentication key. Each time encryption is activated, a new encryption key shall be generated. Thus, the lifetime of the encryption key does not necessarily correspond to the lifetime of the authentication key.

It is anticipated that the authentication key will be more static in its nature than the encryption key – once established, the particular application running on the device decides when, or if, to change it. To underline the fundamental importance of the authentication key to a specific link, it is often referred to as the link key.

RAND is a random number which can be derived from a random process in the device. This is not a static parameter and will change frequently.

In this part, the terms user and application are used interchangeably to designate the entity that is at either side.

1.1 Pausing encryption and role switch

To perform a role switch on a connection encryption must be disabled or paused as the encryption is based off the Central's clock and Bluetooth address information. Unfortunately, if the role switch is required, and encryption is turned off, the device on the other end of the link will not be aware of the reason for disabling encryption, and can therefore take two possible actions: send clear text data, or disconnect. Neither of these possible actions is desirable. When performing a role switch on an encrypted link, the role switch shall be performed as a single operation where possible. If this is not possible because the other device does not support the encryption pause feature, then when a device wishes to have an encrypted link, and encryption is disabled, then the device should not send any user data, and should not disconnect. If both devices support the encryption pause feature, then this procedure shall be used.

1.2 Change connection link keys

It is possible to perform a change of connection link keys while a link is encrypted, but it is not possible to use the new link keys until encryption has been stopped and then restarted. As with role switches, disabling encryption and then re-enabling it again can cause user data to be sent in the clear or a disconnection to occur. The use of encryption pausing prevents this problem from occurring. On devices that do not

support the encryption pause feature, when a device wishes to have an encrypted link, and encryption is disabled, then the device should not send any data, and should not disconnect. If both devices support the encryption pause feature, then this procedure shall be used.

1.3 Periodically refreshing encryption keys

If both devices support the encryption pause feature, then the encryption keys shall be refreshed by the Link Manager at least once every 2^{28} ticks of the Bluetooth clock (about 23.3 hours) when E0 encryption is used and before either the PayloadCounter or dayCounter roll over when AES-CCM encryption is used if it is not refreshed by the Host or the remote Link Manager. To refresh an encryption key, the Host may use the Change Connection Link Key procedure or request an encryption key refresh. If the encryption key has not been refreshed before going stale, a device may disconnect the link.

Note: The roll over will occur after at least 2^{38} ticks of the Bluetooth clock or at least 2.72 years.

2 RANDOM NUMBER GENERATION

Each device shall have a random number generator. Random numbers are used for many purposes within the security functions – or instance, for the challenge-response scheme, for generating authentication and encryption keys, nonces used in Secure Simple Pairing, for Passkeys used in authentication. A device shall use a random number generator compliant with [FIPS PUB 140-2] (http://csrc.nist.gov/publications/fips/fips140-2/fips1402annexc.pdf) or a later update.

When using a pseudo-random number generator, the device shall use a seed with at least the minimum entropy required by that pseudo-random number generator.

The random number generator shall be tested against the [FIPS SP800-22] (http://csrc.nist.gov/publications/nistpubs/800-22-rev1a/SP800-22rev1a.pdf). This encompasses the verification of the following statistical tests performed on the output of the PRNG as specified by the [FIPS SP800-22]:

1. The Frequency (Monobit) Test
2. Frequency Test within a Block
3. The Runs Test
4. Test for the Longest-Run-of-Ones in a Block
5. The Binary Matrix Rank Test
6. The Discrete Fourier Transform (Spectral) Test
7. The Non-overlapping Template Matching Test
8. The Overlapping Template Matching Test
9. Maurer's "Universal Statistical" Test
10. The Linear Complexity Test
11. The Serial Test
12. The Approximate Entropy Test
13. The Cumulative Sums (Cusums) Test
14. The Random Excursions Test
15. The Random Excursions Variant Test

These tests are part of standard statistical mathematical packages. Some test suites, like the Diehard test suite, can be used to verify FIPS compliance. Alternatively, other tools, such as the DieHarder (http://www.phy.duke.edu/~rgb/General/rand_rate.php) or the available NIST tools (http://csrc.nist.gov/groups/ST/toolkit/random_number.html)

and the corresponding recommendations (http://csrc.nist.gov/publications/nistpubs/800-22-rev1/SP800-22rev1.pdf) may also be used.

3 KEY MANAGEMENT

It is important that the encryption key size within a specific device cannot be set by the user – this should be a factory preset entity. In order to prevent the user from over-riding the permitted key size, the Bluetooth Baseband processing shall not accept an encryption key given from higher software layers. Whenever a new encryption key is required, it shall be created as defined in Section 6.4.

Changing a link key shall also be done through the defined Baseband procedures. Depending on what kind of link key it is, different approaches are required. The details are found in Section 3.2.7.

3.1 Key types

The link key is a 128-bit random number which is shared between two or more parties and is the base for all security transactions between these parties. The link key itself is used in the authentication routine. Moreover, the link key is used as one of the parameters when the encryption key is derived.

In the following, a session is defined as the time interval for which the device is a member of a particular piconet. Thus, the session terminates when the device disconnects from the piconet.

The link keys are either semi-permanent or temporary. A semi-permanent link key may be stored in non-volatile memory and may be used after the current session is terminated. Consequently, once a semi-permanent link key is defined, it may be used in the authentication of several subsequent connections between the devices sharing it. The designation semi-permanent is justified by the possibility of changing it. How to do this is described in Section 3.2.7.

The lifetime of a temporary link key is limited by the lifetime of the current session – it shall not be reused in a later session. Typically, in a point-to-multipoint configuration where the same information is to be distributed securely to several recipients, a common encryption key is useful. To achieve this, the temporary link key replaces the semi-permanent link keys. The details of this procedure are found in Section 3.2.6.

In the following, the current link key is the link key in use at the current moment. It can be semi-permanent or temporary. Thus, the current link key is used for all authentications and all generation of encryption keys in the on-going connection (session).

In order to accommodate different types of applications, three types of link keys have been defined:

- the combination key K_{AB}
- the temporary key K_temp
- the initialization key K_{init}

In addition to these keys there is an encryption key, denoted K_enc. This key is derived from the current link key. Whenever encryption is activated by an LM command, the encryption key shall be changed automatically. The purpose of separating the authentication key and encryption key is to facilitate the use of a shorter encryption key without weakening the strength of the authentication procedure. There are no governmental restrictions on the strength of authentication algorithms. However, in some countries, such restrictions exist on the strength of encryption algorithms.

The combination key is derived from information in both devices A and B, and is therefore always dependent on two devices. The combination key is derived for each new combination of two devices.

The temporary link key, K_temp, shall only be used during the current session. It shall only replace the original link key temporarily. For example, this may be utilized when a Central wants to reach more than one device simultaneously using the same encryption key, see Section 3.2.6.

The initialization key, K_{init}, shall be used as the link key during the initialization process when no combination keys have been defined and exchanged yet or when a link key has been lost. The initialization key protects the transfer of initialization parameters. The key is derived from a random number, an L-octet PIN code, and a BD_ADDR. This key shall only be used during initialization.

The PIN may be a fixed number provided with the device (for example when there is no user interface). Alternatively, the PIN can be selected by the user, and then entered in both devices that are to be matched. The latter procedure should be used when both devices have a user interface, for example a phone and a laptop. Entering a PIN in both devices is more secure than using a fixed PIN in one of the devices, and should be used whenever possible. Even if a fixed PIN is used, it shall be possible to change the PIN; this is in order to prevent re-initialization by users who once obtained the PIN. If no PIN is available, a default value of zero may be used. The length of this default PIN is one byte, PIN (default) = 0x00. This default PIN may be provided by the Host.

For many applications the PIN code will be a relatively short string of numbers. Typically, it may consist of only four decimal digits. Even though this gives sufficient security in many cases, there exist countless other, more sensitive, situations where this is not reliable enough. Therefore, the PIN code may be chosen to be any length

from 1 to 16 octets. For the longer lengths, the devices exchanging PIN codes may use software at the application layer rather than mechanical (i.e. human) interaction. For example, this can be a Diffie-Hellman key agreement, where the exchanged key is passed on to the K_{init} generation process in both devices, just as in the case of a shorter PIN code.

3.2 Key generation and initialization

The link keys must be generated and distributed among the devices in order to be used in the authentication procedure. Since the link keys shall be secret, they shall not be obtainable through an inquiry routine in the same way as the Bluetooth Device Addresses. The exchange of the keys takes place during an initialization phase which shall be carried out separately for each two devices that are using authentication and encryption. The initialization procedures consist of the following five parts:

- generation of an initialization key
- generation of link key
- link key exchange
- authentication
- generation of encryption key in each device (optional)

After the initialization procedure, the devices can proceed to communicate, or the link can be disconnected. If encryption is implemented, the E_0 algorithm shall be used with the proper encryption key derived from the current link key. For any new connection established between devices A and B, they shall use the common link key for authentication, instead of once more deriving K_{init} from the PIN. A new encryption key derived from that particular link key shall be created next time encryption is activated.

If no link key is available, the LM shall automatically start an initialization procedure.

3.2.1 Generation of initialization key, K_{init}

A link key is used temporarily during initialization, the initialization key K_{init}. This key shall be derived by the E_{22} algorithm from a BD_ADDR, a PIN code, the length of the PIN (in octets), and a random number IN_RAND. The principle is depicted in Figure 6.4. The 128-bit output from E_{22} shall be used for key exchange during the generation of a link key. When the devices have performed the link key exchange, the initialization key shall be discarded.

When the initialization key is generated, the PIN is augmented with the BD_ADDR. If one device has a fixed PIN the BD_ADDR of the other device shall be used. If both

devices have a variable PIN the BD_ADDR of the device that received IN_RAND shall be used. If both devices have a fixed PIN they cannot be paired. Since the maximum length of the PIN used in the algorithm cannot exceed 16 octets, it is possible that not all octets of BD_ADDR will be used. This procedure ensures that K_{init} depends on the identity of the device with a variable PIN. A fraudulent device may try to test a large number of PINs by claiming another BD_ADDR each time. It is the application's responsibility to take countermeasures against this threat. If the device address is kept fixed, the waiting interval before the next try may be increased exponentially (see Section 5.1).

The details of the E_{22} algorithm can be found in Section 6.3.

3.2.2 Authentication

The legacy authentication procedure shall be carried out as described in Section 5. During each legacy authentication, a new AU_RAND_A shall be issued.

For legacy authentication, mutual authentication is achieved by first performing the authentication procedure in one direction and then immediately performing the authentication procedure in the opposite direction.

The secure authentication procedure is always a mutual authentication. Secure authentication shall be carried out as described in Section 7.7.8. During each secure authentication, new AU_RAND_C and AU_RAND_P shall be used.

As a side effect of a successful authentication procedure an auxiliary parameter, the Authenticated Ciphering Offset (ACO), will be computed. The ACO shall be used for ciphering key generation as described in Section 3.2.5.

The claimant/verifier status is determined by the LM.

3.2.3 [This section is no longer used]

3.2.4 Generation of a combination key

To use a combination key, it is first generated during the initialization procedure. The combination key is the combination of two numbers generated in device A and B, respectively. First, each device shall generate a random number, LK_RAND_A and LK_RAND_B. Then, utilizing E_{21} with the random number and their own BD_ADDRs, the two random numbers

$$LK\_K_A = E_{21}(LK\_RAND_A, BD\_ADDR\_A), \quad \text{(EQ 1)}$$

and

$$LK\_K_B = E_{21}(LK\_RAND_B, BD\_ADDR\_B), \quad \text{(EQ 2)}$$

shall be created in device A and device B, respectively. These numbers constitute the devices' contribution to the combination key that is to be created. Then, the two random numbers *LK_RAND*$_A$ and *LK_RAND*$_B$ shall be exchanged securely by XORing with the current link key, K. Thus, device A shall send $CA = K \oplus LK\_RAND_A$ to device B, while device B shall send $CB = K \oplus LK\_RAND_B$ to device A. If this is done during the initialization phase the link key $K = K_{init}$. If CA is identical to CB, then the devices shall terminate the process of generating the combination key (e.g., by rejecting the following authentication).

When the random numbers LK_RAND_A and LK_RAND_B have been mutually exchanged, each device shall recalculate the other device's contribution to the combination key. This is possible since each device knows the Bluetooth Device Address of the other device. Thus, device A shall calculate (EQ 2) and device B shall calculate (EQ 1). After this, both devices shall XOR the two numbers to generate the 128-bit link key. The result shall be stored in device A as the link key K_{AB} and in device B as the link key K_{BA}. If the resulting link key consists of all zeroes, then the devices shall discard the link key and terminate the process of generating the combination key (see [Vol 2] Part C, Section 4.2.1). When both devices have derived the new combination key, a mutual authentication procedure shall be initiated to confirm the success of the transaction. The old link key shall be discarded after a successful exchange of a new combination key. The message flow between Central and Peripheral and the principle for creating the combination key is depicted in Figure 3.1.

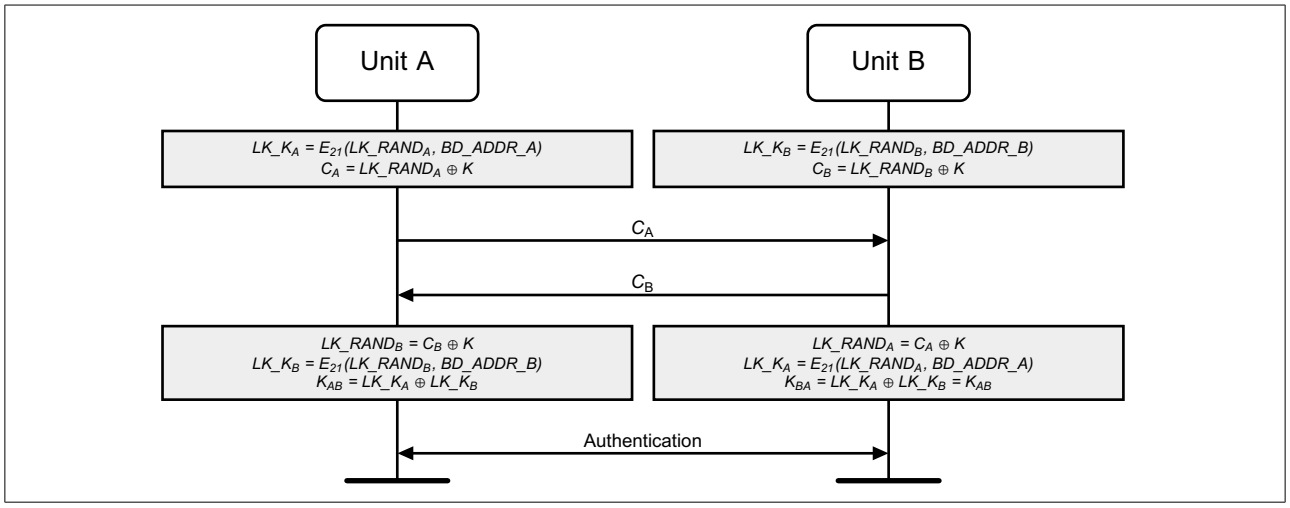

Figure 3.1: Generating a combination key. The old link key (K) is discarded after the exchange of a new combination key has succeeded.

3.2.5 Generating the encryption key

The encryption key, K_enc, is derived by algorithm E_3 from the current link key, a 96-bit Ciphering OFfset number (COF), and a 128-bit random number. The COF is determined in one of two ways. If the current link key is a temporary link key, then COF shall be derived from the Central's BD_ADDR. Otherwise the value of COF shall be set to the value of ACO as computed during the authentication procedure. Therefore:

$$\text{COF} = \begin{cases} \text{BD\_ADDR} \parallel \text{BD\_ADDR}, & \text{if link key is a temporary key} \\ \text{ACO}, & \text{otherwise.} \end{cases} \quad \text{(EQ 3)}$$

There is an explicit call of E_3 when the LM activates encryption. Consequently, the encryption key is automatically changed each time the device enters encryption mode. The details of the key generating function E_3 can be found in Section 6.4.

3.2.6 Point-to-multipoint configuration

It is possible for the Central to use separate encryption keys for each Peripheral in a point-to-multipoint configuration with ciphering activated. Then, if the application requires more than one Peripheral to listen to the same payload, each Peripheral must be addressed individually. This can cause unwanted capacity loss for the piconet. Moreover, a Peripheral might not be capable of switching between two or more encryption keys in real time (e.g., after looking at the LT_ADDR in the header). Thus, the Central cannot use different encryption keys for broadcast messages and individually addressed traffic. Therefore, the Central may tell several Peripherals to use a common link key (and, hence, indirectly also to use a common encryption key) and may then broadcast the information encrypted. For many applications, this key is only of temporary interest. In the following discussion, this key is denoted by K_temp.

The transfer of necessary parameters shall be protected by the routine described in Section 3.2.8. After the confirmation of successful reception in each Peripheral, the Central shall issue a command to the Peripherals to replace their respective current link key by the new temporary link key. Before encryption can be activated, the Central shall also generate and distribute a common EN_RAND to all participating Peripherals. Using this random number and the newly derived temporary link key, each Peripheral shall generate a new encryption key.

The Central negotiates the encryption key length to use individually with each Peripheral that will use the temporary link key. If the Central has already negotiated with some of these Peripherals, it has knowledge of the sizes that can be accepted. There may be situations where the permitted key lengths of some devices are incompatible. In that case, the Central shall exclude the limiting device from the group.

When all Peripherals have received the necessary data, the Central can communicate information on the piconet securely using the encryption key derived from the new

temporary link key. Each Peripheral in possession of the temporary link key can eavesdrop on all encrypted traffic, not only the traffic intended for itself. The Central may tell all participants to fall back to their old link keys simultaneously.

3.2.7 Modifying the link keys

If the key change concerns combination keys, then the procedure is straightforward. The change procedure is identical to the procedure described in Figure 3.1, using the current value of the combination key as link key. This procedure can be carried out at any time after the authentication and encryption start. Since the combination key corresponds to a single link, it can be modified each time this link is established. This will improve the security of the system since then old keys lose their validity after each session.

Starting up an entirely new initialization procedure is also possible. In that case, user interaction is necessary since a PIN will be required in the authentication and encryption procedures.

3.2.8 Generating a temporary link key

The key-change routines described so far are semi-permanent. To create the temporary link key, which can replace the current link key during a session (see Section 3.2.6), other means are needed. First, the Central shall create a new link key from two 128-bit random numbers, RAND1 and RAND2. This shall be done by

$$\text{K\_temp} = E_{22}(\text{RAND1}, \text{RAND2}, 16). \quad \text{(EQ 4)}$$

This key is a 128-bit random number. The reason for using the output of E_{22} and not directly choosing a random number as the key, is to avoid possible problems with degraded randomness due to a poor implementation of the random number generator within the device.

Then, a third random number, RAND, shall be transmitted to the Peripheral. Using E_{22} with the current link key and RAND as inputs, both the Central and the Peripheral shall compute a 128-bit overlay. The Central shall send the bitwise XOR of the overlay and the new link key to the Peripheral. The Peripheral, who knows the overlay, shall recalculate K_temp. To confirm the success of this transaction, the devices shall perform a mutual authentication procedure using the new link key. This procedure shall then be repeated for each Peripheral that receives the new link key. The ACO values from the authentications shall not replace the current ACO, as this ACO is needed to (re)compute a ciphering key when the Central falls back to the previous (semi-permanent) link key.

The Central activates encryption by an LM command. Before activating encryption, the Central shall ensure that all Peripherals receive the same random number, EN_RAND,

since the encryption key is derived through the means of E_3 individually in all participating devices. Each Peripheral shall compute a new encryption key as follows:

$$\text{K\_enc} = E_3(\text{K\_temp}, \text{EN\_RAND}, \text{COF}) \quad \text{(EQ 5)}$$

where the value of COF shall be derived from the Central's BD_ADDR as specified by equation (EQ 3). The details of the encryption key generating function are described in Section 6.4. The message flow between the Central and the Peripheral when generating the temporary link key is depicted in Figure 3.2.

Note: In this case the ACO produced during the authentication is not used when computing the ciphering key.

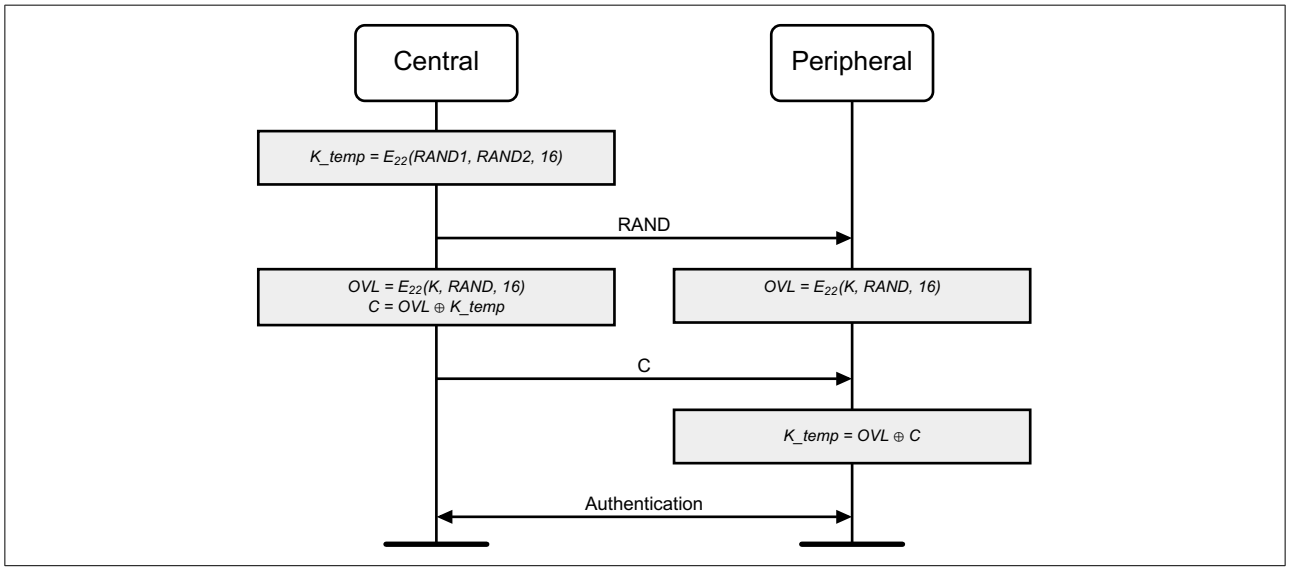

Figure 3.2: Temporary link key distribution and computation of the corresponding encryption key

4 ENCRYPTION (E0)

User information can be protected by encryption of the packet payload; the access code and the packet header shall never be encrypted. The encryption of the payload shall be carried out with a stream cipher called E_0 that shall be re-synchronized for every payload. The overall principle is shown in Figure 4.1.

The stream cipher system E_0 shall consist of three parts:

- the first part performs initialization (generation of the session key). The session key generator shall combine the input bits in an appropriate order and shall shift them into the four LFSRs used in the key stream generator.
- the second part generates the key stream bits and shall use a method derived from the summation stream cipher generator attributable to Massey and Rueppel. The second part is the main part of the cipher system, as it will also be used for initialization.
- the third part performs encryption and decryption.

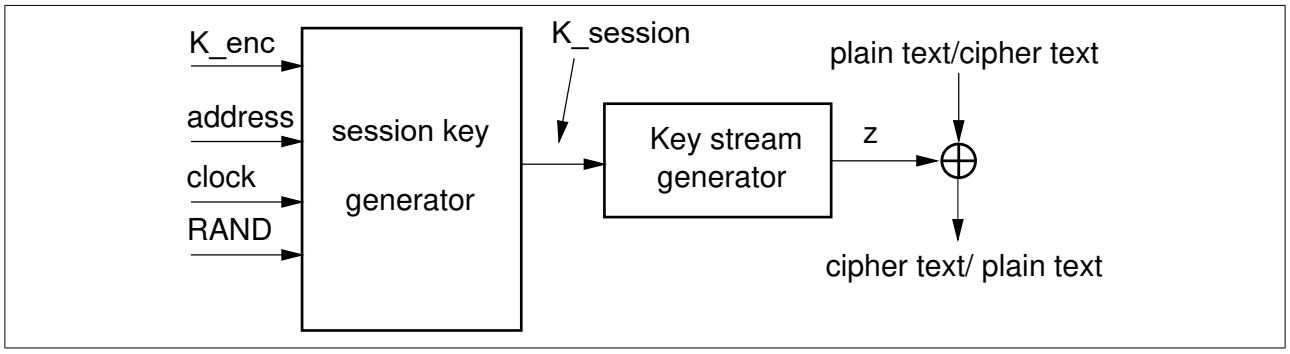

Figure 4.1: Stream ciphering for Bluetooth with E_0.

4.1 Encryption key size negotiation

Each device implementing the Baseband specification shall have a parameter defining the maximal allowed key length, L_max, 1 ≤ L_max ≤ 16 (number of octets in the key). For each application using encryption, a number L_min shall be defined indicating the shortest acceptable key size for that particular application. Before generating the encryption key, the devices involved shall negotiate to decide the key size to use.

The Central shall send a suggested value, L_sug_c, to the Peripheral. Initially, the suggested value shall be set to L_max_c. If L_min_p ≤ L_sug_c, and, the Peripheral supports the suggested length, the Peripheral shall acknowledge and this value shall be the length of the encryption key for this link. However, if both conditions are not fulfilled, the Peripheral shall send a new proposal, L_sug_p < L_sug_c, to the Central. This

value shall be the largest among all supported lengths less than the previous Central suggestion. Then, the Central shall perform the corresponding test on the Peripheral suggestion. This procedure shall be repeated until a key length agreement is reached, or, one device aborts the negotiation. An abort may be caused by lack of support for L_sug and all smaller key lengths, or if L_sug < L_min in one of the devices. In case of an abort link encryption cannot be employed.

The possibility of a failure in setting up a secure link is an unavoidable consequence of letting the application decide whether to accept or reject a suggested key size. However, this is a necessary precaution. Otherwise a fraudulent device could enforce a weak protection on a link by claiming a short maximum key size.

4.2 Encryption of broadcast messages

There may be three settings for the Baseband regarding encryption:

1. No encryption.

   This is the default setting. No messages are encrypted

2. Point-to-point only encryption.

   Broadcast messages are not encrypted. This may be enabled either during the connection establishment procedure or after the connection has been established.

3. Point-to-point and broadcast encryption.

   All messages are encrypted. This may be enabled after the connection has been established only. This setting should not be enabled unless all affected links share the same temporary link key as well as the same EN_RAND value, both used in generating the encryption key.

Broadcast traffic	Individually addressed traffic
No encryption	No encryption
No encryption	Encryption (semi-permanent link key)
Encryption (temporary link key)	Encryption (temporary link key)

Table 4.1: Possible encryption modes for a Peripheral in possession of a temporary link key

4.3 Encryption concept

For the encryption routine, a stream cipher algorithm is used in which ciphering bits are XORed with the data stream to be sent over the air interface. The payload is ciphered after the CRC bits are appended, but, prior to the FEC encoding.

Each packet payload shall be ciphered separately. The cipher algorithm E_0 uses the Central's Bluetooth Device Address (BD_ADDR_C), 26 bits of the Central real-time clock ($CLK_{26\text{-}1}$) and the encryption key K_enc as input, see Figure 4.2.

The encryption key K_enc is derived from the current link key, COF, and a random number, EN_RAND_C (see Section 6.4). The random number shall be issued by the Central before entering encryption mode.

Note: EN_RAND_C is publicly known since it is transmitted as plain text over the air.

Within the E_0 algorithm, the encryption key K_enc is modified into another key denoted K_session. The maximum effective size of this key shall be factory preset and may be set to any multiple of eight between one and sixteen (i.e. 8 to 128 bits). The procedure for deriving the key is described in Section 4.5.

The E_0 algorithm shall be re-initialized at the start of each new packet (i.e. for Central-to-Peripheral as well as for Peripheral-to-Central transmission). By using $CLK_{26\text{-}1}$ at least one bit is changed between two transmissions. Thus, a new keystream is generated after each re-initialization. For packets covering more than a single slot, the Bluetooth clock as found in the first slot shall be used for the entire packet.

The encryption algorithm E_0 generates a binary keystream, K_{cipher}, which shall be XORed with the data to be encrypted. The cipher is symmetric; decryption shall be performed in exactly the same way using the same key as used for encryption.

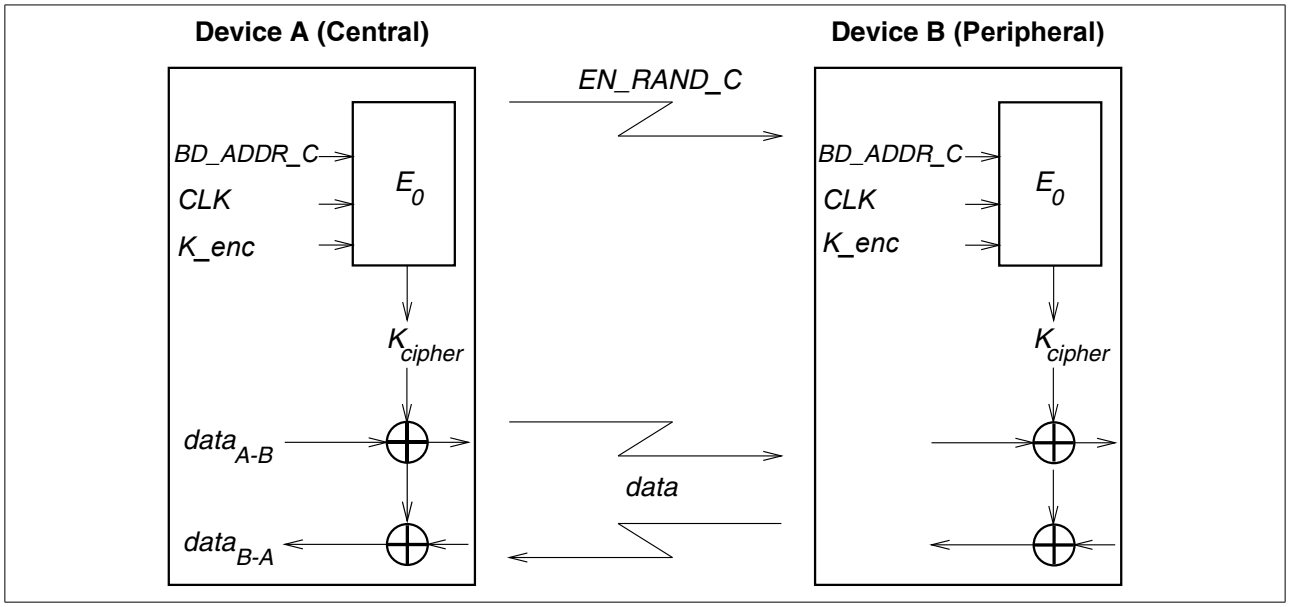

Figure 4.2: Functional description of the encryption procedure

4.4 Encryption algorithm

The system uses linear feedback shift registers (LFSRs) whose output is combined by a simple finite state machine (called the summation combiner) with 16 states. The output of this state machine is the key stream sequence, or, during initialization phase, the randomized initial start value. The algorithm uses an encryption key K_enc, a

48-bit Bluetooth address, the Central's clock bits $CLK_{26\text{-}1}$, and a 128-bit RAND value. Figure 4.3 shows the setup.

There are four LFSRs ($LFSR_1$,...,$LFSR_4$) of lengths $L_1 = 25$, $L_2 = 31$, $L_3 = 33$, and, $L_4 = 39$, with feedback polynomials as specified in Table 4.2. The total length of the registers is 128. These polynomials are all primitive. The Hamming weight of all the feedback polynomials is five.

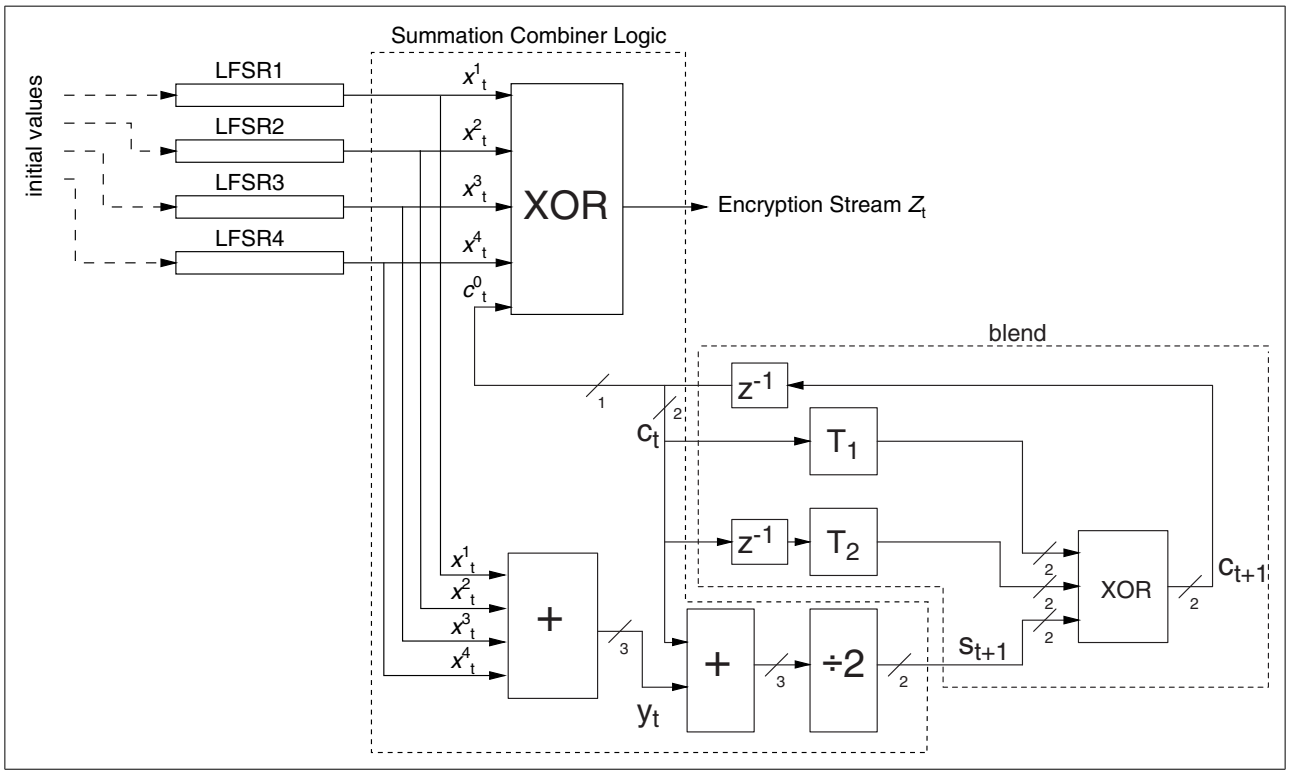

Figure 4.3: Concept of the E_0 encryption algorithm

i	L_i	**feedback** $f_i(t)$	**weight**
1	25	$t^{25} + t^{20} + t^{12} + t^8 + 1$	5
2	31	$t^{31} + t^{24} + t^{16} + t^{12} + 1$	5
3	33	$t^{33} + t^{28} + t^{24} + t^4 + 1$	5
4	39	$t^{39} + t^{36} + t^{28} + t^4 + 1$	5

Table 4.2: The four primitive feedback polynomials

Let x_t^i denote the t^{th} symbol of $LFSR_i$. The value y_t is derived from the four-tuple $x_t^1, \ldots, x_t^4$ using the following equation:

$$y_t = \sum_{i=1}^{4} x_t^i, \qquad \text{(EQ 6)}$$

where the sum is over the integers. Thus y_t can take the values 0,1,2,3, or 4. The output of the summation generator is obtained by the following equations:

$$z_t = x_t^1 \oplus x_t^2 \oplus x_t^3 \oplus x_t^4 \oplus c_t^0 \in \{0, 1\}, \qquad \text{(EQ 7)}$$

$$s_{t+1} = \left(s_{t+1}^1, s_{t+1}^0\right) = \left\lfloor \frac{y_t + c_t}{2} \right\rfloor \in \{0, 1, 2, 3\}, \qquad \text{(EQ 8)}$$

$$c_{t+1} = \left(c_{t+1}^1, c_{t+1}^0\right) = s_{t+1} \oplus T_1[c_t] \oplus T_2[c_{t-1}], \qquad \text{(EQ 9)}$$

where $T_1[\,.\,]$ and $T_2[\,.\,]$ are two different linear bijections over GF(4). Suppose GF(4) is generated by the irreducible polynomial $x^2 + x + 1$, and let α be a zero of this polynomial in GF(4). The mappings T_1 and T_2 are now defined as:

$$T_1 : \mathrm{GF}(4) \rightarrow \mathrm{GF}(4)$$
$$x \mapsto x$$
$$T_2 : \mathrm{GF}(4) \rightarrow \mathrm{GF}(4)$$
$$x \mapsto (\alpha + 1)x\,.$$

The elements of GF(4) can be written as binary vectors. This is summarized in Table 4.3.

x	$T_1[x]$	$T_2[x]$
00	00	00
01	01	11
10	10	01
11	11	10

Table 4.3: The mappings T_1 and T_2

Since the mappings are linear, they can be implemented using XOR gates; i.e.

$$T_1 : (x_1, x_0) \mapsto (x_1, x_0),$$
$$T_2 : (x_1, x_0) \mapsto (x_0, x_1 \oplus x_0)\,.$$

4.4.1 The operation of the cipher

Figure 4.4 gives an overview of the operation in time. The encryption algorithm shall run through the initialization phase before the start of transmission or reception of a new

packet. Thus, for multislot packets the cipher is initialized using the clock value of the first slot in the multislot sequence.

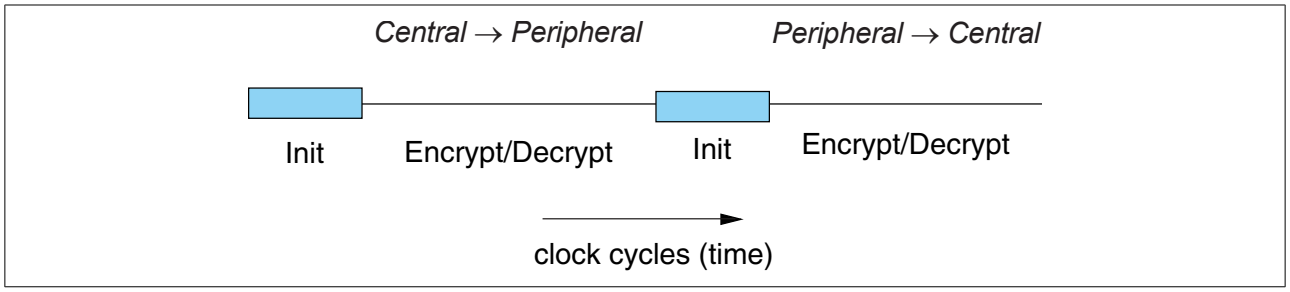

Figure 4.4: Overview of the operation of encryption. Between each start of a packet (TX or RX), the LFSRs are re-initialized.

4.5 LFSR initialization

The key stream generator is loaded with an initial value for the four LFSRs (in total 128 bits) and the 4 bits that specify the values of c_0 and c_{-1}. The 132 bit initial value is derived from four inputs by using the key stream generator. The input parameters are the key K_enc, a 128-bit random number RAND, a 48-bit Bluetooth Device Address, and the 26 Central's clock bits $CLK_{26\text{-}1}$.

The effective length of the encryption key may vary between 8 and 128 bits. The actual key length as obtained from E_3 is 128 bits. Then, within E_0, the key length may be reduced by a *mod* operation between K_enc and a polynomial of desired degree. After reduction, the result is encoded with a block code in order to distribute the starting states more uniformly. The operation shall be as defined in (EQ 10).

When the encryption key has been created the LFSRs are loaded with their initial values. Then, 200 stream cipher bits are created by operating the generator. Of these bits, the last 128 are fed back into the key stream generator as an initial value of the four LFSRs. The values of c_t and c_{t-1} are kept. From this point on, when clocked the generator produces the encryption (decryption) sequence which is bitwise XORed to the transmitted (received) payload data.

In the following, octet i of a binary sequence X is $X[i]$. Bit 0 of X is the LSB. Then, the LSB of $X[i]$ corresponds to bit $8i$ of the sequence X, the MSB of $X[i]$ is bit $8i + 7$ of X. For instance, bit 24 of the Bluetooth Device Address is the LSB of BD_ADDR[3].

The details of the initialization shall be as follows:

1. Create the encryption key to use from the 128-bit secret key K_enc and the 128-bit publicly known EN_RAND. Let L, $1 \leq L \leq 16$, be the effective key length in number of octets. The resulting encryption key is K_session:

$$\text{K\_session}(x) = g_2^{(L)}(x)\left(\text{K\_enc}(x)\ mod\ g_1^{(L)}(x)\right) \quad \text{(EQ 10)}$$

   where $\deg\left(g_1^{(L)}(x)\right) = 8L$ and $\deg\left(g_2^{(L)}(x)\right) \leq 128 - 8L$. The polynomials are defined in Table 4.4.

2. Shift the 3 inputs K_session, the Bluetooth Device Address, the clock, and the six-bit constant 111001 into the LFSRs. In total, 208 bits are shifted in:
   a. Open all switches shown in Figure 4.5;
   b. Arrange inputs bits as shown in Figure 4.5; Set the content of all shift register elements to zero. Set $t = 0$.
   c. Start shifting bits into the LFSRs. The rightmost bit at each level of Figure 4.5 is the first bit to enter the corresponding LFSR.
   d. When the first input bit at level i reaches the rightmost position of $LFSR_i$, close the switch of this LFSR.
   e. At $t = 39$ (when the switch of $LFSR_4$ is closed), reset both blend registers $c_{39} = c_{39-1} = 0$; Up to this point, the content of c_t and c_{t-1} has been of no concern. However, their content will now be used in computing the output sequence.
   f. From now on output symbols are generated. The remaining input bits are continuously shifted into their corresponding shift registers. When the last bit has been shifted in, the shift register is clocked with input = 0;

      Note: When finished, $LFSR_1$ has effectively clocked 30 times with feedback closed, $LFSR_2$ has clocked 24 times, $LFSR_3$ has clocked 22 times, and $LFSR_4$ has effectively clocked 16 times with feedback closed.

3. To mix initial data, continue to clock until 200 symbols have been produced with all switches closed ($t = 239$);

4. Keep blend registers c_t and c_{t-1}, make a parallel load of the last 128 generated bits into the LFSRs according to Figure 4.6 at $t = 240$;

After the parallel load in item 4, the blend register contents shall be updated for each subsequent clock.

Table 4.4: Polynomials used when creating K_session[1]

[1]All polynomials are in hexadecimal notation. The LSB is in the rightmost position.

In Figure 4.5, all bits are shifted into the LFSRs, starting with the least significant bit (LSB). For instance, from the third octet of the address, BD_ADDR[2], first BD_ADDR_{16} is entered, followed by BD_ADDR_{17}, etc. Furthermore, CL_0 corresponds to CLK_1,..., CL_{25} corresponds to CLK_{26}.

Note: The output symbols x_t^i, $i = 1, ..., 4$ are taken from the positions 24, 24, 32, and 32 for $LFSR_1$, $LFSR_2$,$LFSR_3$, and $LFSR_4$, respectively (counting the leftmost position as number 1).

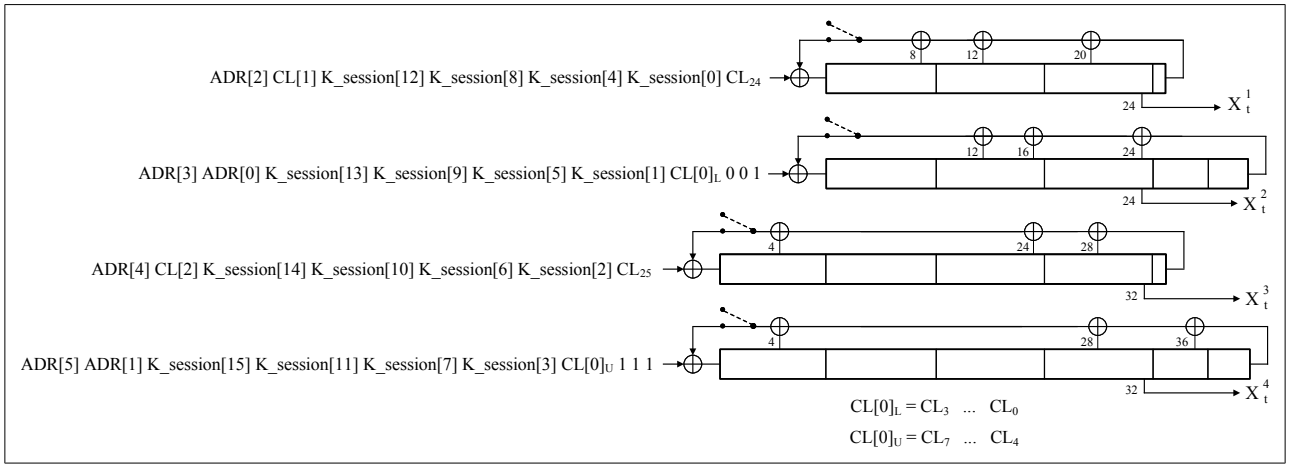

Figure 4.5: Arranging the input to the LFSRs

In Figure 4.6, the 128 binary output symbols Z_0,..., Z_{127} are arranged in octets denoted Z[0],..., Z[15]. The LSB of Z[0] corresponds to the first of these symbols, the MSB of Z[15] is the last output from the generator. These bits shall be loaded into the LFSRs according to the figure. It is a parallel load and no update of the blend registers is done. The first output symbol is generated at the same time. The octets shall be written into the registers with the LSB in the leftmost position (i.e. the opposite of before). For example, Z_{24} is loaded into position 1 of $LFSR_4$.

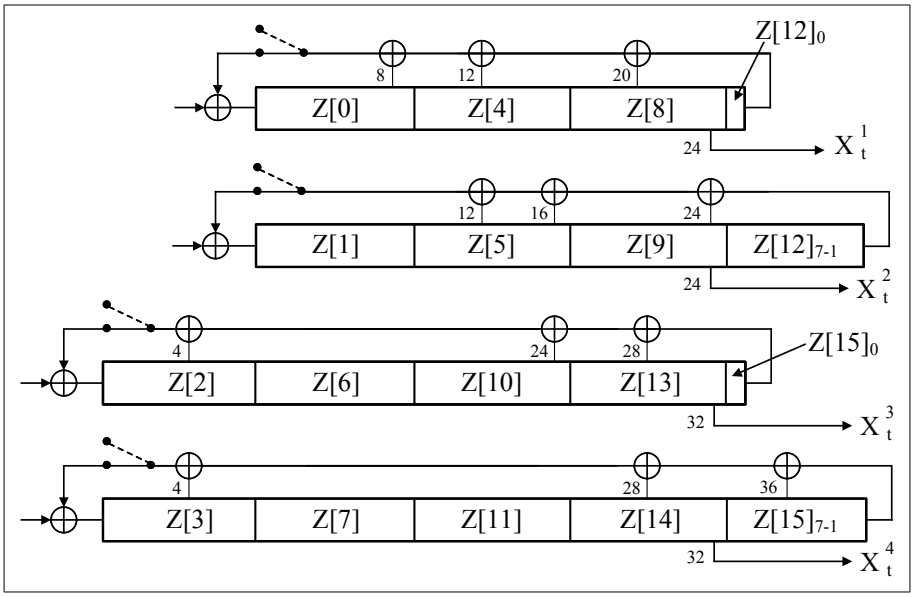

Figure 4.6: Distribution of the 128 last generated output symbols within the LFSRs.

4.6 Key stream sequence

When the initialization is finished, the output from the summation combiner is used for encryption/decryption. The first bit to use shall be the one produced at the parallel load, i.e. at $t = 240$. The circuit shall be run for the entire length of the current payload. Then, before the reverse direction is started, the entire initialization process shall be repeated with updated values on the input parameters.

Sample data of the encryption output sequence can be found in [Vol 2] Part G, Section 1.1. All implementations of encryption shall produce these encryption streams for the given initialization values.

5 AUTHENTICATION

Legacy authentication uses a challenge-response scheme in which a claimant's knowledge of a secret key is checked through a 2-move protocol using symmetric secret keys. The latter implies that a correct claimant/verifier pair share the same secret key, for example K. In the challenge-response scheme the verifier challenges the claimant to authenticate a random input (the challenge), denoted by AU_RAND_A, with an authentication code, denoted by E_1, and return the result SRES to the verifier, see Figure 5.1. This figure also shows that the input to E_1 consists of the tuple AU_RAND_A and the Bluetooth Device Address (BD_ADDR_B) of the claimant. The use of this address prevents a simple reflection attack[1]. The secret K shared by devices A and B is the current link key.

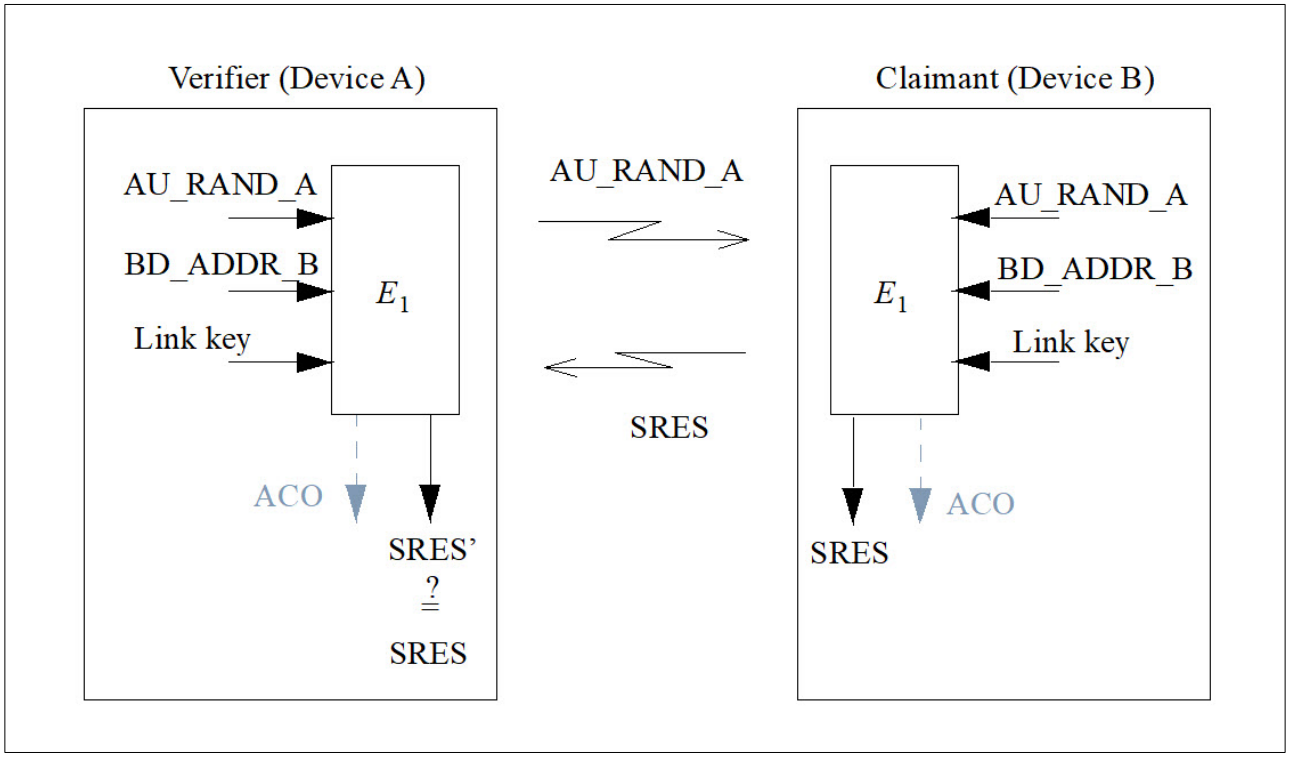

Figure 5.1: Challenge-response for the Bluetooth.

The challenge-response scheme for symmetric keys in legacy authentication is depicted in Figure 5.2.

[1]The reflection attack actually forms no threat because all service requests are dealt with on a FIFO basis. When preemption is introduced, this attack is potentially dangerous.

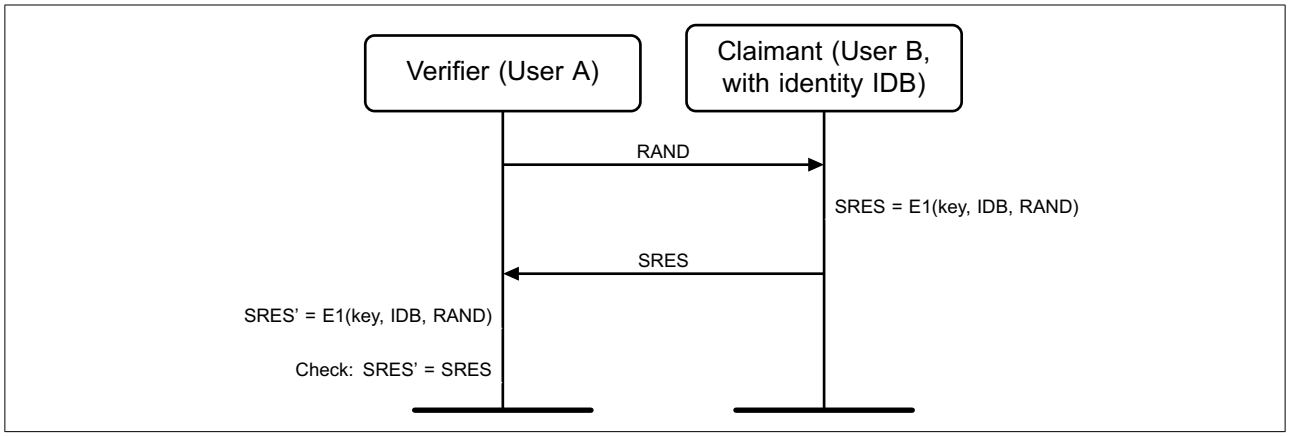

Figure 5.2: Challenge-response for symmetric key systems.

In legacy authentication, the verifier is not required to be the Central. The application indicates which device has to be authenticated. Some applications only require a one-way authentication. However, some peer-to-peer communications, should use a mutual authentication in which each device is subsequently the challenger (verifier) in two authentication procedures. The LM shall process authentication preferences from the application to determine in which direction(s) the authentication(s) takes place. For mutual authentication with the devices of Figure 5.1, after device A has successfully authenticated device B, device B could authenticate device A by sending an AU_RAND_B (different from the AU_RAND_A that device A issued) to device A, and deriving the SRES and SRES' from the new AU_RAND_B, the address of device A, and the link key K_{AB}.

If a legacy authentication is successful the value of ACO as produced by E_1 shall be retained.

Secure Authentication uses a challenge-response scheme in which both devices act as a verifier and claimant in the same sequence where the knowledge of a secret key is checked through a 4-move protocol using symmetric secret keys. The latter implies that a correct claimant/verifier pair share the same secret key, for example K. In the challenge-response scheme the Central challenges the Peripheral to authenticate a random input (the challenge), denoted by AU_RAND_C, with an authentication code, denoted by h4 and h5, and return the resulting SRES_P to the verifier, see Figure 5.3. Similarly, the Peripheral challenges the Central to authenticate a random input (the challenge), denoted AU_RAND_P, with an authentication code, denoted by h4 and h5, and return the resulting SRES_C to the verifier. This figure also shows that the inputs to h4 and h5 consist of a secret, a string “btdk”, the Bluetooth Device Address of the Central (BD_ADDR_C), and the Bluetooth Device Address of the Peripheral (BD_ADDR_P). The use of these addresses prevents a simple reflection attack. The secret *K* shared by the Central and Peripheral is the current link key.

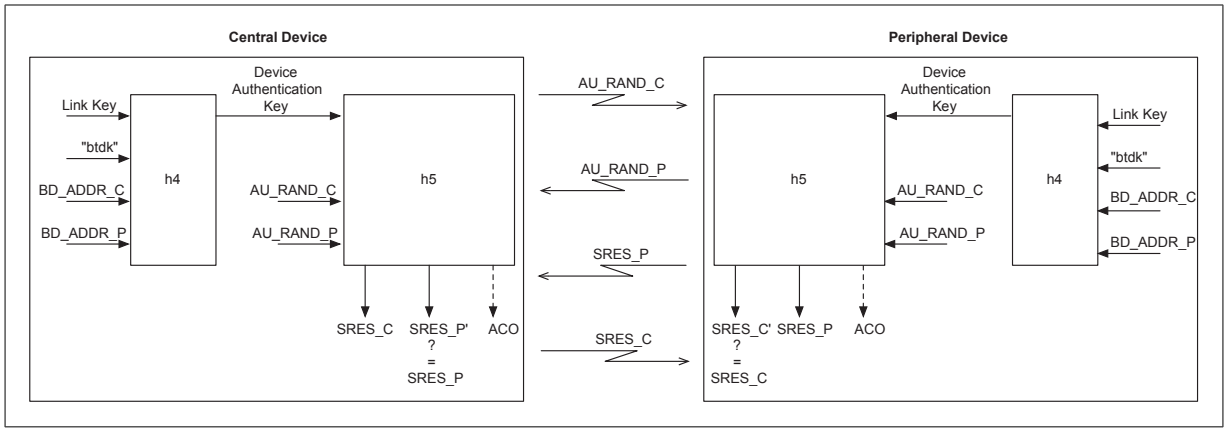

Figure 5.3: Challenge and response for secure authentication.

The challenge-response scheme for symmetric keys in secure authentication when initiated by the Central is depicted in Figure 5.4.

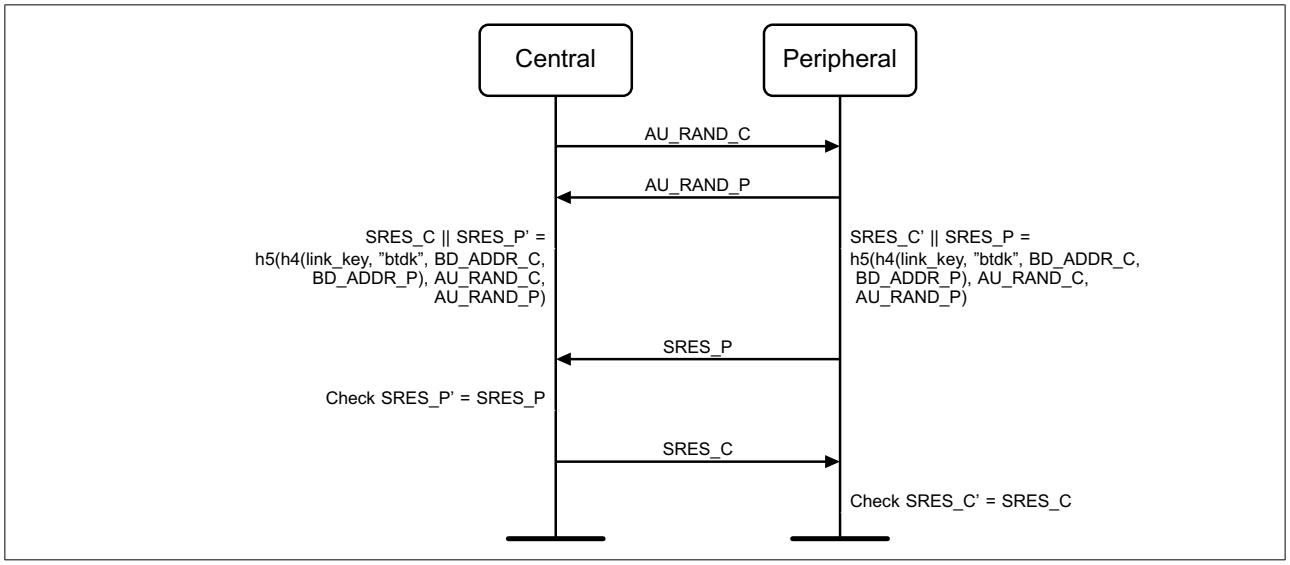

Figure 5.4: Challenge-response for secure authentication.

For the purposes of this authentication protocol the roles used are those applying when the initiating device sends its AU_RAND to the responder, irrespective of whether a role switch happens during the protocol. The device that sends AU_RAND_C shall check SRES_P and the device that sends AU_RAND_P shall check SRES_C. Alternatively, the device may reject the request for a role switch during the protocol.

In secure authentication, both the Central and Peripheral are the verifier and claimant. The application indicates which device has to be authenticated, but secure authentication is always a mutual authentication.

If a secure authentication is successful the value of ACO as produced by h5 shall be retained.

5.1 Repeated attempts

When the authentication attempt fails, a waiting interval shall pass before the verifier will initiate a new authentication attempt to the same claimant, or before it will respond to an authentication attempt initiated by a device claiming the same identity as the failed device. For each subsequent authentication failure, the waiting interval shall be increased exponentially. For example, after each failure, the waiting interval before a new attempt can be made could be twice as long as the waiting interval prior to the previous attempt[1]. The waiting interval shall be limited to a maximum.

The maximum waiting interval depends on the implementation. The waiting time shall exponentially decrease to a minimum when no new failed attempts are made during a certain time period. This procedure restricts the rate at which an intruder can repeat the authentication procedure with different keys.

To protect a device's private key, a device should implement a method to prevent an attacker from retrieving useful information about the device's private key. For this purpose, a device should change its private key after every pairing (successful or failed). Otherwise, it should change its private key whenever S + 3F > 8, where S is the number of successful pairings and F the number of failed attempts since the key was last changed.

[1]Another appropriate value larger than 1 may be used.

6 THE AUTHENTICATION AND KEY-GENERATING FUNCTIONS

This section describes the algorithms used for authentication and key generation.

6.1 The authentication function E_1

The authentication function E_1 is a computationally secure authentication code. E_1 uses the encryption function SAFER+. The algorithm is an enhanced version of an existing 64-bit block cipher SAFER-SK128, and it is freely available. In the following discussion, the block cipher will be denoted as the function A_r which maps using a 128-bit key, a 128-bit input to a 128-bit output, i.e.

$$\begin{aligned} A_r: \{0,1\}^{128} \times \{0,1\}^{128} &\rightarrow \{0,1\}^{128} \\ (k \times x) &\mapsto t\,. \end{aligned} \qquad \text{(EQ 11)}$$

The details of A_r are given in the next section. The function E_1 is constructed using A_r as follows

$$\begin{aligned} E_1: \{0,1\}^{128} \times \{0,1\}^{128} \times \{0,1\}^{48} &\rightarrow \{0,1\}^{32} \times \{0,1\}^{96} \\ (K, \text{RAND}, \text{address}) &\mapsto (\text{SRES}, \text{ACO}), \end{aligned} \qquad \text{(EQ 12)}$$

where $\text{SRES} = Hash(K, \text{RAND}, \text{address}, 6)[0, \ldots, 3]$, where $Hash$ is a keyed hash function defined as[1]

$$\begin{aligned} &Hash: \{0,1\}^{128} \times \{0,1\}^{128} \times \{0,1\}^{8 \times L} \times \{6, 12\} \rightarrow \{0,1\}^{128} \\ &(K, I_1, I_2, L) \mapsto A'_r\left(\left[\widetilde{K}\right], [E(I_2, L) +_{16} (A_r(K, I_1) \oplus I_1)]\right), \end{aligned} \qquad \text{(EQ 13)}$$

and where

$$\begin{aligned} E = \{0,1\}^{8 \times L} \times \{6, 12\} &\rightarrow \{0,1\}^{8 \times 16} \\ (X[0, \ldots, L-1], L) &\mapsto (X[i(mod\ \text{L})] \text{ for } i = 0 \ldots 15), \end{aligned} \qquad \text{(EQ 14)}$$

is an expansion of the L octet word X into a 128-bit word. The function A_r is evaluated twice for each evaluation of E_1. The key $\widetilde{K}$ for the second use of A_r (actually A'_r) is offset from K as follows[2]

[1] In this section and in Figure 6.3, the operator $+_{16}$ denotes addition *mod* 256 of each of the 16 octets separately.

[2] The constants are the largest primes below 257 for which 10 is a primitive root.

$$
\begin{aligned}
\widetilde{K}\left[0\right] &= (K[0] + 233) \mod 256, & \widetilde{K}[1] &= K[1] \oplus 229, \\
\widetilde{K}\left[2\right] &= (K[2] + 223) \mod 256, & \widetilde{K}[3] &= K[3] \oplus 193, \\
\widetilde{K}\left[4\right] &= (K[4] + 179) \mod 256, & \widetilde{K}[5] &= K[5] \oplus 167, \\
\widetilde{K}\left[6\right] &= (K[6] + 149) \mod 256, & \widetilde{K}[7] &= K[7] \oplus 131, \\
\widetilde{K}\left[8\right] &= K[8] \oplus 233, & \widetilde{K}[9] &= (K[9] + 229) \mod 256, \\
\widetilde{K}\left[10\right] &= K[10] \oplus 223, & \widetilde{K}[11] &= (K[11] + 193) \mod 256, \\
\widetilde{K}\left[12\right] &= K[12] \oplus 179, & \widetilde{K}[13] &= (K[13] + 167) \mod 256, \\
\widetilde{K}\left[14\right] &= K[14] \oplus 149, & \widetilde{K}[15] &= (K[15] + 131) \mod 256,
\end{aligned}
\qquad \text{(EQ 15)}
$$

A data flowchart of the computation of E_1 is shown in Figure 6.1. E_1 is also used to deliver the parameter ACO (Authenticated Ciphering Offset) that is used in the generation of the ciphering key by E_3, see equations (EQ 3) and (EQ 23). The value of ACO is formed by octets 4 to 15 of the output of the hash function defined in (EQ 13):

$$\text{ACO} = Hash(K, \text{RAND}, \text{address}, 6)[4, \ldots, 15]. \qquad \text{(EQ 16)}$$

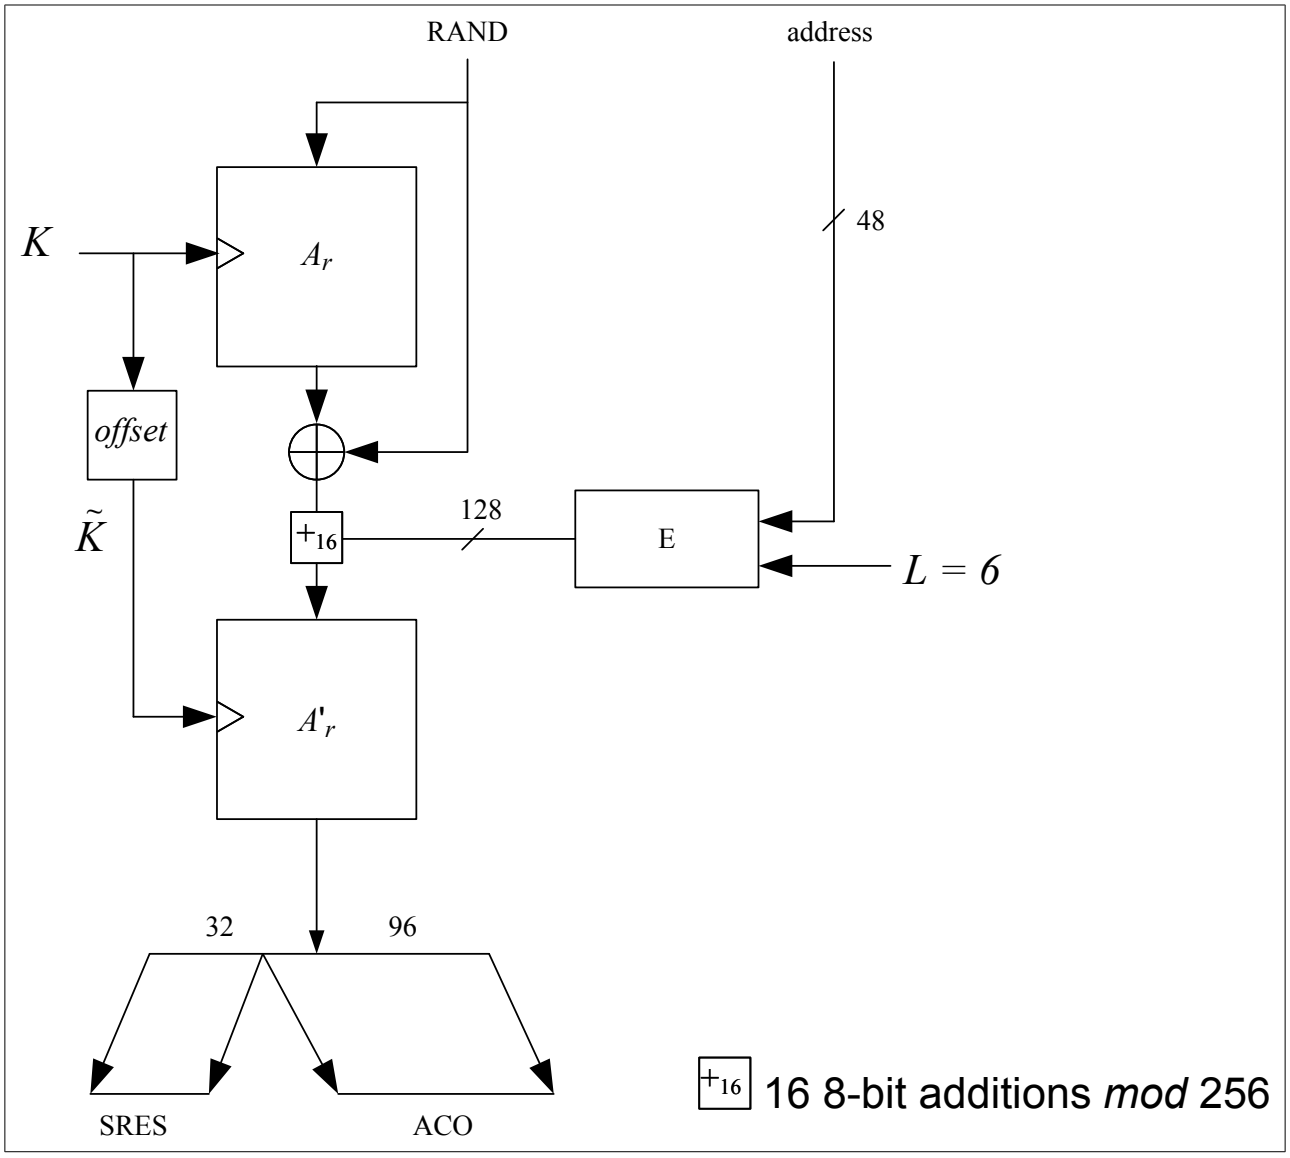

Figure 6.1: Flow of data for the computation of E_1

6.2 The functions A_r and A'_r

The function A_r is identical to SAFER+. It consists of a set of 8 layers, (each layer is called a round) and a parallel mechanism for generating the sub keys $K_p[j], p = 1, 2, \ldots, 17$, which are the round keys to be used in each round. The function will produce a 128-bit result from a 128-bit random input string and a 128-bit key. Besides the function A_r, a slightly modified version referred to as A'_r is used in which the input of round 1 is added to the input of round 3. This is done to make the modified version non-invertible and prevents the use of A'_r (especially in E_{2x}) as an encryption function. See Figure 6.2 for details.

6.2.1 The round computations

The computations in each round are a composition of encryption with a round key, substitution, encryption with the next round key, and, finally, a Pseudo Hadamard Transform (PHT). The computations in a round shall be as shown in Figure 6.2. The sub keys for round *r*,*r* = 1, 2, ..., 8 are denoted $K_{2r-1}[j]$, $K_{2r}[j]$, j = 0, 1, ..., 15. After the last round $K_{17}[j]$ is applied identically to all previous odd numbered keys.

6.2.2 The substitution boxes “e” and “l”

In Figure 6.2 two boxes are shown, marked “e” and “l”. These boxes implement the same substitutions as are used in SAFER+; i.e. they implement

$$\begin{aligned} e, l &: \{0, \ldots, 255\} \rightarrow \{0, \ldots, 255\}, \\ e &: i \mapsto \left(45^i \ mod\ 257\right) mod\ 256, \\ l &: i \mapsto j \text{ s.t. } i = e(j). \end{aligned}$$

Their role, as in the SAFER+ algorithm, is to introduce non-linearity.

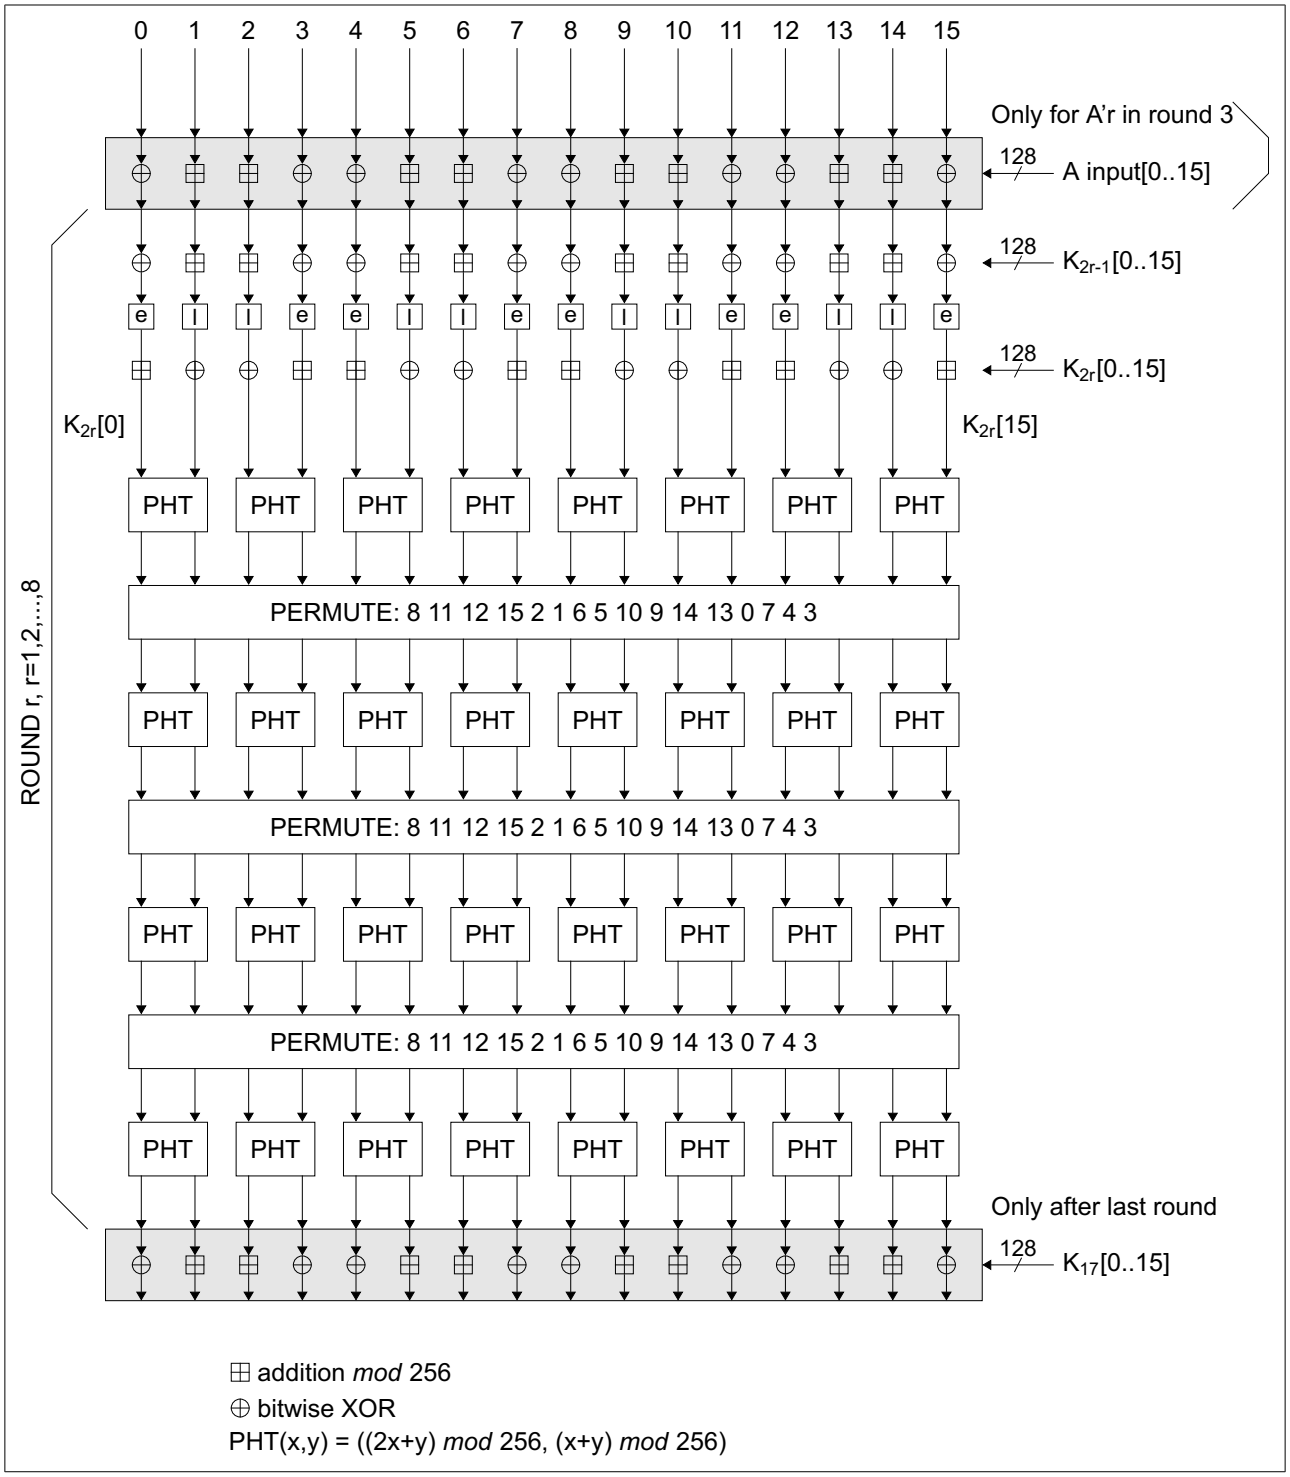

Figure 6.2: One round in A_r and A'_r

In Section 6.2, the permutation boxes show how input byte indices are mapped onto output byte indices. Thus, position 8 is mapped on position 0 (leftmost), position 11 is mapped on position 1, etc.

6.2.3 Key scheduling

In each round, 2 batches of 16 octet-wide keys are needed. These round keys are derived as specified by the key scheduling in SAFER+. Figure 6.3 gives an overview of how the round keys $K_p[j]$ are determined. The bias vectors B_2, B_3, ..., B_{17} shall be computed according to following equation:

$$B_p[i] = \left(\left(45^{\left(45^{17p+i+1} \bmod 257\right)} \bmod 257\right) \bmod 256\right), \text{for } i = 0, \ldots, 15. \quad \text{(EQ 17)}$$

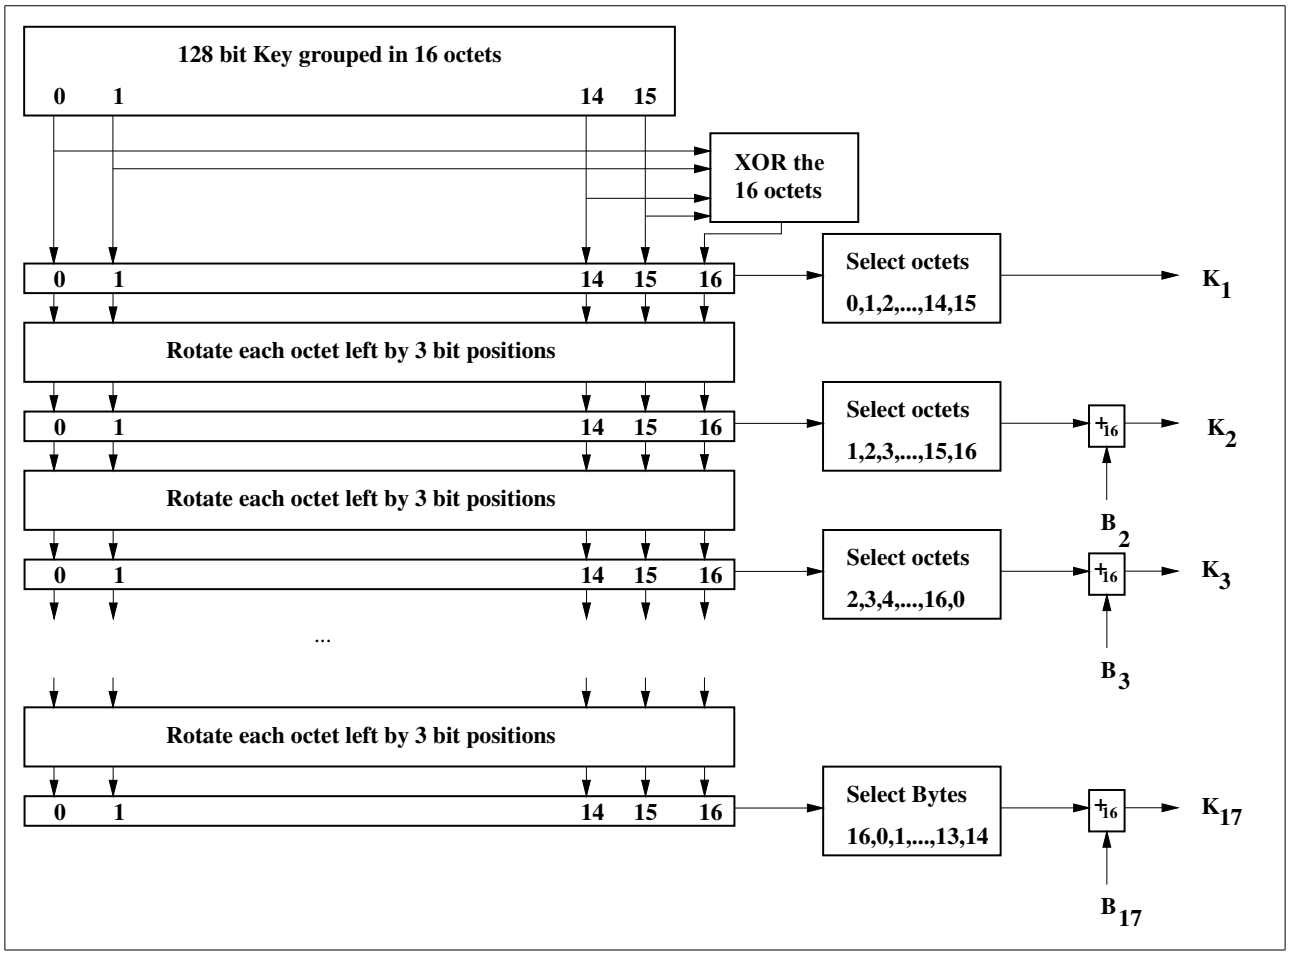

Figure 6.3: Key scheduling in A_r

6.3 E_2-key generation function for authentication

The key used for authentication shall be derived through the procedure that is shown in Figure 6.4. The figure shows two modes of operation for the algorithm. In the first mode, E_{21} produces a 128-bit link key, K, using a 128-bit RAND value and a 48-bit address. This mode shall be utilized when creating combination keys. In the second mode, E_{22} produces a 128-bit link key, K, using a 128-bit RAND value and an L octet

user PIN. The second mode shall be used to create the initialization key, and also when a temporary link key is to be generated.

When the initialization key is generated, the PIN is augmented with the BD_ADDR, see Section 3.2.1 for which address to use. The augmentation shall always start with the least significant octet of the address immediately following the most significant octet of the PIN. Since the maximum length of the PIN used in the algorithm cannot exceed 16 octets, it is possible that not all octets of BD_ADDR will be used.

This key generating algorithm again exploits the cryptographic function E_2. for mode 1 (denoted E_{21}) is computed according to following equations:

$$\begin{aligned} E_{21}&: \{0,1\}^{128} \times \{0,1\}^{48} \rightarrow \{0,1\}^{128} \\ &(\text{RAND}, \text{address}) \mapsto A'_r(X, Y) \end{aligned} \quad \text{(EQ 18)}$$

where (for mode 1)

$$\begin{cases} X = \text{RAND} \oplus \left(6 \times 2^{120}\right) \\ Y = (\text{address} \parallel \text{address} \parallel \text{address})_{127:0} \end{cases} \quad \text{(EQ 19)}$$

Let L be the number of octets in the user PIN. The augmenting is defined by

$$\text{PIN'} = \text{the L' least significant octets of (BD\_ADDR} \parallel \text{PIN)} \quad \text{(EQ 20)}$$

where L' = min { 16, L+6 }.

Then, in mode 2, E_2 (denoted E_{22}) is

$$\begin{aligned} E_{22}&: \{0,1\}^{8L'} \times \{0,1\}^{128} \times \{1,2,\ldots,16\} \rightarrow \{0,1\}^{128} \\ &(\text{PIN'}, \text{RAND}, \text{L}') \mapsto A'_r(X, Y) \end{aligned} \quad \text{(EQ 21)}$$

where

$$\begin{cases} X = (\text{PIN'} \parallel \text{PIN'} \parallel \text{PIN'})_{127:0} \\ Y = \text{RAND} \oplus \left(\text{L'} \times 2^{120}\right) \end{cases} \quad \text{(EQ 22)}$$

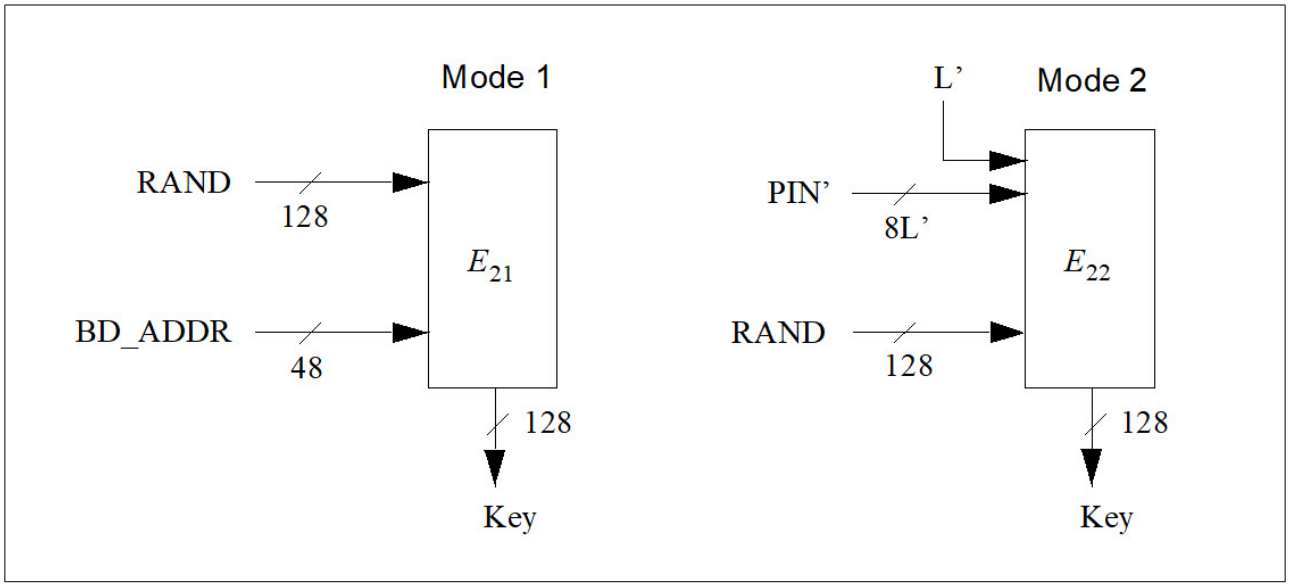

Figure 6.4: Key generating algorithm E_2 and its two modes. Mode 1 is used for combination keys, while mode 2 is used for K_{init} and K_temp

6.4 E_3-key generation function for encryption

The ciphering key K_enc used by E_0 shall be generated by E_3. The function E_3 is constructed using A'_r as follows

$$E_3: \{0,1\}^{128} \times \{0,1\}^{128} \times \{0,1\}^{96} \rightarrow \{0,1\}^{128}$$
$$(K,\ \text{RAND},\ \text{COF}) \mapsto Hash(K,\ \text{RAND},\ \text{COF}, 12) \quad \text{(EQ 23)}$$

where *Hash* is the hash function as defined by (EQ 13). The key length produced is 128 bits. However, before use within E_0, the encryption key K_enc is shortened to the correct encryption key length, as described in Section 4.5. A block scheme of E_3 is depicted in Figure 6.5.

The value of COF is determined as specified by equation (EQ 3).

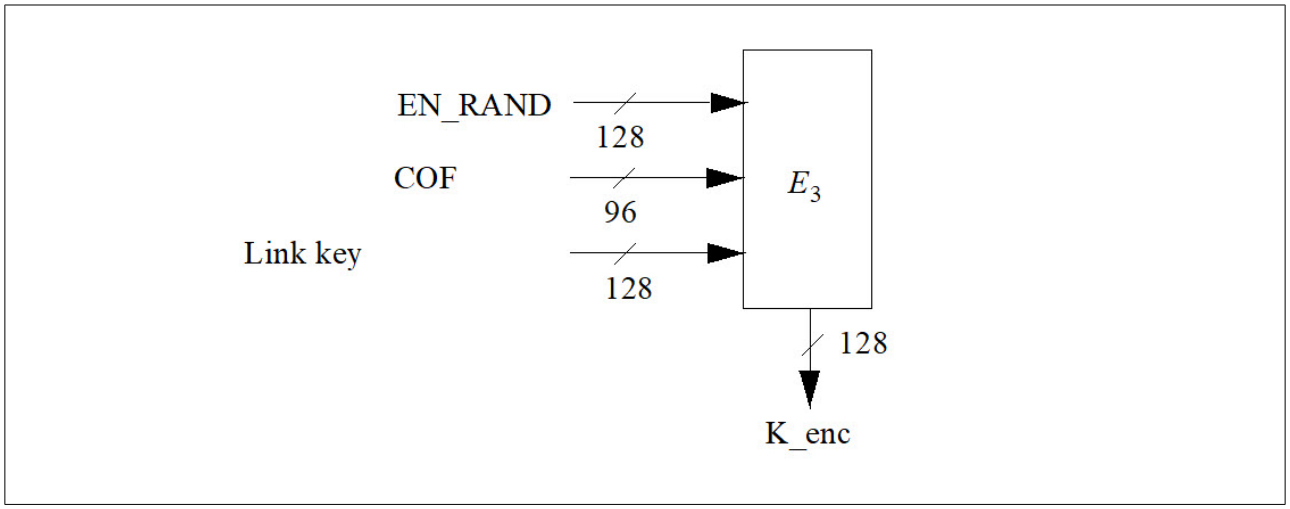

Figure 6.5: Generation of the encryption key

7 SECURE SIMPLE PAIRING

The Secure Simple Pairing security functions and procedures are described in this section. In addition, a cryptographic analysis of each procedure is provided.

There are five phases of Secure Simple Pairing:

- Phase 1: Public key exchange
- Phase 2: Authentication stage 1
- Phase 3: Authentication stage 2
- Phase 4: Link key calculation
- Phase 5: LMP Authentication and Encryption

Phases 1, 3, 4 and 5 are the same for all protocols whereas phase 2 (Authentication stage 1) is different depending on the protocol used. Distributed through these five phases are 13 steps as shown in Figure 7.1.

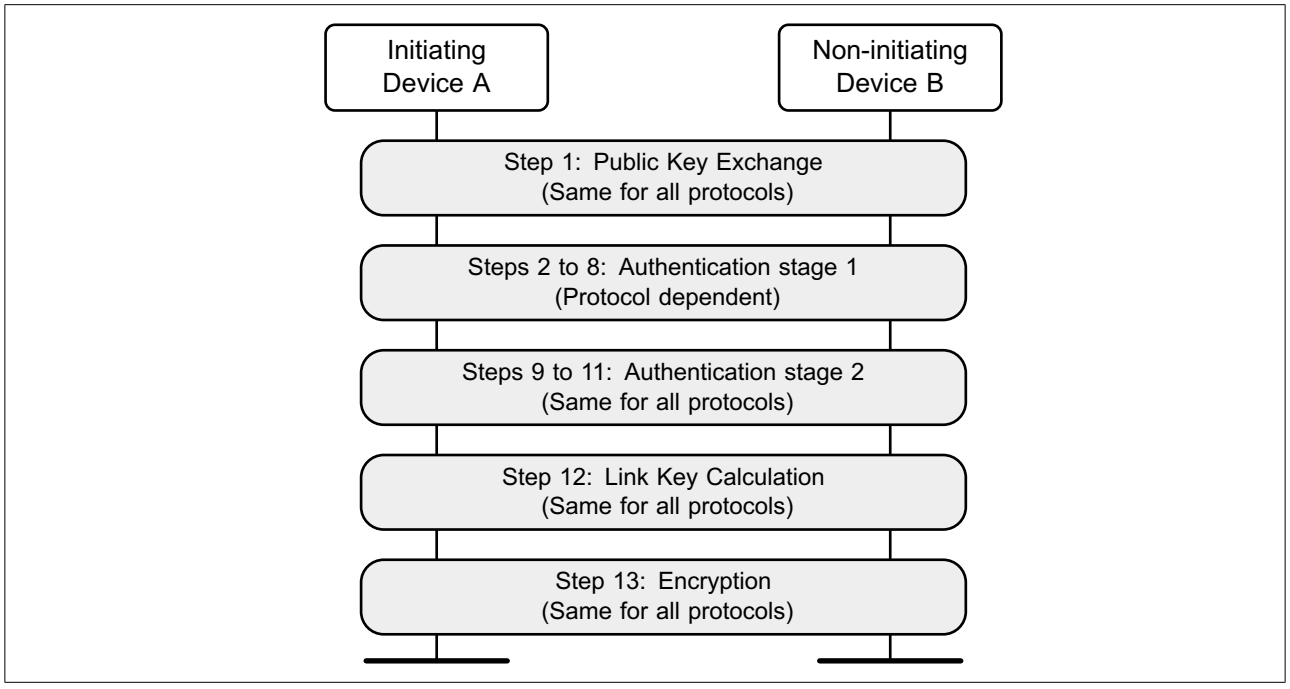

Figure 7.1: Secure Simple Pairing security phases

The terminology used in the security sections is defined in Table 7.1:

Term	Definition
Cx	Commitment value from device X
Cxi	i^{th} commitment value from device X. Only used in the passkey entry protocol
DHKey	Diffie Hellman key
Ex	Check value from device X
f1( )	Used to generate the 128-bit commitment values Ca and Cb
f2( )	Used to compute the link key and possible other keys from the DHKey and random nonces
f3( )	Used to compute check values Ea and Eb in Authentication stage 2
g( )	Used to compute numeric check values
IOcapA	IO capabilities of device A
IOcapB	IO capabilities of device B
LK	Link Key
Nx	Nonce (unique random value) from device X
Nxi	i^{th} nonce (unique random value) from device X. Only used in the passkey entry protocol
PKx	Public Key of device X
rx	Random value generated by device X
rxi	Bit i of the random value rx. Only used in the passkey entry protocol
SKx	Secret (Private) Key of device X
Vx	Confirmation value on device X. Only used in the numeric compare protocol.
X	BD_ADDR of device X

Table 7.1: Terminology

7.1 Phase 1: Public key exchange

Initially, each device generates its own Elliptic Curve Diffie-Hellman (ECDH) public-private key pair (step 1). See Section 5.1 for recommendations on how frequently this key pair should be changed.

Pairing is initiated by the initiating device sending its public key to the receiving device (step 1a). The responding device replies with its own public key (step 1b). If the two public keys have the same X coordinate and neither is the debug key (see [Vol 4] Part E, Section 7.6.4), each device shall fail the pairing process. These public keys are not regarded as secret although they may identify the devices.

When both devices' Controllers and Hosts support Secure Connections, the P-256 elliptic curve is used. When at least one device's Controller or Host doesn't support Secure Connections, the P-192 elliptic curve is used.

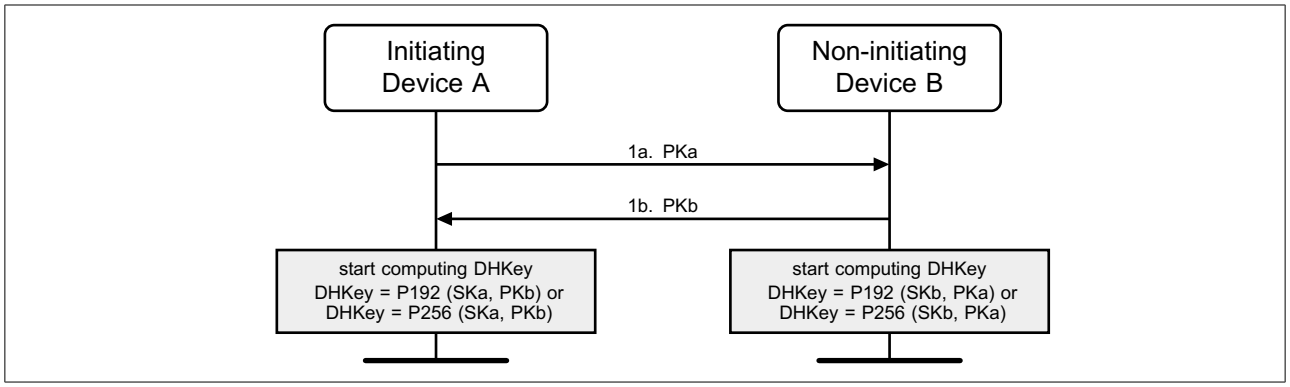

Figure 7.2: Public key exchange details

A device shall validate that any public key received from any BD_ADDR is on the correct curve (P-192 or P-256) - see Section 7.6.

7.2 Phase 2: Authentication stage 1

Authentication stage 1 has three different protocols: Numeric Comparison, Out-of-Band, and Passkey Entry. The Just Works association model shares the Numeric Comparison protocol and does not have a separate protocol.

The protocol is chosen based on the IO capabilities of the two devices.

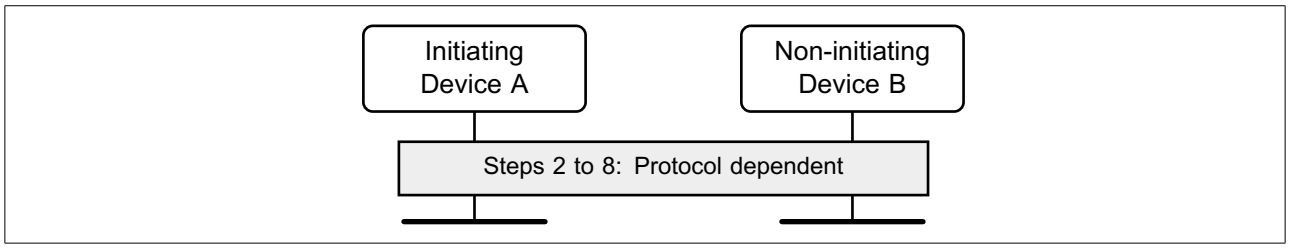

Figure 7.3: Authentication stage 1 (high level)

The three protocols are described in the following sections.

7.2.1 Authentication stage 1: Numeric Comparison protocol

The Numeric Comparison protocol provides limited protection against active "man-in-the-middle" (MITM) attacks as an active man-in-the-middle will succeed with a probability of 0.000001 on each iteration of the protocol. Provided that there is no MITM at the time the pairing is performed, the shared Link Key that is generated is computationally secure from even a passive eavesdropper that may have been present during the pairing.

The sequence diagram of Authentication stage 1 for the Numeric Comparison protocol from the cryptographic point of view is shown in Figure 7.4.

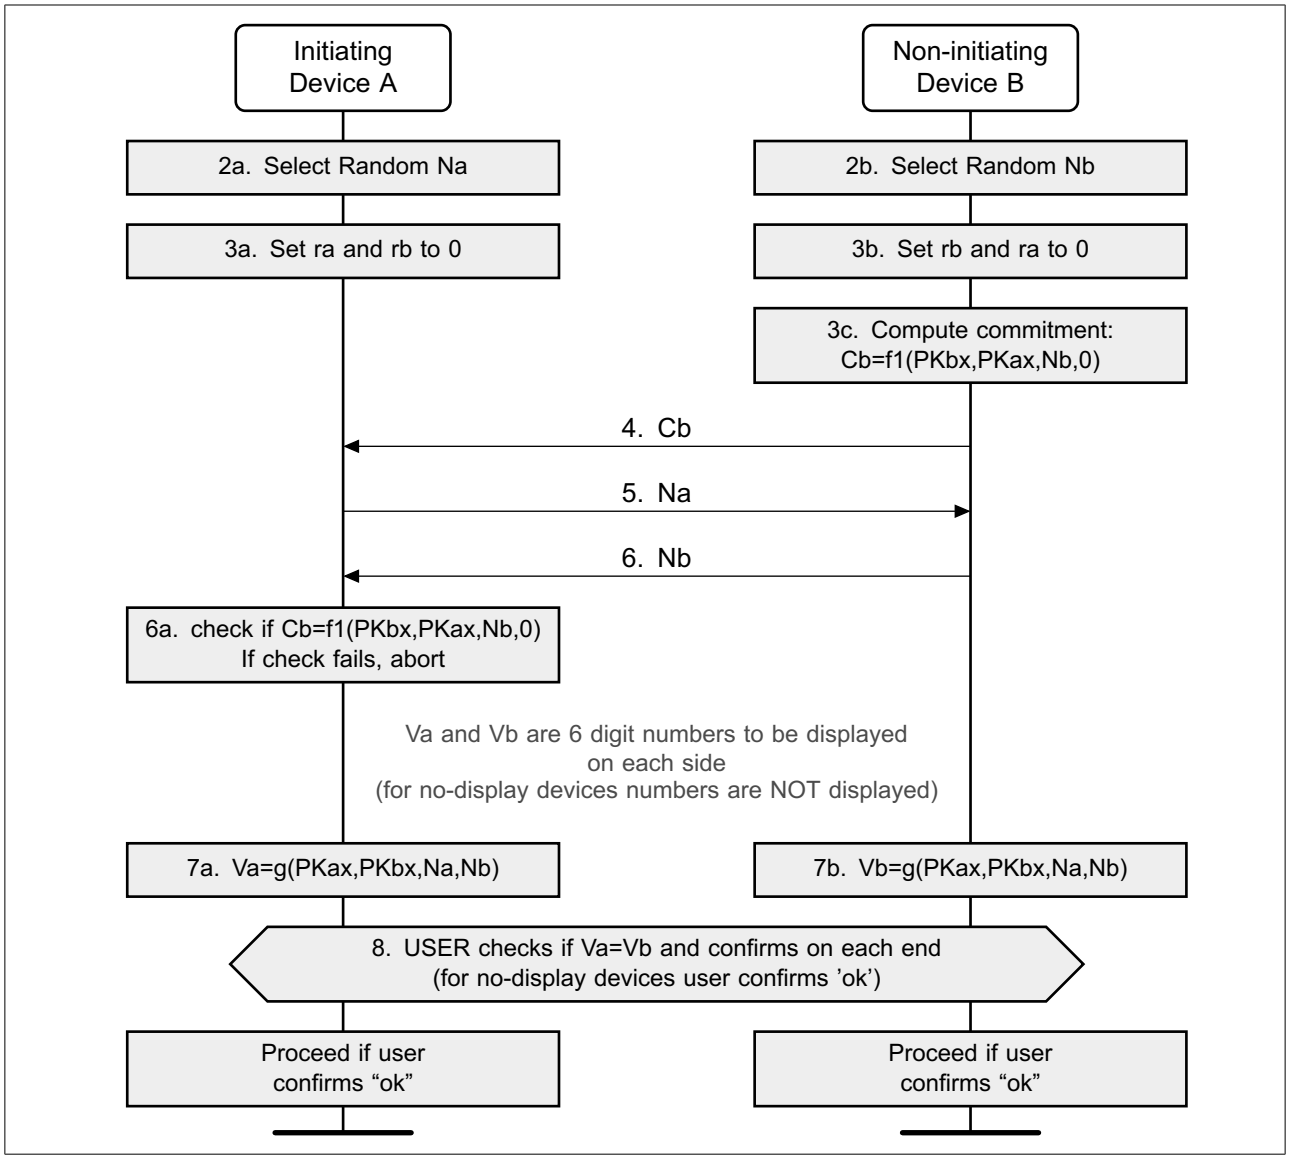

Figure 7.4: Authentication stage 1: Numeric Comparison protocol details

After the public keys have been exchanged, each device selects a random 128-bit nonce (step 2). This value is used to mitigate replay attacks and shall be freshly generated with each instantiation of the pairing protocol. This value shall be generated using a random number generator that meets the requirements of Section 2.

Following this the responding device then computes a commitment to the two public keys that have been exchanged and its own nonce value (step 3c). This commitment is computed as a one-way function of these values and is transmitted to the initiating device (step 4). The commitment prevents an attacker from changing these values at a later time.

The initiating and responding devices then exchange their respective nonce values (steps 5 and 6) and the initiating device confirms the commitment (step 6a). A failure at

this point indicates the presence of an attacker or other transmission error and causes the protocol to abort. The protocol may be repeated with or without the generation of new public-private key pairs, but, as stated above, new nonces must be generated if the protocol is repeated.

Assuming that the commitment check succeeds, the two devices each compute 6-digit confirmation values that are displayed to the user on their respective devices (steps 7a, 7b, and 8). The user is expected to check that these 6-digit values match and to confirm if there is a match. If there is no match, the protocol aborts and, as before, new nonces must be generated if the protocol is to be repeated.

An active MITM must inject its own key material into this process to have any effect other than denial-of-service. A simple MITM attack will result in the two 6-digit display values being different with probability 0.999999. A more sophisticated attack may attempt to engineer the display values to match, but this is thwarted by the commitment sequence. If the attacker first exchanges nonces with the responding device, it must commit to the nonce that it will use with the initiating device before it sees the nonce from the initiating device. If the attacker first exchanges nonces with the initiating device, it must send a nonce to the responding device before seeing the nonce from the responding device. In each case, the attacker must commit to at least the second of its nonces before knowing the second nonce from the legitimate devices. It therefore cannot choose its own nonces in such a way as to cause the display values to match.

7.2.2 Authentication stage 1: Out of Band protocol

The Out-of-Band protocol is used when authentication information has been received by at least one of the devices and indicated in the OOB Authentication Data Present parameter in the LMP IO capability exchange sequence. The mode in which the discovery of the peer device is first done in-band and then followed by the transmission of authentication parameters through OOB interface is not supported. The sequence diagram for Authentication stage 1 for Out of Band from the cryptographic point of view is shown in Figure 7.5.

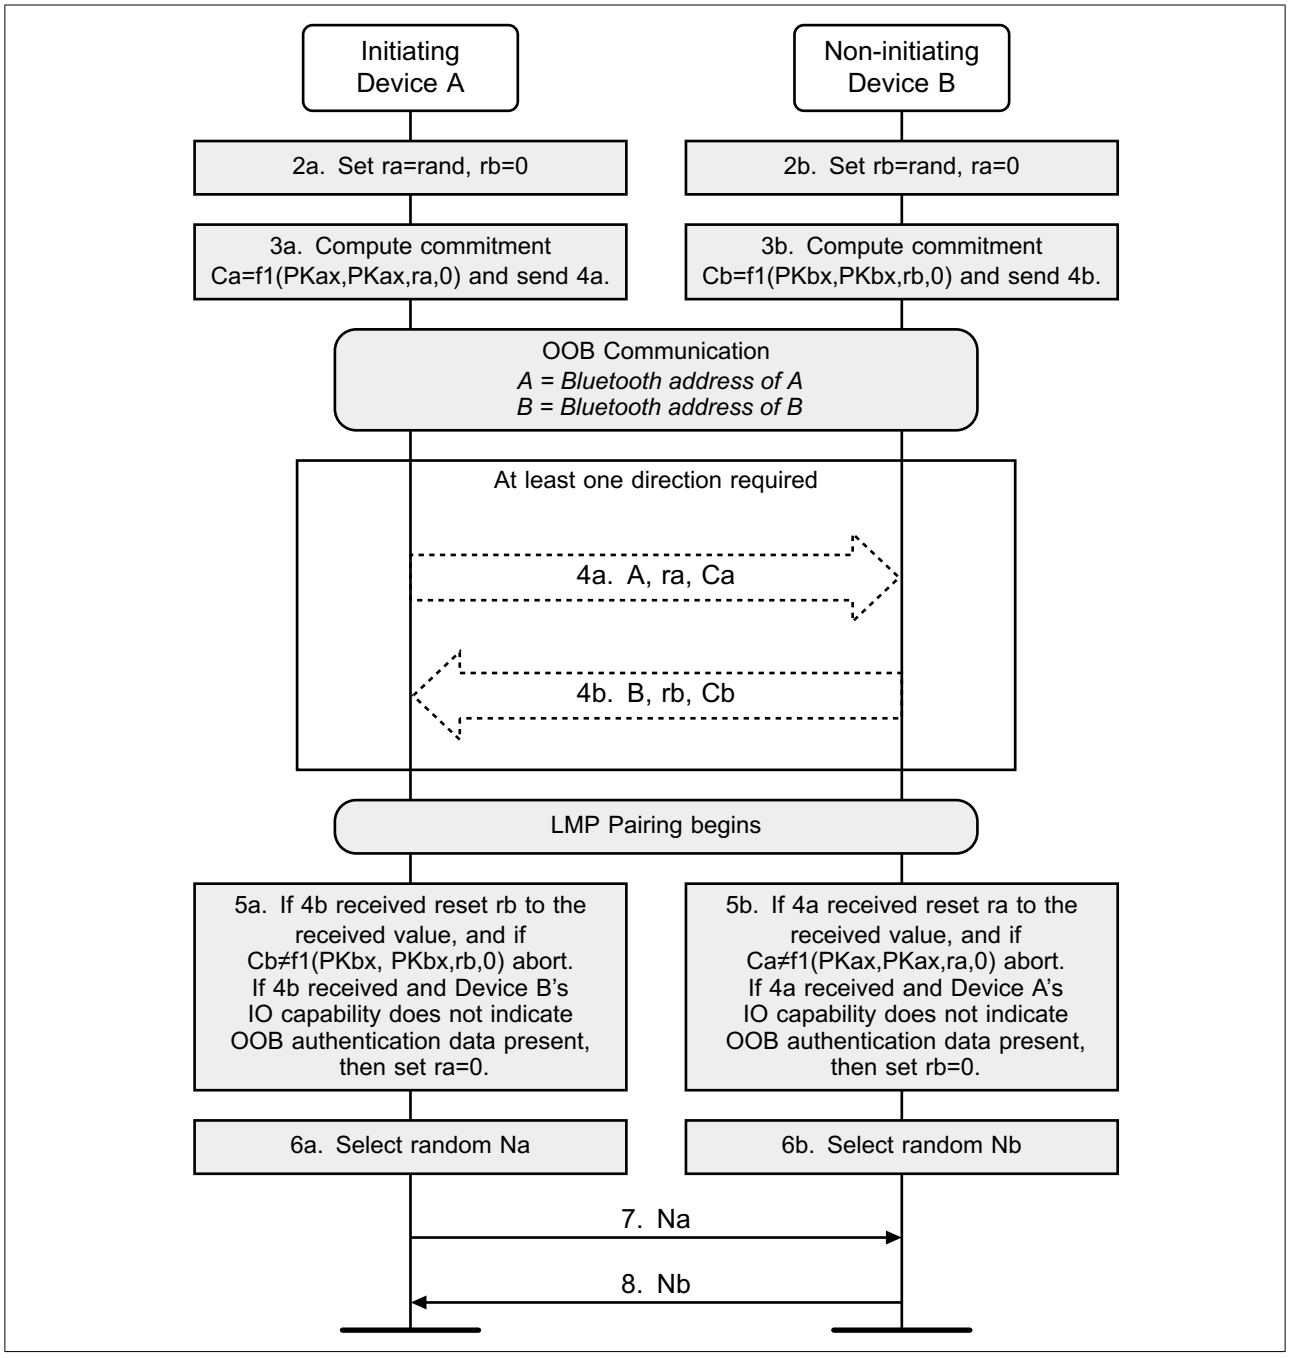

Figure 7.5: Authentication stage 1: Out of Band details

Principle of operation: If both devices can transmit and/or receive data over an out-of-band channel, then mutual authentication will be based on the commitments of the public keys (Ca and Cb) exchanged OOB in Authentication stage 1. If OOB communication is possible only in one direction, then authentication of the device receiving the OOB communication will be based on that device knowing a random number r sent via OOB. In this case, r must be secret: r can be created afresh every

time, or access to the device sending r must be restricted. If r is not sent by a device, it is assumed to be 0 by the device receiving the OOB information in step 4a or 4b.

Roles of A and B: The OOB Authentication stage 1 protocol is symmetric with respect to the roles of A and B. It does not require that device A always will initiate pairing and it automatically resolves asymmetry in the OOB communication, e.g. in the case when one of the devices has an NFC tag and can only transmit OOB.

Order of steps: The public key exchange must happen before the verification step 5. In the diagram the in-band public key exchange between the devices (step 1) is done before the OOB communication (step 4). But when the pairing is initiated by an OOB interface, public key exchange will happen after the OOB communication (step 1 will be between steps 4 and 5).

Values of ra and rb: Since the direction of the peer's OOB interface cannot be verified before the OOB communication takes place, a device should always generate and if possible transmit through its OOB interface a random number r to the peer. Each device applies the following rules locally to set the values of its own r and the value of the peer's r:

1. Initially, r of the device is set to a random number and r of the peer is set to 0 (step 2).
2. If a device has received OOB, it sets the peer's r value to what was sent by the peer (Step 5).
3. If the remote device's OOB Authentication Data parameter sent in the LMP IO capabilities exchange sequence is set to No OOB Data Received, it sets its own r value to 0 (Step 5)

These rules ensure that when entering Authentication stage 2, both A and B have the same values for ra and rb if OOB communication took place.

7.2.3 Authentication stage 1: Passkey Entry protocol

The Passkey Entry protocol is used when LMP IO capability exchange sequence indicates that Passkey Entry shall be used.

The sequence diagram for Authentication stage 1 for Passkey Entry from the cryptographic point of view is shown in Figure 7.6.

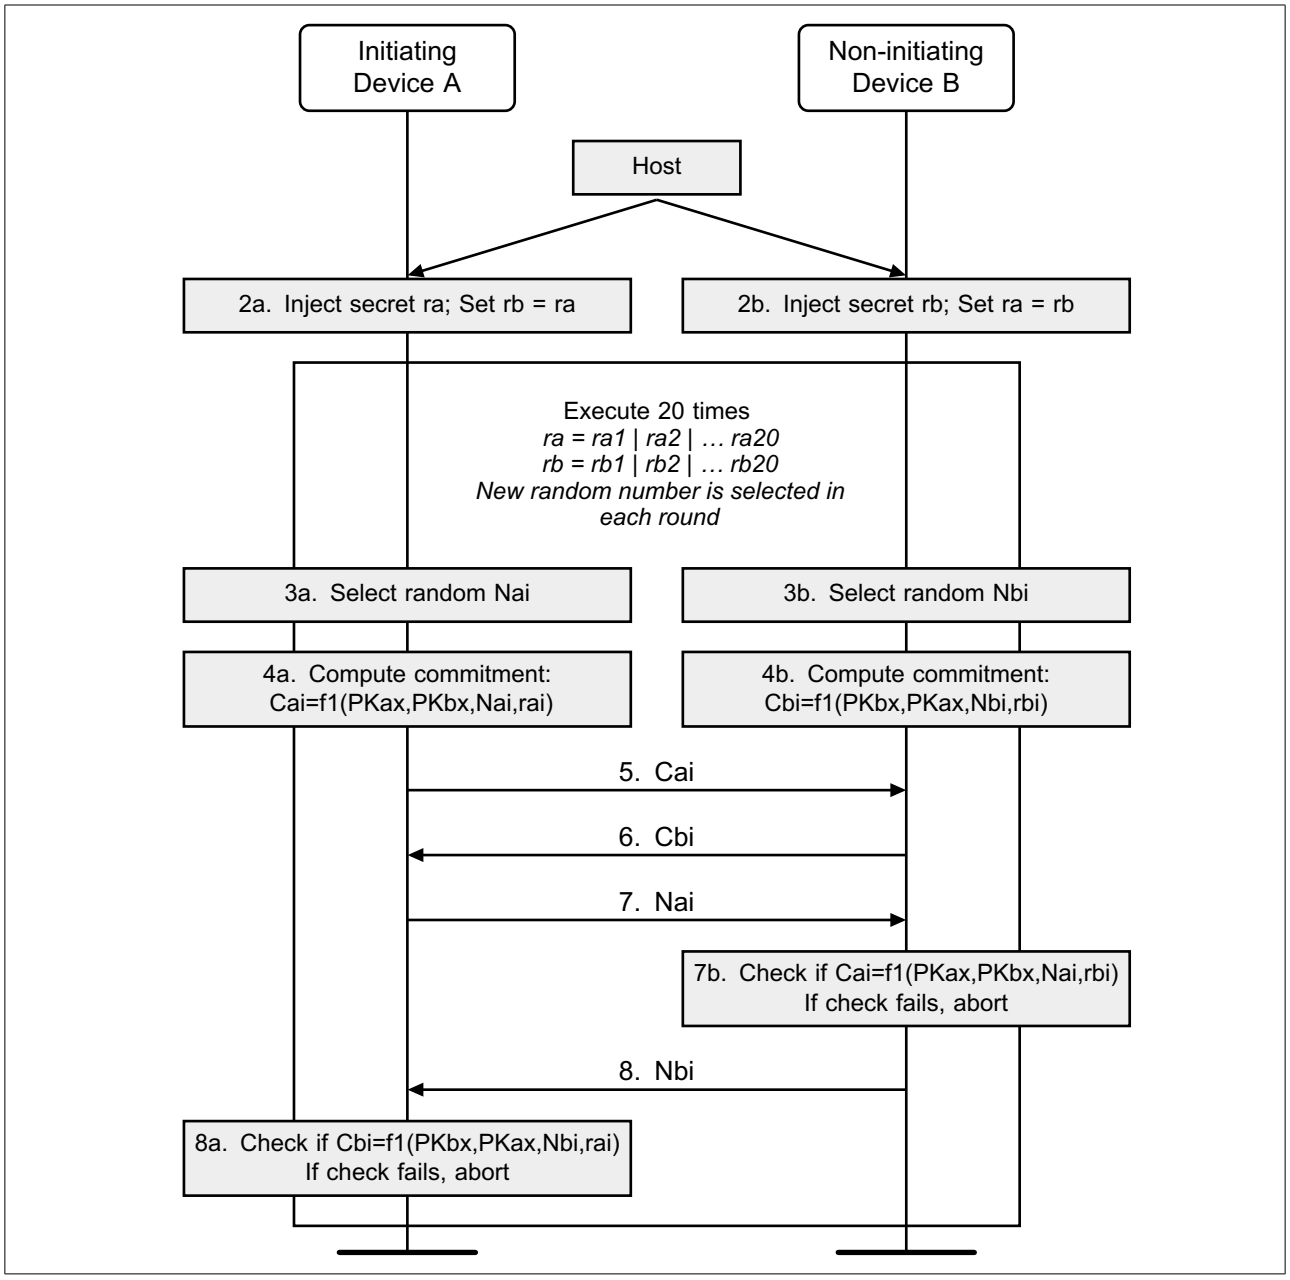

Figure 7.6: Authentication stage 1: Passkey Entry details

The user inputs an identical Passkey into both devices. Alternately, the Passkey may be generated and displayed on one device, and the user then inputs it into the other (step 2). This short shared key will be the basis of the mutual authentication of the devices. The Passkey should be generated randomly during each pairing procedure and not be reused from a previous procedure. Static Passkeys should not be used since they can compromise the security of the link.

Steps 3 to 8 are repeated 20 times since a 6-digit Passkey is 20 bits (999999=0xF423F). If the device allows a shorter passkey to be entered, it shall be prefixed with zeros (e.g. “1234” is equivalent to “001234”).

In Steps 3 to 8, each side commits to each bit of the Passkey, using a long nonce (128 bits), and sending the hash of the nonce, the bit of the Passkey, and both public keys to the other party. The parties then take turns revealing their commitments until the entire Passkey has been mutually disclosed. The first party to reveal a commitment for a given bit of the Passkey effectively reveals that bit of the Passkey in the process, but the other party then has to reveal the corresponding commitment to show the same bit value for that bit of the Passkey, or else the first party will then abort the protocol, after which no more bits of the Passkey are revealed.

This "gradual disclosure" prevents leakage of more than 1 bit of un-guessed Passkey information in the case of a MITM attack. A MITM attacker with only partial knowledge of the Passkey will only receive one incorrectly-guessed bit of the Passkey before the protocol fails. Hence, a MITM attacker who engages first one side, then the other will only gain an advantage of at most two bits over a simple brute-force guesser, making the probability of success 0.000004 instead of 0.000001.

The long nonce is included in the commitment hash to make it difficult to brute-force even after the protocol has failed. The public Diffie-Hellman values are included to tie the Passkey protocol to the original ECDH key exchange, to prevent a MITM from substituting the attacker's public key on both sides of the ECDH exchange in standard MITM fashion.

At the end of this stage, Na is set to Na20 and Nb is set to Nb20 for use in Authentication stage 2.

7.3 Phase 3: Authentication stage 2

The second stage of authentication then confirms that both devices have successfully completed the exchange. This stage is identical in all three protocols and is shown in Figure 7.7.

Each device computes a new confirmation value that includes the previously exchanged values and the newly derived shared key (step 9). The initiating device then transmits its confirmation value which is checked by the responding device (step 10). If this check fails, it indicates that the initiating device has not confirmed the pairing, and the protocol shall be aborted. The responding device then transmits its confirmation value which is checked by the initiating device (step 11). A failure indicates that the responding device has not confirmed the pairing and the protocol should abort.

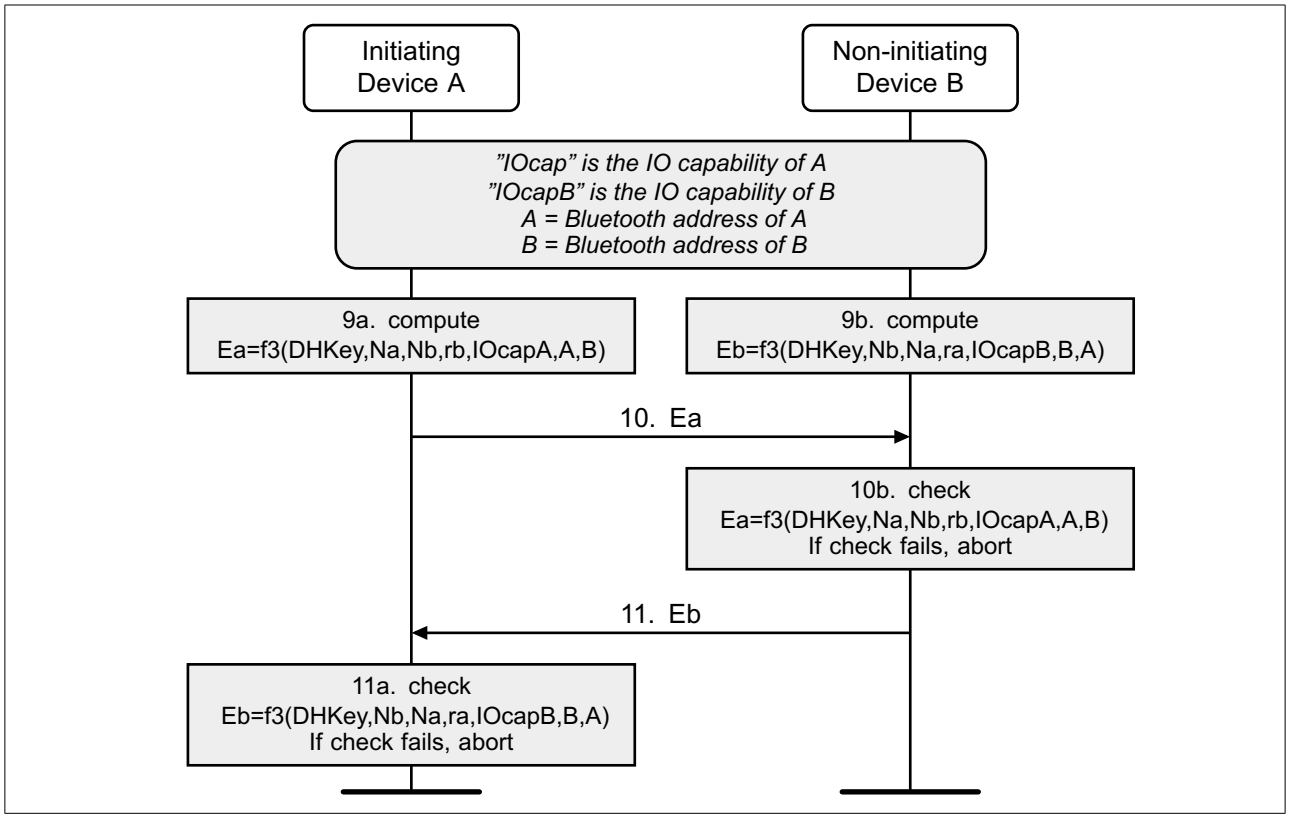

Figure 7.7: Authentication stage 2

7.4 Phase 4: Link key calculation

Once both sides have confirmed the pairing, a link key is computed from the derived shared key and the publicly exchanged data (step 12). The nonces ensure the freshness of the key even if long-term ECDH values are used by both sides. This link key is used to maintain the pairing.

When computing the link key both parties shall input the parameters in the same order (shown in Figure 7.8) to ensure that both devices compute the same key: Nc is whichever of Na and Nb was generated by the Central and Np is the other, while BD_ADDR_C and BD_ADDR_P are the addresses of the Central and Peripheral respectively.

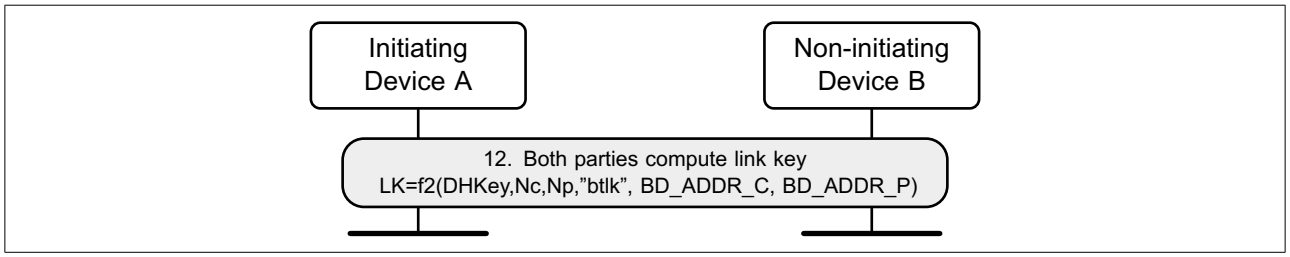

Figure 7.8: Link key calculation

7.5 Phase 5: LMP authentication and encryption

The final phase in Secure Simple Pairing consists of authentication and generation of the encryption key. This is the same as the final steps in legacy pairing.

7.6 Elliptic curve definition

Secure Simple Pairing supports two elliptic curves: P-192 and P-256.

Secure Simple Pairing uses the FIPS P-192 and P-256 curves defined in FIPS 186-4[1]. Elliptic curves are specified by p, a, b and are of the form:

$$E: y^2 = x^3 + ax + b \ (mod\ p)$$

In NIST P-192 and P-256, a is -3 and the following parameters are given:

- The prime modulus p, order r, base point x-coordinate Gx, base point y-coordinate Gy.
- The integers p and r are given in decimal form; bit strings and field elements are given in hex.

For P-192:

```
p =6277101735386680763835789423207666416083908700390324961279
r =6277101735386680763835789423176059013767194773182842284081
b =64210519 e59c80e7 0fa7e9ab 72243049 feb8deec c146b9b1
Gx=188da80e b03090f6 7cbf20eb 43a18800 f4ff0afd 82ff1012
Gy=07192b95 ffc8da78 631011ed 6b24cdd5 73f977a1 1e794811
```

The function P192 is defined as follows. Given an integer u, $0 < u < r$, and a point V on the curve E, the value P192(u,V) is computed as the x-coordinate of the u^{th} multiple uV of the point V.

The private keys shall be between 1 and $r \div 2$, where r is the order of the Abelian group on the elliptic curve (i.e., between 1 and $2^{192} \div 2$).

For P-256:

```
p =115792089210356248762697446949407573530086143415290314195533631308867097853951
r =115792089210356248762697446949407573529996955224135760342422259061068512044369
b =5ac635d8 aa3a93e7 b3ebbd55 769886bc 651d06b0 cc53b0f6 3bce3c3e 27d2604b
Gx=6b17d1f2 e12c4247 f8bce6e5 63a440f2 77037d81 2deb33a0 f4a13945 d898c296
Gy=4fe342e2 fe1a7f9b 8ee7eb4a 7c0f9e16 2bce3357 6b315ece cbb64068 37bf51f5
```

[1] http://dx.doi.org/10.6028/NIST.FIPS.186-4

The function P256 is defined as follows. Given an integer u, $0 < u < r$, and a point V on the curve E, the value P256(u, V) is computed as the x-coordinate of the u^{th} multiple uV of the point V.

The private keys shall be between 1 and $r \div 2$, where r is the order of the Abelian group on the elliptic curve (i.e., between 1 and $2^{256} \div 2$).

A valid public key $Q = (X_Q, Y_Q)$ is one where X_Q and Y_Q are both in the range 0 to p - 1 and satisfy the equation $(Y_Q)^2 = (X_Q)^3 + aX_Q + b$ (*mod* p) in the relevant curve's finite field.

A device can validate a public key by directly checking the curve equation, by implementing elliptic curve point addition and doubling using formulas that are valid only on the correct curve, or by other means.

7.7 Cryptographic function definitions

In addition to computing the Elliptic Curve Diffie Hellman key, the Numeric Comparison, Out-of-Band and Passkey Entry protocols require four cryptographic functions. These functions are known as *f1*, *g*, *f2* and *f3*.

f1 is used to generate the 128-bit commitment values Ca and Cb

g is used to compute the 6-digit numeric check values

f2 is used to compute the link key and possible other keys from the DHKey and random nonces

f3 is used to compute check values Ea and Eb in Authentication stage 2.

The basic building block for these functions is based on SHA-256, specified in [FIPS PUB 180-4] (http://dx.doi.org/10.6028/NIST.FIPS.180-4).

Inside the *f1*, *g*, *f2*, and *f3* cryptographic functions, when a multi-octet integer input parameter is used as input to the SHA-256 and HMAC-SHA-256 functions, the most significant octet of the integer parameter shall be the first octet of the stream and the least significant octet of the integer parameter shall be the last octet of the stream. The output of the *f1*, *g*, *f2*, and *f3* cryptographic functions is a multi-octet integer where the first octet out of SHA-256 and HMAC-SHA-256 shall be the MSB and the last octet shall be the LSB of that parameter.

7.7.1 The Secure Simple Pairing commitment function *f1*

The commitments are computed with function *f1*. The definition of the Secure Simple Pairing commitment function makes use of the MAC function HMAC based on $SHA\text{-}256_x$, which is denoted as $HMAC\text{-}SHA\text{-}256_X$ with 128-bit key X.

The inputs to the Secure Simple Pairing function *f1* are specified in Table 7.2.

Input	Bits with P-192	Bits with P-256
U	192	256
V	192	256
X	128	128
Z	8	8

Table 7.2: Inputs to the f1 function

Z is zero (i.e., 8 bits of zeros) for Numeric Comparison and OOB protocol. In the Passkey protocol the most significant bit of Z is set equal to one and the least significant bit is made up from one bit of the passkey e.g. if the passkey bit is 1 then Z = 0x81 and if the passkey bit is 0 then Z = 0x80.

The output of the Secure Simple Pairing *f1* function is:

$$f1(U, V, X, Z) = \text{HMAC-SHA-256}_X (U \,||\, V \,||\, Z) \div 2^{128}$$

The inputs to *f1* are different depending on the different protocols as specified in Table 7.3.

Numeric Comparison	Out-Of-Band	Passkey Entry
Ca = *f1*(PKax, PKbx, Na, 0)	Ca = *f1*(PKax, PKax, ra, 0)	Cai = *f1*(PKax, PKbx, Nai, rai)
Cb = *f1*(PKbx, PKax, Nb, 0)	Cb = *f1*(PKbx, PKbx, rb, 0)	Cbi = *f1*(PKbx, PKax, Nbi, rbi)

Table 7.3: Inputs to f1 for the different protocols

where PKax denotes the x-coordinate of the public key PKa of A. Similarly, PKbx denotes the x-coordinate of the public key PKb of B. Nai is the nonce value of i^{th} round. For each round Nai value is a new 128 bit number. Similarly, rai is one bit value of the passkey expanded to 8 bits (either 0x80 or 0x81).

Na and Nb are nonces from Devices A and B. ra and rb are random values generated by devices A and B.

7.7.2 The Secure Simple Pairing numeric verification function *g*

The Secure Simple Pairing *g* function is defined as follows:

The inputs to the Secure Simple Pairing function *g* are specified in Table 7.4.

Input	Bits with P-192	Bits with P-256
U	192	256
V	192	256
X	128	128
Y	128	128

Table 7.4: Inputs to the g function

The output of the Secure Simple Pairing *g* function is:

$$g(U, V, X, Y) = \text{SHA-256}(U \,||\, V \,||\, X \,||\, Y) \; mod \; 2^{32}$$

The numeric verification value is taken as six least significant digits of the 32-bit integer *g*(PKax, PKbx, Na, Nb) where PKax denotes the x-coordinate of the public key PKa of A and PKbx denotes the x-coordinate of the public key PKb of B.

Output of SHA-256 is truncated to 32 bits by taking the least significant 32 bits of the output of SHA-256. This value is converted to decimal numeric value. The checksum used for numeric comparison is the least significant six digits.

$$Compare\ Value = g\ (U, V, X, Y)\ mod\ 10^6$$

For example, if output = 0x 01 2e b7 2a then decimal value = 19838762 and the checksum used for numeric comparison is 838762.

7.7.3 The Secure Simple Pairing key derivation function *f2*

The definition of the Secure Simple Pairing key derivation function makes use of the MAC function HMAC based on SHA-256, which is denoted as HMAC-SHA-256$_W$ with 192-bit or 256-bit key W.

The inputs to the Secure Simple Pairing function *f2* are specified in Table 7.5.

Input	Bits with P-192	Bits with P-256
W	192	256
N_1	128	128
N_2	128	128
keyID	32	32
A_1	48	48
A_2	48	48

Table 7.5: Inputs to the f2 function

The string "btlk" is mapped into a keyID using ASCII as 0x62746C6B.

The output of the Secure Simple Pairing *f2* function is:

$$f2(W, N_1, N_2, \text{KeyID}, A_1, A_2) = \text{HMAC-SHA-256}_W (N1 \,||\, N2 \,||\, \text{KeyID} \,||\, A_1 \,||\, A_2) \div 2^{128}$$

The output of *f2* is taken as the 128 most significant (leftmost) bits of the output of HMAC-SHA-256.

The link key is then calculated as:

LK = *f2*(DHKey, Nc, Np, "btlk", BD_ADDR_C, BD_ADDR_P)

Nc is whichever of N1 and N2 was generated by the Central and sent to the Peripheral; Np is the other.

7.7.4 The Secure Simple Pairing check function *f3*

The definition of the Secure Simple Pairing *f3* check function makes use of the MAC function HMAC based on SHA-256, which is denoted as HMAC-SHA-256_W with 192-bit or 256-bit key W.

The inputs to the Secure Simple Pairing function *f3* are specified in Table 7.6.

Input	Bits with P-192	Bits with P-256
W	192	256
N_1	128	128
N_2	128	128
IOcap	24	24
A_1	48	48
A_2	48	48

Table 7.6: Inputs to the f3 function

IOcap is three octets with the most significant octet as the Authentication Requirements parameter, the middle octet as the LMP Out-of-Band Authentication Data parameter, and the least significant octet as the LMP IO capability parameter.

The output of the Secure Simple Pairing *f3* function is:

$$f3(W, N_1, N_2, R, IOcap, A_1, A_2) = HMAC\text{-}SHA\text{-}256W (N_1 \,||\, N_2 \,||\, R \,||\, IOcap \,||\, A_1 \,||\, A_2) \div 2^{128}$$

The output of *f3* is taken as the 128 most significant (leftmost) bits of the output of HMAC-SHA-256. The check values are computed with function *f3*. The inputs to *f3* are different depending on the different protocols, as specified in Table 7.7.

Numeric Comparison	Out-Of-Band	Passkey Entry
Ea = *f3*(DHKey, Na, Nb, 0, IO-capA, A, B)	Ea = *f3(* DHKey, Na, Nb, rb, IO-capA, A, B)	Ea = *f3(* DHKey, Na20, Nb20, rb, IOcapA, A, B)
Eb = *f3*(DHKey, Nb, Na, 0, IO-capB, B, A)	Eb = *f3*(DHKey, Nb, Na, ra, IO-capB, B, A)	Eb = *f3*(DHKey, Nb20, Na20, ra, IOcapB, B, A)

Table 7.7: Inputs to f3 for the different protocols

DHKey denotes the shared secret Diffie-Hellman Key computed as P192(SKa, PKb) or P256(SKa, PKb) by A and as P192(SKb, PKa) or P256(SKb, PKa) by B. IOcapA denotes the IO capability data of A and IOcapB denotes the IO capability data of B. In Passkey Entry, the data ra and rb are 6-digit passkey values which are expressed as a 128-bit integer. For instance, if the 6-digit value of ra is 131313, then

R = 0x 00 00 00 00 00 00 00 00 00 00 00 00 00 02 00 f1.

The input A is the BD_ADDR of device A and the input B is the BD_ADDR of device B.

7.7.5 [This section is no longer used]

7.7.6 The AES encryption key generation function *h3*

AES encryption keys are created using the AES encryption key generation function *h3*. The definition of the AES encryption key generation function makes use of the MAC function HMAC based on SHA-256, which is denoted as HMAC-SHA-256$_T$ with 128-bit key T.

The inputs to function *h3* are specified in Table 7.8.

Input	Bits with P-256
T	128
keyID	32
A_1	48
A_2	48
ACO	64

Table 7.8: Inputs to the h3 function

A_1 is the BD_ADDR of the Central. A_2 is the BD_ADDR of the Peripheral. ACO is the 64 bit ACO output from *h5*. T is the 128 bit Bluetooth Link Key derived from *f2*.

The string “btak” (Bluetooth AES Key) is mapped into a keyID using ASCII as 0x6274616B.

The output of function *h3* is:

$$h3(W, keyID, A_1, A_2, ACO) = HMAC\text{-}SHA\text{-}256_T(KeyID \,||\, A_1 \,||\, A_2 \,||\, ACO) \div 2^{128}$$

The output of *h3* is taken as the 128 most significant (leftmost) bits of the output of HMAC-SHA-256.

7.7.7 The Device authentication key generation function *h4*

With Secure Connections, a device authentication key is created using function *h4*. The definition of the device authentication key generation function makes use of the MAC function HMAC based on SHA-256, which is denoted as $HMAC\text{-}SHA\text{-}256_T$ with 128-bit key T.

The inputs to function *h4* are specified in Table 7.9.

Input	Bits with P-256
T	128
keyID	32
A_1	48
A_2	48

Table 7.9: Inputs to the h4 function

A_1 is the BD_ADDR of the Central. A_2 is the BD_ADDR of the Peripheral. T is the 128 bit Bluetooth Link Key derived from *f2*.

The string “btdk” (Bluetooth Device Key) is mapped into a keyID using ASCII as 0x6274646B.

The output of function *h4* is:

$$h4(W, KeyID, A_1, A_2) = HMAC\text{-}SHA\text{-}256_T(KeyID \,||\, A_1 \,||\, A_2) \div 2^{128}$$

The output of *h4* is taken as the 128 most significant (leftmost) bits of the output of HMAC-SHA-256.

7.7.8 The Device authentication confirmation function *h5*

With Secure Connections, device authentication confirmation values are created using function *h5*. The definition of the device authentication confirmation function makes use of the MAC function HMAC based on SHA-256, which is denoted as $HMAC\text{-}SHA\text{-}256_S$ with 128-bit key S.

The inputs to function *h5* are specified in Table 7.10.

Input	Bits with P-256
S	128
R_1	128
R_2	128

Table 7.10: Inputs to the h5 function

R_1 is the 128 bit random number (AU_RAND_C) from the Central during the Link Manager device authentication sequence. R_2 is the 128 bit random number from the Peripheral (AU_RAND_P) during the Link Manager device authentication sequence. S is the 128-bit Bluetooth Device Authentication Key derived from *h4*.

The output of function *h5* is:

$$h5(W, R_1, R_2) = \text{HMAC-SHA-256}_S(R_1 \,||\, R_2) \div 2^{128}$$

The output of *h5* is taken as the 128 most significant (leftmost) bits of the output of HMAC-SHA-256. The first 32 bits (leftmost) become the SRES_C. The next 32 bits become the SRES_P. The final 64 bits become the Authentication Ciphering Offset (ACO), which is used in *h3* and as the IV for Encryption Start for the encryption nonce.

8 [THIS SECTION IS NO LONGER USED]

9 AES-CCM ENCRYPTION FOR BR/EDR

The Baseband provides security using Counter with CBC-MAC (CCM) as defined in IETF RFC 3610 (http://www.ietf.org/rfc/rfc3610.txt) with a modification to the B_1 counter mode block format that omits the length of the additional authenticated data. The description of the algorithm can also be found in the NIST Special Publication 800-38C (http://csrc.nist.gov/publications/PubsSPs.html).

Using the notation in [4], CCM has two size parameters, M and L.

The Baseband defines these to be:

M = 4; indicating that the MIC length is 4 octets (32 bits)

Size of M represents a trade-off between message expansion and the probability that an attacker can undetectably modify a message.

L = 2; indicating that the Length field is 2 octets (16 bits)

Size of L requires a trade-off between the maximum message size and the size of the Nonce.

9.1 Nonce formats

All of the parameters in the nonce are unique per logical transport. The nonce will be 13 octets and will have two formats. The first format is called the payload counter format and is used for ACL packets on the primary LT_ADDR. The second format is called the clock format and is used for eSCO packets.

The reason for two formats has to do with two factors: potential security attacks and synchronization. Since ACL packets on the primary LT_ADDR carry protocol, they are susceptible to attacks that eSCO packets (only data) are not.

The descriptions of the two nonce formats are provided in Table 9.1.

Octet	Field	Octets	Payload Counter Format Description	Clock Format Description
0	Nonce0	1	PayloadCounter[7:0]	CLK[8:1]
1	Nonce1	1	PayloadCounter[15:8]	CLK[16:9]
2	Nonce2	1	PayloadCounter[23:16]	CLK[24:17]

Octet	Field	Octets	Payload Counter Format Description	Clock Format Description
3	Nonce3	1	PayloadCounter[31:24]	Bits 2-0: CLK[27:25] Bits 7-3: dayCounter[4:0]
4	Nonce4	1	Bits 3-0: PayloadCounter[35:32] Bit 4: zero-length ACL-U continuation packet (1=zero-length ACL-U continuation packet, 0=otherwise) Bit 5: direction (0=Central to Peripheral, 1=Peripheral to Central) Bits 7-6: nonceType = 0b00 (ACL)	Bits 5-0: dayCounter[10:5] Bits 7-6: nonceType = 0b01 (eSCO)
5	Nonce5	1	IV[7:0]	
6	Nonce6	1	IV[15:8]	
7	Nonce7	1	IV[23:16]	
8	Nonce8	1	IV[31:24]	
9	Nonce9	1	IV[39:32]	
10	Nonce10	1	IV[47:40]	
11	Nonce11	1	IV[55:48]	
12	Nonce12	1	IV[63:56]	

Table 9.1: Nonce formats

In the payload counter format, the PayloadCounter starts at zero for the first encrypted packet in each direction after encryption is started or resumed and increments by one every time an encrypted payload including zero-length payloads is accepted by the remote device.

Note: It is possible that when encryption is being enabled or resumed, a packet may first get transmitted unencrypted and then get retransmitted encrypted. In such a case, the PayloadCounter gets incremented by one when the encrypted retransmission of the packet gets accepted by the remote device.

Bit 4 of Octet 4 shall be set to 1 for a zero length ACL-U continuation packet (see [Vol 2] Part B, Section 7.6.2.2), otherwise it shall be set to 0.

In the clock format, the Central's clock (CLK) used for the nonce shall be the value in the first slot of the packet. After a new ACL connection has been established or a role

switch has been successfully performed and when eSCO is successfully established for the first time then the dayCounter value shall be initialized to:

1 if CLK27 in the first clock format nonce is 0, and initialization procedure 2 (see [Vol 2] Part B, Section 8.6.3) is used

0 otherwise.

After the dayCounter has been initialized, it shall increment by one every time the Central's clock (CLK) rolls over to 0x0000000 (approximately every 23.3 hours).

Note: When Security Mode 4 is in use, eSCO will not be established before encryption is started.

The IV is an 8 octet field. For encryption start, all octets of the IV are from the ACO output of the last execution of *h5* prior to the start of encryption. Multiple device authentications may occur prior to starting encryption but only the ACO of the last device authentication is used. After an encryption resume, all 8 octets of the IV are from the EN_RAND sent by the device initiating the encryption pause (see [Vol 2] Part C, Section 4.2.5.5). An encryption pause and resume will be required prior to the PayloadCounter or dayCounter rolling over in order to keep the nonce fresh for an encryption key.

Octet	IV for Encryption Start	IV After Resume Encryption
0	ACO[0]	EN_RAND[0]
1	ACO[1]	EN_RAND[1]
2	ACO[2]	EN_RAND[2]
3	ACO[3]	EN_RAND[3]
4	ACO[4]	EN_RAND[4]
5	ACO[5]	EN_RAND[5]
6	ACO[6]	EN_RAND[6]
7	ACO[7]	EN_RAND[7]

Table 9.2: IV construction

9.2 Counter mode blocks

For calculating the MIC, the payload is broken into two or more counter mode blocks. The CCM specification refers to these blocks as blocks B_0 – B_n. B_0 applies to the nonce, B_1 applies to the associated data {that is packet header and payload header} and additional B blocks are generated as needed for authentication of the payload body.

Offset (octets)	Field	Size (octets)	Value	Description
0	Flags	1	0x49	As per the CCM specification
1	Nonce	13	variable	The nonce as described in Section 9.1. Nonce0 shall have offset 1. Nonce12 shall have offset 13.
14	Length[MSO]	1	variable	The most significant octet of the length of the payload body
15	Length[LSO]	1	variable	The least significant octet of the length of the payload body

Table 9.3: B_0 counter mode block format

Offset	Field	Size (octets)	Value	Description
0	Packet_Header [MSO]	1	Variable	The most significant octet of the packet header: Bit 0: 0 (ARQN masked) Bit 1: 0 (SEQN masked) Bit 7 – Bit 2: 0b000000
1	Packet_Header [LSO]	1	Variable	The least significant octet of the packet header: Bit 2 – Bit 0: LT_ADDR Bit 6 – Bit 3: TYPE Bit 7: 0 (FLOW masked)
2	Payload_Header	1	Variable	The payload header: Bit 1 – Bit 0: LLID Bit 2: 0 (FLOW masked) Bit 7 – Bit 3: 0b00000
3	Padding	13	0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00	These octets are only used to pad the block. They are not part of the packet and never transmitted.

Table 9.4: B_1 counter mode block format

9.3 Encryption blocks

The CCM algorithm uses the A_i blocks to generate a keystream that is used to encrypt the MIC and payload body. Block A_0 is always used to encrypt and decrypt the MIC,

when present. Block A_1 is always used to encrypt and decrypt the first 16 octets of the payload body. Subsequent blocks are always used to encrypt and decrypt the rest of the payload body as needed.

Offset (octets)	Field	Size (octets)	Value	Description
0	Flags	1	0x01	As per the CCM specification
1	Nonce	13	variable	The nonce as described in Section 9.1. Nonce0 shall have offset 1. Nonce12 shall have offset 13.
14	i[MSO]	1	variable	The most significant octet of the counter i
15	i[LSO]	1	variable	The least significant octet of the counter i

Table 9.5: Encryption mode block format

9.4 Encryption key size reduction

When the devices have negotiated a key size shorter than the maximum length, the key will be shortened by replacing the appropriate number of least significant octets of the key with 0x00.

For example, if a 128-bit encryption key is

0x12345678_9ABCDEF0_12345678_9ABCDEF0

and it is reduced to 7 octets (56 bits), then the resulting key is

0x12345678_9ABCDE00_00000000_00000000.

9.5 Repeated MIC failures

Anytime the MIC check fails and the CRC passes on a given packet, it is considered an authentication failure. No more than three authentication failures shall be permitted during the lifetime of an encryption key with a given IV. The third authentication failure shall initiate an encryption key refresh (see [Vol 2] Part C, Section 4.2.5.8). If a fourth authentication failure occurs prior to the encryption key refresh procedure completing, the link shall be disconnected with reason code *Rejected Due to Security Reasons* (0x0E).

Note: The MIC is not checked when the CRC is invalid.

LOGICAL LINK CONTROL AND ADAPTATION PROTOCOL SPECIFICATION

The Bluetooth Logical Link Control and Adaptation Protocol (L2CAP) supports higher level protocol multiplexing, packet segmentation and reassembly, and the conveying of quality of service information. The protocol state machine, packet format, and composition are described in this Part of the specification.

CONTENTS

1 INTRODUCTION

This section of the Bluetooth Specification defines the Logical Link Control and Adaptation Layer Protocol, referred to as L2CAP. L2CAP provides connection-oriented and connectionless data services to upper layer protocols with protocol multiplexing capability and segmentation and reassembly operation. L2CAP permits higher level protocols and applications to transmit and receive upper layer data packets (L2CAP Service Data Units, SDU) up to 64 kilobytes in length. L2CAP also permits per-channel flow control and retransmission.

The L2CAP layer provides logical channels, named L2CAP channels, which are multiplexed over one or more logical links.

1.1 L2CAP features

The functional requirements for L2CAP include protocol/channel multiplexing, segmentation and reassembly (SAR), per-channel flow control, and error control. L2CAP sits above a lower layer composed of one of the following:

1. BR/EDR Controller
2. BR/EDR/LE Controller (supporting BR/EDR and LE)
3. LE Controller (supporting LE only)

L2CAP interfaces with upper layer protocols.

Figure 1.1 breaks down L2CAP into its architectural components. The Channel Manager provides the control plane functionality and is responsible for all internal signaling, L2CAP peer-to-peer signaling and signaling with higher and lower layers. It performs the state machine functionality described in Section 6 and uses message formats described in Section 4, and Section 5. The Retransmission and Flow Control block provides per-channel flow control and error recovery using packet retransmission. The Resource Manager is responsible for providing a frame relay service to the Channel Manager, the Retransmission and Flow Control block and those application data streams that do not require Retransmission and Flow Control services. It is responsible for coordinating the transmission and reception of packets related to multiple L2CAP channels over the facilities offered at the lower layer interface.

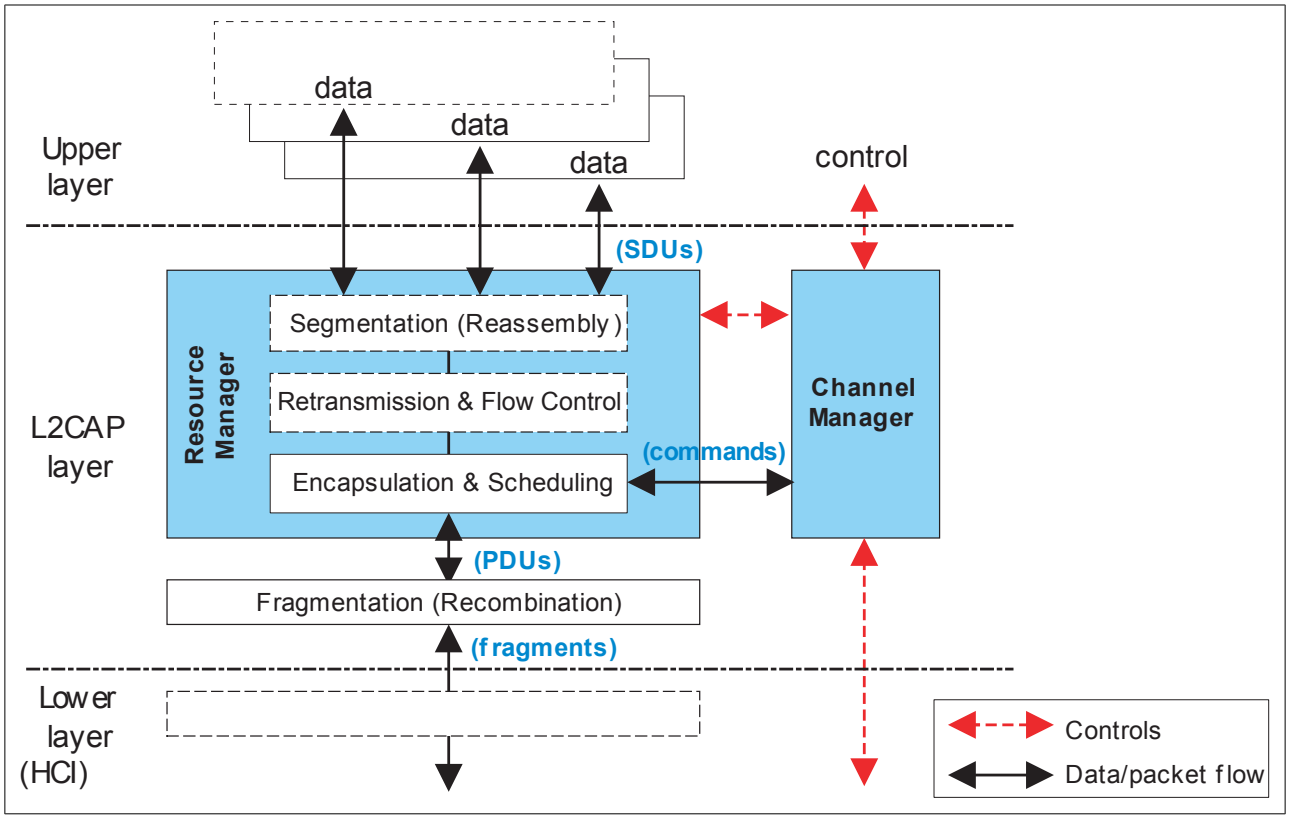

Figure 1.1: L2CAP architectural blocks

- *Protocol/channel multiplexing*

  L2CAP supports multiplexing over individual Controllers. An L2CAP channel shall operate over one Controller. An L2CAP channel cannot move between Controllers.

  During channel setup, protocol multiplexing capability is used to route the connection to the correct upper layer protocol.

  For data transfer, logical channel multiplexing is needed to distinguish between multiple upper layer entities. There may be more than one upper layer entity using the same protocol.

- *Segmentation and reassembly*

  With the frame relay service offered by the Resource Manager, the length of transport frames is controlled by the individual applications running over L2CAP. Many multiplexed applications are better served if L2CAP has control over the PDU length. This provides the following benefits:

  a. Segmentation will allow the interleaving of application data units in order to satisfy latency requirements.

  b. Memory and buffer management is easier when L2CAP controls the packet size.

  c. Error correction by retransmission can be made more efficient.

d. The amount of data that is destroyed when an L2CAP PDU is corrupted or lost can be made smaller than the application's data unit.

e. The application is decoupled from the segmentation required to map the application packets into the lower layer packets.

- *Flow control per L2CAP channel*

  Controllers provide error and flow control for data going over the air and HCI flow control exists for data going over an HCI transport. When several data streams run over the same Controller using separate L2CAP channels, each channel requires individual flow control. A window based flow control scheme is provided.

- *Error control and retransmissions*

  Some applications require a residual error rate much smaller than some Controllers can deliver. L2CAP provides error checks and retransmissions of L2CAP PDUs. The error checking in L2CAP protects against errors due to Controllers falsely accepting packets that contain errors but pass Controller-based integrity checks. L2CAP error checking and retransmission also protect against loss of packets due to flushing by the Controller. The error control works in conjunction with flow control in the sense that the flow control mechanism will throttle retransmissions as well as first transmissions.

- *Support for Streaming*

  Streaming applications such as audio set up an L2CAP channel with an agreed-upon data rate and do not want flow control mechanisms, including those in the Controller, to alter the flow of data. A flush timeout is used to keep data flowing on the transmit side. Streaming mode is used to stop HCI and Controller based flow control from being applied on the receiving side.

- *Fragmentation and Recombination*

  Some Controllers may have limited transmission capabilities and may require fragment sizes different from those created by L2CAP segmentation. Therefore layers below L2CAP may further fragment and recombine L2CAP PDUs to create fragments which fit each layer’s capabilities. During transmission of an L2CAP PDU, many different levels of fragmentation and recombination may occur in both peer devices.

  The HCI driver or Controller may fragment L2CAP PDUs to honor packet size constraints of a Host Controller Interface transport scheme. This results in HCI ACL Data packet payloads carrying start and continuation fragments of the L2CAP PDU. Similarly the Controller may fragment L2CAP PDUs to map them into Controller packets. This may result in Controller packet payloads carrying start and continuation fragments of the L2CAP PDU.

  Each layer of the protocol stack may pass on different sized fragments of L2CAP PDUs, and the size of fragments created by a layer may be different in each peer

device. However the PDU is fragmented within the stack, the receiving L2CAP entity still recombines the fragments to obtain the original L2CAP PDU.

- *Quality of Service*

  The L2CAP connection establishment process allows the exchange of information regarding the quality of service (QoS) expected between two Bluetooth devices. Each L2CAP implementation monitors the resources used by the protocol and ensures that QoS contracts are honored.

  For a BR/EDR or BR/EDR/LE Controller, L2CAP may support both isochronous (Guaranteed) and asynchronous (Best Effort) data flows over the same ACL logical link by marking packets as automatically-flushable or non-automatically-flushable by setting the appropriate value for the Packet_Boundary_Flag in the HCI ACL Data packet (see [Vol 4] Part E, Section 5.4.2). Automatically-flushable L2CAP packets are flushed according to the automatic flush timeout set for the ACL logical link on which the L2CAP channels are mapped (see [Vol 4] Part E, Section 6.19). Non-automatically-flushable L2CAP packets are not affected by the automatic flush timeout and will not be flushed. All L2CAP packets can be flushed by using the HCI_Flush command (see [Vol 4] Part E, Section 7.3.4).

  Note: The terms "Guaranteed" and "Best Effort" are used as a shorthand to indicate that the implementation will or will not attempt to provide some level of quality of service. They do not make any statement as to what actual quality is provided; in particular, "Guaranteed" does not mean that successful delivery of data is guaranteed. Similarly, a "guarantee" is a set of resources (such as bandwidth and buffer space) allocated to a "Guaranteed" connection and does not mean that a specific data rate and latency will be provided under all possible circumstances.

1.2 Assumptions

The protocol is designed based on the following assumptions:

1. Controllers provide orderly delivery of data packets, although there might be individual packet corruption and duplicates. For devices with a BR/EDR or BR/EDR/LE Controller, no more than one ACL-U logical link exists between any two devices. For devices with a BR/EDR/LE or LE Controller, no more than one LE-U logical link exists between any two devices.
2. Controllers always provide the impression of full-duplex communication channels. This does not imply that all L2CAP communications are bi-directional. Unidirectional traffic does not require duplex channels.
3. The L2CAP layer provides a channel with a degree of reliability based on the mechanisms available in Controllers and with additional packet segmentation, error detection, and retransmission that can be enabled in the enhanced L2CAP layer. Some Controllers perform data integrity checks and resend data until it has

been successfully acknowledged or a timeout occurs. Other Controllers will resend data up to a certain number of times whereupon the data is flushed. Because acknowledgments may be lost, timeouts may occur even after the data has been successfully sent.

Note: The use of Baseband Broadcast packets in a BR/EDR or BR/EDR/LE Controller is unreliable and all broadcasts start the first segment of an L2CAP packet with the same sequence bit.

4. Controllers provide error and flow control for data going over the air and HCI flow control exists for data going over an HCI transport but some applications will want better error control than some Controllers provide. The Flow and Error Control block provides four modes. Enhanced Retransmission mode and Retransmission mode offer segmentation, flow control and L2CAP PDU retransmissions. Flow control mode offers just the segmentation and flow control functions. Streaming mode offers segmentation and receiver side packet flushing.

1.3 Scope

The following features are outside the scope of L2CAP's responsibilities:

- L2CAP does not transport synchronous data designated for SCO or eSCO logical transports.
- L2CAP does not support a reliable broadcast channel. See Section 3.2.

1.4 Terminology

The following formal definitions apply:

Term	Description
Upper layer	The system layer above the L2CAP layer, which exchanges data with L2CAP in the form of SDUs. The upper layer may be represented by an application or higher protocol entity known as the Service Level Protocol. The interface of the L2CAP layer with the upper layer is not specified.
Lower layer	The system layer below the L2CAP layer, which exchanges data with the L2CAP layer in the form of PDUs, or fragments of PDUs. The lower layer is mainly represented within the Controller, however a Host Controller interface (HCI) may be involved, such that an HCI Host driver could also be seen as the lower layer. Except for the HCI functional specification (in case HCI is involved) the interface between L2CAP and the lower layer is not specified.
L2CAP channel	The logical connection between two endpoints in peer devices, characterized by their Channel Identifiers (CID), which is multiplexed over one Controller based logical link.

Term	Description
SDU, or L2CAP SDU	Service Data Unit: a packet of data that L2CAP exchanges with the upper layer and transports transparently over an L2CAP channel using the procedures specified here. The term SDU is associated with data originating from upper layer entities only, i.e. does not include any protocol information generated by L2CAP procedures.
Segment, or SDU segment	A part of an SDU, as resulting from the Segmentation procedure. An SDU may be split into one or more segments. Note: This term is relevant only to Enhanced Retransmission mode, Streaming mode, Retransmission mode, Flow Control mode, LE Credit Based Flow Control mode, and Enhanced Credit Based Flow Control mode, not to the Basic L2CAP mode.
Segmentation	A procedure used in the L2CAP Retransmission and Flow Control modes, resulting in an SDU being split into one or more smaller units, called Segments, as appropriate for the transport over an L2CAP channel. Note: This term is relevant only to the Enhanced Retransmission mode, Streaming mode, Retransmission mode, Flow Control mode, LE Credit Based Flow Control mode, and Enhanced Credit Based Flow Control mode, not to the Basic L2CAP mode.
Reassembly	The reverse procedure corresponding to Segmentation, resulting in an SDU being re-established from the segments received over an L2CAP channel, for use by the upper layer. The interface between the L2CAP and the upper layer is not specified; therefore, reassembly may actually occur within an upper layer entity although it is conceptually part of the L2CAP layer. Note: This term is relevant only to Enhanced Retransmission mode, Streaming mode, Retransmission mode, Flow Control mode, LE Credit Based Flow Control mode, and Enhanced Credit Based Flow Control mode, not to the Basic L2CAP mode.
PDU, or L2CAP PDU	Protocol Data Unit: a packet of data containing L2CAP protocol information fields, control information, and/or upper layer information data. A PDU is always started by a Basic L2CAP header. Types of PDUs are: B-frames, I-frames, S-frames, C-frames, G-frames, and K-frames.
Basic L2CAP header	Minimum L2CAP protocol information that is present in the beginning of each PDU: a PDU length field and a field containing the Channel Identifier (CID).
Basic information frame (B-frame)	A B-frame is a PDU used in the Basic L2CAP mode for L2CAP data packets. It contains a complete SDU as its payload, encapsulated by a Basic L2CAP header.
Information frame (I-frame)	An I-frame is a PDU used in Enhanced Retransmission mode, Streaming mode, Retransmission mode, and Flow Control mode. It contains an SDU segment and additional protocol information, encapsulated by a Basic L2CAP header.
Supervisory frame (S-frame)	An S-frame is a PDU used in Enhanced Retransmission mode, Retransmission mode, and Flow Control mode. It contains protocol information only, encapsulated by a Basic L2CAP header, and no SDU data.
Control frame (C-frame)	A C-frame is a PDU that contains L2CAP signaling messages exchanged between the peer L2CAP entities. C-frames are exclusively used on the L2CAP signaling channels.

Term	Description
Group frame (G-frame)	A G-frame is a PDU exclusively used on the Connectionless L2CAP channel. It is encapsulated by a Basic L2CAP header and contains the PSM followed by the completed SDU. G-frames may be used to broadcast data to active Peripherals via Active Peripheral Broadcast or to send unicast data to a single remote device.
Credit-based frame (K-frame)	A K-frame is a PDU used in LE Credit Based Flow Control mode and Enhanced Credit Based Flow Control mode. It contains an SDU segment and additional protocol information, encapsulated by a Basic L2CAP header.
Fragment	A part of a PDU, as resulting from a fragmentation operation. Fragments are used only in the delivery of data to and from the lower layer. They are not used for peer-to-peer transportation. A fragment may be a Start or Continuation Fragment with respect to the L2CAP PDU. A fragment does not contain any protocol information beyond the PDU; the distinction of start and continuation fragments is transported by lower layer protocol provisions. Note: Start Fragments always either begin with the first octet of the Basic L2CAP header of a PDU or they have a length of zero (see [Vol 2] Part B, Section 6.6.2).
Fragmentation	A procedure used to split L2CAP PDUs to smaller parts, named fragments, appropriate for delivery to the lower layer transport. Although described within the L2CAP layer, fragmentation may actually occur in an HCI Host driver, and/or in a Controller, to accommodate the L2CAP PDU transport to HCI ACL Data packet or Controller packet sizes. Fragmentation of PDUs may be applied in all L2CAP modes.
Recombination	The reverse procedure corresponding to fragmentation, resulting in an L2CAP PDU re-established from fragments. In the receive path, full or partial recombination operations may occur in the Controller and/or the Host, and the location of recombination does not necessarily correspond to where fragmentations occurs on the transmit side.
Maximum Transmission Unit (MTU)	The maximum size of an SDU, in octets, that the upper layer entity is capable of accepting.
Payload Size	The amount of SDU data in a single PDU, in octets; equivalently, the number of octets in the Information Payload field of a PDU.
Maximum PDU payload Size (MPS)	The maximum payload size in octets that the L2CAP layer entity is capable of accepting. In the absence of segmentation, or in the Basic L2CAP mode, the Maximum Transmission Unit is the same as the Maximum PDU payload Size and the two configuration parameters shall be set to the same value.
Signaling MTU (MTU_{sig})	The maximum size of command information that the L2CAP layer entity is capable of accepting. The MTU_{sig}, refers to the signaling channel only and corresponds to the maximum size of a C-frame, excluding the Basic L2CAP header. The MTU_{sig} value of a peer is discovered when a C-frame that is too large is rejected by the peer.

Term	Description
Connectionless MTU (MTU_{cnl})	The maximum size of the connection packet information that the L2CAP layer entity is capable of accepting. The MTU_{cnl} refers to the connectionless channel only and corresponds to the maximum G-frame, excluding the Basic L2CAP header and the PSM which immediately follows it. The MTU_{cnl} of a peer can be discovered by sending an L2CAP_INFORMATION_REQ packet.
MaxTransmit	In Enhanced Retransmission mode and Retransmission mode, MaxTransmit controls the number of transmissions of a PDU that L2CAP is allowed to try before assuming that the PDU (and the link) is lost. The minimum value is 1 (only 1 transmission permitted). In Enhanced Retransmission mode a value 0 means infinite transmissions. Note: Setting MaxTransmit to 1 prohibits PDU retransmissions. Failure of a single PDU will cause the link to drop. By comparison, in Flow Control mode, failure of a single PDU will not necessarily cause the link to drop.

Table 1.1: Terminology

2 GENERAL OPERATION

L2CAP is based around the concept of *'channels'*. Each one of the endpoints of an L2CAP channel is referred to by a *channel identifier (CID).*

2.1 Channel identifiers

A channel identifier (CID) is the local name representing a logical channel endpoint on the device. The scope of CIDs is related to the logical link as shown in Figure 2.1. The null identifier (0x0000) shall not be used as a destination endpoint. Identifiers from 0x0001 to 0x003F are reserved for specific L2CAP functions. These channels are referred to as fixed channels. An implementation of L2CAP shall support the fixed channel 0x0001 (see Table 2.1) on all ACL-U logical links and the fixed channels 0x0004, 0x0005, and 0x0006 (see Table 2.3) on all LE-U logical links. Other fixed channels may be supported on each logical link. The L2CAP_INFORMATION_REQ / L2CAP_INFORMATION_RSP mechanism (described in Section 4.10 and Section 4.11) shall be used to determine which fixed channels a remote device supports over the ACL-U logical link. Each fixed channel has the same CID at each end of the logical link carrying the channel.

The characteristics of each fixed channel are defined on a per channel basis. Fixed channel characteristics include configuration parameters (e.g., reliability, MTU size, QoS), security, and the ability to change parameters using the L2CAP configuration mechanism. Table 2.1 lists the defined fixed channels, provides a reference to where the associated channel characteristics are defined and specifies the logical link over which the channel may operate. Fixed channels are available as soon as the ACL-U or LE-U logical link is set up. All initialization that is normally performed when a channel is created shall be performed for each of the supported fixed channels when the ACL-U or LE-U logical link is set up. Fixed channels shall only run over ACL-U, APB-U, or LE-U logical links.

Implementations are free to manage the remaining CIDs in a manner best suited for that particular implementation, with the provision that two simultaneously active L2CAP channels on the same logical link (i.e., to the same peer device using the same transport) shall not share the same CID. A different CID name space exists for each ACL-U, APB-U, and LE-U logical link. Table 2.1 to Table 2.3 summarize the definition and partitioning of the CID name space for each type of logical link.

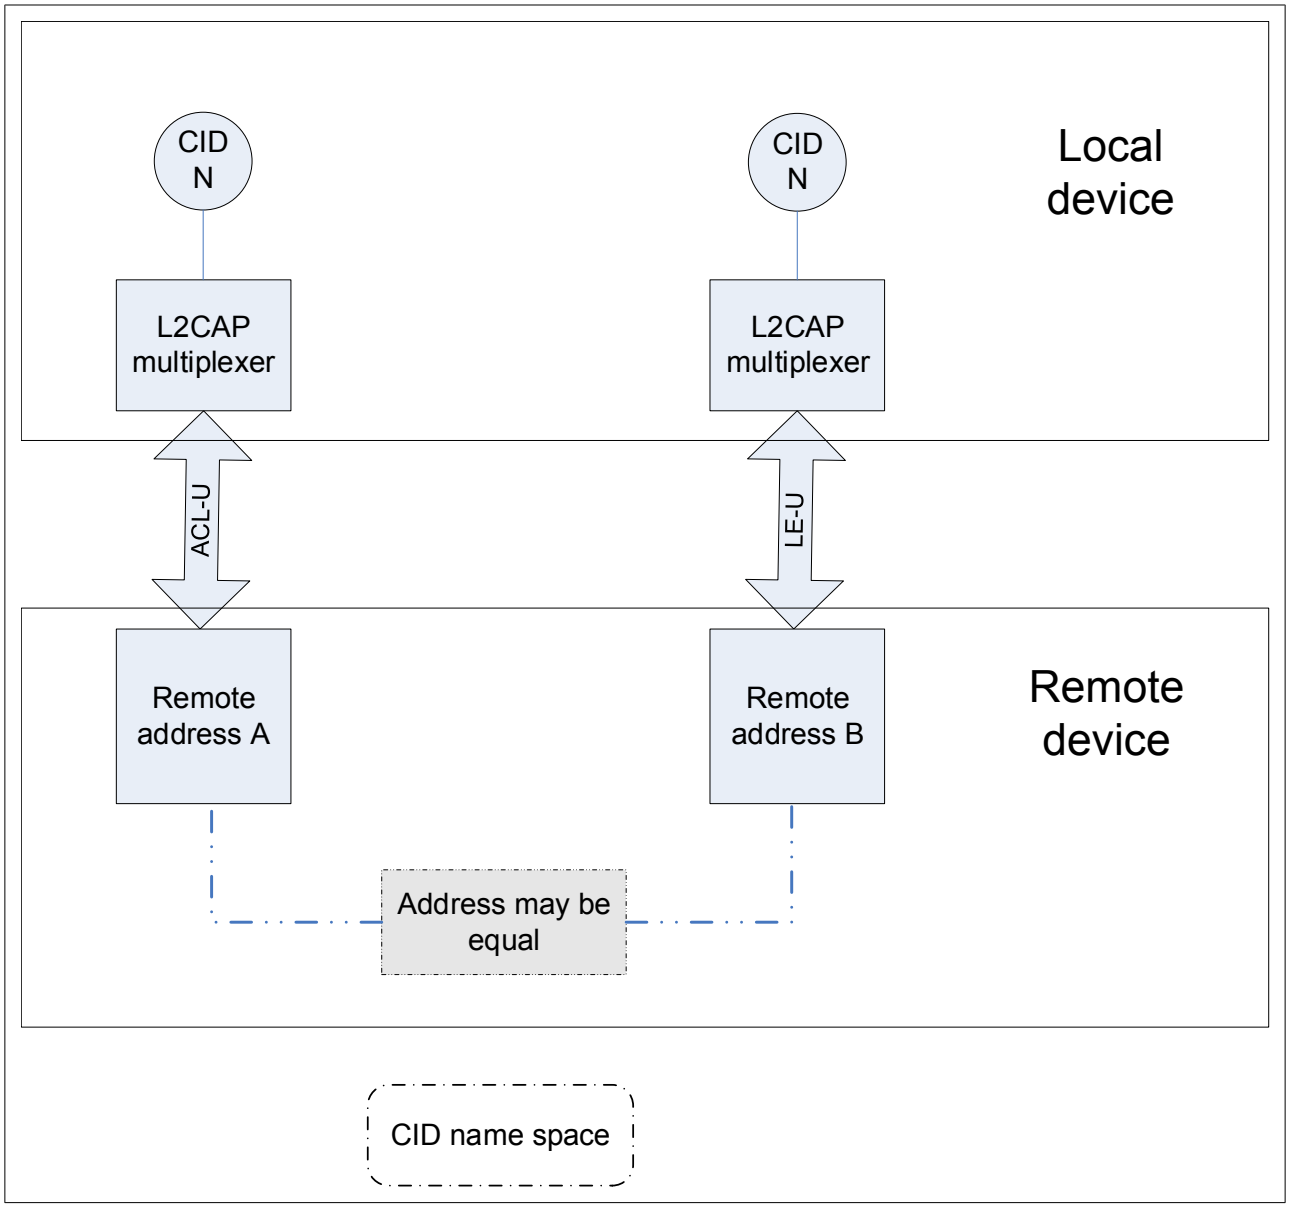

Figure 2.1: Dynamically allocated CID assignments

Assignment of dynamically allocated CIDs is relative to a particular logical link and a device can assign CIDs independently from other devices. Thus, even if the same CID value has been assigned to (remote) channel endpoints by several remote devices connected to a single local device, the local device can still uniquely associate each remote CID with a different device. Further, even if the same CID value has been assigned to (remote) channel endpoints by the same remote device, these can be distinguished because they will be bound to a different logical link.

The CID name space for ACL-U logical links is as follows:

CID	Description	Channel Characteristics
0x0000	Null identifier	Not allowed
0x0001	L2CAP Signaling channel	See Section 4
0x0002	Connectionless channel	See Section 7.6
0x0003	Previously used	Not applicable
0x0007	BR/EDR Security Manager	See [Vol 3] Part H
0x003F	Previously used	Not applicable
0x0040 to 0xFFFF	Dynamically allocated	Communicated using L2CAP configuration mechanism (see Section 7.1) or the L2CAP credit based create connection mechanism (see Section 4.25)
All other values	Reserved for future use	Not applicable

Table 2.1: CID name space on ACL-U logical links

The CID name space for APB-U logical links is as follows:

CID	Description	Channel Characteristics
0x0000	Null identifier	Not allowed
0x0002	Connectionless channel	See Section 7.6
All other values	Reserved for future use	Not applicable

Table 2.2: CID name space on APB-U logical links

The CID name space for LE-U logical links is as follows:

CID	Description	Channel Characteristics
0x0000	Null identifier	Not Allowed
0x0004	Attribute Protocol	See [Vol 3] Part F
0x0005	L2CAP LE Signaling channel	See Section 4
0x0006	Security Manager protocol	See [Vol 3] Part H
0x0020 to 0x003E	Assigned Numbers	

CID	Description	Channel Characteristics
0x0040 to 0x007F	Dynamically allocated	Communicated using the L2CAP LE credit based create connection mechanism (see Section 4.22) or the L2CAP credit based create connection mechanism (see Section 4.25)
All other values	Reserved for future use	Not applicable

Table 2.3: CID name space on LE-U logical links

2.2 Operation between devices

Figure 2.2 illustrates the use of CIDs in a communication between corresponding peer L2CAP entities in separate devices. The connection-oriented data channels represent a connection between two devices, where a CID, combined with the logical link, identifies each endpoint of the channel. When used for broadcast transmissions, the connectionless channel restricts data flow to a single direction. The connectionless channel may be used to transmit data to all active Peripherals, using Active Peripheral Broadcast. When used for unicast transmissions the connectionless channel may be used in either direction between a Central and a Peripheral.

There are also a number of CIDs reserved for special purposes. The L2CAP signaling channels are examples of reserved channels. Fixed channel 0x0001 is used to create and establish connection-oriented data channels and to negotiate changes in the characteristics of connection-oriented channels and to discover characteristics of the connectionless channel operating over the ACL-U logical link.

The L2CAP Signaling channel (0x0001) and all supported fixed channels are available immediately when the ACL-U logical link is established between two devices. Another CID (0x0002) is reserved for all incoming and outgoing connectionless data traffic, whether broadcast or unicast. Connectionless data traffic may flow immediately once the ACL-U logical link is established between two devices and once the transmitting device has determined that the remote device supports connectionless traffic.

The L2CAP LE Signaling channel (0x0005) and all supported fixed channels are available immediately when the LE-U logical link is established between two devices.

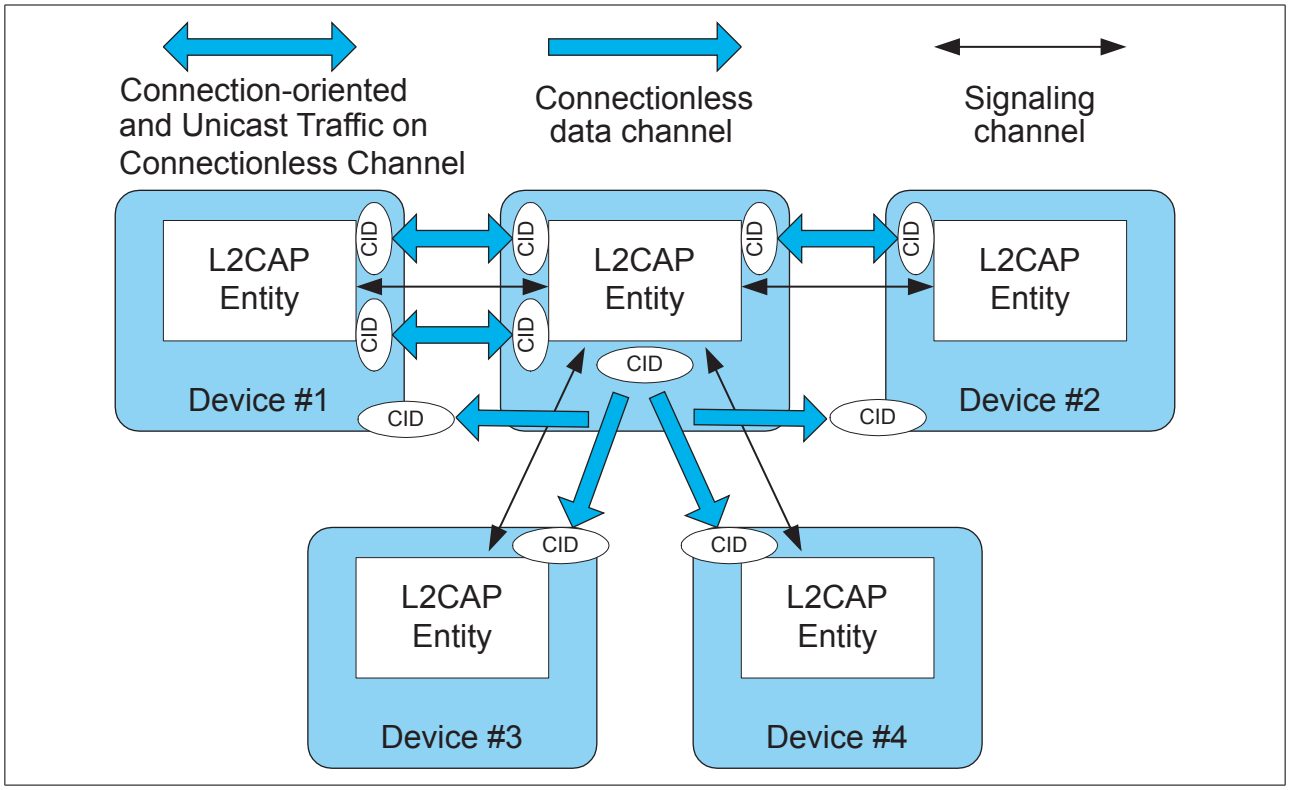

Figure 2.2: Channels between devices

Table 2.4 describes the various channel types and their source and destination identifiers. A dynamically allocated CID is allocated to identify, along with the logical link, the local endpoint and shall be in the range 0x0040 to 0xFFFF for ACL-U, 0x0040 to 0x007F for LE-U. Section 6 describes the state machine associated with each connection-oriented channel with a dynamically allocated CID. Section 3.1 and Section 3.3 describe the packet format associated with connection-oriented channels. Section 3.2 describes the packet format associated with the connectionless channel.

Channel Type	Local CID (sending)	Remote CID (receiving)
Connection-oriented	Dynamically allocated and fixed	Dynamically allocated and fixed
Connectionless data	0x0002 (fixed)	0x0002 (fixed)
L2CAP Signaling	0x0001 and 0x0005 (fixed)	0x0001 and 0x0005 (fixed)

Table 2.4: Types of channel identifiers

2.3 Operation between layers

L2CAP implementations should follow the general architecture described below. L2CAP implementations transfer data between upper layer protocols and the lower layer protocol. This document lists a number of services that should be exported by any L2CAP implementation. Each implementation shall also support a set of signaling commands for use between L2CAP implementations. L2CAP implementations should

also be prepared to accept certain types of events from lower layers and generate events to upper layers. How these events are passed between layers is implementation specific.

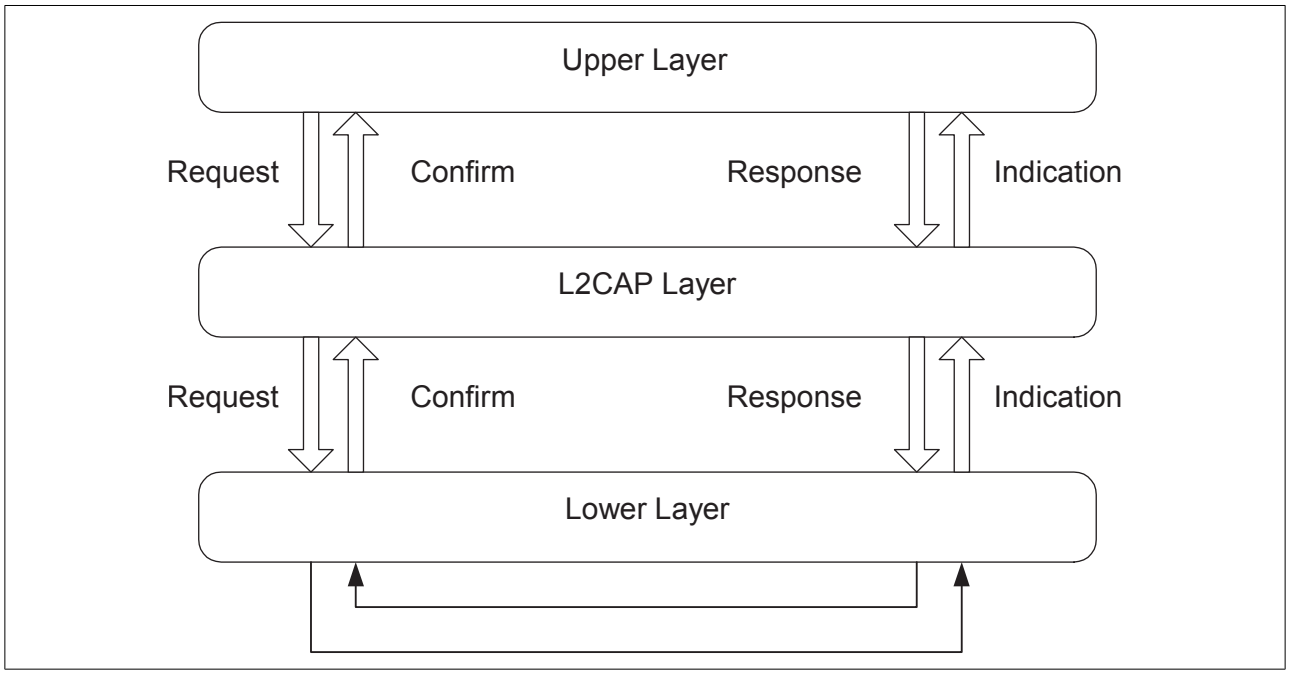

Figure 2.3: L2CAP transaction model

2.4 Modes of operation

L2CAP channels may operate in one of several different modes as selected for each L2CAP channel.

The modes are:

- Basic L2CAP mode (BR/EDR and some LE fixed channels only)
- Flow Control mode (BR/EDR only)
- Retransmission mode (BR/EDR only)
- Enhanced Retransmission mode (BR/EDR only)
- Streaming mode (BR/EDR only)
- LE Credit Based Flow Control mode (LE only)
- Enhanced Credit Based Flow Control mode (BR/EDR and LE)

The modes are enabled using the configuration procedure described in Section 7.1. The Basic L2CAP mode shall be the default mode, which is used when no other mode is agreed. Enhanced Retransmission mode shall be used for ACL-U logical links operating as described in Section 7.10. Enhanced Retransmission mode should

be enabled for reliable channels created over ACL-U logical links not operating as described in Section 7.10. Streaming mode shall be used for ACL-U logical links operating as described in Section 7.10. Streaming mode should be enabled for streaming applications created over ACL-U logical links not operating as described in Section 7.10. Enhanced Retransmission mode, Enhanced Credit Based Flow Control mode, or Streaming mode should be enabled when supported by both L2CAP entities. Flow Control mode and Retransmission mode shall only be enabled when communicating with L2CAP entities that do not support Enhanced Retransmission mode, Enhanced Credit Based Flow Control mode, or Streaming mode.

In Flow Control mode, Retransmission mode, and Enhanced Retransmission mode, PDUs exchanged with a peer entity are numbered and acknowledged. The sequence numbers in the PDUs are used to control buffering, and a TxWindow size is used to limit the required buffer space and/or provide a method for flow control.

In Flow Control mode no retransmissions take place, but missing PDUs are detected and can be reported as lost.

In Retransmission mode a timer is used to ensure that all PDUs are delivered to the peer, by retransmitting PDUs as needed. A go-back-n repeat mechanism is used to simplify the protocol and limit the buffering requirements.

Enhanced Retransmission mode is similar to Retransmission mode. It adds the ability to set a POLL bit to solicit a response from a remote L2CAP entity, adds the SREJ S-frame to improve the efficiency of error recovery and adds an RNR S-frame to replace the R-bit for reporting a local busy condition.

Streaming mode is for real-time isochronous traffic. PDUs are numbered but are not acknowledged. A finite flush timeout is set on the sending side to flush packets that are not sent in a timely manner. On the receiving side if the receive buffers are full when a new PDU is received then a previously received PDU is overwritten by the newly received PDU. Missing PDUs can be detected and reported as lost. TxWindow size is not used in Streaming mode.

LE Credit Based Flow Control mode is used for LE L2CAP connection-oriented channels for flow control using a credit based scheme for L2CAP data (i.e. not signaling packets).

Enhanced Credit Based Flow Control mode is used for L2CAP connection-oriented channels on both LE and BR/EDR for flow control using a credit-based scheme for L2CAP data (i.e. not signaling packets). A BR/EDR/LE device that implements Enhanced Credit Based Flow Control mode may support it on BR/EDR only, on LE only, or on both.

Enhanced Retransmission mode should be used instead of Enhanced Credit Based Flow Control mode for data being transmitted over BR/EDR.

Care should be taken in selecting the parameters used for Enhanced Retransmission mode and Streaming mode when they are used beneath legacy profile implementations to ensure that performance is not negatively impacted relative to the performance achieved when using the same profile with Basic mode on an ACL-U logical link. It may be preferable to configure Basic mode to minimize the risk of negative performance impacts.

2.5 Mapping channels to logical links

L2CAP maps channels to Controller logical links, which in turn run over Controller physical links. All logical links going between a local Controller and remote Controller run over a single physical link. There is one ACL-U logical link per BR/EDR physical link and one LE-U logical link per LE physical link.

All Best Effort and Guaranteed channels going over a BR/EDR physical link between two devices shall be mapped to a single ACL-U logical link. All channels going over an LE physical link between two devices shall be treated as best effort and mapped to a single LE-U logical link.

When a Guaranteed channel is created, a corresponding Guaranteed logical link shall be created to carry the channel traffic. Creation of a Guaranteed logical link involves admission control. Admission control is verifying that the guarantee can be achieved without compromising existing guarantees. For a BR/EDR Controller, admission control (creation of a Guaranteed logical link) shall be performed by the L2CAP layer.

3 DATA PACKET FORMAT

L2CAP is packet-based but follows a communication model based on *channels*. A channel represents a data flow between L2CAP entities in remote devices. Channels may be connection-oriented or connectionless. All channels other than the L2CAP connectionless channel (CID 0x0002) and the two L2CAP signaling channels (CIDs 0x0001 and 0x0005) are connection-oriented. All L2CAP layer packet fields shall use little-endian byte order with the exception of the information payload field. The endianness of higher layer protocols encapsulated within L2CAP information payload is protocol-specific.

If a PDU is received on a CID that is not assigned or is reserved for future use on the logical link type, the recipient shall ignore that PDU.

In all L2CAP PDUs, the PDU Length field indicates the size of the entire L2CAP PDU in octets, excluding the 4 octets of the Basic L2CAP header. Therefore a PDU cannot be more than 65539 octets long.

In PDUs that contain an Information Payload field, the number of octets in that field (the payload size) shall not be greater than the peer device's MPS for the channel.

3.1 Connection-oriented channels in Basic L2CAP mode

Figure 3.1 illustrates the format of the L2CAP PDU used on connection-oriented channels. In basic L2CAP mode, the L2CAP PDU on a connection-oriented channel is also referred to as a "B-frame".

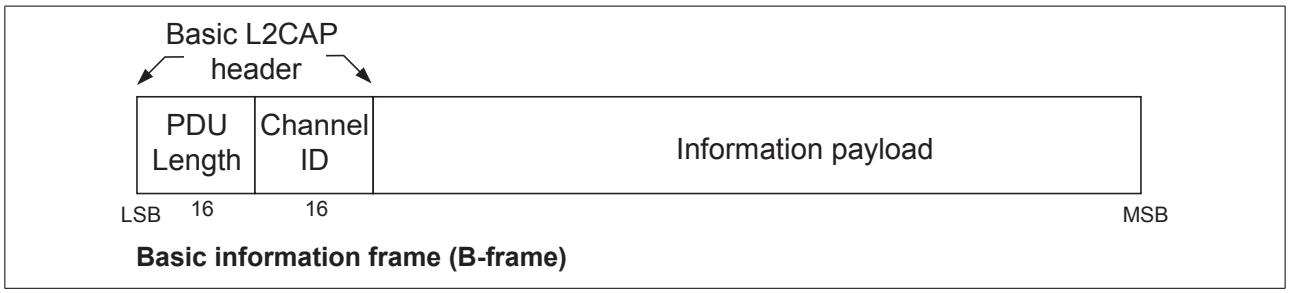

Figure 3.1: L2CAP PDU format in Basic L2CAP mode on connection-oriented channels (field sizes in bits)

The fields shown are:

- *PDU Length: 2 octets (16 bits)*

  For B-frames, the PDU Length equals the payload size and can be up to 65535 octets. The PDU Length field is used for recombination and serves as a simple integrity check of the recombined L2CAP packet on the receiving end.

- *Channel ID: 2 octets*

  The channel ID (CID) identifies the destination channel endpoint of the packet.

- *Information payload: 0 to 65535 octets*

  This contains the payload received from the upper layer protocol (outgoing packet), or delivered to the upper layer protocol (incoming packet). The payload size shall not be greater than the peer device's MTU for the channel. The MTU for channels with dynamically allocated CIDs is determined during channel configuration (see Section 5.1). The minimum supported MTU values for the signaling PDUs are shown in Table 4.1.

3.2 Connectionless data channel in Basic L2CAP mode

Figure 3.2 illustrates the L2CAP PDU format within a connectionless data channel. Here, the L2CAP PDU is also referred to as a "G-frame".

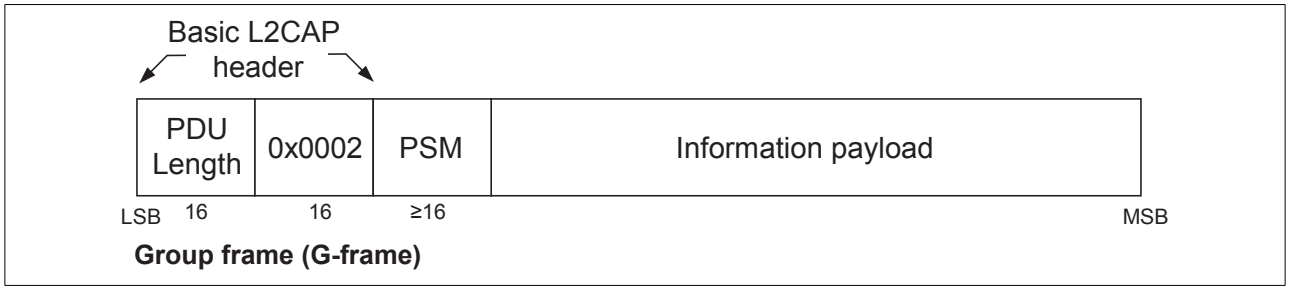

Figure 3.2: L2CAP PDU format on the connectionless channel

The fields shown are:

- *PDU Length: 2 octets*

  For G-frames, the PDU Length equals the payload size plus the number of octets in the PSM.

- *Channel ID: 2 octets*

  Channel ID (0x0002) reserved for connectionless traffic.

- *Protocol/Service Multiplexer (PSM): 2 octets (minimum)*

  For information on the PSM field see Section 4.2.

- *Information payload: 0 to 65533 octets*

  This parameter contains the payload information to be distributed to all Peripherals in the piconet for broadcast connectionless traffic, or to a specific remote device for data sent via the L2CAP connectionless channel. The payload size shall not be greater than the peer device's MTU for the channel. Implementations shall support a connectionless MTU (MTU_{cnl}) of 48 octets on the connectionless channel. Devices may also explicitly change to a larger or smaller connectionless MTU (MTU_{cnl}).

Note: The maximum size of the Information payload field decreases accordingly if the PSM field is extended beyond the two octet minimum.

3.3 Connection-oriented channel in Retransmission/Flow Control/ Streaming modes

To support flow control, retransmissions, and streaming, L2CAP PDU types with protocol elements in addition to the Basic L2CAP header are defined. The information frames (I-frames) are used for information transfer between L2CAP entities. The supervisory frames (S-frames) are used to acknowledge I-frames and request retransmission of I-frames. Figure 3.3 illustrates these frames.

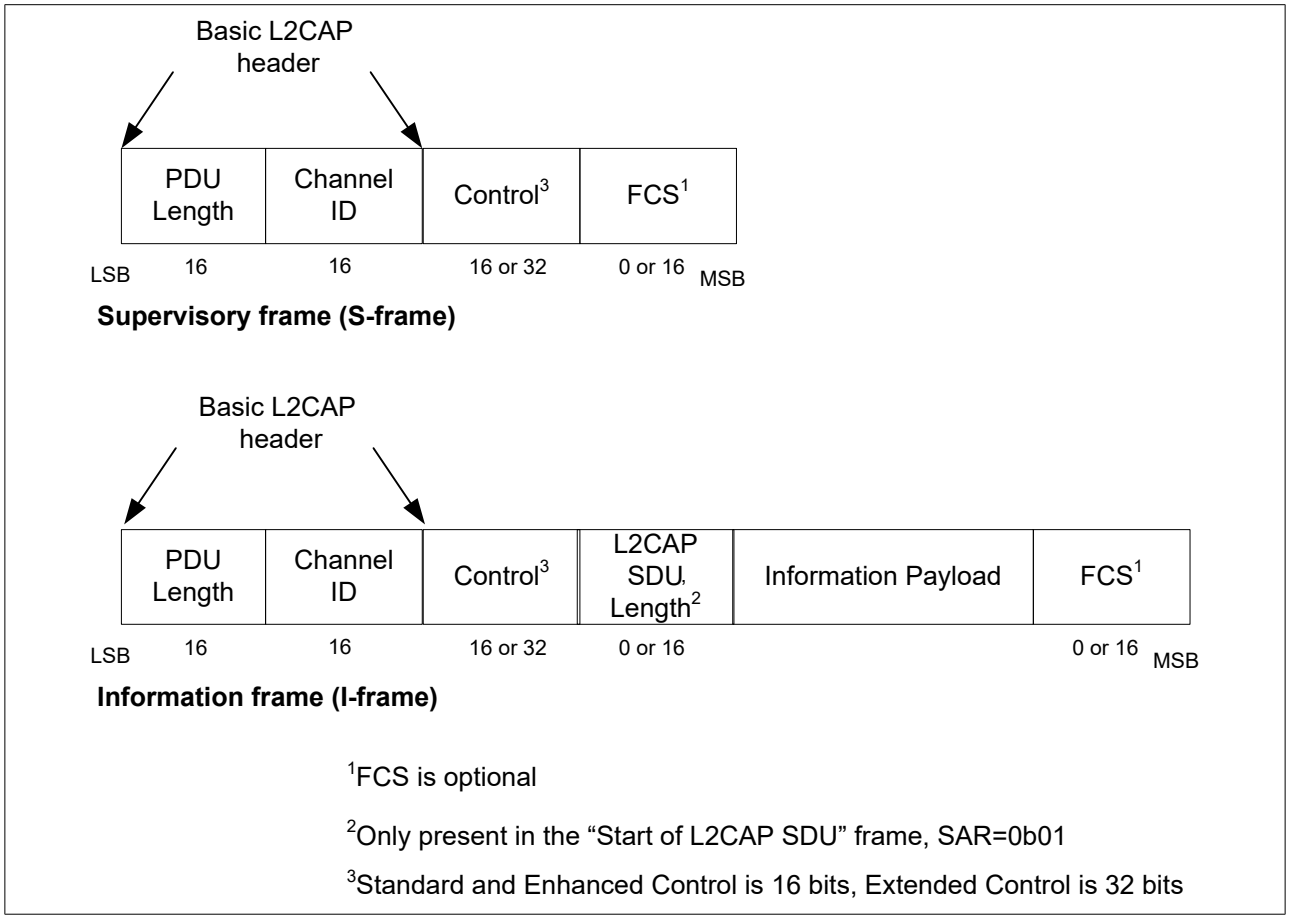

Figure 3.3: L2CAP PDU formats in Flow Control and Retransmission modes

3.3.1 L2CAP header fields

- *PDU Length: 2 octets*

  For I-frames and S-frames, the PDU Length equals the sum of the octet lengths of the Control, L2CAP SDU Length (when present), Information Payload, and frame check sequence (FCS) (when present) fields. The PDU Length field of an S-frame therefore equals 2, 4, or 6.

The maximum number of Information octets (the payload size) in one I-frame is based on which fields are present and the type of the Control Field. The maximum number of Information octets in an I-frame with a Standard Control field is as follows:

L2CAP SDU Length present and FCS present	65529 octets
L2CAP SDU Length present and FCS not present	65531 octets
L2CAP SDU Length not present and FCS present	65531 octets
L2CAP SDU Length not present and FCS not present	65533 octets

The maximum number of Information octets in an I-frame with an Extended Control field is as follows:

L2CAP SDU Length present and FCS present	65527 octets
L2CAP SDU Length present and FCS not present	65529 octets
L2CAP SDU Length not present and FCS present	65529 octets
L2CAP SDU Length not present and FCS not present	65531 octets

- *Channel ID: 2 octets*

  This field contains the Channel Identification (CID).

3.3.2 Control field

The Control Field identifies whether the frame is an S-frame or I-frame and contains various information about the frame. There are three different Control Field formats: the Standard Control Field, the Enhanced Control Field, and the Extended Control Field. Which format is used is determined by the mode and is not indicated within the frame. The Standard Control Field shall be used for Retransmission mode and Flow Control mode. The Enhanced and Extended Control Fields shall be used for Enhanced Retransmission mode and Streaming mode. The Enhanced Control Fields shall be used until the first successful use of the Extended Window Size option (see Section 5.7) and Extended Control Fields thereafter. The Control Field will contain sequence numbers where applicable. Its coding is shown in Figure 3.4 to Figure 3.9. There are two different frame types, Information frame types and Supervisory frame types. Information and Supervisory frames types are distinguished by the least significant bit in the Control Field.

- *Information frame format (I-frame)*

  The I-frames are used to transfer information between L2CAP entities. Each I-frame has a TxSeq(Send sequence number), ReqSeq(Receive sequence number) which can acknowledge additional I-frames received by the data Link Layer entity. Each I-frame with a Standard Control field has a retransmission bit (R bit) that affects whether I-frames are retransmitted. Each I-frame with an Enhanced Control Field or an Extended Control Field has an F-bit that is used in Poll/Final bit functions.

The SAR field in the I-frame is used for segmentation and reassembly control. The L2CAP SDU Length field specifies the length of an SDU, including the aggregate length across all segments if segmented.

- *Supervisory frame format (S-frame)*

  S-frames are used to acknowledge I-frames and request retransmission of I-frames. Each S-frame has an ReqSeq sequence number which may acknowledge additional I-frames received by the data Link Layer entity. Each S-frame with a Standard Control Field has a retransmission bit (R bit) that affects whether I-frames are retransmitted. Each S-frame with an Enhanced Control field or an Extended Control Field has a Poll bit (P-bit) and a Final bit (F-bit) and does not have an R-bit.

  Defined types of S-frames are RR (Receiver Ready), REJ (Reject), RNR (Receiver Not Ready) and SREJ (Selective Reject).

I-frame Standard Control Field				
LSB				MSB
Type (1 bit)	TxSeq (6 bits)	R (1 bit)	ReqSeq (6 bits)	SAR (2 bits)

S-frame Extended Control Field					
LSB					MSB
Type (1 bit)	F (1 bit)	ReqSeq (14 bits)	S (2 bits)	P (1 bit)	RFU (13 bits)

Figure 3.9: S-frame Extended Control Field format

- *Type*

  The type bit shall be 0 for an I-frame and 1 for an S-frame.

- *Send Sequence Number - TxSeq*

  The send sequence number is used to number each I-frame, to enable sequencing and retransmission.

- *Receive Sequence Number - ReqSeq*

  The receive sequence number is used by the receiver side to acknowledge I-frames, and in the REJ and SREJ frames to request the retransmission of an I-frame with a specific send sequence number.

- *Retransmission Disable Bit - R*

  The Retransmission Disable bit is used to implement Flow Control. The receiver sets the bit when its internal receive buffer is full, this happens when one or more I-frames have been received but the SDU reassembly function has not yet pulled all the frames received. When the sender receives a frame with the Retransmission

Disable bit set it shall disable the RetransmissionTimer, this causes the sender to stop retransmitting I-frames.

R=0: Normal operation. Sender uses the RetransmissionTimer to control retransmission of I-frames. Sender does not use the MonitorTimer.

R=1: Receiver side requests sender to postpone retransmission of I-frames. Sender monitors signaling with the MonitorTimer. Sender does not use the RetransmissionTimer.

The functions of ReqSeq and R are independent.

- *Segmentation and Reassembly - SAR*

  The SAR bits define whether an L2CAP SDU is segmented. For segmented SDUs, the SAR bits also define which part of an SDU is in this I-frame, thus allowing one L2CAP SDU to span several I-frames.

  An I-frame with SAR=”Start of L2CAP SDU” also contains an L2CAP SDU Length field, specifying the number of information octets in the total L2CAP SDU. The encoding of the SAR bits is shown in Table 3.1.

0b00	Unsegmented L2CAP SDU
0b01	Start of L2CAP SDU
0b10	End of L2CAP SDU
0b11	Continuation of L2CAP SDU

Table 3.1: SAR control element format

- *Supervisory function - S*

  The S-bits mark the type of S-frame. There are four types defined: RR (Receiver Ready), REJ (Reject), RNR (Receiver Not Ready) and SREJ (Selective Reject). The encoding is shown in Table 3.2.

0b00	RR - Receiver Ready
0b01	REJ - Reject
0b10	RNR - Receiver Not Ready
0b11	SREJ - Select Reject

Table 3.2: S control element format: type of S-frame

- *Poll - P*

  The P-bit is set to 1 to solicit a response from the receiver. The receiver shall respond immediately with a frame with the F-bit set to 1.

- *Final - F*

  The F-bit is set to 1 in response to an S-frame with the P bit set to 1.

3.3.3 L2CAP SDU Length field (2 octets)

When an SDU spans more than one I-frame, the first I-frame in the sequence shall be identified by SAR=0b01=”Start of L2CAP SDU”. The L2CAP SDU Length field shall specify the total number of octets in the SDU and shall not be greater than the peer device's MTU for the channel. The L2CAP SDU Length field shall be present in I-frames with SAR=0b01 (Start of L2CAP SDU) and shall not be used in any other I-frames. When the SDU is unsegmented (SAR=0b00), the L2CAP SDU Length field is not needed and shall not be present.

3.3.4 Information Payload field

The information payload field consists of an integer number of octets. The maximum number of octets in this field is the same as the negotiated value of the MPS configuration parameter. The maximum number of octets in this field also depends on which other fields are present (see Section 3.3.1). If SAR=0b00 (Unsegmented L2CAP SDU) then the payload size shall not be greater than the peer device's MTU for the channel.

3.3.5 Frame Check Sequence (2 octets)

The Frame Check Sequence (FCS) is 2 octets. This field is mandatory in Retransmission and Flow Control modes. Whether it is present or absent in Enhanced Retransmission and Streaming modes is configurable (see Section 5.5).

The FCS is constructed using the generator polynomial $g(D) = D^{16} + D^{15} + D^2 + 1$ (see Figure 3.10). The 16 bit LFSR is initially loaded with the value 0x0000, as depicted in Figure 3.11. The switch S is set in position 1 while data is shifted in, LSB first for each octet. After the last bit has entered the LFSR, the switch is set in position 2, and the register contents are transmitted from right to left (i.e. starting with position 15, then position 14, etc.). The FCS covers the Basic L2CAP header, Control, L2CAP SDU Length, and Information Payload fields, if present, as shown in Figure 3.3.

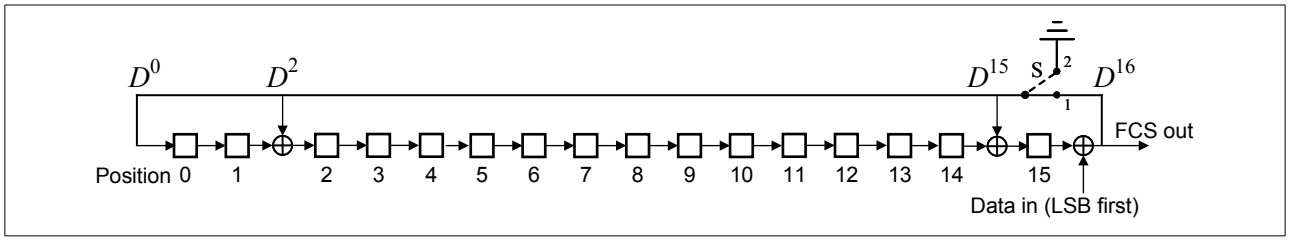

Figure 3.10: The LFSR circuit generating the FCS

Position	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
LFSR	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 3.11: Initial state of the FCS generating circuit

Examples of FCS calculation, $g(D) = D^{16} + D^{15} + D^2 + 1$:

1. ***I Frame***

   PDU Length = 14
   Channel ID = 0x0040
   Control = 0x0002 (SAR=0b00, ReqSeq=0b000000, R=0, TxSeq=0b000001)
   Information Payload = 00 01 02 03 04 05 06 07 08 09 (10 octets, hexadecimal notation)
   ==> FCS = 0x6138
   ==> Data to Send = 0E 00 40 00 02 00 00 01 02 03 04 05 06 07 08 09 38 61 (hexadecimal notation)

2. ***RR Frame***

   PDU Length = 4
   Channel ID = 0x0040
   Control = 0x0101 (ReqSeq=0b000001, R=0, S=0b00)
   ==> FCS = 0x14D4
   ==> Data to Send = 04 00 40 00 01 01 D4 14 (hexadecimal notation)

3.3.6 Invalid Frame Detection (Retransmission and Flow Control modes)

For Retransmission mode and Flow Control mode, a received PDU shall be regarded as invalid if one of the following conditions occurs:

1. Contains an unknown CID.
2. Contains an FCS error.
3. I-frame with a payload size greater than the maximum PDU payload size (MPS).
4. I-frame that has fewer than 8 octets (i.e., PDU Length less than 4).
5. I-frame with SAR=0b01 (Start of L2CAP SDU) that has fewer than 10 octets (i.e., PDU Length less than 6).
6. I-frame with SAR bits that do not correspond to a normal sequence of either unsegmented or start, continuation, end for the given CID.
7. S-frame where the PDU Length field is not equal to 4.

These error conditions may be used for error reporting.

3.3.7 Invalid Frame Detection algorithm

For Enhanced Retransmission mode and Streaming mode the following algorithm shall be used for received PDUs. It may be used for Retransmission mode and Flow Control mode:

1. Check the CID. If the PDU contains an unknown CID then it shall be ignored.
2. Check the FCS. If the PDU contains an FCS error then it shall be ignored. If the channel is configured to use "No FCS" then the PDU is considered to have a good FCS (no FCS error).
3. Check the following conditions. If one of the conditions occurs the channel shall be closed or in the case of fixed channels the ACL shall be disconnected.
    a. I-frame with a payload size greater than the maximum PDU payload size (MPS).
    b. I-frame that has fewer than the required number of octets. If the channel is configured to use a Standard or Enhanced Control Field then the required number of octets is 6 if "No FCS" is configured; otherwise, it is 8. If the channel is configured to use the Extended Control Field then the required number of octets is 8 if "No FCS" is configured; otherwise, it is 10.
    c. S-frame where the PDU Length field is invalid. If the channel is configured to use a Standard or Enhanced Control Field then the PDU Length field shall be 2 if "No FCS" is configured; otherwise, the PDU Length field shall be 4. If the channel is configured to use the Extended Control Field then the PDU Length field shall be 4 if "No FCS" is configured; otherwise, the PDU Length field shall be 6.
4. Check the SAR bits. The SAR check is performed after the frame has been successfully received in the correct sequence. The PDU is invalid if one of the following conditions occurs:
    a. I-frame with SAR=0b01 (Start of L2CAP SDU) that has fewer than the required number of octets. If the channel is configured to use a Standard or Enhanced Control field then the required number of octets is 8 if "No FCS" is configured; otherwise, the required number of octets is 10. If the channel is configured to use an Extended Control field then the required number of octets is 10 if "No FCS" is configured; otherwise, the required number of octets is 12.
    b. I-frame with SAR bits that do not correspond to a normal sequence of either unsegmented or start, continuation, end for the given CID.
    c. I-frame with SAR= 0b01 (Start of L2CAP SDU) where the value in the L2CAP SDU Length field exceeds the configured MTU.
5. If the I-frame has been received in the correct sequence and is invalid as described in 4 then the channel shall be closed or in the case of fixed channels the ACL

shall be disconnected. For Streaming mode and Flow Control mode if one or more I-frames are missing from a sequence of I-frames using SAR bits of start, continuation and end then received I-frames in the sequence may be ignored. For Flow Control mode and Streaming mode I-frames received out of sequence with SAR bits of unsegmented may be accepted.

If the algorithm is used for Retransmission mode or Flow control mode then it shall be used instead of Invalid Frame detection described in Section 3.3.6.

These error conditions may be used for error reporting.

3.4 Connection-oriented channels in LE Credit Based Flow Control mode and Enhanced Credit Based Flow Control mode

To support LE Credit Based Flow Control mode and Enhanced Credit Based Flow Control mode, an L2CAP PDU type with protocol elements in addition to the Basic L2CAP header is defined. In LE Credit Based Flow Control mode and Enhanced Credit Based Flow Control mode, the L2CAP PDU on a connection-oriented channel is a Credit-based frame (K-frame) as illustrated in Figure 3.12.

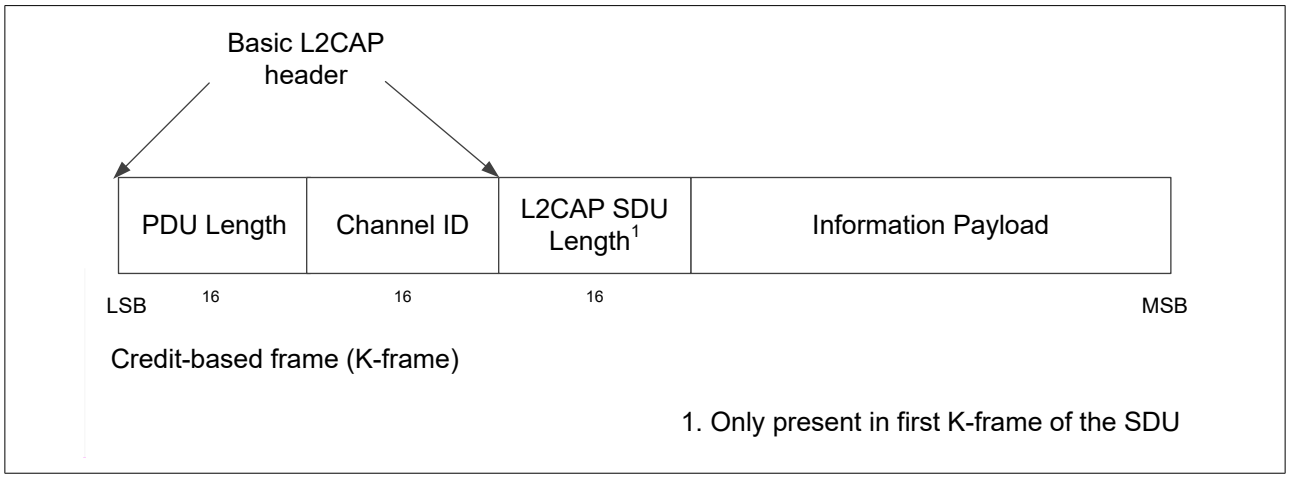

Figure 3.12: L2CAP PDU format in LE Credit Based Flow Control and Enhanced Credit Based Flow Control modes

3.4.1 L2CAP Header fields

- *PDU Length: 2 octets*

  For K-frames, the PDU Length field equals the payload size plus the octet length of the L2CAP SDU Length (when present).

- *Channel ID: 2 octets*

  The channel ID (CID) identifies the destination channel endpoint of the packet.

3.4.2 L2CAP SDU Length field (2 octets)

The first K-frame of the SDU shall contain the L2CAP SDU Length field that shall specify the total number of octets in the SDU. The value shall not be greater than the peer device's MTU for the channel. All subsequent K-frames that are part of the same SDU shall not contain the L2CAP SDU Length field.

3.4.3 Information Payload field

The information payload field consists of an integer number of octets.

The number of octets contained in the first K-frame information payload of the SDU is equal to the PDU Length minus 2 octets. All subsequent K-frames of the same SDU contain the number of octets in the information payload equal to the PDU Length.

If the SDU length field value exceeds the receiver's MTU, the receiver shall disconnect the channel. If the payload size of any K-frame exceeds the receiver's MPS, the receiver shall disconnect the channel. If the sum of the payload sizes for the K-frames exceeds the specified SDU length, the receiver shall disconnect the channel.

4 SIGNALING PACKET FORMATS

This section describes the signaling commands passed between two L2CAP entities on peer devices. All signaling commands are sent over a signaling channel. The signaling channel for managing channels over ACL-U logical links shall use CID 0x0001 and the signaling channel for managing channels over LE-U logical links shall use CID 0x0005. Signaling channels are available as soon as the lower layer logical transport is set up and L2CAP traffic is enabled. Figure 4.1 illustrates the general format of L2CAP PDUs containing signaling commands (C-frames). Multiple commands may be sent in a single C-frame over fixed channel CID 0x0001 while only one command per C-frame shall be sent over fixed channel CID 0x0005. Commands take the form of requests, responses, and indications. All L2CAP implementations shall support the reception of C-frames with a payload size that does not exceed the signaling MTU. The minimum supported payload size for the C-frame (MTU_{sig}) is defined in Table 4.1. L2CAP implementations should not use C-frames that exceed the MTU_{sig} of the peer device. If a device receives a C-frame that exceeds its MTU_{sig} then it shall send an L2CAP_COMMAND_REJECT_RSP packet containing the supported MTU_{sig}. Implementations shall be able to handle the reception of multiple commands in an L2CAP packet sent over fixed channel CID 0x0001.

Note: The name of a signalling packet has a suffix indicating its type: _REQ for requests, _RSP for responses, and _IND for indications.

A signaling packet that is not correctly formed is invalid behavior (see [Vol 1] Part E, Section 2.7). Examples of signaling packets that are not correctly formed include:

- The packet is less than 4 octets long.
- The Data Length field is not correct for the type of packet, such as an L2CAP_CONNECTION_REQ packet with a Data Length other than 4 or an L2CAP_INFORMATION_RSP with InfoType = 0x0003, Result = 0x0000, and Data Length not equal to 12.
- The PDU Length of the C-frame does not equal the sum of the sizes of the contained packets.
- The Reason or Status field has an unknown value.
- A C-frame on fixed channel 0x0005 contains more than one signaling packet.

Logical Link	Minimum Supported Payload Size for the C-frame (MTU_{sig})
ACL-U not supporting Extended Flow Specification	48 octets
ACL-U supporting the Extended Flow Specification feature	672 octets
LE-U	23 octets

Table 4.1: Minimum signaling MTU

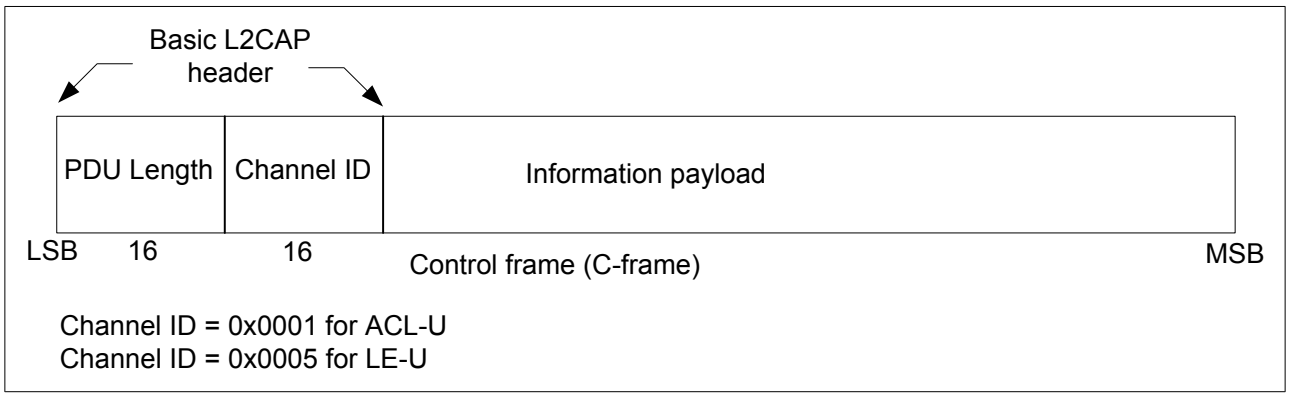

Figure 4.1: L2CAP PDU format on a signaling channel

For C-frames, the PDU Length equals the payload size.

Figure 4.2 displays the general format of all signaling commands.

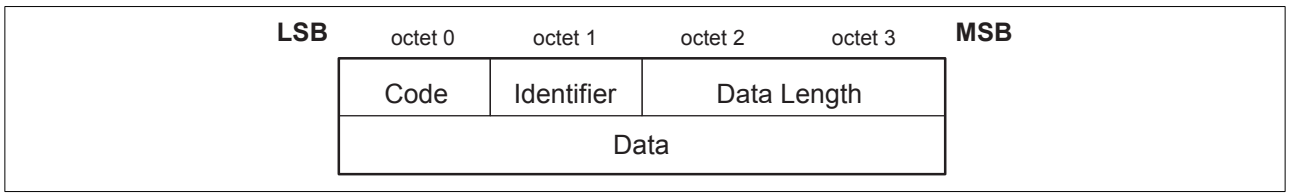

Figure 4.2: Command format

The fields shown are:

- *Code (1 octet)*

  The Code field is one octet long and identifies the type of command. When a packet is received with a Code field that is unknown or disallowed on the signaling channel it is received on, an L2CAP_COMMAND_REJECT_RSP packet (defined in Section 4.1) is sent in response.

  Table 4.2 lists the codes defined by this document. All codes are specified with the most significant bit in the left-most position.

Code	Description	CIDs on which Code is Allowed
0x01	L2CAP_COMMAND_REJECT_RSP	0x0001 and 0x0005
0x02	L2CAP_CONNECTION_REQ	0x0001
0x03	L2CAP_CONNECTION_RSP	0x0001
0x04	L2CAP_CONFIGURATION_REQ	0x0001
0x05	L2CAP_CONFIGURATION_RSP	0x0001
0x06	L2CAP_DISCONNECTION_REQ	0x0001 and 0x0005
0x07	L2CAP_DISCONNECTION_RSP	0x0001 and 0x0005
0x08	L2CAP_ECHO_REQ	0x0001
0x09	L2CAP_ECHO_RSP	0x0001
0x0A	L2CAP_INFORMATION_REQ	0x0001
0x0B	L2CAP_INFORMATION_RSP	0x0001
0x0C to 0x11	Previously used	None
0x12	L2CAP_CONNECTION_PARAMETER_UPDATE_REQ	0x0005
0x13	L2CAP_CONNECTION_PARAMETER_UPDATE_RSP	0x0005
0x14	L2CAP_LE_CREDIT_BASED_CONNECTION_REQ	0x0005
0x15	L2CAP_LE_CREDIT_BASED_CONNECTION_RSP	0x0005
0x16	L2CAP_FLOW_CONTROL_CREDIT_IND	0x0001 and 0x0005
0x17	L2CAP_CREDIT_BASED_CONNECTION_REQ	0x0001 and 0x0005
0x18	L2CAP_CREDIT_BASED_CONNECTION_RSP	0x0001 and 0x0005
0x19	L2CAP_CREDIT_BASED_RECONFIGURE_REQ	0x0001 and 0x0005
0x1A	L2CAP_CREDIT_BASED_RECONFIGURE_RSP	0x0001 and 0x0005
Other	Reserved for future use	Any

Table 4.2: Signaling command codes

- *Identifier (1 octet)*

  The Identifier field is one octet long and matches responses with requests. The requesting device sets this field and the responding device uses the same value in its response. Within each signaling channel a different Identifier shall be used for each successive command. Following the original transmission of an Identifier in a command, the Identifier may be recycled if all other Identifiers have subsequently been used.

  RTX and ERTX timers are used to determine when the remote end point is not responding to signaling requests. On the expiration of a RTX or ERTX timer, the same identifier shall be used if a duplicate request is re-sent as stated in Section 6.2.

A device receiving a duplicate request on a particular signaling channel should reply with a duplicate response on the same signaling channel. A command response with an invalid identifier is silently discarded. Signaling identifier 0x00 is an invalid identifier and shall never be used in any command.

- *Data Length (2 octets)*

  The Data Length field is two octets long and indicates the size in octets of the data field of the command only, i.e., it does not cover the Code, Identifier, and Data Length fields.

- *Data (0 or more octets)*

  The Data field is variable in length. The Code field determines the format of the Data field. The Data Length field specifies the length of the Data field.

4.1 L2CAP_COMMAND_REJECT_RSP (code 0x01)

An L2CAP_COMMAND_REJECT_RSP packet shall be sent in response to a command packet with an unknown command code or when sending the corresponding response is inappropriate. Figure 4.3 defines the format of the packet. The identifier shall match the identifier of the command packet being rejected. Implementations shall always send these packets in response to unidentified signaling packets. L2CAP_COMMAND_REJECT_RSP packets should not be sent in response to an identified response packet.

When multiple commands are included in an L2CAP packet and the packet exceeds the signaling MTU (MTU_{sig}) of the receiver, a single L2CAP_COMMAND_REJECT_RSP packet shall be sent in response. The identifier shall match the first request command in the L2CAP packet. If only responses are recognized, the packet shall be silently discarded.

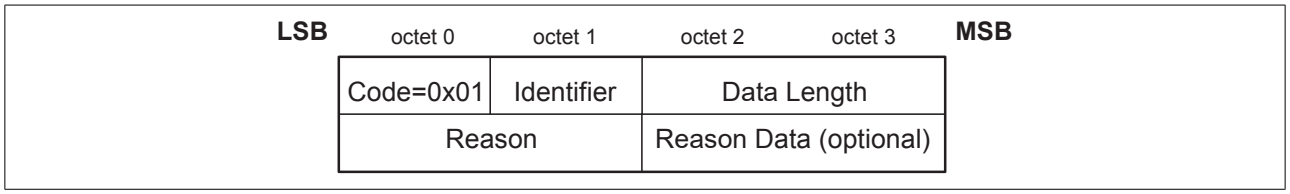

Figure 4.3: L2CAP_COMMAND_REJECT_RSP packet

The data fields are:

- *Reason (2 octets)*

  The Reason field describes why the request packet was rejected, and is set to one of the Reason codes in Table 4.3.

Reason value	Description
0x0000	Command not understood
0x0001	Signaling MTU exceeded
0x0002	Invalid CID in request
Other	Reserved for future use

Table 4.3: Reason code descriptions

- *Reason Data (0 or more octets)*

  The length and content of the Reason Data field depends on the Reason code. If the Reason code is 0x0000, “Command not understood”, no Reason Data field is used. If the Reason code is 0x0001, “Signaling MTU Exceeded”, the 2-octet Reason Data field represents the maximum signaling MTU the sender of this packet can accept.

  If a command refers to an invalid channel then the Reason code 0x0002 will be returned. Typically a channel is invalid because it does not exist. The Reason Data field shall be 4 octets containing the local (first) and remote (second) channel endpoints (relative to the sender of the L2CAP_COMMAND_REJECT_RSP packet) of the disputed channel. The remote endpoint is the source CID from the rejected command. The local endpoint is the destination CID from the rejected command. If the rejected command contains only one of the channel endpoints, the other one shall be replaced by the null CID 0x0000.

Reason value	Reason Data length	Reason Data value
0x0000	0 octets	
0x0001	2 octets	Actual MTU_{sig}
0x0002	4 octets	Requested CIDs

Table 4.4: Reason data values

4.2 L2CAP_CONNECTION_REQ (code 0x02)

L2CAP_CONNECTION_REQ packets are sent to create an L2CAP channel between two devices. The L2CAP channel shall be established before configuration begins. Figure 4.4 defines the format of the packet.

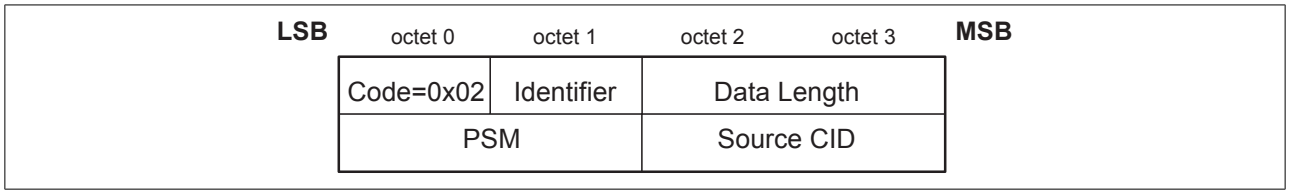

Figure 4.4: L2CAP_CONNECTION_REQ packet

The data fields are:

- *Protocol/Service Multiplexer - PSM (2 octets (minimum))*

  The PSM field is at least two octets in length. All PSM values shall have the least significant bit of the most significant octet equal to 0 and the least significant bit of all other octets equal to 1.

  Note: This means that all PSMs are odd numbers and that the end of a PSM can be easily found by searching for the first even octet.

  PSM values are separated into two ranges. Valid values in the first range are assigned by the Bluetooth SIG and indicate protocols. The second range of values are dynamically allocated and used in conjunction with the Service Discovery protocol (SDP). The dynamically assigned values may be used to support multiple implementations of a particular protocol.

  PSM values in the first range are defined in Assigned Numbers.

Range	Type	Server Usage	Client Usage
0x0001 to 0x0EFF (Note [1])	Fixed, SIG assigned	PSM is fixed for all implementations.	PSM may be obtained via SDP or may be assumed for a fixed service. Protocol used is indicated by the PSM.
>0x1000	Dynamic	PSM may be fixed for a given implementation or may be assigned at the time the service is registered in SDP.	PSM shall be obtained via SDP upon every reconnection. PSM for one direction will typically be different from the other direction.

Table 4.5: PSM ranges and usage

[1] Since PSMs are odd and the least significant bit of the most significant byte is zero, the following ranges do not contain valid PSMs: 0x0100-0x01FF, 0x0300-0x03FF, 0x0500-0x05FF, 0x0700-0x07FF, 0x0900-0x09FF, 0x0B00-0x0BFF, 0x0D00-0x0DFF. All even values are also not valid as PSMs.

- *Source CID - SCID (2 octets)*

  The source CID is two octets in length and represents a channel endpoint on the device sending the request. Once the channel has been configured, data packets flowing to the sender of the request shall be sent to this CID. Thus, the Source CID represents the channel endpoint on the device sending the request and receiving the response. The value of the Source CID shall be from the dynamically allocated range as defined in Table 2.1 and shall not be already allocated to a different channel on the same logical link on the device sending the request.

4.3 L2CAP_CONNECTION_RSP (code 0x03)

When a device receives an L2CAP_CONNECTION_REQ packet, it shall send an L2CAP_CONNECTION_RSP packet. Figure 4.5 defines the format of the packet.

Note: Implementations conforming to a version of the specification lower than version 4.2 may respond with an L2CAP_COMMAND_REJECT_RSP (Reason 0x0002 – Invalid CID In Request) packet under conditions now covered by result codes of 0x0006 and 0x0007.

If the device sends an L2CAP_CONNECTION_RSP packet with result code "pending", then it shall subsequently send another L2CAP_CONNECTION_RSP (see also [Vol 3] Part C, Section 5.2.2.2).

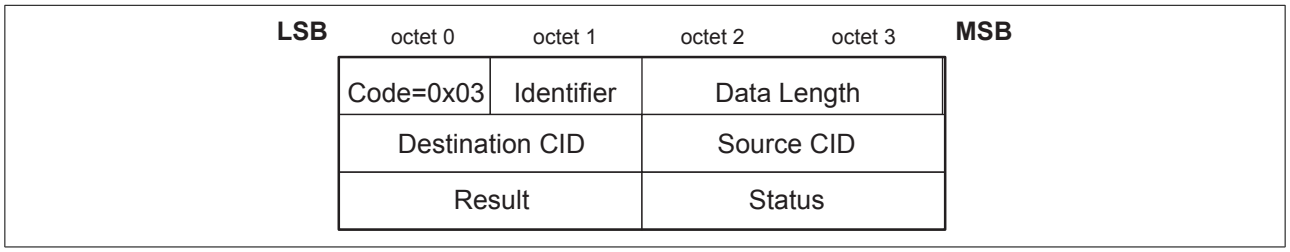

Figure 4.5: L2CAP_CONNECTION_RSP packet

The data fields are:

- *Destination Channel Identifier - DCID (2 octets)*

  This field contains the channel endpoint on the device sending this response packet. Thus, the Destination CID represents the channel endpoint on the device receiving the request and sending the response. The value of the Destination CID shall be from the dynamically allocated range as defined in Table 2.1 and shall not be already allocated to a different channel on the same logical link on the device sending the response.

- *Source Channel Identifier - SCID (2 octets)*

  This field contains the channel endpoint on the device receiving this response packet. This is copied from the SCID field of the L2CAP_CONNECTION_REQ packet.

- *Result (2 octets)*

  The result field indicates the outcome of the connection request. The result value of 0x0000 indicates success while a non-zero value indicates the connection request failed or is pending. A logical channel is established on the receipt of a successful result unless the DCID field is outside of the dynamically allocated range (see Table 2.1) or is already allocated on the device sending the response. Table 4.6 defines values for this field. If the result field does not indicate the connection was successful, the DCID and SCID fields may be invalid and shall be ignored.

Value	Description
0x0000	Connection successful
0x0001	Connection pending

Value	Description
0x0002	Connection refused – PSM not supported
0x0003	Connection refused – security block
0x0004	Connection refused – no resources available
0x0006	Connection refused – invalid Source CID
0x0007	Connection refused – Source CID already allocated
Other	Reserved for future use

Table 4.6: Result values for the L2CAP_CONNECTION_RSP packet

- *Status (2 octets)*

  Only defined for Result = Pending. Indicates the status of the connection. The status is set to one of the values shown in Table 4.7.

Value	Description
0x0000	No further information available
0x0001	Authentication pending
0x0002	Authorization pending
Other	Reserved for future use

Table 4.7: Status values for the L2CAP_CONNECTION_RSP packet

4.4 L2CAP_CONFIGURATION_REQ (code 0x04)

L2CAP_CONFIGURATION_REQ packets are sent to establish an initial logical link transmission contract between two L2CAP entities and also to re-negotiate this contract whenever appropriate. The contract consists of a set of configuration parameter options defined in Section 5. All parameter options have default values and can have previously agreed values which are values that were accepted in a previous configuration process or in a previous step in the current configuration process. The only parameters that should be included in the L2CAP_CONFIGURATION_REQ packet are those that require different values than the default or previously agreed values.

If no parameters need to be negotiated or specified then no options shall be inserted and the continuation flag (C) shall be set to zero. Any missing configuration parameters are assumed to have their most recently explicitly or implicitly accepted values. Even if all default values are acceptable, an L2CAP_CONFIGURATION_REQ packet with no options shall be sent. Implicitly accepted values are default values for the configuration parameters that have not been explicitly negotiated for the specific channel under configuration.

See Section 7.1 for details of the configuration procedure.

Figure 4.6 defines the format of the packet.

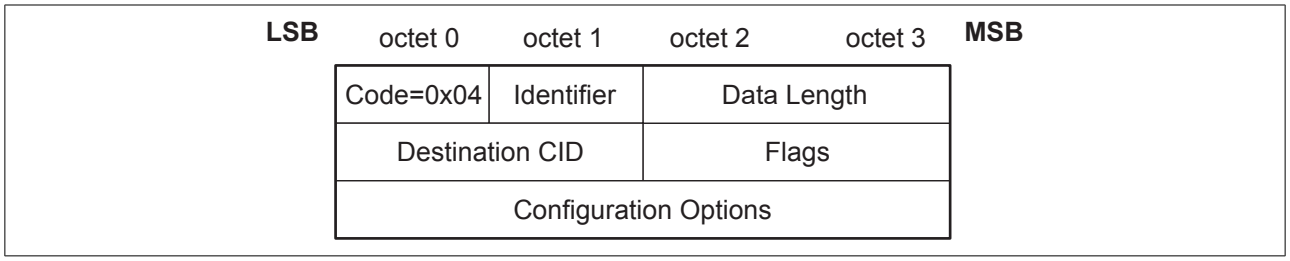

Figure 4.6: L2CAP_CONFIGURATION_REQ packet

The data fields are:

- *Destination CID - DCID (2 octets)*

  This field contains the channel endpoint on the device receiving this request packet.

- *Flags (2 octets)*

  Figure 4.7 shows the two-octet Flags field. Note the most significant bit is shown on the left.

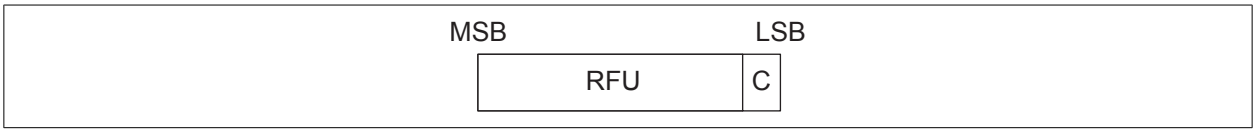

Figure 4.7: L2CAP_CONFIGURATION_REQ Flags field format

Only one flag is defined, the Continuation flag (C).

When both L2CAP entities support the Extended Flow Specification option, the Continuation flag shall not be used and shall be set to zero in all L2CAP_CONFIGURATION_REQ and L2CAP_CONFIGURATION_RSP packets.

When all configuration options cannot fit into an L2CAP_CONFIGURATION_REQ packet with a payload size that does not exceed the receiver's MTU_{sig}, the options shall be passed in multiple L2CAP_CONFIGURATION_REQ packets. If all options fit into the receiver's MTU_{sig}, then they shall be sent in a single L2CAP_CONFIGURATION_REQ packet with the continuation flag set to zero. Each L2CAP_CONFIGURATION_REQ packet shall only contain complete options - partially formed options shall not be sent in a packet. Each L2CAP_CONFIGURATION_REQ packet shall be tagged with a different Identifier and shall be matched with an L2CAP_CONFIGURATION_RSP packet with the same Identifier.

When used in the L2CAP_CONFIGURATION_REQ packet, the continuation flag indicates the responder should expect to receive multiple request packets. The responder shall reply to each L2CAP_CONFIGURATION_REQ packet. The responder may reply to each L2CAP_CONFIGURATION_REQ packet with an L2CAP_CONFIGURATION_RSP packet containing the same option(s)

present in the request (except for those error conditions more appropriate for an L2CAP_COMMAND_REJECT_RSP packet), or the responder may reply with a "Success" L2CAP_CONFIGURATION_RSP packet containing no options, delaying those options until the full request has been received. The L2CAP_CONFIGURATION_REQ packet with the continuation flag cleared shall be treated as the L2CAP_CONFIGURATION_REQ event in the channel state machine.

When used in the L2CAP_CONFIGURATION_RSP packet, the continuation flag shall be set to one if the flag is set to one in the request. If the continuation flag is set to one in the response when the matching request has the flag set to zero, it indicates the responder has additional options to send to the requestor. In this situation, the requestor shall send null-option L2CAP_CONFIGURATION_REQ packets (with continuation flag set to zero) to the responder until the responder replies with an L2CAP_CONFIGURATION_RSP packet where the continuation flag is set to zero. The L2CAP_CONFIGURATION_RSP packet with the continuation flag set to zero shall be treated as the L2CAP_CONFIGURATION_RSP event in the channel state machine.

The result of the configuration transaction is success if all the individual result values are success, and is failure otherwise.

Other flags are reserved for future use.

- *Configuration Options*

  A list of the parameters and their values to be negotiated shall be provided in the Configuration Options field. These are defined in Section 5; in addition, as described in that section, an implementation shall be prepared to receive any number of unknown options. An L2CAP_CONFIGURATION_REQ packet may contain no options (referred to as an empty or null configuration request) and can be used to request a response. For an empty configuration request the Data Length field is set to 0x0004.

4.5 L2CAP_CONFIGURATION_RSP (code 0x05)

L2CAP_CONFIGURATION_RSP packets shall be sent in reply to L2CAP_CONFIGURATION_REQ packets except when the error condition is covered by an L2CAP_COMMAND_REJECT_RSP packet response. Each configuration parameter value (if any is present) in an L2CAP_CONFIGURATION_RSP packet reflects an ‘adjustment’ to a configuration parameter value that has been sent (or, in case of default values, implied) in the corresponding L2CAP_CONFIGURATION_REQ packet. For example, if an L2CAP_CONFIGURATION_REQ packet relates to traffic flowing from device A to device B, the sender of the L2CAP_CONFIGURATION_RSP packet may adjust this value for the same traffic flowing from device A to device B, but the response cannot adjust the value in the reverse direction.

The options sent in the L2CAP_CONFIGURATION_RSP packet depend on the value in the Result field. Figure 4.8 defines the format of the packet. See also Section 7.1 for details of the configuration process, including use of the result code "pending".

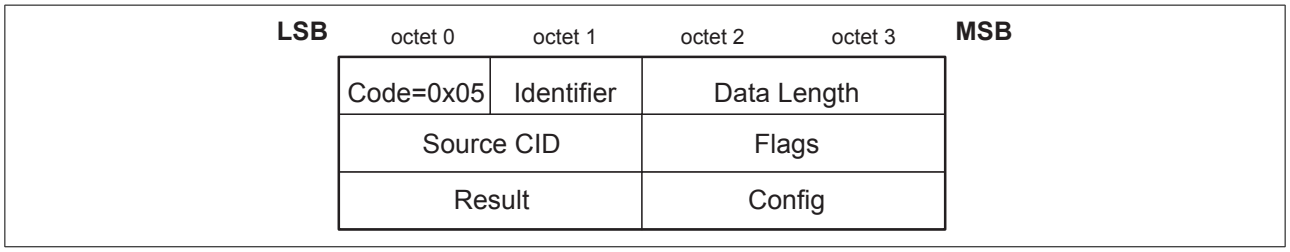

Figure 4.8: L2CAP_CONFIGURATION_RSP packet

The data fields are:

- *Source CID - SCID (2 octets)*

  This field contains the channel endpoint on the device receiving this response packet. The device receiving the L2CAP_CONFIGURATION_RSP packet shall check that the Identifier field matches the same field in the corresponding L2CAP_CONFIGURATION_REQ packet and the SCID matches its local CID paired with the original DCID.

- *Flags (2 octets)*

  Figure 4.9 displays the two-octet Flags field. Note the most significant bit is shown on the left.

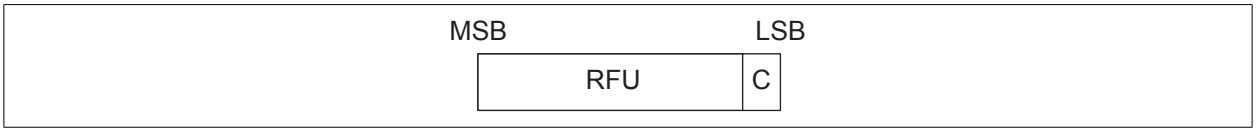

Figure 4.9: L2CAP_CONFIGURATION_RSP Flags field format

  Only one flag is defined, the Continuation flag (C).

  When both L2CAP entities support the Extended Flow Specification option, the Continuation flag shall not be used and shall be set to zero in all L2CAP_CONFIGURATION_REQ and L2CAP_CONFIGURATION_RSP packets.

  More L2CAP_CONFIGURATION_RSP packets will follow when C is set to one. This flag indicates that the parameters included in the response are a partial subset of parameters being sent by the device sending the L2CAP_CONFIGURATION_RSP packet.

  The other flag bits are reserved for future use.

- *Result (2 octets)*

  The Result field indicates whether or not the request was acceptable. See Table 4.8 for possible result codes.

Result	Description
0x0000	Success
0x0001	Failure – unacceptable parameters
0x0002	Failure – rejected (no reason provided)
0x0003	Failure – unknown options
0x0004	Pending
0x0005	Failure - flow spec rejected
Other	Reserved for future use

Table 4.8: L2CAP_CONFIGURATION_RSP result codes

- *Configuration options*

  This field contains the list of parameters being configured. These are defined in Section 5. On a successful result (Result=0x0000) and pending result (Result=0x0004), these parameters contain the return values for any wild card parameter values (see Section 5.3) and “adjustments” to non-negotiated configuration parameter values contained in the request. A response with a successful result is also referred to as a positive response.

  On an unacceptable parameters failure (Result=0x0001) the rejected parameters shall be sent in the response with the values that would have been accepted if sent in the original request. Any missing configuration parameters in the L2CAP_CONFIGURATION_REQ packet are assumed to have their default value or previously agreed value and they too shall be included in the L2CAP_CONFIGURATION_RSP packet if they need to be changed. A response with an unacceptable parameters failure is also referred to as a negative response.

  On an unknown option failure (Result=0x0003), the option(s) that contain an option type field that is not understood by the recipient of the L2CAP_CONFIGURATION_REQ packet shall be included in the L2CAP_CONFIGURATION_RSP packet unless they are hints. Hints are those options in the L2CAP_CONFIGURATION_REQ packet that are skipped if not understood (see Section 5). Hints shall not be included in the L2CAP_CONFIGURATION_RSP packet and shall not be the sole cause for rejecting the L2CAP_CONFIGURATION_REQ packet.

  On a flow spec rejected failure (Result=0x0005), an Extended Flow Spec option may be included to reflect the QoS level that would be acceptable (see Section 7.1.3).

  The decision on the amount of time (or messages) spent arbitrating the channel parameters before terminating the negotiation is implementation specific.

4.6 L2CAP_DISCONNECTION_REQ (code 0x06)

Terminating an L2CAP channel requires that an L2CAP_DISCONNECTION_REQ packet be sent and acknowledged by an L2CAP_DISCONNECTION_RSP packet. Figure 4.10 defines the format of the packet. The receiver shall not initiate a disconnection if the source or destination CIDs do not match.

Once an L2CAP_DISCONNECTION_REQ packet is issued, all incoming data in transit on this L2CAP channel shall be discarded and any new additional outgoing data shall be discarded. Once an L2CAP_DISCONNECTION_REQ packet for a channel has been received, all data queued to be sent out on that channel shall be discarded.

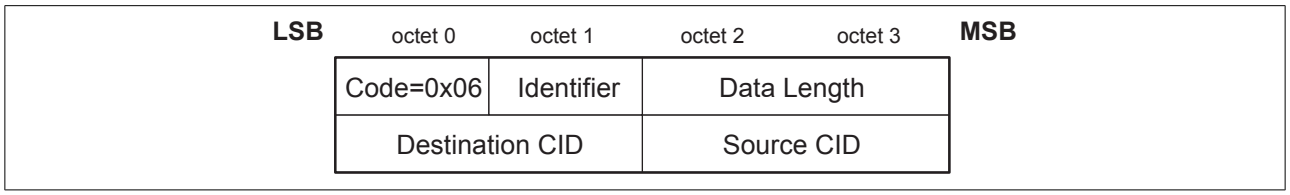

Figure 4.10: L2CAP_DISCONNECTION_REQ packet

The data fields are:

- *Destination CID - DCID (2 octets)*

  This field specifies the endpoint of the channel to be disconnected on the device receiving this request.

- *Source CID - SCID (2 octets)*

  This field specifies the endpoint of the channel to be disconnected on the device sending this request.

The SCID and DCID are relative to the sender of this request and shall match those of the channel to be disconnected. If the DCID is not recognized by the receiver of this message, an L2CAP_COMMAND_REJECT_RSP packet with ‘invalid CID’ result code shall be sent in response. If the receiver finds a DCID match but the SCID fails to find the same match, the request should be silently discarded.

4.7 L2CAP_DISCONNECTION_RSP (code 0x07)

L2CAP_DISCONNECTION_RSP packets shall be sent in response to each valid L2CAP_DISCONNECTION_REQ packet. Figure 4.11 defines the format of the packet.

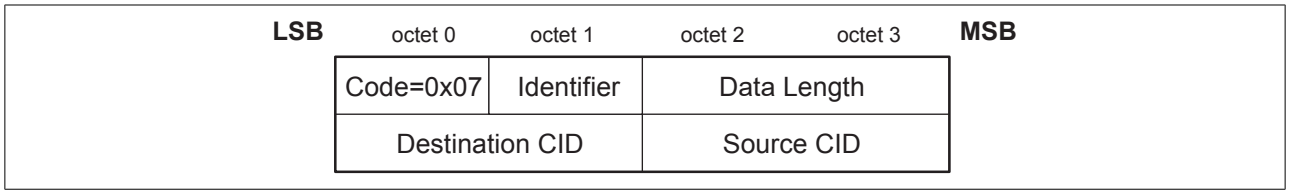

Figure 4.11: L2CAP_DISCONNECTION_RSP packet

The data fields are:

- *Destination CID - DCID (2 octets)*

  This field identifies the channel endpoint on the device sending the L2CAP_DISCONNECTION_RSP packet.

- *Source CID - SCID (2 octets)*

  This field identifies the channel endpoint on the device receiving the L2CAP_DISCONNECTION_RSP packet.

  The DCID and the SCID (which are relative to the sender of the L2CAP_DISCONNECTION_REQ packet), and the Identifier fields shall match those of the corresponding L2CAP_DISCONNECTION_REQ packet. If the CIDs do not match, the L2CAP_DISCONNECTION_RSP packet should be silently discarded at the receiver.

4.8 L2CAP_ECHO_REQ (code 0x08)

L2CAP_ECHO_REQ packets are used to request a response from a remote L2CAP entity. Figure 4.12 defines the format of the packet. These requests may be used for testing the link or for passing vendor specific information using the optional data field. L2CAP entities shall respond to a valid L2CAP_ECHO_REQ packet with an L2CAP_ECHO_RSP packet. The Echo Data field is optional and implementation specific. L2CAP entities should ignore the contents of this field if present.

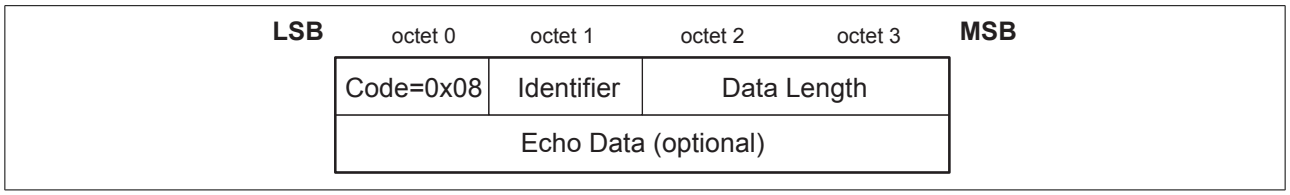

Figure 4.12: L2CAP_ECHO_REQ packet

4.9 L2CAP_ECHO_RSP (code 0x09)

An L2CAP_ECHO_RSP packet shall be sent upon receiving a valid L2CAP_ECHO_REQ packet. Figure 4.13 defines the format of the packet. The identifier in the L2CAP_ECHO_RSP packet shall match the identifier sent in the

L2CAP_ECHO_REQ packet. The Echo Data field is optional and implementation specific. It may contain the contents of the Echo Data field in the L2CAP_ECHO_REQ packet, different data, or no data at all. L2CAP entities should ignore the contents of this field if present.

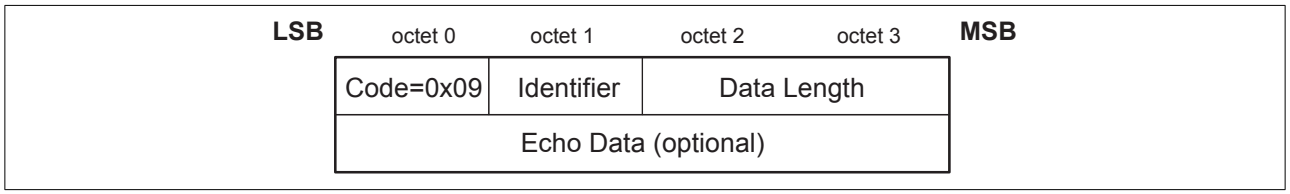

Figure 4.13: L2CAP_ECHO_RSP packet

4.10 L2CAP_INFORMATION_REQ (code 0x0A)

L2CAP_INFORMATION_REQ packets are used to request implementation specific information from a remote L2CAP entity. Figure 4.14 defines the format of the packet. L2CAP implementations shall respond to a valid L2CAP_INFORMATION_REQ packet with an L2CAP_INFORMATION_RSP packet. It is optional to send L2CAP_INFORMATION_REQ packets.

An L2CAP implementation shall only use optional features or attribute ranges for which the remote L2CAP entity has indicated support through an L2CAP_INFORMATION_RSP packet. Until an L2CAP_INFORMATION_RSP packet which indicates support for optional features or ranges has been received only mandatory features and ranges shall be used.

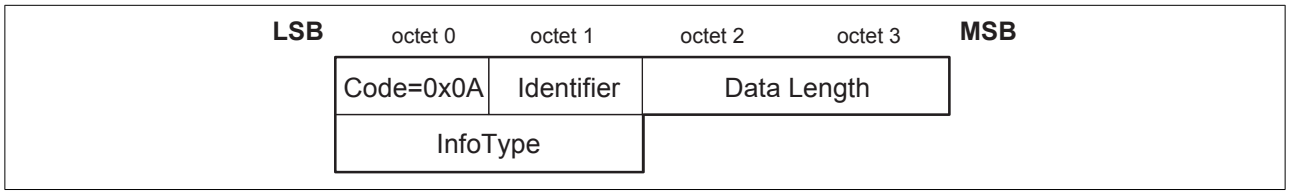

Figure 4.14: L2CAP_INFORMATION_REQ packet

The data field is:

- *InfoType (2 octets)*

  The InfoType defines the type of implementation specific information being requested. See Section 4.11 for details on the type of information requested.

Value	Description
0x0001	Connectionless MTU
0x0002	Extended features supported

Value	Description
0x0003	Fixed channels supported over BR/EDR
Other	Reserved for future use

Table 4.9: InfoType definitions

L2CAP entities shall not send an L2CAP_INFORMATION_REQ packet with InfoType 0x0003 over fixed channel CID 0x0001 until first verifying that the Fixed Channels bit is set in the Extended feature mask of the remote device. Support for fixed channels is mandatory for devices with BR/EDR/LE or LE Controllers. L2CAP_INFORMATION_REQ and L2CAP_INFORMATION_RSP packets shall not be used over fixed channel CID 0x0005.

4.11 L2CAP_INFORMATION_RSP (code 0x0B)

An L2CAP_INFORMATION_RSP packet shall be sent upon receiving a valid L2CAP_INFORMATION_REQ packet. Figure 4.15 defines the format of the packet. The identifier in the L2CAP_INFORMATION_RSP packet shall match the identifier sent in the L2CAP_INFORMATION_REQ packet. The Info field shall contain the value associated with the InfoType field sent in the L2CAP_INFORMATION_REQ packet, or shall be empty if the InfoType is not supported.

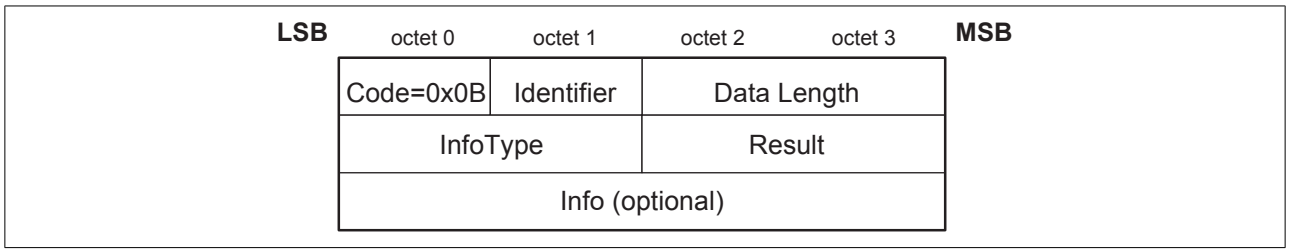

Figure 4.15: L2CAP_INFORMATION_RSP packet

The data fields are:

- *InfoType (2 octets)*

  The InfoType defines the type of implementation specific information that was requested. This value shall be copied from the InfoType field in the L2CAP_INFORMATION_REQ packet.

- *Result (2 octets)*

  The Result contains information about the success of the request. If result is "Success," the data field contains the information as specified in Table 4.11. If result is "Not supported," no data shall be returned.

Value	Description
0x0000	Success
0x0001	Not supported
Other	Reserved for future use

Table 4.10: Result values for the L2CAP_INFORMATION_RSP packet

- *Info (0 or more octets)*

  The contents of the Info field depends on the InfoType.

  For InfoType = 0x0001, the field contains the remote entity's 2-octet acceptable connectionless MTU. The default value is defined in Section 3.2.

  For InfoType = 0x0002, the Info field contains the 4 octet L2CAP extended feature mask. The feature mask refers to the extended features that the L2CAP entity sending the L2CAP_INFORMATION_RSP packet supports. The feature bits contained in the L2CAP feature mask are specified in Section 4.12.

  For InfoType = 0x0003, the Info field contains an 8 octet bit map that indicates which Fixed L2CAP Channels (i.e., the L2CAP channels that use a CID from 0x0000 to 0x003F) are supported over BR/EDR. A list of available fixed channels is provided in Table 2.1 in Section 2.1. A detailed description of this Info field is given in Section 4.13.

  Note: Implementations conforming to a version lower than 1.2, receiving an L2CAP_INFORMATION_REQ packet with InfoType = 0x0002 for an L2CAP feature discovery, return an L2CAP_INFORMATION_RSP packet with result code "Not supported." Implementations conforming to versions 1.2, 2.0 + EDR, or 2.1 + EDR that have an all zero extended features mask may return an L2CAP_INFORMATION_RSP packet with result code "Not supported."

InfoType	Info	Info length (octets)
0x0001	Connectionless MTU	2
0x0002	Extended feature mask	4
0x0003	Fixed channels supported over BR/EDR	8

Table 4.11: L2CAP_INFORMATION_RSP Info fields

4.12 Extended Feature Mask

The features are represented as a bit mask in the L2CAP_INFORMATION_RSP packet's Info field (see Section 4.11). For each feature a single bit is specified which shall be set to 1 if the feature is supported and set to 0 otherwise. All unknown or unassigned feature bits are reserved for future use.

The feature mask shown in Table 4.12 consists of 4 octets (numbered octet 0 to 3), with bit numbers 0 to 7 each.

No.	Supported feature	Octet	Bit
0	Flow control mode	0	0
1	Retransmission mode	0	1
2	Bi-directional QoS[1]	0	2
3	Enhanced Retransmission mode	0	3
4	Streaming mode	0	4
5	FCS Option[2]	0	5
6	Extended Flow Specification for BR/EDR	0	6
7	Fixed Channels supported over BR/EDR	0	7
8	Extended Window Size	1	0
9	Unicast Connectionless Data Reception	1	1
10	Enhanced Credit Based Flow Control mode over BR/EDR	1	2
31	Reserved for feature mask extension	3	7
All others	Reserved for future use	All others	

Table 4.12: Extended feature mask

[1]Peer side supports upper layer control of the Link Manager's Bi-directional QoS, see Section 5.3 for more details.

[2]Peer side supports negotiating omitting FCS; see Section 5.5 for more details and the required behavior if this bit is not set.

4.13 Fixed Channels Supported over BR/EDR

Each fixed channel supported over BR/EDR is represented by a single bit in an 8 octet bit mask. The bit associated with a channel shall be set to 1 if the L2CAP entity supports that channel. The L2CAP Signaling channel is mandatory and therefore the bit associated with that channel shall be set to 1. Table 4.13 shows the format of the bit mask.

CID	Fixed Channel	Value	Octet	Bit
0x0000	Null identifier	Shall be set to 0	0	0
0x0001	L2CAP Signaling channel	Shall be set to 1	0	1
0x0002	Connectionless reception	0 – if not supported 1 – if supported	0	2
0x0003	Previously used		0	3
0x0004 to 0x0006	Reserved for future use		0	4-6

CID	Fixed Channel	Value	Octet	Bit
0x0007	BR/EDR Security Manager	0 – if not supported 1 – if supported	0	7
0x0008 to 0x003E	Reserved for future use		1-6 7	0-7 0-6
0x003F	Previously used		7	7
Other	Reserved for future use		Other	

Table 4.13: Fixed Channels Supported bit mask

An L2CAP entity shall not transmit on any fixed channel (with the exception of the L2CAP Signaling channel) until it has received a Fixed Channels Supported InfoType from the peer L2CAP entity indicating support for that channel, or has received a valid packet from the remote device on that fixed channel. All packets received on a non-supported fixed channel shall be ignored.

4.17 [This section is no longer used]

4.18 [This section is no longer used]

4.19 [This section is no longer used]

4.20 L2CAP_CONNECTION_PARAMETER_UPDATE_REQ (code 0x12)

This command shall only be sent from the Peripheral to the Central and only if one or more of the Peripheral's Controller, the Central's Controller, the Peripheral's Host and the Central's Host do not support the Connection Parameters Request Link Layer Control procedure ([Vol 6] Part B, Section 5.1.7). If a Peripheral's Host receives an L2CAP_CONNECTION_PARAMETER_UPDATE_REQ packet it shall respond with an L2CAP_COMMAND_REJECT_RSP packet with reason 0x0000 (Command not understood). Figure 4.16 defines the format of the packet.

The L2CAP_CONNECTION_PARAMETER_UPDATE_REQ packet allows the Peripheral's Host to request a set of new connection parameters. When the Central's Host receives an L2CAP_CONNECTION_PARAMETER_UPDATE_REQ packet, depending on the parameters of other connections, the Central's Host may accept the requested parameters and deliver the requested parameters to its Controller

or reject the request. In devices supporting HCI, the Central's Host delivers the requested parameters to its Controller using the HCI_LE_Connection_Update command (see [Vol 4] Part E, Section 7.8.18). If the Central's Host accepts the requested parameters it shall send the L2CAP_CONNECTION_PARAMETER_UPDATE_RSP packet with result 0x0000 (Parameters accepted) otherwise it shall set the result to 0x0001 (request rejected).

The Peripheral's Host will receive an indication from the Peripheral's Controller when the connection parameters have been updated. In devices supporting HCI, this notification will be in the form of an HCI_LE_Connection_Update_Complete event (see [Vol 4] Part E, Section 7.7.65.3). If the Central's Controller rejects the updated connection parameters no indication from the Peripheral's Controller will be sent to the Peripheral's Host.

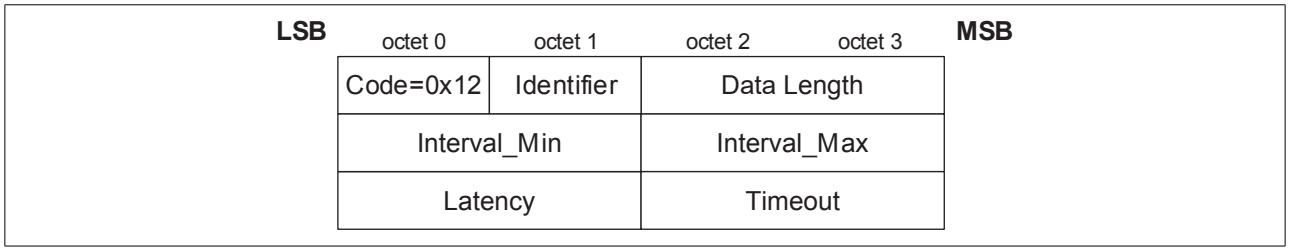

Figure 4.16: L2CAP_CONNECTION_PARAMETER_UPDATE_REQ packet

The data fields shall have the same meanings and requirements as the fields of the LL_CONNECTION_PARAM_REQ PDU (see [Vol 6] Part B, Section 2.4.2.16) with the same names.

4.21 L2CAP_CONNECTION_PARAMETER_UPDATE_RSP (code 0x13)

This response shall only be sent from the Central to the Peripheral.

The L2CAP_CONNECTION_PARAMETER_UPDATE_RSP packet shall be sent by the Central's Host when it receives an L2CAP_CONNECTION_PARAMETER_UPDATE_REQ packet. Figure 4.17 defines the format of the packet. If the Central's Host accepts the request it shall send the connection parameter update to its Controller.

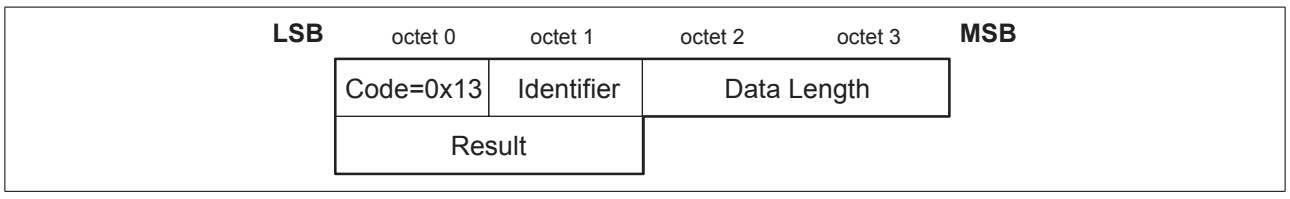

Figure 4.17: L2CAP_CONNECTION_PARAMETER_UPDATE_RSP packet

The data field is:

- *Result (2 octets)*

  The result field indicates the response to the request. The result value of 0x0000 indicates that the Central's Host has accepted the connection parameters while 0x0001 indicates that the Central's Host has rejected the connection parameters.

Result	Description
0x0000	Connection Parameters accepted
0x0001	Connection Parameters rejected
Other	Reserved for future use

Table 4.14: Result values for the L2CAP_CONNECTION_PARAMETER_UPDATE_RSP packet

4.22 L2CAP_LE_CREDIT_BASED_CONNECTION_REQ (code 0x14)

L2CAP_LE_CREDIT_BASED_CONNECTION_REQ packets are sent to create and configure an L2CAP channel between two devices using LE Credit Based Flow Control mode. Figure 4.18 defines the format of the packet.

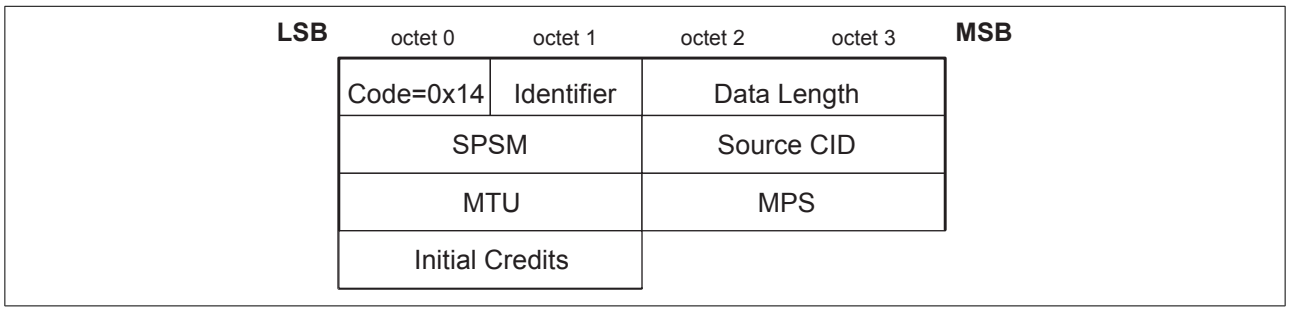

Figure 4.18: L2CAP_LE_CREDIT_BASED_CONNECTION_REQ packet

The data fields are:

- *Simplified Protocol/Service Multiplexer – SPSM*[1] *(2 octets)*

  The SPSM field is two octets in length. SPSM values are separated into two ranges. Values in the first range are assigned by the Bluetooth SIG and indicate protocols. Values in the second range are dynamically allocated and used in conjunction with services defined in the GATT Server. The dynamically assigned values may be used to support multiple implementations of a particular protocol.

  Note: Unlike a normal PSM (see Section 4.2), the length of an SPSM is not variable and each octet may be either odd or even.

  SPSM values are defined in Table 4.15.

[1]This was called LE_PSM in versions 4.1 to 5.1.

Range	Type	Server Usage	Client Usage
0x0001 to 0x007F	Fixed, SIG assigned	SPSM is fixed for all implementations	SPSM may be assumed for fixed service. Protocol used is indicated by the SPSM as defined in Assigned Numbers.
0x0080 to 0x00FF	Dynamic	SPSM may be fixed for a given implementation or may be assigned at the time the service is registered in GATT	SPSM shall be obtained from the service in GATT upon every reconnection. SPSM for one direction will typically be different from the other direction.
Other	RFU	Not applicable	Not applicable

Table 4.15: L2CAP_LE_CREDIT_BASED_CONNECTION_REQ SPSM ranges

- *Source CID – SCID (2 octets)*

  The source CID is two octets in length and represents a channel endpoint on the device sending the request. Once the channel has been created, data packets flowing to the sender of the request shall be sent to this CID. Thus, the Source CID represents the channel endpoint on the device sending the request and receiving the response. The value of the Source CID shall be from the dynamically allocated range as defined in Table 2.3 and shall not be already allocated to a different channel on the same logical link on the device sending the request.

- *Maximum Transmission Unit – MTU (2 octets)*

  The MTU field specifies the maximum SDU size (in octets) that the L2CAP layer entity sending the L2CAP_LE_CREDIT_BASED_CONNECTION_REQ packet can receive on this channel. L2CAP implementations shall support a minimum MTU size of 23 octets.

- *Maximum PDU Payload Size – MPS (2 octets)*

  The MPS field specifies the maximum PDU payload size (in octets) that the L2CAP layer entity sending the L2CAP_LE_CREDIT_BASED_CONNECTION_REQ packet is capable of receiving on this channel. L2CAP implementations shall support a minimum MPS of 23 octets and may support an MPS up to 65533 octets.

- *Initial Credits – (2 octets)*

  The initial credit value indicates the number of K-frames that the peer device can send to the L2CAP layer entity sending the L2CAP_LE_CREDIT_BASED_CONNECTION_REQ packet. The initial credit value shall be in the range 0 to 65535.

4.23 L2CAP_LE_CREDIT_BASED_CONNECTION_RSP (code 0x15)

When a device receives an L2CAP_LE_CREDIT_BASED_CONNECTION_REQ packet, it shall send an L2CAP_LE_CREDIT_BASED_CONNECTION_RSP packet. Figure 4.19 defines the format of the packet.

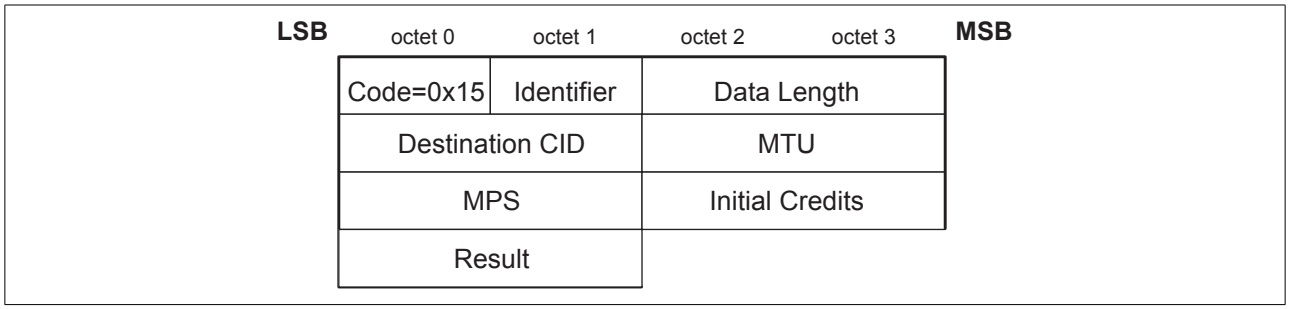

Figure 4.19: L2CAP_LE_CREDIT_BASED_CONNECTION_RSP packet

The data fields are:

- *Destination CID – DCID (2 octets)*

  The destination CID is two octets in length and represents a channel endpoint on the device sending the response. Once the channel has been created, data packets flowing to the sender of the response shall be sent to this CID. Thus, the destination CID represents the channel endpoint on the device receiving the request and sending the response. The value of the Destination CID shall be from the dynamically allocated range as defined in Table 2.3 and shall not be already allocated to a different channel on the same logical link on the device sending the response.

- *Maximum Transmission Unit – MTU (2 octets)*

  The MTU field specifies the maximum SDU size (in octets) that the L2CAP layer entity sending the L2CAP_LE_CREDIT_BASED_CONNECTION_RSP packet can receive on this channel. L2CAP implementations shall support a minimum MTU size of 23 octets.

- *Maximum PDU Payload Size – MPS (2 octets)*

  The MPS field specifies the maximum PDU payload size (in octets) that the L2CAP layer entity sending the L2CAP_LE_CREDIT_BASED_CONNECTION_RSP packet is capable of receiving on this channel. L2CAP implementations shall support a minimum MPS of 23 octets and may support an MPS up to 65533 octets.

- *Initial Credits – (2 octets)*

  The initial credit value indicates the number of K-frames that the peer device can send to the L2CAP layer entity sending the L2CAP_LE_CREDIT_BASED_CONNECTION_RSP packet. The initial credit value shall be in the range 0 to 65535.

- *Result – (2 octets)*

  The result field indicates the outcome of the connection request. A result value of 0x0000 indicates success while a non-zero value indicates the connection request was refused. A logical channel is established on the receipt of a successful result.

Table 4.16 defines values for this field. The DCID, MTU, MPS and Initial Credits fields shall be ignored when the result field indicates the connection was refused.

Value	Description
0x0000	Connection successful
0x0002	Connection refused – SPSM not supported
0x0004	Connection refused – no resources available
0x0005	Connection refused – insufficient authentication
0x0006	Connection refused – insufficient authorization
0x0007	Connection refused – encryption key size too short[1]
0x0008	Connection refused – insufficient encryption
0x0009	Connection refused – invalid Source CID
0x000A	Connection refused – Source CID already allocated
0x000B	Connection refused – unacceptable parameters
Other	Reserved for future use

Table 4.16: Result values for the L2CAP_LE_CREDIT_BASED_CONNECTION_RSP packet

[1]This was previously "Connection refused - insufficient encryption key size".

4.24 L2CAP_FLOW_CONTROL_CREDIT_IND (code 0x16)

A device shall send an L2CAP_FLOW_CONTROL_CREDIT_IND packet when it is capable of receiving additional K-frames (for example after it has processed one or more K-frames) in LE Credit Based Flow Control mode and Enhanced Credit Based Flow Control mode. Figure 4.20 defines the format of the packet.

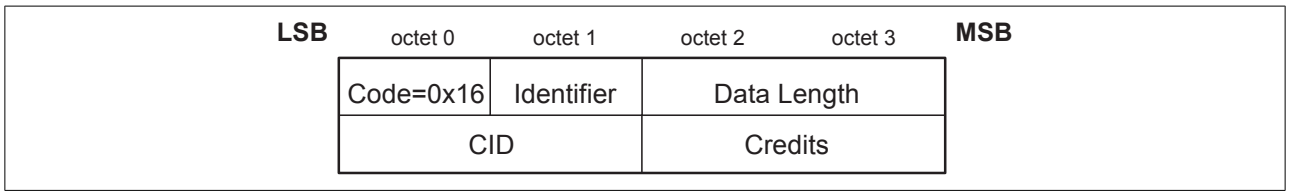

Figure 4.20: L2CAP_FLOW_CONTROL_CREDIT_IND packet

The data fields are:

- *CID – (2 octets)*

  The CID is two octets in length and represents the source channel endpoint of the device sending the L2CAP_FLOW_CONTROL_CREDIT_IND packet. For example, a received L2CAP_FLOW_CONTROL_CREDIT_IND packet with a given CID (0x0042) would provide credits for the receiving device's destination CID (0x0042).

- *Credits – (2 octets)*

  The credit value field represents number of credits the receiving device can increment, corresponding to the number of K-frames that can be sent to the peer device sending the L2CAP_FLOW_CONTROL_CREDIT_IND packet. The credit value field shall be a number between 1 and 65535.

4.25 L2CAP_CREDIT_BASED_CONNECTION_REQ (code 0x17)

L2CAP_CREDIT_BASED_CONNECTION_REQ packets are sent to create and configure up to five L2CAP channels between two devices. Figure 4.21 defines the format of the packet.

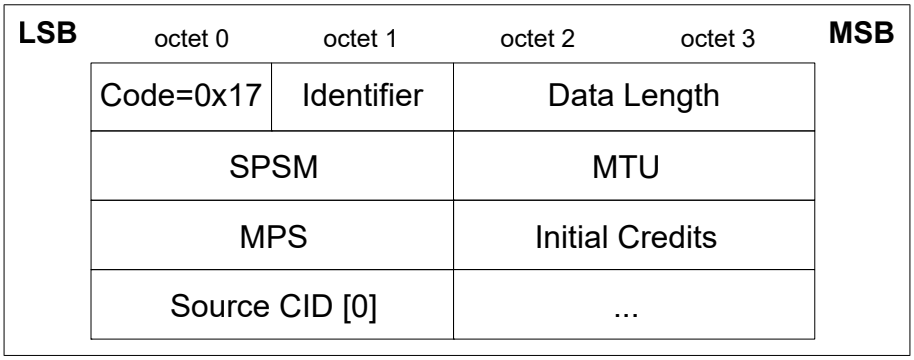

Figure 4.21: L2CAP_CREDIT_BASED_CONNECTION_REQ packet

The data fields are:

- *Simplified Protocol/Service Multiplexer – SPSM (2 octets)*

  The SPSM is defined in Section 4.22.

- *Maximum Transmission Unit – MTU (2 octets)*

  The MTU field specifies the maximum SDU size (in octets) that the L2CAP layer entity sending the L2CAP_CREDIT_BASED_CONNECTION_REQ packet can receive on each of the Source CID channels. L2CAP implementations shall support a minimum MTU size of 64 octets for these channels.

- *Maximum PDU Payload Size – MPS (2 octets)*

  The MPS field specifies the maximum PDU payload size (in octets) that the L2CAP layer entity sending the L2CAP_CREDIT_BASED_CONNECTION_REQ packet is capable of receiving on each of the Source CID channels. L2CAP implementations shall support a minimum MPS of 64 octets and may support an MPS up to 65533 octets for these channels.

- *Initial Credits – (2 octets)*

  The Initial Credit field value indicates the number of K-frames that the peer device can send to the L2CAP layer entity sending the

L2CAP_CREDIT_BASED_CONNECTION_REQ packet on each of the Source CID channels. The initial credit value shall be in the range of 1 to 65535.

- *Source CID – (2 to 10 octets)*

  The Source CID is an array of up to 5 two-octet values and represents the channel endpoints on the device sending the request. Once a channel has been created, data packets flowing to the sender of the request shall be sent to these CIDs. Each entry in the array shall be non-zero and represents a request for a channel. The value of each Source CID shall be from the dynamically allocated range as defined in Table 2.1 or Table 2.3 (depending on the transport in use) and shall not be already allocated to a different channel on the same logical link on the device sending the request.

4.26 L2CAP_CREDIT_BASED_CONNECTION_RSP (code 0x18)

When a device receives an L2CAP_CREDIT_BASED_CONNECTION_REQ packet, it shall send an L2CAP_CREDIT_BASED_CONNECTION_RSP packet. If the device sends an L2CAP_CREDIT_BASED_CONNECTION_RSP packet with a result code "pending", then it shall subsequently send another L2CAP_CREDIT_BASED_CONNECTION_RSP (see also [Vol 3] Part C, Section 5.2.2.2). Figure 4.22 defines the format of the packet.

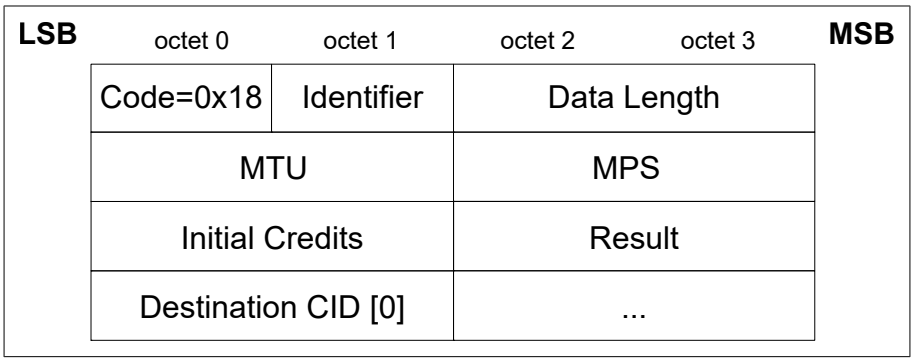

Figure 4.22: L2CAP_CREDIT_BASED_CONNECTION_RSP packet

The data fields are:

- *Maximum Transmission Unit – MTU (2 octets)*

  The MTU field specifies the maximum SDU size (in octets) that the L2CAP layer entity sending the L2CAP_CREDIT_BASED_CONNECTION_RSP packet can receive on each of the Destination CID channels. L2CAP implementations shall support a minimum MTU size of 64 octets.

- *Maximum PDU Payload Size – MPS (2 octets)*

  The MPS field specifies the maximum PDU payload size (in octets) that the L2CAP layer entity sending the L2CAP_CREDIT_BASED_CONNECTION_RSP packet is capable of receiving on each of the Destination CID channels. L2CAP

implementations shall support a minimum MPS of 64 octets and may support an MPS up to 65533 octets.

- *Initial Credits – (2 octets)*

  The Initial Credit field value indicates the number of K-frames that the peer device can send to the L2CAP layer entity sending the L2CAP_CREDIT_BASED_CONNECTION_RSP packet on each of the Destination CID channels. The initial credit value shall be in the range of 1 to 65535.

- *Result – (2 octets)*

  The Result field indicates the outcome of the connection request. Table 4.17 defines values for this field. The Destination CID, MTU, MPS and Initial Credits fields shall be ignored when the Result field indicates that all connections were refused or all connections are pending.

Value	Description
0x0000	All connections successful
0x0002	All connections refused – SPSM not supported
0x0004	Some connections refused – insufficient resources available
0x0005	All connections refused – insufficient authentication
0x0006	All connections refused – insufficient authorization
0x0007	All connections refused – encryption key size too short[1]
0x0008	All connections refused – insufficient encryption
0x0009	Some connections refused – invalid Source CID
0x000A	Some connections refused – Source CID already allocated
0x000B	All connections refused – unacceptable parameters
0x000C	All connections refused – invalid parameters
0x000D	All connections pending – no further information available
0x000E	All connections pending – authentication pending
0x000F	All connections pending – authorization pending
Other	Reserved for future use

Table 4.17: Result values for the L2CAP_CREDIT_BASED_CONNECTION_RSP packet

[1]This was previously "All connections refused - insufficient encryption key size".

- *Destination CID – (2 to 10 octets)*

  The Destination CID is an array of up to 5 two-octet values and represents the channel endpoints on the device sending the L2CAP_CREDIT_BASED_CONNECTION_RSP packet. The value of the Destination CID shall be from the dynamically allocated range as defined in Table 2.1 or Table 2.3

(depending on the transport in use) and shall not be already allocated to a different channel on the same logical link on the device sending the response. Once a channel has been created, data packets flowing to the sender of the response shall be sent to these CIDs. The order of the Destination CIDs shall correspond to the order of the Source IDs in the corresponding L2CAP_CREDIT_BASED_CONNECTION_REQ packet. If a Destination CID is non-zero, the channel was established. If a Destination CID is 0x0000, the channel was not established. If a device receives an L2CAP_CREDIT_BASED_CONNECTION_RSP packet with an already-assigned Destination CID, then both the original channel and the new channel shall not be used.

4.27 L2CAP_CREDIT_BASED_RECONFIGURE_REQ (code 0x19)

A device shall send an L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet when its receive MTU or MPS values have changed compared to when the channel was created or last reconfigured. Figure 4.23 defines the format of the packet.

Note: The current MTU and MPS values of the channels may be different before this packet is sent.

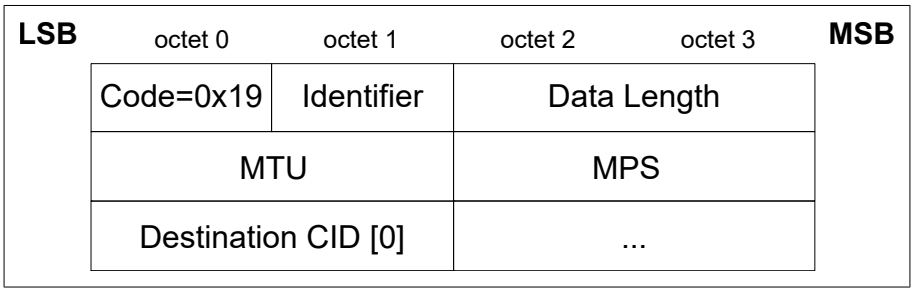

Figure 4.23: L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet

The data fields are:

- *Maximum Transmission Unit – MTU (2 octets)*

  The MTU field specifies the maximum SDU size (in octets) that the L2CAP layer entity sending the L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet can receive on each of the Destination CID channels. The MTU field shall be greater than or equal to the greatest current MTU size of these channels.

- *Maximum PDU Payload Size – MPS (2 octets)*

  The MPS field specifies the maximum PDU payload size (in octets) that the L2CAP layer entity sending the L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet is capable of receiving on each of the Destination CID channels. If more than one channel is being configured, the MPS field shall be greater than or equal to the current MPS size of each of these channels. If only one channel is being configured, the MPS field may be less than the current MPS of that channel.

- *Destination CID – (2 to 10 octets)*

  The Destination CID is an array of up to 5 two-octet values which shall be non-zero and represent the channel endpoints on the device sending the L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet.

4.28 L2CAP_CREDIT_BASED_RECONFIGURE_RSP (code 0x1A)

When a device receives an L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet, it shall send an L2CAP_CREDIT_BASED_RECONFIGURE_RSP packet. Figure 4.24 defines the format of the packet.

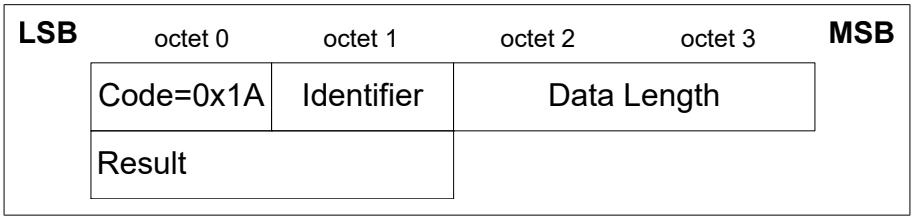

Figure 4.24: L2CAP_CREDIT_BASED_RECONFIGURE_RSP

The data fields are:

- *Result (2 octets)*

The Result field contains information about the success of the request.

Value	Description
0x0000	Reconfiguration successful
0x0001	Reconfiguration failed - reduction in size of MTU not allowed
0x0002	Reconfiguration failed - reduction in size of MPS not allowed for more than one channel at a time
0x0003	Reconfiguration failed - one or more Destination CIDs invalid
0x0004	Reconfiguration failed - other unacceptable parameters
All other values	Reserved for future use

Table 4.18: Result values for the L2CAP_CREDIT_BASED_RECONFIGURE_RSP packet

5 CONFIGURATION PARAMETER OPTIONS

Options are a mechanism to extend the configuration parameters. Options shall be transmitted as information elements containing an option type, an option length, and one or more option data fields. Figure 5.1 illustrates the format of an option.

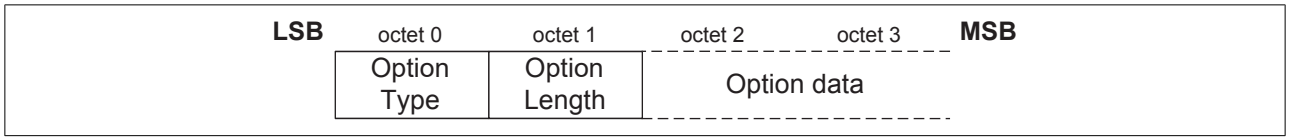

Figure 5.1: Configuration option format

The configuration option fields are:

- *Option Type (1 octet)*

  The Option Type field defines the parameters being configured. If the option is not recognized (e.g. because the option is defined in a higher version of the specification than the version the implementation conforms to) then:

  – If the most significant bit of the type is 0 (i.e. types 0x00 to 0x7F), the recipient shall refuse the entire configuration request.

  – If the most significant bit of the type is 1 (i.e. types 0x80 to 0xFF), the recipient shall ignore the option and continue processing with the next option (if any).

- *Option Length (1 octet)*

  The Option Length field defines the number of octets in the option data. Thus an option type without option data has a length of 0.

- *Option data*

  The contents of this field are dependent on the option type.

5.1 Maximum Transmission Unit (MTU)

This option specifies the maximum SDU size the sender of this option is capable of accepting for a channel. The Option Type is 0x01, and the Option Length is 2 octets, carrying the two-octet MTU size value as the only information element (see Figure 5.2).

MTU is not a negotiated value, it is an informational parameter that each device can specify independently. It indicates to the remote device that the local device can receive, in this channel, an MTU larger than the minimum required. All L2CAP implementations shall support a minimum MTU of 48 octets over the ACL-U logical link and 23 octets over the LE-U logical link; however, some protocols and profiles explicitly require support for a larger MTU. The minimum MTU for a channel is the larger of the L2CAP

minimum 48 octet MTU and any MTU explicitly required by the protocols and profiles using that channel.

Note: The MTU is only affected by the profile directly using the channel. For example, if a service discovery transaction is initiated by a non service discovery profile, that profile does not affect the MTU of the L2CAP channel used for service discovery.

The following rules shall be used when responding to an L2CAP_CONFIGURATION_REQ packet specifying the MTU for a channel:

- A request specifying any MTU greater than or equal to the minimum MTU for the channel shall be accepted.
- A request specifying an MTU smaller than the minimum MTU for the channel may be rejected.

The signaling described in Section 4.5 may be used to reject an MTU smaller than the minimum MTU for a channel. The "failure-unacceptable parameters" result sent to reject the MTU shall include the proposed value of MTU that the remote device intends to transmit. It is implementation specific whether the local device continues the configuration process or disconnects the channel.

If the remote device sends a positive L2CAP_CONFIGURATION_RSP packet it should include the actual MTU to be used on this channel for traffic flowing into the local device. Following the above rules, the actual MTU cannot be less than 48 bytes.This is the minimum of the MTU in the L2CAP_CONFIGURATION_REQ packet and the outgoing MTU capability of the device sending the L2CAP_CONFIGURATION_RSP packet. The new agreed value (the default value in a future re-configuration) is the value specified in the response.

Note: For backwards compatibility reception of the MTU option in a negative L2CAP_CONFIGURATION_RSP packet where the MTU option is not in error should be interpreted in the same way as it is in a positive L2CAP_CONFIGURATION_RSP packet (e.g. the case where another configuration option value is unacceptable but the negative L2CAP_CONFIGURATION_RSP packet contains the MTU option in addition to the unacceptable option).

The MTU to be used on this channel for the traffic flowing in the opposite direction will be established when the remote device sends its own L2CAP_CONFIGURATION_REQ packet as explained in Section 4.4.

If the configured mode is Enhanced Retransmission mode or Streaming mode then MTU shall not be reconfigured to a smaller size.

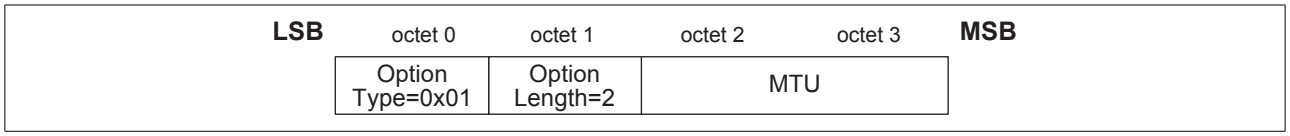

Figure 5.2: MTU option format

The option data field is:

- *Maximum Transmission Unit - MTU (2 octets)*

  The MTU field is the maximum SDU size, in octets, that the originator of the request can accept for this channel. The MTU is asymmetric and the sender of the request shall specify the MTU it can receive on this channel if it differs from the default value. L2CAP implementations shall support a minimum MTU size of 48 octets. The default value is 672 octets.

5.2 Flush Timeout option

This option is used to inform the recipient of the Flush Timeout the sender is going to use. This option shall not be used if the Extended Flow Specification is used. The Flush Timeout is defined in the BR/EDR Baseband specification [Vol 2] Part B, Section 3.3. The Option Type is 0x02 and the Option Length is 2 octets (see Figure 5.3). The Flush Timeout option is negotiable.

If the remote device returns a negative response to this option and the local device cannot honor the proposed value, then it shall either continue the configuration process by sending a new request with the original value, or disconnect the channel. The flush timeout applies to all channels on the same ACL logical transport but may be overridden on a packet by packet basis by marking individual L2CAP packets as non-automatically-flushable via the Packet_Boundary_Flag in the HCI ACL Data packet (see Section 1.1).

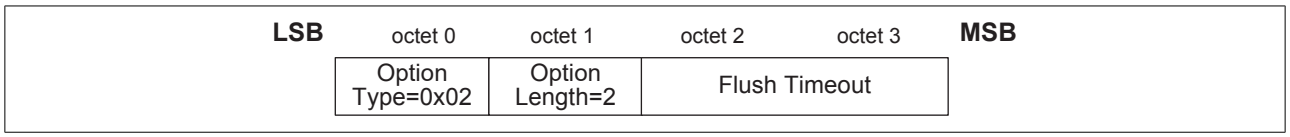

Figure 5.3: Flush Timeout option format

The option data field is:

- *Flush Timeout*

  This value is the Flush Timeout in milliseconds. This is an asymmetric value and the sender of the request shall specify its flush timeout value if it differs from the default value of 0xFFFF.

Possible values are:

0x0001 - no retransmissions at the Baseband level should be performed since the minimum polling interval is 1.25 ms.

0x0002 to 0xFFFE - Flush Timeout used by the Baseband.

0xFFFF - an infinite amount of retransmissions. This is also referred to as a 'reliable channel'. In this case, the Baseband shall continue retransmissions until physical link loss is declared by link manager timeouts.

5.3 Quality of Service (QoS) option

This option specifies a flow specification similar to RFC 1363[1]. Although the RFC flow specification addresses only the transmit characteristics, the Bluetooth QoS interface can handle the two directions (Tx and Rx) in the negotiation as described below.

If no QoS configuration parameter is negotiated the link shall assume the default parameters. The Option Type is 0x03. This option shall not be used if the Extended Flow Specification option is used. The QoS option is negotiable. Figure 5.4 specifies the format of this option.

In an L2CAP_CONFIGURATION_REQ packet, this option describes the outgoing traffic flow from the device sending the request. In a positive L2CAP_CONFIGURATION_RSP packet, this option describes the incoming traffic flow agreement to the device sending the response. In a negative L2CAP_CONFIGURATION_RSP packet, this option describes the preferred incoming traffic flow to the device sending the response.

L2CAP implementations are only required to support 'Best Effort' service, support for any other service type is optional. Best Effort does not require any guarantees. If no QoS option is placed in the request, Best Effort shall be assumed. If any QoS guarantees are required then a QoS configuration request shall be sent.

The remote device's L2CAP_CONFIGURATION_RSP packet contains information that depends on the value of the result field (see Section 4.5). If the request was for Guaranteed Service, the response shall include specific values for any wild card parameters (see Token Rate and Token Bucket Size descriptions) contained in the request. If the result is "Failure – unacceptable parameters", the response shall include a list of outgoing flow specification parameters and parameter values that would make a new L2CAP_CONNECTION_REQ packet from the local device acceptable by the remote device. Both explicitly referenced in an L2CAP_CONFIGURATION_REQ packet or implied configuration parameters can be included in an L2CAP_CONFIGURATION_RSP packet. Recall that any missing configuration parameters from an L2CAP_CONFIGURATION_REQ packet are assumed to have their most recently accepted values.

[1]Internet Engineering Task Force, "A Proposed Flow Specification", RFC 1363, September 1992.

If an L2CAP_CONFIGURATION_REQ packet contains any QoS option parameters set to “do not care” then the L2CAP_CONFIGURATION_RSP packet shall set the same parameters to “do not care”. This rule applies for Best Effort and, if the parameter is allowed to be set to the "do not care" value, for Guaranteed Service.

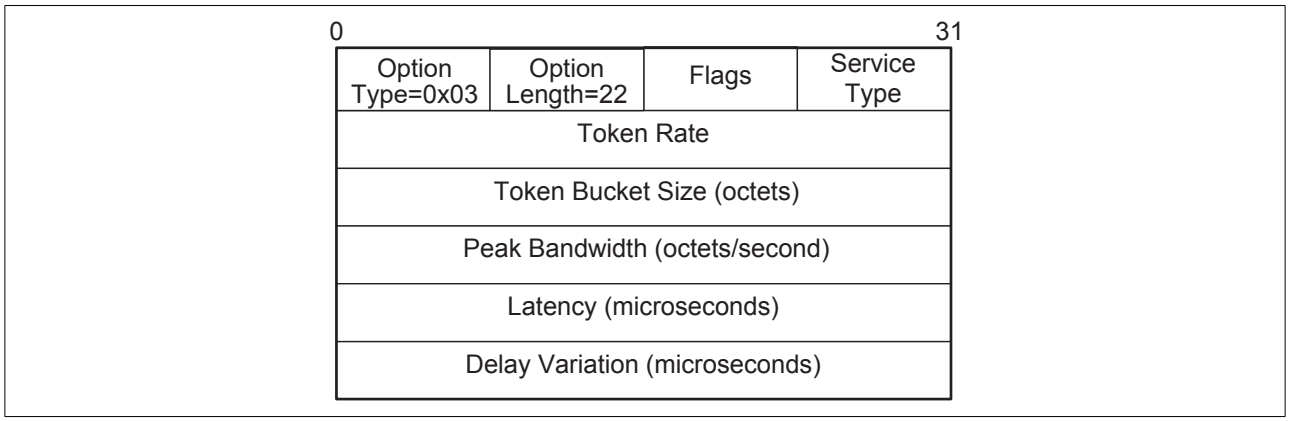

Figure 5.4: Quality of Service (QoS) option format containing Flow Specification

The option data fields are:

- *Flags (1 octet)*

  Reserved for future use.

- *Service Type (1 octet)*

  This field indicates the level of service required. Table 5.1 defines the different services available. The default value is ‘Best effort’.

  If ‘Best effort’ is selected, the remaining parameters should be treated as optional by the remote device. The remote device may choose to ignore the fields, try to satisfy the parameters but provide no response (QoS option omitted in the response message), or respond with the settings it will try to meet.

  If ‘No traffic’ is selected, the remainder of the fields shall be ignored because there is no data being sent across the channel in the outgoing direction.

Value	Description
0x00	No traffic
0x01	Best effort (Default)
0x02	Guaranteed
Other	Reserved for future use

Table 5.1: Service type definitions

- *Token Rate (4 octets)*

  The value of this field represents the average data rate with which the application transmits data. The application may send data at this rate continuously. On a short

time scale the application may send data in excess of the average data rate, dependent on the specified Token Bucket Size and Peak Bandwidth (see below). The Token Bucket Size and Peak Bandwidth allow the application to transmit data in a 'bursty' fashion.

The Token Rate signaled between two L2CAP peers is the data transmitted by the application and shall exclude the L2CAP protocol overhead. The Token Rate signaled over the interface between L2CAP and the Link Manager shall include the L2CAP protocol overhead. Furthermore the Token Rate value signaled over this interface may also include the aggregation of multiple L2CAP channels onto the same ACL logical transport.

The Token Rate is the rate with which traffic credits are provided. Credits can be accumulated up to the Token Bucket Size. Traffic credits are consumed when data is transmitted by the application. When traffic is transmitted, and there are insufficient credits available, the traffic is non-conformant. The Quality of Service guarantees are only provided for conformant traffic. For non-conformant traffic there may be insufficient resources such as bandwidth and buffer space. Furthermore non-conformant traffic may violate the QoS guarantees of other traffic flows.

The Token Rate is specified in octets per second. The value 0x00000000 indicates no token rate is specified. This is the default value and means “do not care”. When the Guaranteed service is selected, the default value shall not be used. The value 0xFFFFFFFF is a wild card matching the maximum token rate available. The meaning of this value depends on the service type. For best effort, the value is a hint that the application wants as much bandwidth as possible. For Guaranteed service the value represents the maximum bandwidth available at the time of the request.

- *Token Bucket Size (4 octets)*

  The Token Bucket Size specifies a limit on the 'burstiness' with which the application may transmit data. The application may offer a burst of data equal to the Token Bucket Size instantaneously, limited by the Peak Bandwidth (see below). The Token Bucket Size is specified in octets.

  The Token Bucket Size signaled between two L2CAP peers is the data transmitted by the application and shall exclude the L2CAP protocol overhead. The Token Bucket Size signaled over the interface between L2CAP and Link Manager shall include the L2CAP protocol overhead. Furthermore the Token Bucket Size value over this interface may include the aggregation of multiple L2CAP channels onto the same ACL logical transport.

  The value of 0x00000000 means that no token bucket is needed; this is the default value. When the Guaranteed service is selected, the default value shall not be used. The value 0xFFFFFFFF is a wild card matching the maximum token bucket available. The meaning of this value depends on the service type. For best effort, the value

indicates the application wants a bucket as big as possible. For Guaranteed service the value represents the maximum L2CAP SDU size.

The Token Bucket Size is a property of the traffic carried over the L2CAP channel. The Maximum Transmission Unit (MTU) is a property of an L2CAP implementation. For the Guaranteed service the Token Bucket Size shall be smaller or equal to the MTU.

- *Peak Bandwidth (4 octets)*

  The value of this field, expressed in octets per second, limits how fast packets from applications may be sent back-to-back. Some systems can take advantage of this information, resulting in more efficient resource allocation.

  The Peak Bandwidth signaled between two L2CAP peers specifies the data transmitted by the application and shall exclude the L2CAP protocol overhead. The Peak Bandwidth signaled over the interface between L2CAP and Link Manager shall include the L2CAP protocol overhead. Furthermore the Peak Bandwidth value over this interface may include the aggregation of multiple L2CAP channels onto the same ACL logical transport.

  The value of 0x00000000 means "do not care." This states that the device has no preference on incoming maximum bandwidth, and is the default value. When the Guaranteed service is selected, the default value shall not be used.

- *Access Latency (4 octets)*

  The value of this field is the maximum acceptable delay of an L2CAP packet to the air-interface. The precise interpretation of this number depends on over which interface this flow parameter is signaled. When signaled between two L2CAP peers, the Access Latency is the maximum acceptable delay between the instant when the L2CAP SDU is received from the upper layer and the start of the L2CAP SDU transmission over the air. When signaled over the interface between L2CAP and the Link Manager, it is the maximum delay between the instant the first fragment of an L2CAP PDU is stored in the Controller buffer and the initial transmission of the L2CAP packet on the air.

  Thus the Access Latency value may be different when signaled between L2CAP and the Link Manager to account for any queuing delay at the L2CAP transmit side. Furthermore the Access Latency value may include the aggregation of multiple L2CAP channels onto the same ACL logical transport.

  The Access Latency is expressed in microseconds. The value 0xFFFFFFFF means “do not care” and is the default value. When the Guaranteed service is selected, the default value shall not be used.

- *Delay Variation (4 octets)*

  The value of this field is the difference, in microseconds, between the maximum and minimum possible delay of an L2CAP SDU between two L2CAP peers. The Delay

Variation is a purely informational parameter. The value 0xFFFFFFFF means “do not care” and is the default value.

5.4 Retransmission and Flow Control option

This option specifies whether retransmission and flow control is used. If the feature is used both incoming and outgoing parameters are specified by this option. The Retransmission and Flow Control option contains both negotiable parameters and non-negotiable parameters. The mode parameter controls both incoming and outgoing data flow (i.e. both directions have to agree) and is negotiable. The other parameters control incoming data flow and are non-negotiable. Figure 5.5 specifies the format of this option.

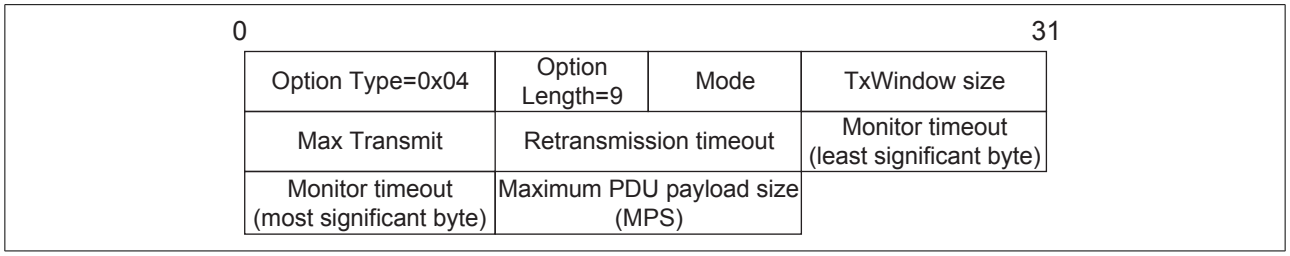

Figure 5.5: Retransmission and Flow Control option format

The option data fields are:

- *Mode (1 octet)*

  The field contains the requested mode of the link. Possible values are shown in Table 5.2.

Value	Description
0x00	L2CAP Basic mode
0x01	Retransmission mode
0x02	Flow control mode
0x03	Enhanced Retransmission mode
0x04	Streaming mode
Other	Reserved for future use

Table 5.2: Mode definitions

  The Basic L2CAP mode is the default. If Basic L2CAP mode is requested then all other parameters shall be ignored.

  Enhanced Retransmission mode should be enabled if a reliable channel has been requested. Enhanced Retransmission mode shall only be sent to an L2CAP entity that has previously advertised support for the mode in its Extended Feature Mask (see Section 4.12).

Streaming mode should be enabled if a finite L2CAP Flush Timeout is set on an L2CAP connection. Streaming mode shall only be sent to a device that has previously advertised support for the mode in the Extended Feature Mask (see Section 4.12).

Flow Control mode and Retransmission mode shall only be used for backwards compatibility with L2CAP entities that do not support Enhanced Retransmission mode or Streaming mode.

- *TxWindow size (1 octet)*

  This field specifies the size of the transmission window for Flow Control mode, Retransmission mode, and Enhanced Retransmission mode. The range is 1 to 32 for Flow Control mode and Retransmission mode. The range is 1 to 63 for Enhanced Retransmission mode.

  In Retransmission mode and Flow Control mode this parameter should be negotiated to reflect the buffer sizes allocated for the connection on both sides. In general, the Tx Window size should be made as large as possible to maximize channel utilization. Tx Window size also controls the delay on flow control action. The transmitting device can send as many PDUs fit within the window.

  In Enhanced Retransmission mode this value indicates the maximum number of I-frames that the sender of the option can receive without acknowledging some of the received frames. It is not negotiated. It is an informational parameter that each L2CAP entity can specify separately. In general, the TxWindow size should be made as large as possible to maximize channel utilization. The transmitting L2CAP entity can send as many PDUs as will fit within the receiving L2CAP entity's TxWindow. TxWindow size values in an L2CAP_CONFIGURATION_RSP packet indicate the maximum number of packets the sender can send before it requires an acknowledgment. In other words it represents the number of unacknowledged packets the sender can hold. The value sent in an L2CAP_CONFIGURATION_RSP packet shall be less than or equal to the TxWindow size sent in the L2CAP_CONFIGURATION_REQ packet. The receiver of this option in the L2CAP_CONFIGURATION_RSP packet may use this value as part of its acknowledgment algorithm.

  In Streaming mode this value is reserved for future use.

- *MaxTransmit (1 octet)*

  This field controls the number of transmissions of a single I-frame that L2CAP is allowed to try in Retransmission mode and Enhanced Retransmission mode. The minimum value is 1 (one transmission is permitted).

  MaxTransmit controls the number of retransmissions that L2CAP is allowed to try in Retransmission mode and Enhanced Retransmission mode before accepting that a packet and the channel is lost. When a packet is lost after being transmitted MaxTransmit times the channel shall be disconnected by sending a Disconnect request (see Section 4.6). In Enhanced Retransmission mode MaxTransmit controls

the number of retransmissions for I-frames and S-frames with P-bit set to 1. The sender of the option in an L2CAP_CONFIGURATION_REQ packet specifies the value that shall be used by the receiver of the option. MaxTransmit values in an L2CAP_CONFIGURATION_RSP packet shall be ignored. Lower values might be appropriate for services requiring low latency. Higher values will be suitable for a link requiring robust operation. A value of 1 means that no retransmissions will be made but also means that the channel will be disconnected as soon as a packet is lost. MaxTransmit shall not be set to zero in Retransmission mode. In Enhanced Retransmission mode a value of zero for MaxTransmit means infinite retransmissions.

In Streaming mode this value is reserved for future use.

- *Retransmission timeout (2 octets)*

  This is the value in milliseconds of the retransmission timeout (this value is used to initialize the RetransmissionTimer).

  The purpose of this timer in retransmission mode is to activate a retransmission in some exceptional cases. In such cases, any delay requirements on the channel may be broken, so the value of the timer should be set high enough to avoid unnecessary retransmissions due to delayed acknowledgments. Suitable values could be 100's of milliseconds and up.

  The purpose of this timer in flow control mode is to supervise I-frame transmissions. If an acknowledgment for an I-frame is not received within the time specified by the RetransmissionTimer value, either because the I-frame has been lost or the acknowledgment has been lost, the timeout will cause the transmitting side to continue transmissions. Suitable values are implementation dependent.

  The purpose of this timer in Enhanced Retransmission mode is to detect lost I-frames and initiate appropriate error recovery. The value used for the Retransmission timeout is specified in Section 8.6.2. The value sent in an L2CAP_CONFIGURATION_REQ packet is also specified in Section 8.6.2. A value for the Retransmission timeout shall be sent in a positive L2CAP_CONFIGURATION_RSP packet and indicates the value that will be used by the sender of the L2CAP_CONFIGURATION_RSP packet.

  In Streaming mode this value is reserved for future use.

- *Monitor timeout (2 octets)*

  In Retransmission mode this is the value in milliseconds of the interval at which S-frames should be transmitted on the return channel when no frames are received on the forward channel. (this value is used to initialize the MonitorTimer, see below).

  This timer ensures that lost acknowledgments are retransmitted. Its main use is to recover Retransmission Disable Bit changes in lost frames when no data is being sent. The timer shall be started immediately upon transitioning to the open state. It shall remain active as long as the connection is in the open state and the retransmission timer is not active. Upon expiration of the Monitor timer an S-frame

shall be sent and the timer shall be restarted. If the monitor timer is already active when an S-frame is sent, the timer shall be restarted. An idle connection will have periodic monitor traffic sent in both directions. The value for this timeout should also be set to 100's of milliseconds or higher.

In Enhanced Retransmission mode the Monitor timeout is used to detect lost S-frames with P-bit set to 1. If the timeout occurs before a response with the F-bit set to 1 is received the S-frame is resent. The value used for the Monitor timeout is specified in Section 8.6.3. The value sent in an L2CAP_CONFIGURATION_REQ packet is also specified in Section 8.6.2. A value for the Monitor timeout shall be sent in a positive L2CAP_CONFIGURATION_RSP packet and indicates the value that will be used by the sender of the L2CAP_CONFIGURATION_RSP packet.

In Streaming mode this value is reserved for future use.

- *Maximum PDU payload Size - MPS (2 octets)*

  The maximum payload size that the L2CAP layer entity sending the option in an L2CAP_CONFIGURATION_REQ packet is capable of accepting, i.e. the MPS corresponds to the maximum PDU payload size. Each device specifies the value separately. An MPS value sent in a positive L2CAP_CONFIGURATION_RSP packet is the actual MPS the receiver of the L2CAP_CONFIGURATION_REQ packet will use on this channel for traffic flowing into the local device. An MPS value sent in a positive L2CAP_CONFIGURATION_RSP packet shall be equal to or smaller than the value sent in the L2CAP_CONFIGURATION_REQ packet.

When using Retransmission mode and Flow Control mode the settings are configured separately for the two directions of an L2CAP connection. For example, in operating with an L2CAP entity implementing a lower version of the specification, an L2CAP connection can be configured as Flow Control mode in one direction and Retransmission mode in the other direction. If Basic L2CAP mode is configured in one direction and Retransmission mode or Flow control mode is configured in the other direction on the same L2CAP channel then the channel shall not be used.

Note: This asymmetric configuration only occurs during configuration.

When using Enhanced Retransmission mode or Streaming mode, both directions of the L2CAP connection shall be configured to the same mode. A precedence algorithm shall be used by both devices so a mode conflict can be resolved in a quick and deterministic manner.

There are two operating states:

- A device has a preferred mode but is willing to use another mode (known as "state 1"), and
- A device requires a specific mode (known as "state 2"). This includes cases where channels are created over ACL-U logical links operating as described in Section 7.10.

In state 1, Basic L2CAP mode has the highest precedence and shall take precedence over Enhanced Retransmission mode and Streaming mode. Enhanced Retransmission mode has the second highest precedence and shall take precedence over all other modes except Basic L2CAP mode. Streaming mode shall have the next level of precedence after Enhanced Retransmission mode.

In state 2, a layer above L2CAP requires Enhanced Retransmission mode or Streaming mode. In this case, the required mode takes precedence over all other modes.

A device does not know in which state the remote device is operating so the state 1 precedence algorithm assumes that the remote device may be a state 2 device. If the mode proposed by the remote device has a higher precedence (according to the state 1 precedence) then the algorithm will operate such that creation of a channel using the remote device's mode has higher priority than disconnecting the channel.

The algorithm for state 1 devices is divided into two parts. Part one covers the case where the remote device proposes a mode with a higher precedence than the state 1 local device. Part two covers the case where the remote device proposes a mode with a lower precedence than the state 1 local device. Part one of the algorithm is as follows:

- When the remote device receives the L2CAP_CONFIGURATION_REQ packet from the local device it will either reject the local device's L2CAP_CONFIGURATION_REQ packet by sending a negative L2CAP_CONFIGURATION_RSP packet or disconnect the channel. The negative L2CAP_CONFIGURATION_RSP packet will contain the remote device's desired mode.
- Upon receipt of the negative L2CAP_CONFIGURATION_RSP packet the local device shall either send a second L2CAP_CONFIGURATION_REQ packet proposing the mode contained in the remote device's negative L2CAP_CONFIGURATION_RSP packet or disconnect the channel.
- When the local device receives the L2CAP_CONFIGURATION_REQ packet from the remote device it shall send a positive L2CAP_CONFIGURATION_RSP packet or disconnect the channel.
- If the mode in the remote Device's negative L2CAP_CONFIGURATION_RSP packet does not match the mode in the remote device's L2CAP_CONFIGURATION_REQ packet then the local device shall disconnect the channel.

Part two of the algorithm is as follows:

- When the local device receives the L2CAP_CONFIGURATION_REQ packet from the remote device it shall reject the L2CAP_CONFIGURATION_REQ packet by sending a negative L2CAP_CONFIGURATION_RSP packet proposing its desired mode. The local device's desired mode shall be the same mode it sent in its L2CAP_CONFIGURATION_REQ packet. Upon receiving the negative

L2CAP_CONFIGURATION_RSP packet the remote device will either send a second L2CAP_CONFIGURATION_REQ packet or disconnect the channel.

- If the local device receives a second L2CAP_CONFIGURATION_REQ packet from the remote device that does not contain the desired mode then the local device shall disconnect the channel.
- If the local device receives a negative L2CAP_CONFIGURATION_RSP packet then it shall disconnect the channel.

An example of the algorithm for state 1 devices is as follows:

- The remote device proposes Basic L2CAP mode in an L2CAP_CONFIGURATION_REQ packet and the local device proposes Enhanced Retransmission mode or Streaming mode. The remote device rejects the local device's L2CAP_CONFIGURATION_REQ packet by sending a negative L2CAP_CONFIGURATION_RSP packet proposing Basic mode. The local device will send a second L2CAP_CONFIGURATION_REQ packet proposing Basic L2CAP mode or disconnect the channel. If the local device sends a second L2CAP_CONFIGURATION_REQ packet that does not propose Basic L2CAP mode then the remote device will disconnect the channel. If the local device rejects the remote device's L2CAP_CONFIGURATION_REQ packet then the remote device will disconnect the channel.

The algorithm for state 2 devices is as follows:

- If the local device proposes a mode in an L2CAP_CONFIGURATION_REQ packet and the remote device proposes a different mode or rejects the local device's L2CAP_CONFIGURATION_REQ packet then the local device shall disconnect the channel.

For Enhanced Retransmission mode and Streaming mode the Retransmission timeout and Monitor Timeout parameters of the Retransmission and Flow Control option parameters may be changed but all other parameters shall not be changed in a subsequent reconfiguration after the channel has reached the OPEN state.

5.5 Frame Check Sequence (FCS) option

This option is used to specify the type of Frame Check Sequence (FCS) that will be included on S/I-frames that are sent. It is non-negotiable. The FCS option shall only be used when the mode is configured to, or in an L2CAP_CONFIGURATION_REQ packet that contains an option configuring it to, Enhanced Retransmission mode or Streaming mode. This option shall only be used if the peer L2CAP entity has indicated support for the FCS Option in the Extended Features Mask (see Section 4.12).

Figure 5.6 specifies the format of this option. The Option Type is 0x05. "No FCS" shall only be used if both L2CAP entities send the FCS Option with value 0x00 (No

FCS) in an L2CAP_CONFIGURATION_REQ packet. If one L2CAP entity sends the FCS Option with "No FCS" in an L2CAP_CONFIGURATION_REQ packet and the other L2CAP sends the FCS Option with a value other than "No FCS" then the default shall be used. If one or both L2CAP entities do not send the FCS option in an L2CAP_CONFIGURATION_REQ packet then the default shall be used.

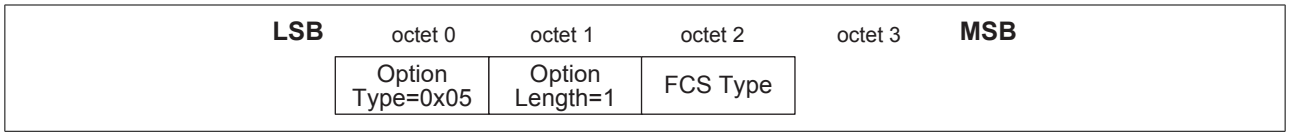

Figure 5.6: FCS option format

The FCS types are shown in Table 5.3

Value	Description
0x00	No FCS
0x01	16-bit FCS defined in section 3.3.5 (default)
Other	Reserved for future use

Table 5.3: FCS types

Value of 0x00 is set when the sender wishes to omit the FCS from S/I-frames.

5.6 Extended Flow Specification option

This option specifies a flow specification for requesting a desired Quality of Service (QoS) on a channel. It is non-negotiable. Extended Flow Specification may be supported on channels created over ACL-U logical links (see Section 7.10). If both devices show support for Extended Flow Specification for BR/EDR in the Extended Feature mask (see Table 4.12) then all channels created between the two devices shall use an Extended Flow Specification. The Quality of Service option and Flush Timeout option shall not be used if the Extended Flow Specification is used.

The parameters in the Extended Flow Specification option specify the traffic stream in the outgoing direction (transmitted traffic). The Option Type is 0x06. Figure 5.7 specifies the format of this option.

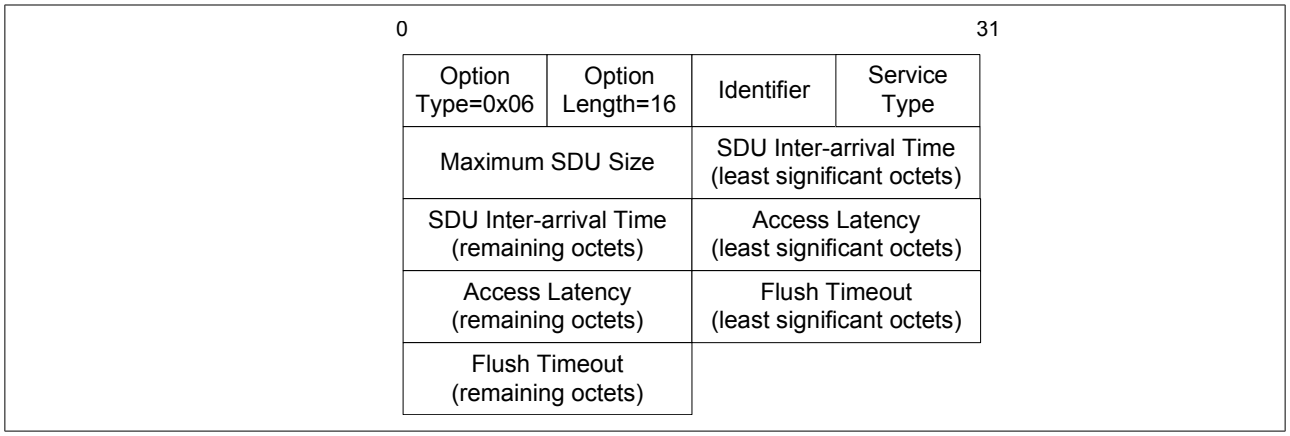

Figure 5.7: Extended Flow Specification option format

If no Extended Flow Specification is provided by the upper layer, an Extended Flow Specification with following default values shall be used:

Qos Parameter	Default Value
Identifier	0x01
Service Type	Best Effort
Maximum SDU size	0xFFFF
SDU Inter-arrival Time	0xFFFFFFFF
Access Latency	0xFFFFFFFF
Flush Timeout	0xFFFFFFFF

Table 5.4: Default values for Extended Flow Specification

For a Best Effort channel no latency, air-time or bandwidth guarantees shall be assumed.

The parameters of the Extended Flow Specification are shown in Table 5.5:

QoS parameter	Parameter Size in Octets	Unit
Identifier	1	*none*
Service Type	1	*none*
Maximum SDU Size	2	octets
SDU Inter-arrival Time	4	microseconds
Access Latency	4	microseconds
Flush Timeout	4	microseconds

Table 5.5: Traffic parameters for L2CAP QoS configuration

- *Identifier (1 octet)*

  This field provides a unique identifier for the flow specification. This identifier is used by some Controllers in the process of setting up the QoS request. Each active flow specification sent by a device to configure an L2CAP channel shall have a unique Identifier. An Identifier can be reused when the L2CAP channel associated with the flow spec is disconnected. The Identifier shall be unique within the scope of a physical link. Extended Flow Specifications for channels on different physical links may have the same Identifier. The Identifier for an Extended Flow Specification with Service Type Best Effort shall be 0x01.

  Since the Identifier for an Extended Flow Specification with Service Type Best Effort is fixed to 0x01 it is possible to generate a Best Effort Extended Flow Specification for the remote device without performing the Lockstep Configuration process. (The Lockstep Configuration process is described in Section 7.1.3).

- *Service Type (1 octet)*

  This field indicates the level of service required. Table 5.6 defines the different Service Types values. The default value is 'Best effort'. If 'Best effort' is selected then Access Latency and Flush Timeout shall both be set to 0xFFFFFFFF. Maximum SDU size and SDU Inter-arrival Time are used to indicate the maximum data rate that the application can deliver to L2CAP for transmission. The remote device should respond with lower settings indicating the maximum rate at which it can receive data (for example, maximum rate data it can write to a mass storage device, etc.). Values of 0xFFFF for Maximum SDU size and 0xFFFFFFFF for SDU Inter-arrival time are used when the actual values are not known. If Maximum SDU size is set to 0xFFFF then SDU Inter-arrival time shall be set to 0xFFFFFFFF, if SDU Inter-arrival time is set to 0xFFFFFFFF then Maximum SDU size shall be set to 0xFFFF. This tells the Controller to allocate as much bandwidth as possible.

If “Guaranteed” is selected the QoS parameters can be used to identify different types of Guaranteed traffic.

- **Guaranteed bandwidth** traffic is traffic with a minimum data rate but no particular latency requested. Latency will be related to the link supervision timeout. For this type of traffic Access Latency is set to 0xFFFFFFFF.
- **Guaranteed Latency** traffic is traffic with only latency requirements. For this type of traffic SDU Inter-arrival time is set to 0xFFFFFFFF. HID interrupt channel and AVRCP are examples of this type of traffic.
- **Both Guaranteed Latency and Bandwidth** traffic has both a latency and bandwidth requirement. An example is Audio/Video streaming.

If 'No Traffic' is selected the remainder of the fields shall be ignored because there is no data being sent across the channel in the outgoing direction.

Value	Description
0x00	No Traffic
0x01	Best effort (Default)
0x02	Guaranteed
Other	Reserved for future use

Table 5.6: Service type definitions

A channel shall not be configured as “Best Effort” in one direction and “Guaranteed” in the other direction. If a channel is configured in this way it shall be disconnected. A channel may be configured as “No Traffic” in one direction and “Best Effort” in the other direction. The “No Traffic” refers to the application traffic not the Enhanced Retransmission mode supervisory traffic. A channel configured in this way is considered to have a service type of Best Effort. A channel may be configured as “No Traffic” in one direction and “Guaranteed” in the other direction. A channel configure in this way is considered to have a service type of Guaranteed.

Once configured the service type of a channel shall not be changed during reconfiguration.

- *Maximum SDU Size (2 octets)*

  The Maximum SDU Size parameter specifies the maximum size of the SDUs transmitted by the application. If the Service Type is “Guaranteed” then traffic submitted to L2CAP with a larger size is considered non-conformant. QoS guarantees are only provided for conformant traffic.

- *SDU Inter-arrival time (4 octets)*

  The SDU Inter-arrival time parameter specifies the time between consecutive SDUs generated by the application. For streaming traffic, SDU Inter-arrival time should be set to the average time between SDUs. For variable rate traffic and best effort traffic, SDU Inter-arrival time should be set to the minimum time between SDUs. If the Service Type is “Guaranteed” then traffic submitted to L2CAP with a smaller interval, is considered non-conformant. QoS guarantees are only provided for conformant traffic.

- *Access Latency (4 octets)*

  The Access Latency parameter specifies the maximum delay between consecutive transmission opportunities on the air-interface for the connection. Access latency is based on the time base of the Controller, which is not necessarily synchronous to the time base being used by the Host or the application.

  For streaming traffic (such as in A2DP), the Access Latency should be set to indicate the time budgeted for transmission of the data over the air, and would normally be

roughly equal to the Flush Timeout minus the duration of streaming data which can be stored in the receive side application buffers.

For non-streaming, bursty traffic (such as in HID and AVRCP), the Access Latency parameter value sent in the L2CAP_CONFIGURATION_REQ packet should be set to the desired latency, minus any HCI transport delays and any other stack delays that may be expected on the device and on target Host systems. The remote device receiving the L2CAP_CONFIGURATION_REQ packet may send an Access Latency parameter value in the L2CAP_CONFIGURATION_RSP packet which is equal to or lower than the value it received. The remote device may send a lower value to account for other traffic it may be carrying, or overhead activities it may be carrying out.

If HCI is used then the Host should take into account the latency of the HCI transport when determining the value for the Access Latency. For example if the application requires an Access Latency of 20 ms and the HCI transport has a latency of 5 ms then the value for Access Latency should be 15 ms.

- *Flush Timeout (4 Octets)*

  The Flush Timeout defines a maximum period after which all segments of the SDU are flushed from L2CAP and the Controller. A Flush Timeout value of 0xFFFFFFFF indicates that data will not be discarded by the transmitting side, even if the link becomes congested, and thus in this case data is treated as reliable and is never flushed.

  The device receiving the L2CAP_CONFIGURATION_REQ packet with Flush Timeout set to 0xFFFFFFFF should not modify this parameter. The Flush Timeout for a “Best Effort” channel shall be set to 0xFFFFFFFF.

  However, if the Traffic Type is “Guaranteed” and the transmit side buffer is limited, then the Flush Timeout parameter given in the L2CAP_CONFIGURATION_REQ packet may be set to a value corresponding to the duration of streaming data which the transmit buffer can hold before it must begin discarding data. The side receiving the L2CAP_CONFIGURATION_REQ packet may then set the Flush Timeout parameter in the L2CAP_CONFIGURATION_RSP packet to a lower value if the receive side buffer is smaller than the transmit side buffer.

  Note: The total available buffer space is typically a combination of application buffers, any buffers maintained by the L2CAP implementation, and HCI buffers provided by the Controller.

  The Flush Timeout should normally be set to a value which is larger than the Access Latency, and which also accounts for buffers maintained by the application on the receive side such as de-jitter buffers used in audio and video streaming applications. In general, the Flush Timeout value should be selected to ensure that the Flush Timeout expires when the application buffers are about to be exhausted.

Flush Timeout may be set to 0x00000000 to indicate that no retransmissions are to occur. Data may be flushed immediately after transmission in this case. This behavior is useful in applications such as gaming where the tolerable latency is on the order of a few milliseconds, and hence the information contained in a packet will become stale very rapidly. In such applications, it is preferable to send “fresher” data if the last SDU submitted for transmission was not transmitted as a result of interference.

5.7 Extended Window Size option

This option is used to negotiate the maximum extended window size. The Option Type is 0x07 and the option is non-negotiable. Figure 5.8 specifies the format of this option.

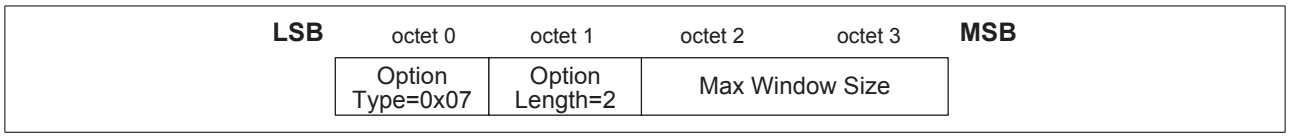

Figure 5.8: Extended Window Size option format

The allowable values for the Maximum Extended Window Size are:

Value	Description
0x0000	Invalid value for Enhanced Retransmission mode Valid for Streaming mode
0x0001 to 0x3FFF	Valid maximum window size (frames) for Enhanced Retransmission mode. Invalid for Streaming mode
Other	Reserved for future use

Table 5.7: Extended Window Size values

This option shall only be sent if the peer L2CAP entity has indicated support for the Extended Window size feature in the Extended Features Mask (see Section 4.12).

This option shall be ignored if the channel is configured to use Basic L2CAP mode (see Section 5.4).

For Enhanced Retransmission mode, this option has the same directional semantics as the Retransmission and Flow Control option (see Section 5.4). The sender of an L2CAP_CONFIGURATION_REQ packet containing this option is suggesting the maximum window size (possibly based on its own internal L2CAP receive buffer resources) that the peer L2CAP entity should use when sending data.

For Streaming mode, this option is used to enable use of the Extended Control Field and if sent, shall have a value of 0.

If this option is successfully configured then the Maximum Window Size negotiated using the Retransmission and Flow Control option (see Section 5.4) shall be ignored.

If this option is successfully configured in either direction then both L2CAP entities shall use the Extended Control Fields in all S/I-frames (see Section 3.3.2).

If the option is only configured in one direction then the maximum window size for the opposite direction shall be taken from the maximum window size value in the existing Retransmission and Flow Control option. In this configuration both L2CAP entities shall use the extended control fields in all S/I-frames.

6 STATE MACHINE

The state machine does not necessarily represent all possible scenarios.

6.1 General rules for the state machine

It is implementation specific, and outside the scope of the specification, how the transmissions are triggered.

“Ignore” means that the signal can be silently discarded.

The following states have been defined to clarify the protocol; the actual number of states and naming in a given implementation is outside the scope of the specification:

- CLOSED – channel not connected.
- WAIT_CONNECT – a connection request has been received, but only a connection response with indication “pending” can be sent.
- WAIT_CONNECT_RSP – a connection request has been sent, pending a positive connect response.
- CONFIG – the different options are being negotiated for both sides; this state comprises a number of substates, see Section 6.1.3.
- OPEN – user data transfer state.
- WAIT_DISCONNECT – a disconnect request has been sent, pending a disconnect response.

In the following state tables and descriptions, the L2CAP_Data message corresponds to one of the PDU formats used on connection-oriented data channels as described in Section 3, including PDUs containing B-frames, I-frames, or S-frames.

Some state transitions and actions are triggered only by internal events effecting one of the L2CAP entity implementations, not by preceding L2CAP signaling messages. It is implementation-specific and out of the scope of the specification, how these internal events are realized; just for the clarity of specifying the state machine, the following abstract internal events are used in the state event tables, as far as needed:

- *OpenChannel_Req* – a local L2CAP entity is requested to set up a new connection-oriented channel.
- *OpenChannel_Rsp* – a local L2CAP entity is requested to finally accept or refuse a pending connection request.
- *ConfigureChannel_Req* – a local L2CAP entity is requested to initiate an outgoing configuration request.

- *CloseChannel_Req* – a local L2CAP entity is requested to close a channel.
- *SendData_Req* – a local L2CAP entity is requested to transmit an SDU.
- *ReconfigureChannel_Req* – a local L2CAP entity is requested to reconfigure the parameters of a connection-oriented channel.
- *ControllerLogicalLinkInd* – a Controller indicates the acceptance or rejection of a logical link request with an Extended Flow Specification.

There is a single state machine for each L2CAP connection-oriented channel that is active. A state machine is created for each new L2CAP_CONNECTION_REQ received. The state machine always starts in the CLOSED state.

To simplify the state event tables, the RTX and ERTX timers, as well as the handling of request retransmissions are described in Section 6.2 and not included in the state tables.

L2CAP messages not bound to a specific data channel and thus not impacting a channel state (e.g. L2CAP_INFORMATION_REQ, L2CAP_ECHO_REQ) are not covered in this section.

The following states and transitions are illustrated in Figure 6.1.

6.1.1 CLOSED state

Event	Condition	Action	Next State
OpenChannel_req	-	Send L2CAP_CONNEC-TION_REQ	WAIT_-CONNECT_RSP
L2CAP_CONNEC-TION_REQ	Normal, connection is possible	Send L2CAP_CONNEC-TION_RSP (success)	CONFIG (substate WAIT_CONFIG)
L2CAP_CONNEC-TION_REQ	Need to indicate pending	L2CAP_CONNEC-TION_RSP (pending)	WAIT_CONNECT
L2CAP_CONNEC-TION_REQ	No resource, not approved, etc.	Send L2CAP_CONNEC-TION_RSP (refused)	CLOSED
L2CAP_CONNEC-TION_RSP	-	Ignore	CLOSED
L2CAP_CONFIGURA-TION_REQ	-	Send L2CAP_COM-MAND_REJECT_RSP (with reason Invalid CID)	CLOSED
L2CAP_CONFIGURA-TION_RSP	-	Ignore	CLOSED

Event	Condition	Action	Next State
L2CAP_DISCONNEC-TION_REQ	-	Send L2CAP_DISCONNEC-TION_RSP	CLOSED
L2CAP_DISCONNEC-TION_RSP	-	Ignore	CLOSED
L2CAP_Data	-	Ignore	CLOSED

Table 6.1: CLOSED state event table

Note: The L2CAP_CONNECTION_REQ message is not mentioned in any of the other states apart from the CLOSED state, as it triggers the establishment of a new channel, thus the branch into a new instance of the state machine.

6.1.2 WAIT_CONNECT_RSP state

Event	Condition	Action	Next State
L2CAP_CONNEC-TION_RSP	Success indica-ted in result	Send L2CAP_CONFIGURA-TION_REQ	CONFIG (substate WAIT_CONFIG)
L2CAP_CONNEC-TION_RSP	Result pending	-	WAIT_CONNECT_RSP
L2CAP_CONNEC-TION_RSP	Remote side refu-ses connection	-	CLOSED
L2CAP_CONFIGU-RATION_REQ	-	Send L2CAP_COMMAND_-REJECT_RSP (with reason Invalid CID)	WAIT_CONNECT_RSP
L2CAP_CONFIGU-RATION_RSP	-	Ignore	WAIT_CONNECT_RSP
L2CAP_DISCON-NECTION_RSP	-	Ignore	WAIT_CONNECT_RSP
L2CAP_Data	-	Ignore	WAIT_CONNECT_RSP

Table 6.2: WAIT_CONNECT_RSP state event table

Note: An L2CAP_DISCONNECTION_REQ message is not included here, since the Source and Destination CIDs are not available yet to relate it correctly to the state machine of a specific channel.

6.1.3 WAIT_CONNECT state

Event	Condition	Action	Next State
OpenChannel_Rsp	Pending connection request is finally acceptable	Send L2CAP_CONNECTION_RSP (success)	CONFIG (substate WAIT_CONFIG)
OpenChannel_Rsp	Pending connection request is finally refused	Send L2CAP_CONNECTION_RSP (refused)	CLOSED
L2CAP_CONNECTION_RSP	-	Ignore	WAIT_CONNECT
L2CAP_CONFIGURATION_RSP	-	Ignore	WAIT_CONNECT
L2CAP_DISCONNECTION_RSP	-	Ignore	WAIT_CONNECT
L2CAP_Data	-	Ignore	WAIT_CONNECT

Table 6.3: WAIT_CONNECT state event table

Note: An L2CAP_DISCONNECTION_REQ or L2CAP_CONFIGURATION_REQ message is not included here, since the Source and Destination CIDs are not available yet to relate it correctly to the state machine of a specific channel.

6.1.4 CONFIG state

Two configuration processes exist as described in Section 7.1. The configuration processes are the Standard process and the Lockstep process.

In the Standard and Lockstep configuration processes both L2CAP entities initiate a configuration request during the configuration process. This means that each device adopts an initiator role for the outgoing configuration request, and an acceptor role for the incoming configuration request. Configurations in both directions may occur sequentially, but can also occur in parallel.

In the Lockstep configuration process both L2CAP entities send L2CAP_CONFIGURATION_REQ packets and receive L2CAP_CONFIGURATION_RSP packets with a pending result code before submitting the flow specifications to their local Controllers. A final L2CAP_CONFIGURATION_RSP packet is sent by each L2CAP entity indicating the response from its local Controller.

The following substates are distinguished within the CONFIG state:

- WAIT_CONFIG – a device has sent or received a connection response, but has neither initiated a configuration request yet, nor received a configuration request with acceptable parameters.
- WAIT_SEND_CONFIG – for the initiator path, a configuration request has not yet been initiated, while for the response path, a request with acceptable options has been received.
- WAIT_CONFIG_REQ_RSP – for the initiator path, a request has been sent but a positive response has not yet been received, and for the acceptor path, a request with acceptable options has not yet been received.
- WAIT_CONFIG_RSP – the acceptor path is complete after having responded to acceptable options, but for the initiator path, a positive response on the recent request has not yet been received.
- WAIT_CONFIG_REQ – the initiator path is complete after having received a positive response, but for the acceptor path, a request with acceptable options has not yet been received.
- WAIT_IND_FINAL_RSP – for both the initiator and acceptor, the Extended Flow Specification has been sent to the local Controller but neither a response from Controller nor the final configuration response has yet been received.
- WAIT_FINAL_RSP – the device received an indication from the Controller accepting the Extended Flow Specification and has sent a positive response. It is waiting for the remote device to send a configuration response.
- WAIT_CONTROL_IND – the device has received a positive response and is waiting for its Controller to accept or reject the Extended Flow Specification.

According to Section 6.1.1 and Section 6.1.2, the CONFIG state is entered via WAIT_CONFIG substate from either the CLOSED state, the WAIT_CONNECT state, or the WAIT_CONNECT_RSP state. The CONFIG state is left for the OPEN state if both the initiator and acceptor paths complete successfully.

For better overview, separate tables are given: Table 6.4 shows the success transitions; therein, transitions on one of the minimum paths (no previous non-success transitions) are shaded. Table 6.5 shows the non-success transitions within the configuration process, and Table 6.6 shows further transition cause by events not belonging to the configuration process itself. The following configuration states and transitions are illustrated in Figure 6.2.

Previous state	Event	Condition	Action	Next State
WAIT_CONFIG	*ConfigureChannel_ Req*	Standard process	Send L2CAP_CONFIGURATION_REQ	WAIT_CONFIG_REQ_RSP
WAIT_CONFIG	*ConfigureChannel_ Req*	Lockstep process	Send L2CAP_CONFIGURATION_REQ (Ext Flow Spec plus other options)	WAIT_CONFIG_REQ_RSP
WAIT_CONFIG	L2CAP_CONFIGURATION_REQ	Options acceptable Standard process	Send L2CAP_CONFIGURATION_RSP (success)	WAIT_SEND_CONFIG
WAIT_CONFIG	L2CAP_CONFIGURATION_REQ	Options acceptable Lockstep process	Send L2CAP_CONFIGURATION_RSP (pending)	WAIT_SEND_CONFIG
WAIT_CONFIG_REQ_RSP	L2CAP_CONFIGURATION_REQ	Options acceptable	Send L2CAP_CONFIGURATION_RSP (success)	WAIT_CONFIG_RSP
WAIT_CONFIG_REQ_RSP	L2CAP_CONFIGURATION_RSP	Remote side accepts options	(continue waiting for configuration request)	WAIT_CONFIG_REQ
WAIT_CONFIG_REQ	L2CAP_CONFIGURATION_REQ	Options acceptable Standard process	Send L2CAP_CONFIGURATION_RSP (success)	OPEN
WAIT_CONFIG_REQ	L2CAP_CONFIGURATION_REQ	Options acceptable Lockstep process	Send L2CAP_CONFIGURATION_RSP (pending)	WAIT_IND_FINAL_RSP
WAIT_SEND_CONFIG	*ConfigureChannel_ Req*	*none*	Send L2CAP_CONFIGURATION_REQ	WAIT_CONFIG_RSP
WAIT_CONFIG_RSP	L2CAP_CONFIGURATION_RSP	Remote side accepts options Standard process	*none*	OPEN

Previous state	Event	Condition	Action	Next State
WAIT_CONFIG_RSP	L2CAP_CONFIG-URATION_RSP	Remote side accepts op-tion Lockstep proc	*none*	WAIT_IND_-FINAL_RSP
WAIT_IND_FINAL_-RSP	ControllerLogical LinkInd	Reject	Send L2CAP_CONFIG-URATION_RSP (fail)	WAIT_CONFIG
WAIT_IND_FINAL_-RSP	ControllerLogical LinkInd	Accept	Send L2CAP_CONFIG-URATION_RSP (success)	WAIT_FINAL_-RSP
WAIT_IND_FINAL_-RSP	L2CAP_CONFIG-URATION_RSP	Remote side fail	*none*	WAIT_CONFIG
WAIT_IND_FINAL_-RSP	L2CAP_CONFIG-URATION_RSP	Remote side success	*none*	WAIT_-CONTROL_IND
WAIT_FINAL_RSP	L2CAP_CONFIG-URATION_RSP	Remote side fail	*none*	WAIT_CONFIG
WAIT_FINAL_RSP	L2CAP_CONFIG-URATION_RSP	Remote side success	*none*	OPEN
WAIT_CONTROL_IND	ControllerLogical LinkInd	Reject	Send L2CAP_CONFIG-URATION_RSP (fail)	WAIT_CONFIG
WAIT_CONTROL_IND	ControllerLogical LinkInd	Accept	Send L2CAP_CONFIG-URATION_RSP (success)	OPEN

Table 6.4: CONFIG state event table

Previous state	Event	Condition	Action	Next State
WAIT_CONFIG	L2CAP_CONFIG-URATION_REQ	Options not acceptable	Send L2CAP_CONFIG-URATION_RSP (fail)	WAIT_CONFIG
WAIT_CONFIG	L2CAP_CONFIG-URATION_RSP	*none*	Ignore	WAIT_CONFIG
WAIT_SEND_CONFIG	L2CAP_CONFIG-URATION_RSP	*none*	Ignore	WAIT_SEND_-CONFIG

Previous state	Event	Condition	Action	Next State
WAIT_CONFIG_-REQ_RSP	L2CAP_CONFIG-URATION_REQ	Options not acceptable	Send L2CAP_CONFIG-URATION_RSP (fail)	WAIT_CONFIG_-REQ_RSP
WAIT_CONFIG_-REQ_RSP	L2CAP_CONFIG-URATION_RSP	Remote side rejects op-tions	Send L2CAP_CONFIG-URATION_REQ (new options)	WAIT_CONFIG_-REQ_RSP
WAIT_CONFIG_REQ	L2CAP_CONFIG-URATION_REQ	Options not acceptable	Send L2CAP_CONFIG-URATION_RSP (fail)	WAIT_CONFIG_-REQ
WAIT_CONFIG_REQ	L2CAP_CONFIG-URATION_RSP	*none*	Ignore	WAIT_CONFIG_-REQ
WAIT_CONFIG_RSP	L2CAP_CONFIG-URATION_RSP	Remote side rejects op-tions	Send L2CAP_CONFIG-URATION_REQ (new options)	WAIT_CONFIG_-RSP

Table 6.5: CONFIG state/substates event table: non-success transitions within configuration process

Previous state	Event	Condition	Action	Next State
CONFIG (any sub-state)	*CloseChan-nel_Req*	Any internal rea-son to stop	Send L2CAP_DISCON-NECTION_REQ	WAIT_-DISCONNECT
CONFIG (any sub-state)	L2CAP_DIS CONNECTI ON_REQ	*none*	Send L2CAP_DISCON-NECTION_RSP	CLOSED
CONFIG (any sub-state)	L2CAP_DIS CONNECTI ON_RSP	*none*	Ignore	CONFIG (remain in substate)
CONFIG (any sub-state)	L2CAP_Da-ta	*none*	Process the PDU	CONFIG (remain in substate)

Table 6.6: CONFIG state/substates event table: events not related to configuration process

Notes:

- Receiving data PDUs (L2CAP_Data) in CONFIG state should be relevant only in case of a transition to a reconfiguration procedure (from OPEN state). Discarding the received data is allowed only in Retransmission mode and Enhanced Retransmission mode. Discarding an S-frame is allowed but not recommended. If a S-frame is discarded, the monitor timer will cause a new S-frame to be sent after a time out.
- Indicating a failure in a configuration response does not necessarily imply a failure of the overall configuration procedure; instead, based on the information received in the negative response, a modified configuration request may be triggered.

6.1.5 OPEN state

Event	Condition	Action	Next State
SendData_req	*none*	Send L2CAP_Data packet according to configured mode	OPEN
ReconfigureChannel_Req	*none*	Complete outgoing SDU Send L2CAP_CONFIGURATION_REQ	CONFIG (substate WAIT_CONFIG_REQ_RSP)
CloseChannel_Req	*none*	Send L2CAP_DISCONNECTION_REQ	WAIT_-DISCONNECT
L2CAP_CONNECTION_RSP	*none*	Ignore	OPEN
L2CAP_CONFIGURATION_-REQ	Incoming config options acceptable	Complete outgoing SDU Send L2CAP_CONFIGURATION_RSP (ok)	CONFIG (substate WAIT_SEND_-CONFIG)
L2CAP_CONFIGURATION_-REQ	Incoming config options not acceptable	Complete outgoing SDU Send L2CAP_CONFIGURATION_RSP (fail)	OPEN
L2CAP_DISCONNECTION_-REQ	*none*	Send L2CAP_DISCONNECTION_RSP	CLOSED
L2CAP_DISCONNECTION_-RSP	*none*	Ignore	OPEN
L2CAP_Data	*none*	Process the PDU	OPEN

Table 6.7: OPEN state event table

The outgoing SDU shall be completed from the view of the remote entity. Therefore all PDUs forming the SDU shall have been reliably transmitted by the local entity and acknowledged by the remote entity, before entering the configuration state.

6.1.6 WAIT_DISCONNECT state

Event	Condition	Action	Next State
L2CAP_CONNECTION_RSP	*none*	Ignore	WAIT_DIS-CONNECT
L2CAP_CONFIGURATION_-REQ	*none*	Send L2CAP_COMMAND_-REJECT_RSP with reason Invalid CID	WAIT_DIS-CONNECT
L2CAP_CONFIGURATION_-RSP	*none*	Ignore	WAIT_DIS-CONNECT
L2CAP_DISCONNECTION_-REQ	*none*	Send L2CAP_DISCONNECTION_-RSP	CLOSED
L2CAP_DISCONNECTION_-RSP	*none*	*none*	CLOSED
L2CAP_Data	*none*	Ignore	WAIT_DIS-CONNECT

Table 6.8: WAIT_DISCONNECT state event table

6.2 Timers events

6.2.1 RTX

The Response Timeout eXpired (RTX) timer is used to terminate the channel when the remote endpoint is unresponsive to signaling requests. This timer is started when a signaling request (see Section 7) is sent to the remote device. This timer is disabled when the response is received. If the initial timer expires, a duplicate Request message may be sent or the channel identified in the request may be disconnected. If a duplicate Request message is sent, the RTX timeout value shall be reset to a new value at least double the previous value. When retransmitting the Request message, the context of the same state shall be assumed as with the original transmission. If a Request message is received that is identified as a duplicate (retransmission), it shall be processed in the context of the same state which applied when the original Request message was received.

Implementations have the responsibility to decide on the maximum number of Request retransmissions performed at the L2CAP level before terminating the channel identified by the Requests. The exception is fixed channel CIDs since they can never be terminated. On the LE transport, the Peripheral's Host may disconnect the link on the expiry of the RTX timer. The decision should be based on the flush timeout of the signaling link. The longer the flush timeout, the more retransmissions may be performed at the physical layer and the reliability of the channel improves, requiring fewer retransmissions at the L2CAP level.

For example, if the flush timeout is infinite, no retransmissions should be performed at the L2CAP level. When terminating the channel, it is not necessary to send an L2CAP_DISCONNECTION_REQ and enter WAIT_DISCONNECT state. Channels can be transitioned directly to the CLOSED state.

The value of this timer is implementation-dependent but the minimum initial value is 1 second and the maximum initial value is 60 seconds. One RTX timer shall exist for each outstanding signaling request, including each L2CAP_ECHO_REQ. The timer disappears on the final expiration, when the response is received, or the physical link is lost. The maximum elapsed time between the initial start of this timer and the initiation of channel termination (if no response is received) is 60 seconds.

6.2.2 ERTX

The Extended Response Timeout eXpired (ERTX) timer is used in place of the RTX timer when it is suspected the remote endpoint is performing additional processing of a request signal. This timer is started when the remote endpoint responds that a request is pending, e.g., when an L2CAP_CONNECTION_RSP event with a “connect pending” result (0x0001) is received. This timer is disabled when the formal response is received or the physical link is lost. If the initial timer expires, a duplicate Request may be sent or the channel may be disconnected.

If a duplicate Request is sent, the particular ERTX timer disappears, replaced by a new RTX timer and the whole timing procedure restarts as described previously for the RTX timer.

The value of this timer is implementation-dependent but the minimum initial value is 60 seconds and the maximum initial value is 300 seconds. Similar to RTX, there shall be at least one ERTX timer for each outstanding request that received a Pending response. There should be at most one (RTX or ERTX) associated with each outstanding request. The maximum elapsed time between the initial start of this timer and the initiation of channel termination (if no response is received) is 300 seconds. When terminating the channel, it is not necessary to send an L2CAP_DISCONNECTION_REQ and enter WAIT_DISCONNECT state. Channels should be transitioned directly to the CLOSED state.

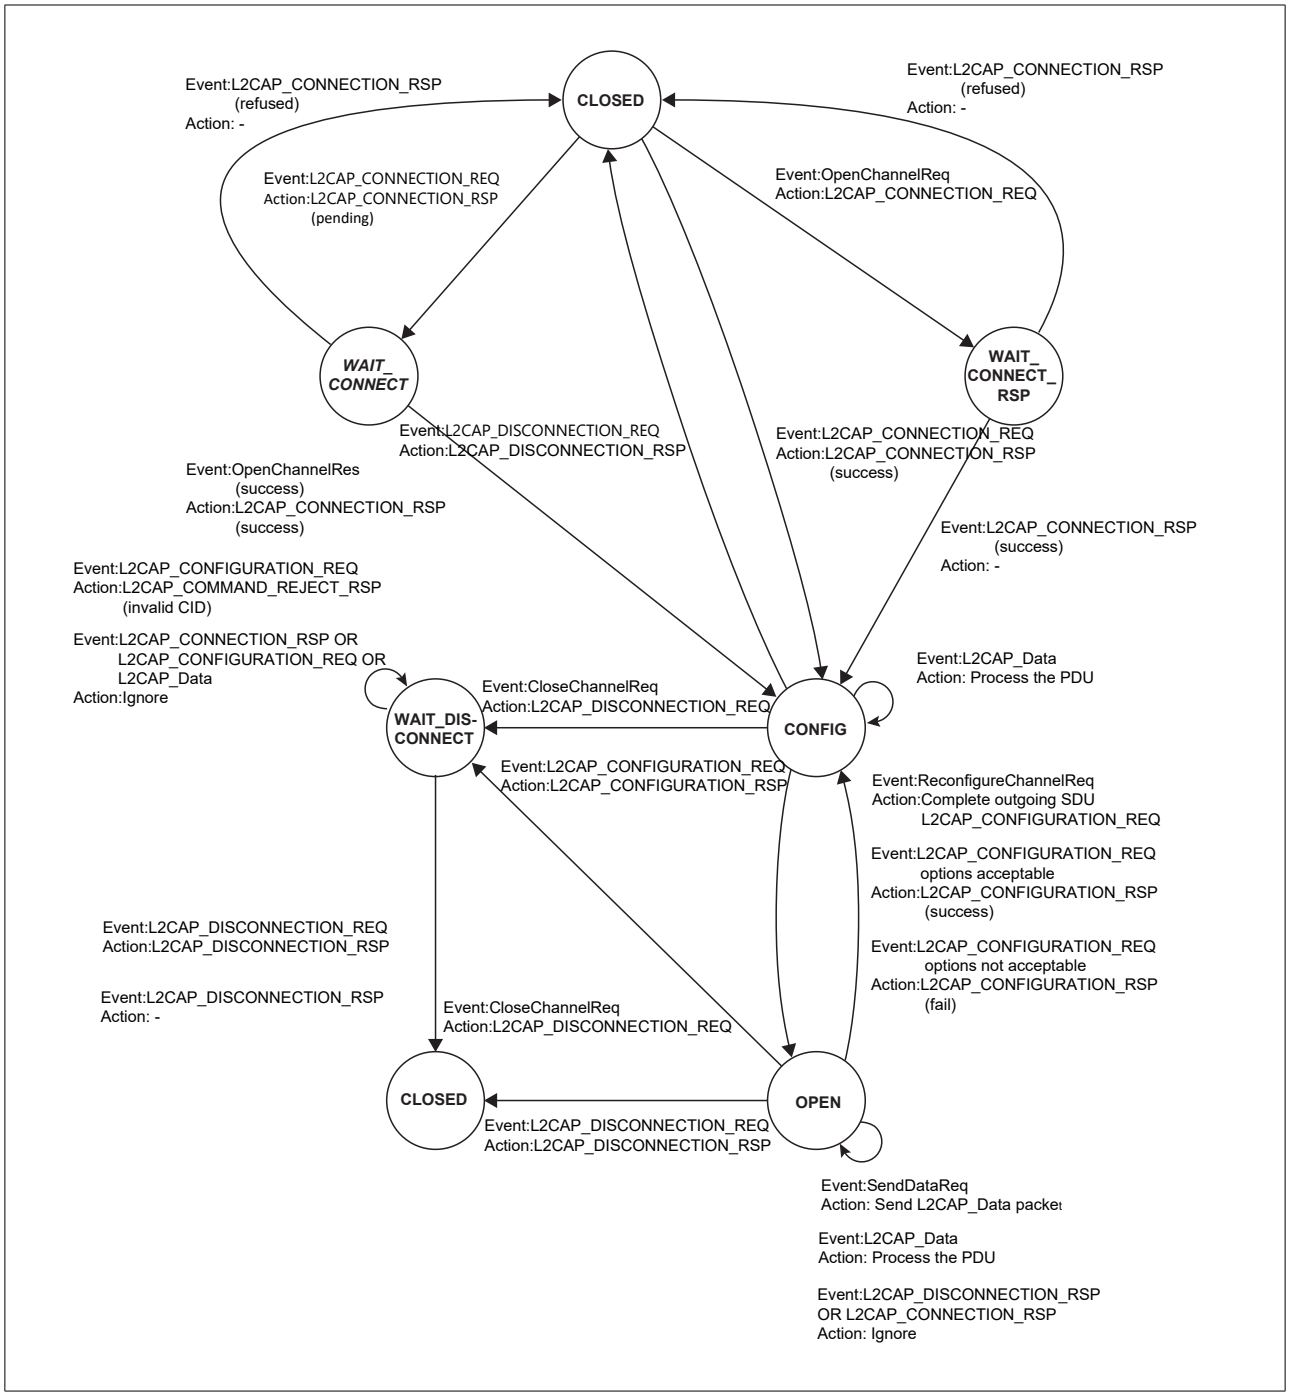

Figure 6.1: States and transitions

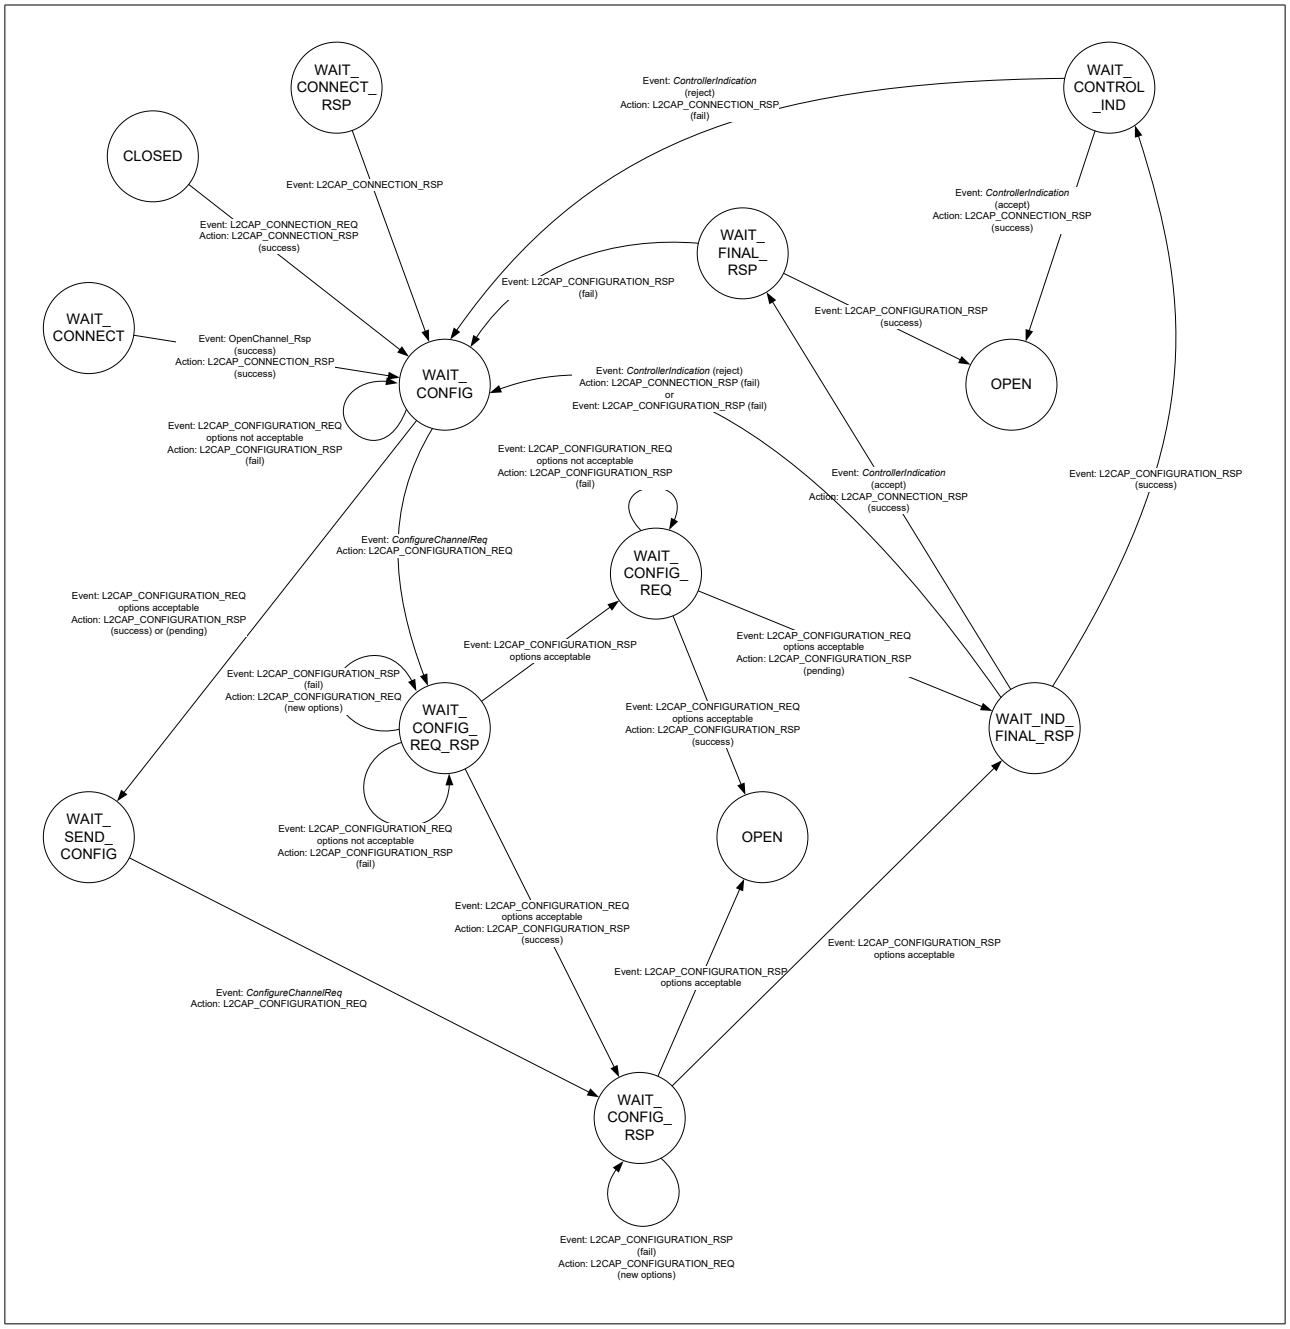

Figure 6.2: Configuration states and transitions

7 GENERAL PROCEDURES

This section describes the general operation of L2CAP, including the configuration process, the handling and the processing of user data for transportation over the air interface. This section also describes the operation of L2CAP features including the delivery of erroneous packets, the flushing of expired data and operation in connectionless mode, operation collision resolution, aggregation of best effort flow specifications, and prioritizing data over HCI.

Procedures for the flow control and retransmission modes are described in Section 8.

7.1 Configuration process

Configuration consists of two processes, the Standard process and the Lockstep process. The Lockstep process shall be used if both L2CAP entities support the Extended Flow Specification option otherwise the Standard process shall be used.

For both processes, configuring the channel parameters shall be done independently for both directions. Both configurations may be done in parallel.

Each configuration parameter is one-directional. The configuration parameters describe the non default parameters the device sending an L2CAP_CONFIGURATION_REQ packet will accept. The configuration request cannot request a change in the parameters the device receiving the request will accept.

If a device needs to establish the value of a configuration parameter the remote device will accept, then it must wait for an L2CAP_CONFIGURATION_REQ packet containing that configuration parameter to be sent from the remote device.

The Lockstep process is used when the channel parameters include an Extended Flow Specification option. The Lockstep process can be divided into two phases. In the first phase, each L2CAP entity shall receive an Extended Flow Specification option along with all non-default parameters from its peer L2CAP entity and then present the pair of Extended Flow specifications (local and remote) to its local Controller. In the second phase, each L2CAP entity shall report the result from its local Controller to the peer L2CAP entity. The Lockstep process is described in Section 7.1.3. The Standard process is described in Section 7.1.4.

Both the Lockstep and Standard processes can be abstracted into the initial Request configuration path and a Response configuration path, followed by the reverse direction phase. Reconfiguration follows a similar two-phase process by requiring configuration in both directions.

During a reconfiguration session, all data traffic on the channel should be suspended pending the outcome of the configuration. If an L2CAP entity receives an L2CAP_CONFIGURATION_REQ packet while it is waiting for a response it shall not block sending the L2CAP_CONFIGURATION_RSP packet, otherwise the configuration process may deadlock.

7.1.1 Request Path

The Request Path can configure the following:

- requester's incoming MTU
- requester's outgoing flush timeout
- requester's outgoing QoS
- requester's incoming and outgoing flow and error control information
- requester's incoming and outgoing Frame Check Sequence option
- requester's outgoing QoS using Extended Flow Specification option
- requester's incoming Extended Window size option plus incoming and outgoing frame format.

Table 7.1 defines the configuration options that may be placed in an L2CAP_CONFIGURATION_REQ packet.

Parameter	Description
MTU	Incoming MTU information
FlushTO	Outgoing flush timeout[1]
QoS	Outgoing QoS information[1]
RFCMode	Incoming and outgoing Retransmission and Flow Control mode
FCS	Incoming and outgoing Frame Check Sequence
ExtFlowSpec	Outgoing QoS information[1]
ExtWindow	Incoming Extended Window size plus incoming and outgoing frame format

Table 7.1: Parameters allowed in request

[1]FlushTO, QoS and ExtFlowSpec are considered QoS information. ExtFlowSpec is used instead of FlushTO and QoS when both devices support ExtFlowSpec.

The state machine for the configuration process is described in Section 6.

7.1.2 Response Path

The Response Path can configure the following:

- responder's outgoing MTU, that is the remote side's incoming MTU
- remote side's flush timeout
- responder's incoming QoS Flow Specification (remote side's outgoing QoS Flow Specification)
- responder's incoming and outgoing Flow and Error Control information
- responder's incoming QoS Extended Flow Specification (remote side's outgoing QoS Flow Specification)
- responder's outgoing Extended Window size.

For the Standard process, if a request-oriented parameter is not present in the Request message (reverts to last agreed value), the remote side may negotiate for a non-default value by including the proposed value in a negative Response message. Table 7.2 defines the configuration options that may be placed in an L2CAP_CONFIGURATION_RSP packet.

Parameter	Description
MTU	Outgoing MTU information
FlushTO	Incoming flush timeout[1]
QoS	Incoming QoS information[1]
RFCMode	Incoming and outgoing Retransmission and Flow Control mode
ExtFlowSpec	Incoming QoS information[1]
ExtWindow	Outgoing Extended Window size

Table 7.2: Parameters allowed in response

[1]FlushTO, QoS and ExtFlowSpec are considered QoS information. ExtFlowSpec is used instead of FlushTO and QoS when both devices support ExtFLowSpec

7.1.3 Lockstep Configuration process

L2CAP_CONFIGURATION_REQ packets are sent to establish or change the channel parameters including the QoS contract between two L2CAP entities. An Extended Flow Specification option along with any non-default parameters shall be sent in an L2CAP_CONFIGURATION_REQ packet following the sending or receipt of a Connect Response which accepts an L2CAP Connect Request for the channel being configured. Unlike the Standard process, negotiation involving the sending of multiple L2CAP_CONFIGURATION_REQ packets shall not be performed. In other words, only one L2CAP_CONFIGURATION_REQ packet shall be sent by each L2CAP entity during

the Lockstep configuration process. The Lockstep process shall only be used during channel reconfiguration when an Extended Flow Specification option is present in the L2CAP_CONFIGURATION_REQ packet used for reconfiguration.

The Extended Flow Specification shall only be sent for channels created on the ACL-U logical link if both the local and remote L2CAP entities have indicated support for the Extended Flow Specification for BR/EDR in their Extended Features masks. The Extended Features mask shall be obtained via the L2CAP_INFORMATION_REQ/L2CAP_INFORMATION_RSP signaling mechanism (InfoType = 0x0002) prior to the issuance of the L2CAP_CONFIGURATION_REQ packet. If an L2CAP_CONFIGURATION_REQ packet is sent containing the Extended Flow Specification option then the Quality of Service option and Flush Timeout option shall not be included.

L2CAP_CONFIGURATION_RSP packets shall be sent in reply to L2CAP_CONFIGURATION_REQ packets except when the error condition is covered by an L2CAP_COMMAND_REJECT_RSP response. Although the L2CAP Configuration signaling mechanism allows for the use of wildcards, wildcard values are not supported in the Extended Flow Specification since each parameter represents a property of the traffic in one direction only, and no negotiation is intended to be performed at the L2CAP Configuration level.

The recipient of an L2CAP_CONFIGURATION_REQ packet shall perform all necessary checks with the Controller to validate that the requested QoS can be granted. In the case of a BR/EDR or BR/EDR/LE Controller the L2CAP layer performs the Controller checks. If HCI is used then the L2CAP entity should check that the requested QoS can be achieved over the HCI transport. In order to perform these checks, the recipient needs to have the QoS parameters for both directions. In order for each side to determine when to perform relevant Controller checks, each side will reply with a result “Pending” (0x0004). If no parameters are sent in the L2CAP_CONFIGURATION_RSP packet with result “Pending” then the parameters sent in the L2CAP_CONFIGURATION_REQ packet have been accepted without change. This Lockstep procedure results in both L2CAP entities performing the following:

- Receiving an L2CAP_CONFIGURATION_REQ packet containing the Extended Flow Specification option along with all non-default parameters
- Sending an L2CAP_CONFIGURATION_RSP packet with any modifications to the Extended Flow Specification option and allowed modifications to non-default parameters (result “Pending”)
- Sending an L2CAP_CONFIGURATION_REQ packet containing the Extended Flow Specification option along with all non-default parameters

- Receiving an L2CAP_CONFIGURATION_RSP packet containing any modifications to the Extended Flow Specification option and allowed modifications to non-default parameters (result “Pending”).

The ERTX timer is used when an L2CAP_CONFIGURATION_RSP packet is received with result “Pending” (see Section 6.2.2).

If an L2CAP_CONFIGURATION_RSP packet with result “success” is received before an L2CAP_CONFIGURATION_RSP packet with result “pending” is received the recipient shall disconnect the channel. This is a violation of the Lockstep configuration process.

If a device sends an Extended Flow Specification option in an L2CAP_CONFIGURATION_REQ packet with service type “Best Effort” and receives an L2CAP_CONFIGURATION_REQ packet with service type “Guaranteed,” the channel shall be disconnected. If a device sends an Extended Flow Specification in an L2CAP_CONFIGURATION_REQ packet with type “Guaranteed” and receives an L2CAP_CONFIGURATION_REQ packet with service type “Best Effort,” the channel shall be disconnected.

If the service type is “Best Effort” then values for certain parameters may be sent in an L2CAP_CONFIGURATION_RSP packet with result “Pending” to indicate the maximum bandwidth the sender of the L2CAP_CONFIGURATION_RSP packet is capable to receive. The values sent in an L2CAP_CONFIGURATION_RSP packet with result “Pending” and service type Best Effort shall be in accordance with Table 7.3.

Parameter	Changes permitted by responder
Maximum SDU Size	May decrease only
SDU Inter-arrival Time	May increase only
Access Latency	None
Flush Timeout	None

Table 7.3: Permitted parameter in L2CAP_CONFIGURATION_RSP packets for service type “Best Effort”

After the L2CAP_CONFIGURATION_RSP packet is received with result “Pending,” L2CAP may issue the necessary checks with the Controller.

If the Controller cannot support the Extended Flow Specifications with service type “Guaranteed,” then the recipient of the L2CAP_CONFIGURATION_REQ packet shall send an L2CAP_CONFIGURATION_RSP packet indicating a result code of “Failure - flow spec rejected” (0x0005). If the Controller indicates that it can support the Extended Flow Specifications, then the recipient of the L2CAP_CONFIGURATION_REQ packet shall send an L2CAP_CONFIGURATION_RSP packet with result code of “Success” (0x0000) with no parameters.

If the Result of the L2CAP_CONFIGURATION_RSP packet is Failure (0x0005) for service type “Guaranteed” then an Extended Flow Specification option may be sent in the L2CAP_CONFIGURATION_RSP packet. The Extended Flow Specification parameters sent in the L2CAP_CONFIGURATION_RSP packet may be changed to reflect a QoS level that would be acceptable, but shall only be changed in accordance with Table 7.4.

Parameter	Changes permitted by responder
Maximum SDU Size	None
SDU Inter-arrival Time	None
Access Latency	May decrease only
Flush Timeout	May decrease only (unless set to 0xFFFFFFFF, in which case no change is permitted)

Table 7.4: Permitted parameter changes in L2CAP_CONFIGURATION_RSP packets for service type “Guaranteed”

If an L2CAP_CONFIGURATION_RSP packet is received containing the Extended Flow Specification option with the same values sent earlier, the upper layer shall be notified of the error.

7.1.4 Standard Configuration process

For the Standard process the following general procedure shall be used for each direction:

1. Local device informs the remote device of the parameters that the local device will accept using an L2CAP_CONFIGURATION_REQ packet.
2. Remote device responds, agreeing or disagreeing with these values, including the default ones, using an L2CAP_CONFIGURATION_RSP packet.
3. The local and remote devices repeat steps (1) and (2) until agreement on all parameters is reached.

The decision on the amount of time (or messages) spent configuring the channel parameters before terminating the configuration is left to the implementation, but it shall not last more than 120 seconds.

There are two types of configuration parameters: negotiable and non-negotiable.

Negotiable parameters are those that a remote side receiving an L2CAP_CONFIGURATION_REQ packet can disagree with by sending an L2CAP_CONFIGURATION_RSP packet with the *Unacceptable Parameters* (0x0001) result code, proposing new values that can be accepted. Non-negotiable parameters

are only informational and the recipient of an L2CAP_CONFIGURATION_REQ packet cannot disagree with them but can provide adjustments to the values in a positive L2CAP_CONFIGURATION_RSP packet. Section 5 identifies each parameter as negotiable or non-negotiable.

Note: MTU is non-negotiable but can be rejected if a value lower than the mandated minimum is proposed (See Section 5.1).

The following rules shall be used for parameter negotiation in the Request Path:

1. An L2CAP entity shall send at least one L2CAP_CONFIGURATION_REQ packet as part of initial configuration or reconfiguration. If all default or previously agreed values are acceptable, an L2CAP_CONFIGURATION_REQ packet with no options shall be sent.
2. When an L2CAP entity receives a positive L2CAP_CONFIGURATION_RSP packet from the remote device it shall consider all configuration parameters explicitly contained in the L2CAP_CONFIGURATION_REQ packet along with the default and previously agreed values not explicitly contained in the L2CAP_CONFIGURATION_REQ packet as accepted by the remote device.
3. When an L2CAP entity receives a negative L2CAP_CONFIGURATION_RSP packet and sends a new L2CAP_CONFIGURATION_REQ packet it shall include all the options it sent in the previous L2CAP_CONFIGURATION_REQ packet with the same values except the negotiable options that were explicitly rejected in the negative L2CAP_CONFIGURATION_RSP packet which will have new values.

   Note: The resending of all the options provides backwards compatibility with remote implementations that don’t assume rule 4 when responding.
4. Negotiable options not included in a negative L2CAP_CONFIGURATION_RSP packet are considered accepted by the remote device.

   Note: For backwards compatibility if non-negotiable options are included in a negative L2CAP_CONFIGURATION_RSP packet, they should be processed as if the response was positive.

The following rules shall be used for parameter negotiation in the Response Path:

1. A positive L2CAP_CONFIGURATION_RSP packet accepts the values of all configuration parameters explicitly contained in the received L2CAP_CONFIGURATION_REQ packet and the default and previously agreed values not explicitly provided.
2. An L2CAP Entity shall send a negative L2CAP_CONFIGURATION_RSP packet to reject negotiable parameter values that are unacceptable, be it values explicitly provided in the received L2CAP_CONFIGURATION_REQ packet or

previously agreed or default values. The rejected parameters sent in a negative L2CAP_CONFIGURATION_RSP packet shall have values that are acceptable to the L2CAP entity sending the negative L2CAP_CONFIGURATION_RSP packet.

3. All negotiable options being rejected shall be rejected in the same negative L2CAP_CONFIGURATION_RSP packet.
4. The only options allowed in a negative L2CAP_CONFIGURATION_RSP packet are the negotiable options being rejected. No wildcards or adjustments to non-negotiable options shall be in a negative L2CAP_CONFIGURATION_RSP packet.
5. Negotiable options not included in the negative L2CAP_CONFIGURATION_RSP packet are considered accepted.

7.2 Fragmentation and recombination

Fragmentation is the breaking down of PDUs into smaller pieces for delivery from L2CAP to the lower layer. Recombination is the process of reassembling a PDU from fragments delivered up from the lower layer. Fragmentation and Recombination may be applied to any L2CAP PDUs.

7.2.1 Fragmentation of L2CAP PDUs

An L2CAP implementation may fragment any L2CAP PDU for delivery to the lower layers, whether directly to the Controller or over HCI. All fragments associated with a specific L2CAP PDU shall be sent to the Controller, in the same order as their contents occur in the PDU, before any other fragment associated with the same logical link. Fragments associated with different logical links may be interleaved. (See [Vol 2] Part B, Section 5.3 and [Vol 6] Part B, Section 4.5.17 for related requirements on the Controller.)

For example, in the BR/EDR Controller the two LLID bits defined in the first octet of Baseband payload (also called the frame header) are used to signal the start and continuation of L2CAP PDUs. LLID shall be 0b10 for the first segment in an L2CAP PDU and 0b01 for a continuation segment. An illustration of fragmentation for a BR/EDR Controller is shown in Figure 7.1. An example of how fragmentation might be used in a device with HCI is shown in Figure 7.2.

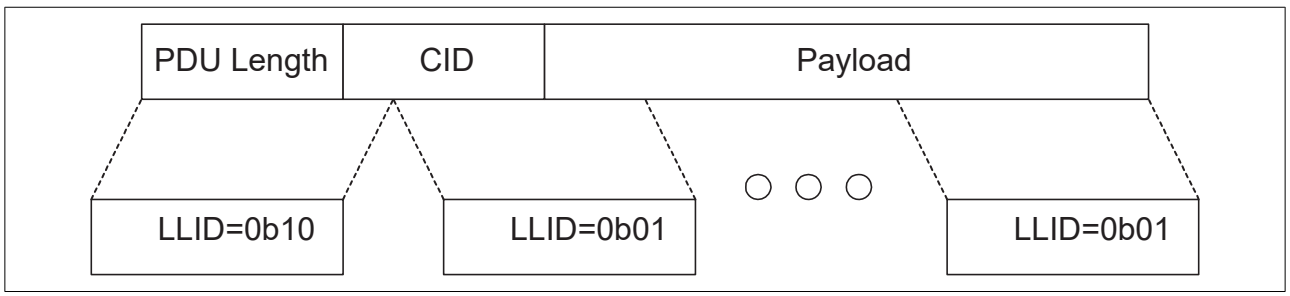

Figure 7.1: L2CAP fragmentation in a BR/EDR Controller

Note: The BR/EDR Link Controller is able to impose a different fragmentation on the PDU by using “start” and “continuation” indications as fragments are translated into Baseband packets. Thus, both L2CAP and the BR/EDR Link Controller use the same mechanism to control the size of fragments.

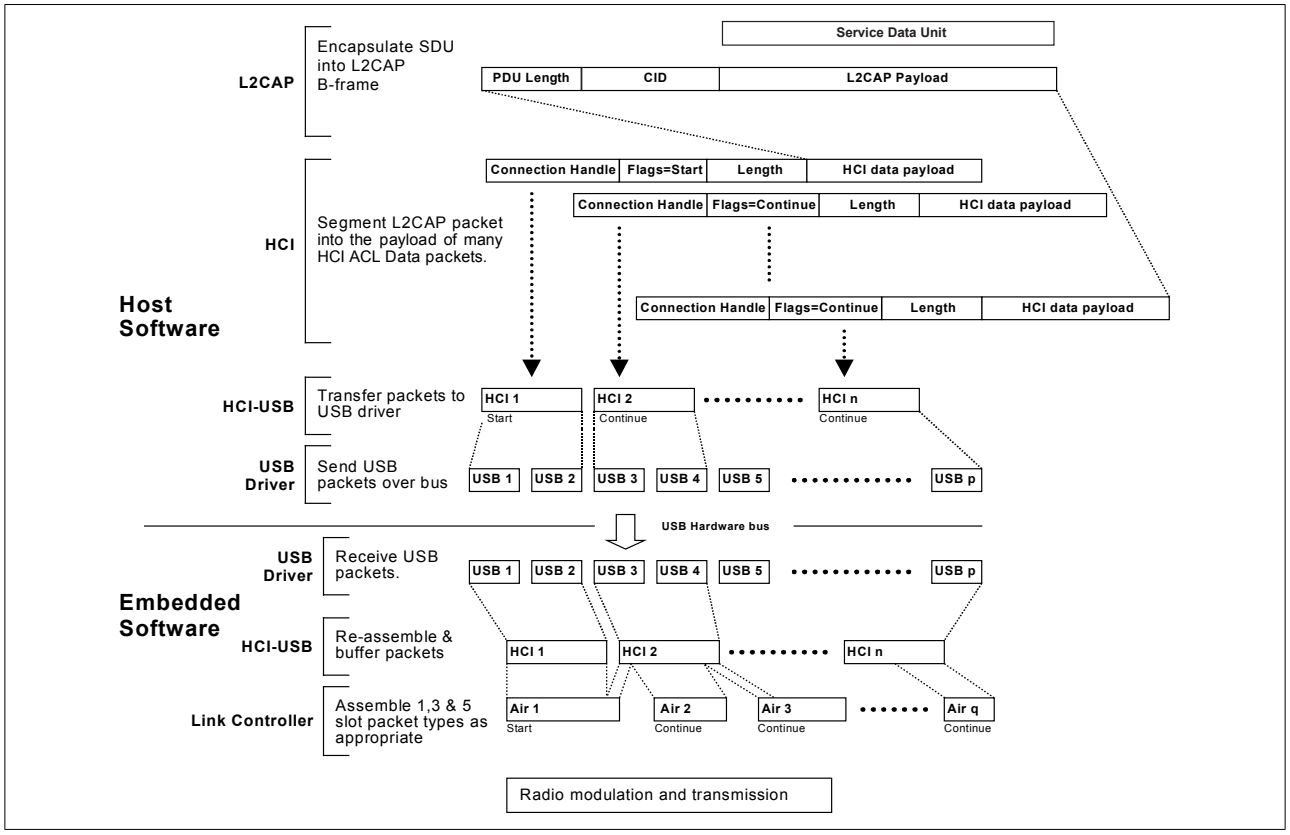

Figure 7.2: Example of fragmentation processes in a device with a BR/EDR Controller and USB HCI transport

7.2.2 Recombination of L2CAP PDUs

The Controller will provide fragments of L2CAP PDUs to the L2CAP implementation. It is the responsibility of L2CAP to reassemble PDUs and SDUs and to check the length field of the SDUs. The L2CAP layer shall reassemble the fragments it receives from the Controller into complete PDUs, which may then further be combined into SDUs. (See [Vol 2] Part B, Section 5.3 and [Vol 6] Part B, Section 4.5.17 for related requirements on the Controller.)

An L2CAP implementation shall use the PDU Length field in the header of L2CAP PDUs, see Section 3, as a consistency check and shall discard any L2CAP PDUs that fail to match the PDU Length field. If channel reliability is not needed, packets with invalid lengths may be silently discarded. For reliable channels using Basic mode, an L2CAP implementation shall indicate to the upper layer that the channel has become unreliable. Reliable channels are defined by having an infinite flush timeout value as

specified in Section 5.2. For higher data integrity L2CAP should be operated in the Enhanced Retransmission mode.

7.3 Encapsulation of SDUs

All SDUs are encapsulated into one or more L2CAP PDUs.

In Basic L2CAP mode, an SDU shall be encapsulated with a minimum of L2CAP protocol elements, resulting in a type of L2CAP PDU called a Basic Information Frame (B-frame).

Segmentation and Reassembly operations are only used in Enhanced Retransmission mode, Streaming mode, Retransmission mode, Flow Control mode, LE Credit Based Flow Control mode, and Enhanced Credit Based Flow Control mode. SDUs may be segmented into a number of smaller packets called SDU segments. Each segment shall be encapsulated with L2CAP protocol elements resulting in an L2CAP PDU called an Information Frame (I-frame) or a Credit-based Frame (K-frame).

The maximum size of an SDU segment shall be given by the Maximum PDU Payload Size (MPS). The MPS parameter may be exported using an implementation specific interface to the upper layer.

The specification does not describe a service interface with the upper layer, nor does it assume any specific buffer management scheme of a Host implementation. Consequently, a reassembly buffer may be part of the upper layer entity. It is assumed that SDU boundaries are preserved between peer upper layer entities.

7.3.1 Segmentation of L2CAP SDUs

In Flow Control, Streaming, or Retransmission modes, incoming SDUs may be broken down into segments, which shall then be individually encapsulated with L2CAP protocol elements (header and checksum fields) to form I-frames. I-frames are subject to flow control and may be subject to retransmission procedures. The header carries a 2 bit SAR field that is used to identify whether the I-frame is a 'start', 'end' or 'continuation' packet or whether it carries a complete, unsegmented SDU.

In LE Credit Based Flow Control or Enhanced Credit Based Control modes, incoming SDUs may be broken down into segments, which shall then be individually encapsulated with L2CAP protocol elements (header fields) to form K-frames. The header of the first segment contains the length of the entire SDU.

Figure 7.3 illustrates segmentation and fragmentation.

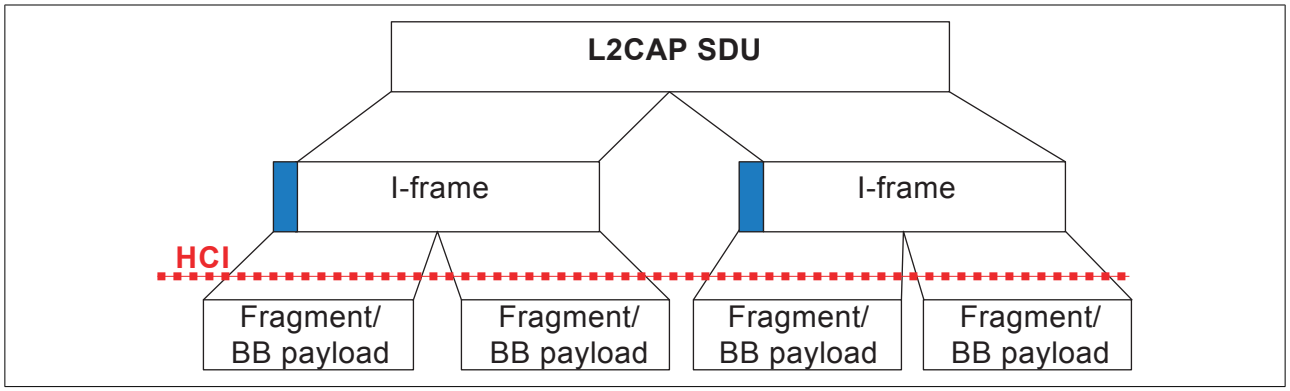

Figure 7.3: Segmentation and fragmentation of an SDU in a BR/EDR Controller

7.3.2 Reassembly of L2CAP SDUs

The receiving side uses the SAR field of incoming 'I-frames' for the reassembly process. The L2CAP SDU Length field, present in the “start of SDU” I-frame, is an extra integrity check, and together with the sequence numbers may be used to indicate lost L2CAP SDUs to the application.

The receiving side uses the SDU length of the first K-frame and the PDU length of each K-frame for the reassembly process.

Figure 7.3 illustrates segmentation and fragmentation.

7.3.3 Segmentation and fragmentation

Figure 7.4 illustrates the use of segmentation and fragmentation operations to transmit a single SDU. While SDUs and L2CAP PDUs are transported in peer-to-peer fashion, the fragment size used by the Fragmentation and Recombination routines are implementation specific and may be different in the sender and the receiver. The over-the-air sequence of packet fragments as created by the sender is common to both devices.

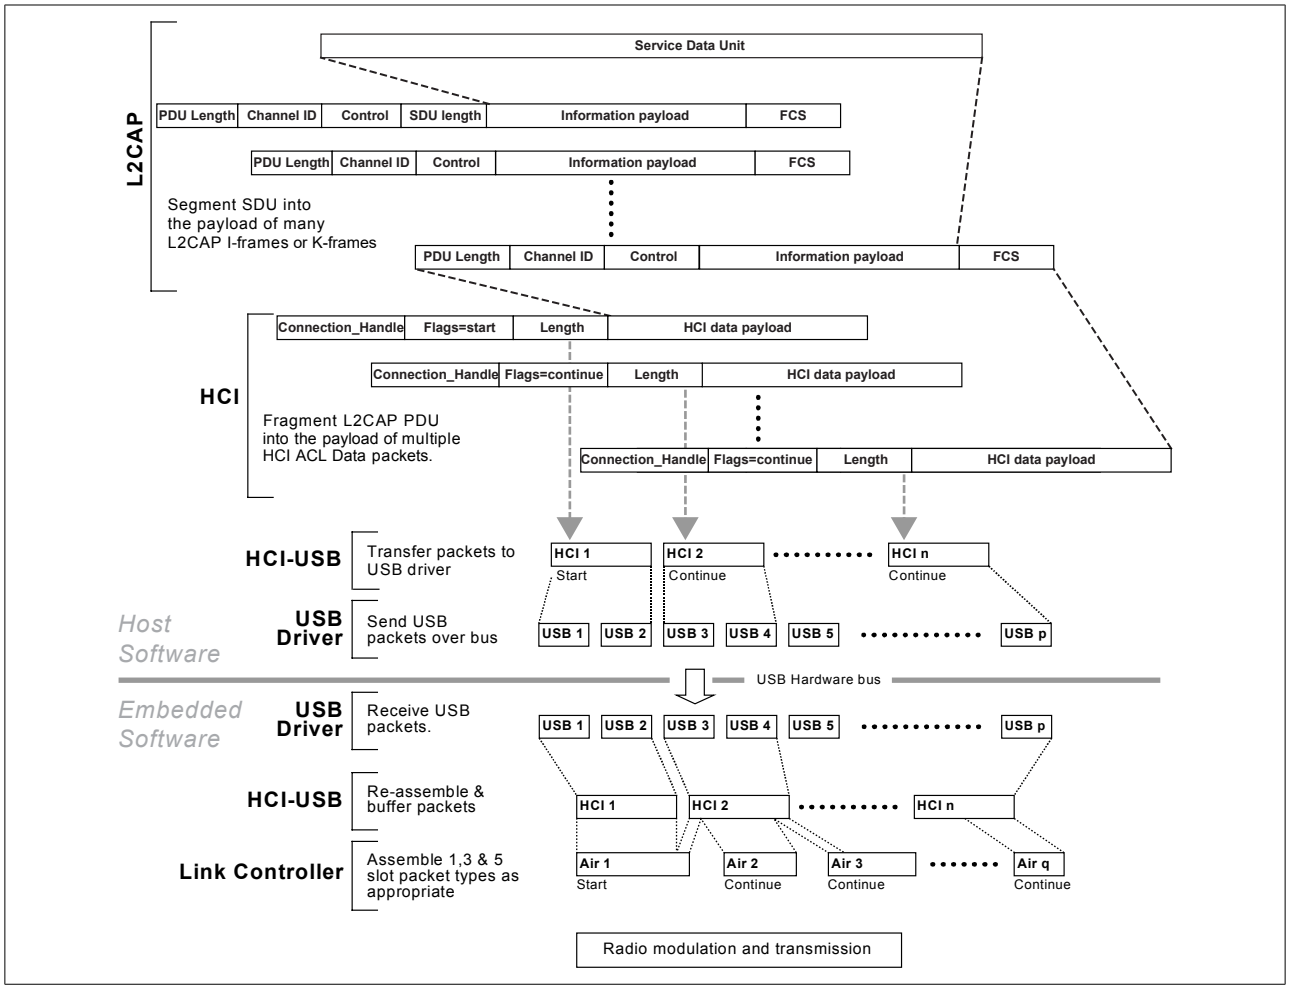

Figure 7.4: Example of segmentation and fragment processes in a device with a BR/EDR Controller and USB HCI Transport[1]

7.4 Delivery of erroneous L2CAP SDUs

Some applications may require corrupted or incomplete L2CAP SDUs to be delivered to the upper layer. If delivery of erroneous L2CAP SDUs is enabled, the receiving side will pass information to the upper layer on which parts of the L2CAP SDU (i.e., which L2CAP frames) have been lost, failed the error check, or passed the error check. If delivery of erroneous L2CAP SDUs is disabled, the receiver shall discard any L2CAP SDU segment with any missing frames or any frames failing the error checks. L2CAP SDUs whose SDU Length field (if provided) does not equal the sum of the segment payload sizes shall also be discarded.

[1]For simplicity, the stripping of any additional HCI and USB specific information fields prior to the creation of the Baseband packets (Air_1, Air_2, etc.) is not shown in the figure.

7.5 Operation with flushing On ACL-U logical links

In the L2CAP configuration using either the Flush Timeout option or the Extended Flow Specification option, the Flush timeout may be set separately per L2CAP channel, but in the BR/EDR Baseband, the flush mechanisms operate per ACL logical transport.

When there is more than one L2CAP channel mapped to the same ACL logical transport, the automatic flush timeout does not discriminate between L2CAP channels. The automatic flush timeout also applies to unicast data sent via the L2CAP connectionless channel. The exception is packets marked as non-automatically-flushable via the Packet_Boundary_Flag in the HCI ACL Data packet (see Section 1.1). The automatic flush timeout flushes a specific automatically-flushable L2CAP PDU. The HCI_Flush command flushes all outstanding L2CAP PDUs for the ACL logical transport including L2CAP PDUs marked as non-automatically-flushable. Therefore, care has to be taken when using the Automatic Flush Timeout and the HCI_Flush command. The HCI_Enhanced_Flush command should be used instead.

All packets associated with a reliable connection shall be marked as non-automatically-flushable (if it is mapped to an ACL logical transport with a finite automatic flush timeout) or L2CAP Enhanced Retransmission mode or Retransmission mode shall be used. In Enhanced Retransmission mode or Retransmission mode, loss of flushed L2CAP PDUs on the channel is detected by the L2CAP ARQ mechanism and they are retransmitted. L2CAP Enhanced Retransmission mode or Retransmission mode can be used for other purposes such as the need for a residual error rate that is much smaller than the Baseband can deliver. In this situation L2CAP Enhanced Retransmission mode or Retransmission mode and the Non-Flushable Packet Boundary Flag feature can be used at the same time.

If it is desired to send unicast data via the L2CAP connectionless channel which is not subject to automatic flushing, then the data should be marked as non-automatically flushable if it is mapped to an ACL logical transport with a finite automatic flush timeout. Unicast data sent via the L2CAP connectionless channel may be marked flushable.

There is only one automatic flush timeout setting per ACL logical transport. Therefore, all time bounded L2CAP channels on an ACL logical transport with an automatic flush timeout setting should configure the same flush timeout value at the L2CAP level. The flush timeout setting for the ACL logical transport also applies to unicast data sent via the L2CAP connectionless channel which are marked flushable.

If Automatic Flush Timeout is used, then it should be taken into account that it only flushes one L2CAP PDU. If one PDU has timed out and needs flushing, then other automatically-flushable packets on the same logical transport are also likely to need flushing. Therefore, flushing can be handled by the HCI_Enhanced_Flush command so that all outstanding automatically-flushable L2CAP PDUs are flushed.

When both reliable and isochronous data is to be sent over the same ACL logical transport, an infinite Automatic Flush Timeout can be used. In this case the isochronous data can be flushed using the HCI_Enhanced_Flush command with Packet_Type set to “Automatically-Flushable Only,” thus preserving the reliable data.

7.6 Connectionless data channel

In addition to connection-oriented channels, L2CAP also provides a connectionless channel. Data sent on the connectionless channel shall only be sent over the BR/EDR radio. The connectionless channel allows broadcast transmissions from the Central to all members of the piconet or unicast transmissions from either a Central or Peripheral to a single remote device. Data sent through the connectionless channel is sent in a best-effort manner. The connectionless channel provided by L2CAP has no quality of service.

While L2CAP itself does not provide retransmission for data sent via the connectionless channel, the Baseband does provide an ARQ scheme for unicast data (see [Vol 2] Part B, Section 7.6). If a higher degree of reliability is desired for unicast data sent via the connectionless L2CAP channel than is provided by the Baseband ARQ scheme then an ARQ scheme should be implemented at a higher layer.

No acknowledgment is provided by the Baseband for broadcast transmissions and hence broadcast transmissions sent via the connectionless L2CAP channel are unreliable and hence might or might not reach each member of the piconet.

The receiving L2CAP entity may silently discard data received via the connectionless L2CAP channel if the data packet is addressed to a PSM and no application is registered to receive data on that PSM.

L2CAP does not provide flow control for either connection-oriented L2CAP channels operating in Basic mode or for traffic on the connectionless L2CAP channel. Hence if data received by L2CAP is not accepted by the target applications in a timely manner, congestion can occur in a receiving L2CAP implementation. For connection-oriented channels, the receiving L2CAP entity may elect to close a channel if the target application for that channel does not accept the data in a timely manner. Since this option is not available for unicast data received via the connectionless L2CAP channel, the receiving L2CAP entity may instead elect to de-register the application receiving the data or to disconnect the underlying physical link. An application shall be notified if it is de-registered. If the underlying physical link is disconnected then all applications utilizing that physical link shall be notified.

Unicast data shall only be sent via the connectionless L2CAP channel to a remote device if the remote device indicates support for Unicast Connectionless Data Reception in the L2CAP Extended Features Mask.[1]

The L2CAP Extended Features Mask should be retrieved using the L2CAP_INFORMATION_REQ packet to determine if Unicast Connectionless Data Reception is supported. Optionally, support for Unicast Connectionless Data Reception can be inferred from information obtained via a SDP or EIR. For example, if a service is found via SDP or EIR that is known to mandate the support of UCD, then it may be assumed that the device indicating support for the service supports Unicast Connectionless Data Reception.

Unicast data sent via the L2CAP connectionless channel are subject to automatic flushing and hence the packet boundary flags should be set appropriately if the Controller supports the Packet Boundary Flag feature. See Section 7.5 for further details. Since the receiving L2CAP entity has no mechanism to enable it to know whether received packets were originally marked as flushable or non-flushable on the transmitting device, the receiving L2CAP entity should treat all unicast packets received via the connectionless L2CAP packet as non-flushable.

If encryption is required for a given profile, then the profile or application shall ensure that authentication is performed and encryption is enabled prior to sending any unicast data on the connectionless L2CAP channel by utilizing Security mode 4 as defined in GAP ([Vol 3] Part C, Section 5.2.2). There is no mechanism provided in the specification to prevent reception of unencrypted data on the connectionless L2CAP channel. An application which requires received data to be encrypted must ignore any unencrypted data it receives over the connectionless channel.

Broadcast transmissions to the connectionless channel are sent with the broadcast LT_ADDR and hence may be received by any of the Peripherals in the piconet. If it is desirable to restrict the reception of the transmitted data to only a subset of the Peripherals in the piconet, then higher level encryption may be used to support private communication.

The Central will not receive transmissions broadcast on the connectionless channel. Therefore, higher layer protocols must loopback any broadcast data traffic being sent to the Central if required.

The connectionless data channel shall not be used with Enhanced Retransmission mode, Retransmission mode or Flow Control mode.

[1]The Unicast Connectionless Data Reception bit in the L2CAP Extended Features Mask does not in any way indicate support or lack of support for reception of broadcast data on the connectionless L2CAP channel even though both broadcast data and unicast data are sent and received using the same CID (0x0002). For historical reasons, there is no bit to indicate support for sending or receiving of broadcast data on the connectionless L2CAP channel.

7.7 Operation collision resolution

When two devices request the same operation by sending a request packet with the same code, a collision can occur. Some operations require collision resolution. The description of each operation in Section 4 will indicate if collision resolution is required. Both devices must know which request will be rejected. The following algorithm shall be used by both devices to determine which request to reject.

1. Set i=0 (representing the least significant octet of the BD_ADDR).
2. Compare the octet[i] of the BD_ADDR of both devices. If the octets are not equal go to step 4.
3. Increment i by 1. Go to step 2.
4. The device with the larger BD_ADDR octet shall reject the request from the other device.

7.8 [This section is no longer used]

7.9 Prioritizing data over HCI

In order for Guaranteed channels to meet their guarantees, L2CAP should prioritize traffic over the HCI transport in devices that support HCI. Packets for Guaranteed channels should receive higher priority than packets for Best Effort channels.

7.10 Supporting Extended Flow Specification for BR/EDR and BR/EDR/LE Controllers

If both the local L2CAP entity and the remote L2CAP entity indicate support for Extended Flow Specification for BR/EDR in the Extended Feature Mask then all channels created between the two devices shall send an Extended Flow Specification option and shall use the Lockstep configuration procedure. In addition all channels shall use Enhanced Retransmission mode or Streaming mode. If one or both L2CAP entities do not indicate support for Extended Flow Specification for BR/EDR in the Extended Feature Mask then the Lockstep configuration procedure shall not be used and the Extended Flow Specification option shall not be sent for channels created over the ACL-U logical link between the two devices.

The L2CAP entity shall perform admission control for Guaranteed channels during the Lockstep configuration procedure (see Section 7.1.3). Admission control is performed to determine if the requested Guaranteed QoS can be achieved by the BR/EDR or BR/EDR/LE Controller over an ACL-U logical link without compromising existing Guaranteed channels running on the Controller. If HCI is used then the L2CAP entity shall also verify that the QoS can be achieved over the HCI transport.

In performing admission control the L2CAP layer shall reject a Guaranteed QoS request that causes at least one of the following rules to be violated.

- The total guaranteed data rate in both directions shall not exceed two times the highest Symmetric Max of an ACL-U logical link over the BR/EDR or BR/EDR/LE Controller (see [Vol 2] Part B, Section 6.7). For example, for a Basic Rate Controller the highest Symmetric Max Rate is 433.9 kb/s (DH5) from [Vol 2] Part B, Table 6.8. Two times that value is 867.8 kb/s.
- The total guaranteed data rate in any one direction shall not exceed the highest Asymmetric Max Rate of an ACL-U logical link (see [Vol 2] Part B, Section 6.7). For example, the highest Asymmetric Max Rate for Basic Rate is 723.2 kb/s (DH5 packet) from [Vol 2] Part B, Table 6.8.

The data rate of a Guaranteed channel is calculated by dividing the Maximum SDU size in an Extended Flow Specification by the SDU Inter-arrival time. Total guaranteed data rate in both directions is calculated by taking the sum of the data rates in both directions for all existing Guaranteed channels plus the data rate in both directions of the requested Guaranteed channel (i.e. data rates from the both outgoing and incoming Extended Flow Specifications). Total guaranteed data rate for one direction is calculated by taking the sum of the data rates in one direction for all existing Guaranteed channels plus the data rate in the same direction of the requested Guaranteed channel.

An L2CAP entity should use additional information for admission control that may result in a Guaranteed QoS request being rejected even if none of the rules are violated. This allows the L2CAP entity to account for things such as CQDDR, SCO/eSCO channels, LMP traffic, page scanning, etc.

In order to meet the access latency and/or data rate required by a Guaranteed channel, the L2CAP entity should:

- Prioritize traffic over the HCI transport in devices that support HCI.
- Give conformant packets for Guaranteed channels higher priority than packets for Best Effort channels. Packets for Best Effort channels should have higher priority than non-conformant packets for Guaranteed channels. (See Section 5.6 for a discussion of non-conformant and conformant traffic).
- Utilize the SAR feature to restrict the PDU sizes of Best Effort SDUs so that they do not prevent the Controller from sending the SDUs of the Guaranteed channel within the time periods required by its Extended Flow Specification.

When a channel is reconfigured the Lockstep configuration process is only used when an Extended Flow Specification option is present in the L2CAP_CONFIGURATION_REQ packet as described in Section 7.1.3.

7.11 Enhanced Credit-Based Flow Control Reconfiguration

In Enhanced Credit Based Flow Control mode, each individual channel has its own MTU and MPS; both of these values can be reconfigured independently.

To perform reconfiguration, a device shall send an L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet to the peer device with the new proposed MTU and MPS values and a set of channels to be reconfigured. The request shall not decrease the MTU of any channel and shall not decrease the MPS of a channel if more than one channel is specified.

When an L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet is received and all the parameters are valid, the recipient shall complete sending all existing PDUs that require an MPS larger than the new MPS value for the channel in the L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet and then send the L2CAP_CREDIT_BASED_RECONFIGURE_RSP packet, with a zero Result field, to the peer device.

After the L2CAP_CREDIT_BASED_RECONFIGURE_RSP packet is sent, the MTU and MPS values of the channels included in the L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet shall be set to the MTU and MPS fields from that packet, and new SDUs shall be sent using the new MTU and MPS values.

When an L2CAP_CREDIT_BASED_RECONFIGURE_REQ packet is received with invalid parameters, the recipient shall send an L2CAP_CREDIT_BASED_RECONFIGURE_RSP PDU with a non-zero Result field and not change any MTU and MPS values.

8 PROCEDURES FOR FLOW CONTROL AND RETRANSMISSION

When Enhanced Retransmission mode, Streaming mode, Flow Control mode, or Retransmission mode is used, the procedures defined in this section shall be used, including the numbering of information frames, the handling of SDU segmentation and reassembly, and the detection and notification of frames with errors. Retransmission mode and Enhanced Retransmission mode also allow the sender to resend frames with errors on request from the receiver.

8.1 Information retrieval

Before attempting to configure Enhanced Retransmission mode, Streaming mode, Flow Control mode, or Retransmission mode on a channel, support for the suggested mode shall be verified by performing an information retrieval for the “Extended features supported” information type (0x0002). If the information retrieval is not successful or the “Extended features mask” bit is not set for the wanted mode, the mode shall not be suggested in a configuration request.

8.2 Function of PDU Types for Flow Control and Retransmission

Two frame formats are defined for Enhanced Retransmission mode, Streaming mode, Flow Control mode, and Retransmission mode (see Section 3.3). The I-frame is used to transport user information instead of the B-frame. The S-frame is used for supervision.

8.2.1 Information frame (I-frame)

I-frames are sequentially numbered frames containing information fields. I-frames also include some of the functionality of RR frames (see below).

8.2.2 Supervisory frame (S-frame)

The S-frame is used to control the transmission of I-frames. For Retransmission mode and Flow Control mode, the S-frame has two formats: Receiver Ready (RR) and Reject (REJ). A description of how S-frames are used in Enhanced Retransmission mode is given in Section 8.6.1. S-frames are not used in Streaming mode. The following description of S-frames only applies to Retransmission mode and Flow Control mode.

8.2.2.1 Receiver Ready (RR)

The receiver ready (RR) S-frame is used to:

1. Acknowledge I-frames numbered up to and including ReqSeq - 1.
2. Enable or disable retransmission of I-frames by updating the receiver with the current status of the Retransmission Disable Bit.

The RR frame has no information field.

8.2.2.2 Reject (REJ)

The reject (REJ) S-frame is used to request retransmission of all I-frames starting with the I-frame with TxSeq equal to ReqSeq specified in the REJ. The value of ReqSeq in the REJ frame acknowledges I-frames numbered up to and including ReqSeq - 1. I-frames that have not been transmitted, shall be transmitted following the retransmitted I-frames.

When a REJ is transmitted, it triggers a REJ Exception condition. A second REJ frame shall not be transmitted until the REJ Exception condition is cleared. The receipt of an I-frame with a TxSeq equal to the ReqSeq of the REJ frame clears the REJ Exception. The REJ Exception condition only applies to traffic in one direction.

Note: This means that only valid I-frames can be rejected.

8.3 Variables and sequence numbers

The sending peer uses the following variables and sequence numbers:

- TxSeq – the send sequence number used to sequentially number each new I-frame transmitted.
- NextTxSeq – the sequence number to be used in the next new I-frame transmitted.
- ExpectedAckSeq – the sequence number of the next I-frame expected to be acknowledged by the receiving peer.

The receiving peer uses the following variables and sequence numbers:

- ReqSeq – The sequence number sent in an acknowledgment frame to request transmission of I-frame with TxSeq = ReqSeq and acknowledge receipt of I-frames up to and including (ReqSeq-1).
- ExpectedTxSeq – the value of TxSeq expected in the next I-frame.
- BufferSeq – When segmented I-frames are buffered this is used to delay acknowledgment of received I-frame so that new I-frame transmissions do not cause buffer overflow.

All variables have the range 0 to 63. Arithmetic operations on state variables (NextTxSeq, ExpectedTxSeq, ExpectedAckSeq, BufferSeq) and sequence numbers (TxSeq, ReqSeq) contained in this document shall be taken *mod* 64.

8.3.1 Sending peer

8.3.1.1 Send sequence number TxSeq

I-frames contain TxSeq, the send sequence number of the I-frame. When an I-frame is first transmitted, TxSeq is set to the value of the send state variable NextTxSeq. TxSeq is not changed if the I-frame is retransmitted.

8.3.1.2 Send state variable NextTxSeq

The CID sent in the information frame is the destination CID and identifies the remote endpoint of the channel. A send state variable NextTxSeq shall be maintained for each remote endpoint. NextTxSeq is the sequence number of the next in-sequence I-frame to be transmitted to that remote endpoint. When the link is created NextTxSeq shall be initialized to 0.

The value of NextTxSeq shall be incremented by 1 after each in-sequence I-frame transmission, and shall not exceed ExpectedAckSeq by more than the maximum number of outstanding I-frames (TxWindow). The value of TxWindow shall be in the range 1 to 32 for Retransmission mode and Flow Control mode. The value of TxWindow shall be in the range 1 to 63 for Enhanced Retransmission mode.

8.3.1.3 Acknowledge state variable ExpectedAckSeq

The CID sent in the information frame is the destination CID and identifies the remote endpoint of the channel. An acknowledge state variable ExpectedAckSeq shall be maintained for each remote endpoint. ExpectedAckSeq is the sequence number of the next in-sequence I-frame that the remote receiving peer is expected to acknowledge. (ExpectedAckSeq – 1 equals the TxSeq of the last acknowledged I-frame). When the link is created ExpectedAckSeq shall be initialized to 0.

Note: If the next acknowledgment acknowledges a single I-frame then its ReqSeq will be expectedAckSeq + 1.

If a valid ReqSeq is received from the peer then ExpectedAckSeq is set to ReqSeq. A valid ReqSeq value is one that is in the range ExpectedAckSeq ≤ ReqSeq ≤ NextTxSeq.

Note: The comparison with NextTxSeq must be ≤ in order to handle the situations where there are no outstanding I-frames.

These inequalities shall be interpreted in the following way: ReqSeq is valid, if and only if (ReqSeq-ExpectedAckSeq) *mod* 64 ≤ (NextTxSeq-ExpectedAckSeq) *mod* 64.

Furthermore, from the description of NextTxSeq, it can be seen that (NextTxSeq-ExpectedAckSeq) *mod* 64 ≤ TxWindow.

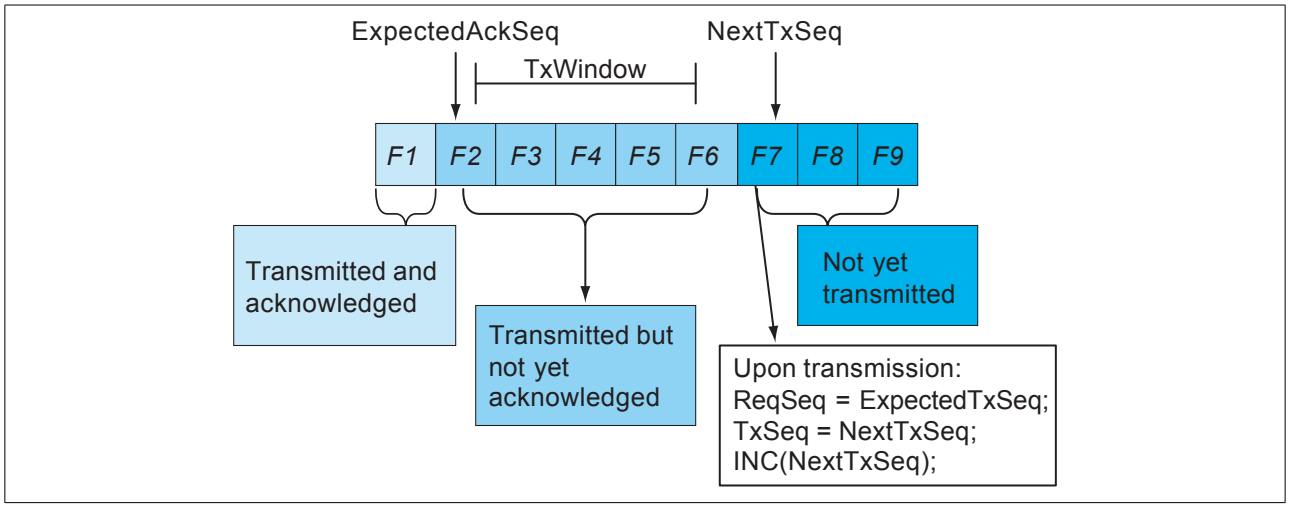

Figure 8.1: Example of the transmitter side

Figure 8.1 shows TxWindow=5, and three frames awaiting transmission. The frame with number *F7* may be transmitted when the frame with *F2* is acknowledged. When the frame with *F7* is transmitted, TxSeq is set to the value of NextTxSeq. After TxSeq has been set, NextTxSeq is incremented by one.

The sending peer expects to receive valid ReqSeq values, which are in the range ExpectedAckSeq to NextTxSeq. Upon receipt of a ReqSeq value equal to the current NextTxSeq all outstanding I-frames have been acknowledged by the receiver.

8.3.2 Receiving peer

8.3.2.1 Receive sequence number ReqSeq

All I-frames and S-frames contain ReqSeq, the send sequence number (TxSeq) that the receiving peer requests in the next I-frame.

When an I-frame or an S-frame is transmitted, the value of ReqSeq shall be set to the current value of the receive state variable ExpectedTxSeq or the buffer state variable BufferSeq. The value of ReqSeq shall indicate that the data Link Layer entity transmitting the ReqSeq has correctly received all I-frames numbered up to and including ReqSeq – 1.

Note: The option to set ReqSeq to BufferSeq instead of ExpectedTxSeq allows the receiver to impose flow control for buffer management or other purposes. In this situation, if BufferSeq<>ExpectedTxSeq, the receiver should also set the retransmission disable bit to 1 to prevent unnecessary retransmissions.

8.3.2.2 Receive state variable ExpectedTxSeq

Each channel shall have a receive state variable (ExpectedTxSeq). The receive state variable is the sequence number (TxSeq) of the next in-sequence I-frame expected.

The value of the receive state variable shall be the last in-sequence, valid I-frame received.

8.3.2.3 Buffer state variable BufferSeq

Each channel may have an associated BufferSeq. BufferSeq is used to delay acknowledgment of frames until they have been pulled by the upper layers, thus preventing buffer overflow. BufferSeq and ExpectedTxSeq are equal when there is no extra segmentation performed and frames are pushed to the upper layer immediately on reception. When buffer space is scarce, for example when frames reside in the buffer for a period, the receiver may choose to set ReqSeq to BufferSeq instead of ExpectedTxSeq, incrementing BufferSeq as buffer space is released. The windowing mechanism will ensure that transmission is halted when ExpectedTxSeq - BufferSeq is equal to TxWindow.

Note: Owing to the variable size of I-frames, updates of BufferSeq may be based on changes in available buffer space instead of delivery of I-frame contents.

I-frames shall have sequence numbers in the range ExpectedTxSeq ≤ TxSeq < (BufferSeq + TxWindow).

On receipt of an I-frame with TxSeq equal to ExpectedTxSeq, ExpectedTxSeq shall be incremented by one regardless of how many I-frames with TxSeq greater than ExpectedTxSeq were previously received.

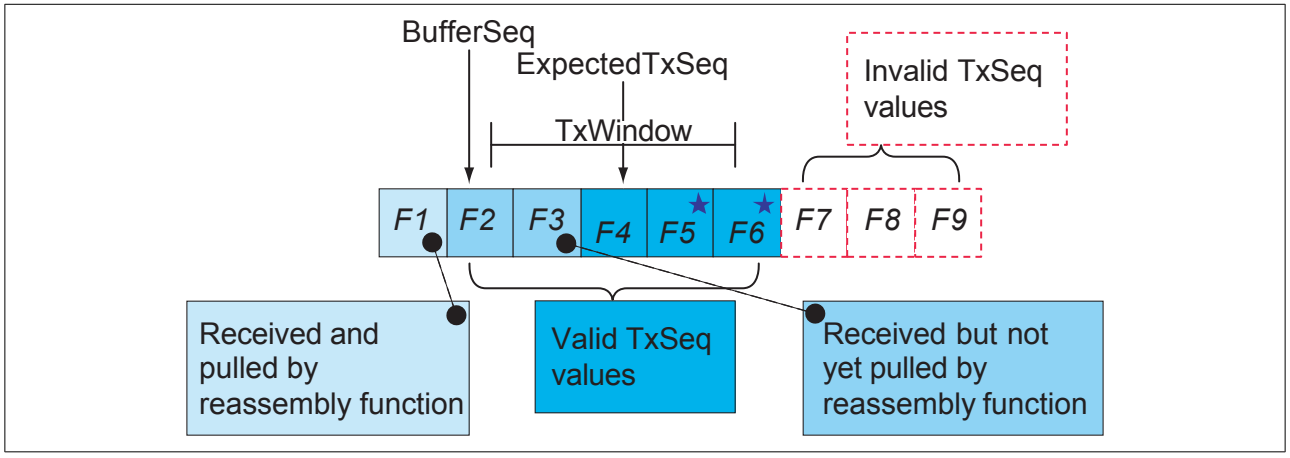

Figure 8.2: Example of the receiver side

Figure 8.2 shows TxWindow=5. *F1* is successfully received and pulled by the upper layer. BufferSeq shows that *F2* is the next I-frame to be pulled, and ExpectedTxSeq

points to the next I-frame expected from the peer. An I-frame with TxSeq equal to 5 has been received thus triggering an SREJ or REJ exception. The star indicates I-frames received but discarded owing to the SREJ or REJ exception. They will be resent as part of the error recovery procedure.

In Figure 8.2 there are several I-frames in a buffer awaiting the SDU reassembly function to pull them and the TxWindow is full. The receiver would usually disable retransmission in Retransmission mode or Flow Control mode by setting the Retransmission Disable Bit to 1 and send an RR back to the sending side. This tells the transmitting peer that there is no point in performing retransmissions. Both sides will send S-frames to make sure the peer entity knows the current value of the Retransmission Disable Bit.

8.4 Retransmission mode

8.4.1 Transmitting frames

A new I-frame shall only be transmitted when the TxWindow is not full. No I-frames shall be transmitted if the last RetransmissionDisableBit (R) received is set to one.

A previously transmitted I-frame may be retransmitted as a result of an error recovery procedure, even if the TxWindow is full. When an I-frame is retransmitted it shall always be sent with the same TxSeq value used in its initial transmission.

The state of the RetransmissionDisableBit (R) is stored and used along with the state of the RetransmissionTimer to decide the actions when transmitting I-frames. The RetransmissionTimer is running whenever I-frames have been sent but not acknowledged.

8.4.1.1 Last received R was set to zero

If the last R received was set to zero, then I-frames may be transmitted. If there are any I-frames which have been sent and not acknowledged then they shall be retransmitted when the RetransmissionTimer elapses. If the retransmission timer has not elapsed then a retransmission shall not be sent and only new I-frames may be sent.

- If unacknowledged I-frames have been sent and the RetransmissionTimer has elapsed, then an unacknowledged I-frame shall be retransmitted. The RetransmissionTimer shall be restarted.
- If unacknowledged I-frames have been sent but the Retransmission timer has not elapsed, then a new I-frame shall be sent if one is waiting and no timer action shall be taken.
- If no unacknowledged I-frames have been sent and a new I-frame is waiting, then the new I-frame shall be sent, the RetransmissionTimer shall be started, and the Monitor Timer shall be stopped if it is running.

- If no unacknowledged I-frames have been sent, no new I-frames are waiting to be transmitted, and the RetransmissionTimer is running, then the retransmission timer shall be stopped and the monitor timer shall be started.

Table 8.1 summarizes actions when the RetransmissionTimer is in use and R=0.

Unacknowledged I-frames sent = Retransmission Timer is running	**Retransmission Timer has elapsed**	**New I-frames are waiting**	**Transmit Action**	**Timer Action**
True	True	True or False	Retransmit unacknowledged I-frame	Restart Retransmission Timer
True	False	True	Transmit new I-frame	No timer action
True	False	False	No transmit action	No Timer action
False	False	True	Transmit new I-frame	Restart Retransmission Timer
False	False	False	No Transmit action	If MonitorTimer is not running then restart MonitorTimer

Table 8.1: Summary of actions when the RetransmissionTimer is in use and R=0

If the RetransmissionTimer is not in use, no unacknowledged I-frames have been sent and no new I-frames are waiting to be transmitted

- If the MonitorTimer is running and has not elapsed, then no transmit action shall be taken and no timer action shall be taken.
- If the MonitorTimer has elapsed, then an S-frame shall be sent and the MonitorTimer shall be restarted.

If any I-frames become available for transmission, then the MonitorTimer shall be stopped, the RetransmissionTimer shall be started, and the rules for when the RetransmissionTimer is in use shall be applied.

When an I-frame is sent ReqSeq shall be set to ExpectedTxSeq, TxSeq shall be set to NextTxSeq and NextTxSeq shall be incremented by one.

8.4.1.2 Last received R was set to one

If the last R received was set to one, then I-frames shall not be transmitted. The only frames which may be sent are S-frames. An S-frame shall be sent according to the rules below:

- If the MonitorTimer is running and has not elapsed, then no transmit action shall be taken and no timer action shall be taken.
- If the MonitorTimer has elapsed, then an S-frame shall be sent and the MonitorTimer shall be restarted.

8.4.2 Receiving I-frames

Upon receipt of a valid I-frame with TxSeq equal to ExpectedTxSeq, the frame shall be accepted for the SDU reassembly function. ExpectedTxSeq is used by the reassembly function.

The first valid I-frame received after an REJ was sent, with a TxSeq of the received I-frame equal to ReqSeq of the REJ, shall clear the REJ Exception condition.

The ReqSeq shall be processed according to Section 8.4.6.

If a valid I-frame with TxSeq ≠ ExpectedTxSeq is received then an exception condition shall be triggered which is handled according to Section 8.4.7.

8.4.3 I-frames pulled by the SDU reassembly function

When the L2CAP layer has removed one or more I-frames from the buffer, BufferSeq may be incremented in accordance with the amount of buffer space released. If BufferSeq is incremented, an acknowledgment shall be sent to the peer entity.

Note: Since the primary purpose of BufferSeq is to prevent buffer overflow, an implementation may choose to set BufferSeq in accordance with how many new incoming I-frames could be stored rather than how many have been removed.

The acknowledgment may either be an RR or an I-frame. The acknowledgment shall be sent to the peer L2CAP entity with ReqSeq equal to BufferSeq. When there are no I-frames buffered for pulling ExpectedTxSeq is equal to BufferSeq.

If the MonitorTimer is active then it shall be restarted to indicate that a signal has been sent to the peer L2CAP entity.

8.4.4 Sending and receiving acknowledgments

Either the MonitorTimer or the RetransmissionTimer shall be active while in Retransmission mode. Both timers shall not be active concurrently.

8.4.4.1 Sending acknowledgments

Whenever an L2CAP entity transmits an I-frame or an S-frame, ReqSeq shall be set to ExpectedTxSeq or BufferSeq.

8.4.4.2 Receiving acknowledgments

On receipt of a valid S-frame or I-frame, the ReqSeq contained in the frame shall acknowledge previously transmitted I-frames. ReqSeq acknowledges I-frames with a TxSeq up to and including ReqSeq – 1.

The following rules shall be applied:

1. If the RetransmissionDisableBit changed value from 0 to 1 (stop retransmissions) then the receiving entity shall
    a. If the RetransmissionTimer is running then stop it and start the MonitorTimer.
    b. Store the state of the RetransmissionDisableBit received.
2. If the RetransmissionDisableBit changed value from 1 to 0 (start retransmissions) then the receiving entity shall
    a. Store the state of the RetransmissionDisableBit received.
    b. If there are any I-frames that have been sent but not acknowledged, then stop the MonitorTimer and start the RetransmissionTimer.
    c. Any buffered I-frames shall be transmitted according to Section 8.4.1.
3. If any unacknowledged I-frames were acknowledged by the ReqSeq contained in the frame, and the RetransmissionDisableBit equals 1 (retransmissions stopped), then the receiving entity shall
    a. Follow the rules in Section 8.4.1.
4. If any unacknowledged I-frames were acknowledged by the ReqSeq contained in the frame and the RetransmissionDisableBit equals 0 (retransmissions started) then the receiving entity shall
    a. If the RetransmissionTimer is running, then stop it.
    b. If any unacknowledged I-frames have been sent then the RetransmissionTimer shall be restarted.
    c. Follow the rules in Section 8.4.1.
    d. If the RetransmissionTimer is not running and the MonitorTimer is not running, then start the MonitorTimer.

On receipt of a valid S-frame or I-frame the ReqSeq contained in the frame shall acknowledge previously transmitted I-frames. ExpectedAckSeq shall be set to ReqSeq

to indicate that the I-frames with TxSeq up to and including (ReqSeq - 1) have been acknowledged.

8.4.5 Receiving REJ frames

Upon receipt of a valid REJ frame, where ReqSeq identifies an I-frame not yet acknowledged, the ReqSeq acknowledges I-frames with TxSeq up to and including ReqSeq - 1. Therefore the REJ acknowledges all I-frames before the I-frame it is rejecting.

ExpectedAckSeq shall be set equal to ReqSeq to mark I-frames up to and including ReqSeq - 1 as received.

NextTxSeq shall be set to ReqSeq to cause transmissions of I-frames to resume from the point where TxSeq equals ReqSeq.

If ReqSeq equals ExpectedAckSeq then the REJ frame shall be ignored.

8.4.6 Waiting acknowledgments

A counter, TransmitCounter, counts the number of times an L2CAP PDU has been transmitted. This shall be set to 1 after the first transmission. If the RetransmissionTimer expires the following actions shall be taken:

1. If the TransmitCounter is less than MaxTransmit then:
   a. Increment the TransmitCounter by one.
   b. Retransmit the last unacknowledged I-frame, according to Section 8.4.1.
2. If the TransmitCounter is equal to MaxTransmit this channel to the peer entity shall be assumed lost. The channel shall move to the CLOSED state and appropriate action shall be taken to report this to the upper layers.

8.4.7 Exception conditions

Exception conditions may occur as the result of physical layer errors or L2CAP procedural errors. The error recovery procedures which are available following the detection of an exception condition at the L2CAP layer in Retransmission mode are defined in this section.

8.4.7.1 TxSeq sequence error

A TxSeq sequence error exception condition occurs in the receiver when a valid I-frame is received which contains a TxSeq value which is not equal to the expected value, thus TxSeq is not equal to ExpectedTxSeq.

The TxSeq sequence error may be due to three different causes:

- *Duplicated I-frame*

  The duplicated I-frame is identified by a TxSeq in the range BufferSeq to ExpectedTxSeq – 1 (BufferSeq ≤TxSeq<ExpectedTxSeq). The ReqSeq and RetransmissionDisableBit shall be processed according to Section 8.4.4. The Information field shall be discarded since it has already been received.

- *Out-of-sequence I-frame*

  The out-of-sequence I-frame is identified by a TxSeq within the valid range. The ReqSeq and RetransmissionDisableBit shall be processed according to Section 8.4.4.

  A REJ exception is triggered, and an REJ frame with ReqSeq equal to ExpectedTxSeq shall be sent to initiate recovery. The received I-frame shall be discarded.

- *Invalid TxSeq*

  An invalid TxSeq value is a value that does not meet either of the above conditions. An I-frame with an invalid TxSeq is likely to have errors in the control field and shall be silently discarded.

8.4.7.2 ReqSeq sequence error

An ReqSeq sequence error exception condition occurs in the transmitter when a valid S-frame or I-frame is received which contains an invalid ReqSeq value. An invalid ReqSeq is one that is not in the range ExpectedAckSeq ≤ ReqSeq ≤ NextTxSeq.

The L2CAP entity shall close the channel as a consequence of an ReqSeq Sequence error.

8.4.7.3 Timer recovery error

If an L2CAP entity fails to receive an acknowledgment for the last I-frame sent, then it will not detect an out-of-sequence exception condition and therefore will not transmit an REJ frame.

The L2CAP entity that transmitted an unacknowledged I-frame shall, on the expiry of the RetransmissionTimer, take appropriate recovery action as defined in Section 8.4.6.

8.4.7.4 Invalid frame

Any frame received which is invalid (as defined in Section 3.3.6) shall be discarded, and no action shall be taken as a result of that frame.

8.5 Flow Control mode

When a link is configured to work in flow control mode, the flow control operation is similar to the procedures in retransmission mode, but all operations dealing with CRC errors in received packets are not used. Therefore

- REJ frames shall not be used in Flow Control mode.
- The RetransmissionDisableBit shall always be set to zero in the transmitter, and shall be ignored in the receiver.

The behavior of flow control mode is specified in this section.

Assuming that the TxWindow size is equal to the buffer space available in the receiver (counted in number of I-frames), in flow control mode the number of unacknowledged frames in the transmitter window is always less than or equal to the number of frames for which space is available in the receiver.

Note: A missing frame still occupies a place in the window.

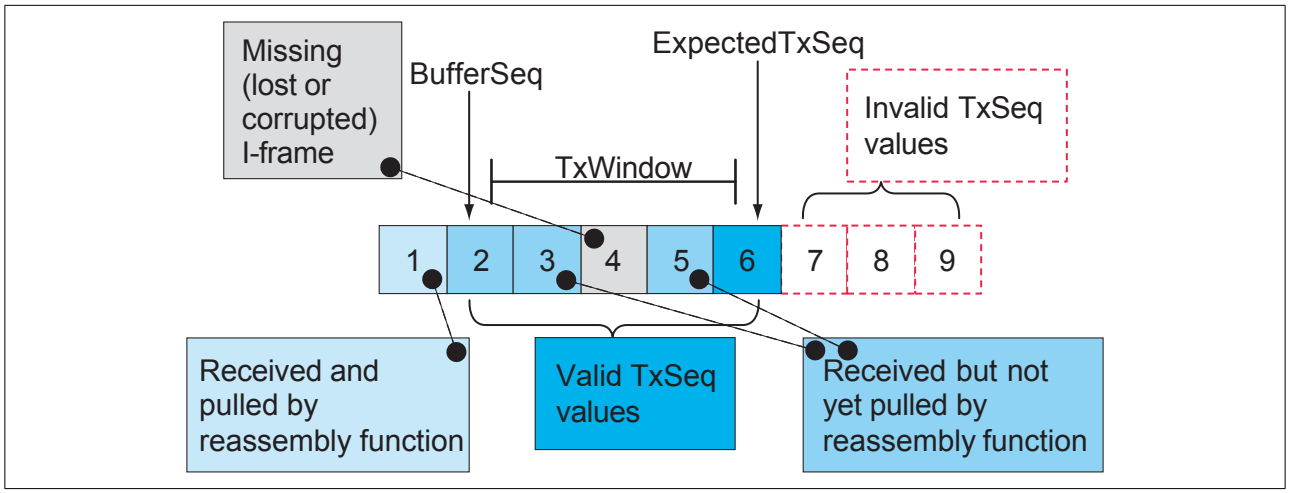

Figure 8.3: Overview of the receiver side when operating in Flow Control mode

8.5.1 Transmitting I-frames

A new I-frame shall only be transmitted when the TxWindow is not full.

Upon transmission of the I-frame the following actions shall be performed:

- If no unacknowledged I-frames have been sent then the MonitorTimer shall be stopped and the RetransmissionTimer shall be started.
- If any I-frames have been sent and not acknowledged then the RetransmissionTimer remains active and no timer operation is performed.

The control field parameter ReqSeq shall be set to ExpectedTxSeq, TxSeq shall be set to NextTxSeq, and NextTxSeq shall be incremented by one.

8.5.2 Receiving I-frames

Upon receipt of a valid I-frame with TxSeq equal to ExpectedTxSeq, the frame shall be made available to the reassembly function. ExpectedTxSeq shall be incremented by one. An acknowledgment shall not be sent until the SDU reassembly function has pulled the I-frame.

Upon receipt of a valid I-frame with an out-of-sequence TxSeq (see Section 8.5.6) all frames with a sequence number less than TxSeq shall be assumed lost and marked as missing. The missing I-frames are in the range from ExpectedTxSeq (the frame that the device was expecting to receive) up to TxSeq-1, (the frame that the device actually received). ExpectedTxSeq shall be set to TxSeq +1. The received I-frame shall be made available for pulling by the reassembly function. The acknowledgment shall not occur until the SDU reassembly function has pulled the I-frame. The ReqSeq shall be processed according to Section 8.5.4.

8.5.3 I-frames pulled by the SDU reassembly function

When the L2CAP layer has removed one or more I-frames from the buffer, BufferSeq may be incremented in accordance with the amount of buffer space released. If BufferSeq is incremented, an acknowledgment shall be sent to the peer entity. If the MonitorTimer is active then it shall be restarted to indicate that a signal has been sent to the peer L2CAP entity.

Note: Since the primary purpose of BufferSeq is to prevent buffer overflow, an implementation may choose to set BufferSeq in accordance with how many new incoming I-frames could be stored rather than how many have been removed.

The acknowledgment may be an RR or an I-frame. The acknowledgment shall be sent to the peer L2CAP entity with ReqSeq equal to BufferSeq. When there is no I-frame buffered for pulling, ExpectedTxSeq is equal to BufferSeq.

8.5.4 Sending and receiving acknowledgments

One of the timers MonitorTimer or RetransmissionTimer shall always be active while in Flow Control mode. Both timers shall never be active concurrently.

8.5.4.1 Sending acknowledgments

Whenever a data Link Layer entity transmits an I-frame or a S-frame, ReqSeq shall be set to ExpectedTxSeq or BufferSeq.

8.5.4.2 Receiving acknowledgments

On receipt of a valid S-frame or I-frame the ReqSeq contained in the frame shall be used to acknowledge previously transmitted I-frames. ReqSeq acknowledges I-frames with a TxSeq up to and including ReqSeq – 1.

1. If any outstanding I-frames were acknowledged then
   a. Stop the RetransmissionTimer
   b. If there are still unacknowledged I-frames then restart the RetransmissionTimer, otherwise start the MonitorTimer.
   c. Transmit any I-frames awaiting transmission according to Section 8.5.1.

ExpectedAckSeq shall be set to ReqSeq to indicate that the I-frames with TxSeq up to and including ExpectedAckSeq have been acknowledged.

8.5.5 Waiting acknowledgments

If the RetransmissionTimer expires the following actions shall be taken:

The I-frame supervised by the RetransmissionTimer shall be considered lost, and ExpectedAckSeq shall be incremented by one.

1. If I-frames are waiting to be sent
   a. the RetransmissionTimer is restarted.
   b. I-frames awaiting transmission are transmitted according to Section 8.5.1.
2. If there are no I-frames waiting to be sent
   a. If there are still unacknowledged I-frames the RetransmissionTimer is restarted, otherwise the MonitorTimer is started.

8.5.6 Exception conditions

Exception conditions may occur as the result of physical layer errors or L2CAP procedural errors. The error recovery procedures which are available following the detection of an exception condition at the L2CAP layer in flow control only mode are defined in this section.

8.5.6.1 TxSeq sequence error

A TxSeq sequence error exception condition occurs in the receiver when a valid I-frame is received which contains a TxSeq value which is not equal to the expected value, thus TxSeq is not equal to ExpectedTxSeq.

The TxSeq sequence error may be due to three different causes:

- *Duplicated I-frame*

  The duplicated I-frame is identified by a TxSeq in the range BufferSeq to ExpectedTxSeq – 1. The ReqSeq shall be processed according to Section 8.5.4. The Information field shall be discarded since it has already been received.

- *Out-of-sequence I-frame*

  The out-of-sequence I-frame is identified by a TxSeq such that ExpectedTxSeq < TxSeq < (BufferSeq + TxWindow). The ReqSeq shall be processed according to Section 8.5.4.

  The missing I-frame(s) are considered lost and ExpectedTxSeq is set equal to TxSeq+1 as specified in Section 8.5.2. The missing I-frame(s) are reported as lost to the SDU reassembly function.

- *Invalid TxSeq*

  An invalid TxSeq value is a value that does not meet either of the above conditions and TxSeq is not equal to ExpectedTxSeq. An I-frame with an invalid TxSeq is likely to have errors in the control field and shall be silently discarded.

8.5.6.2 ReqSeq sequence error

An ReqSeq sequence error exception condition occurs in the transmitter when a valid S-frame or I-frame is received which contains an invalid ReqSeq value. An invalid ReqSeq is one that is not in the range ExpectedAckSeq ≤ ReqSeq ≤ NextTxSeq.

The L2CAP entity shall close the channel as a consequence of an ReqSeq Sequence error.

An L2CAP entity that fails to receive an acknowledgment for an I-frame shall, on the expiry of the RetransmissionTimer, take appropriate recovery action as defined in Section 8.5.5.

8.5.6.3 Invalid frame

Any frame received that is invalid (as defined in Section 3.3.6) shall be discarded, and no action shall be taken as a result of that frame, unless the receiving L2CAP entity is configured to deliver erroneous frames to the layer above L2CAP. In that case, the data contained in invalid frames may also be added to the receive buffer and made available for pulling from the SDU reassembly function.

8.6 Enhanced Retransmission mode

Enhanced Retransmission mode operates as an HDLC balanced data link operational mode. Either L2CAP entity may send frames at any time without receiving explicit

permission from the other L2CAP entity. A transmission may contain single or multiple frames and shall be used for I-frame transfer and/or to indicate status change.

8.6.1 Function of PDU types

Enhanced Retransmission mode uses I-frames to transfer upper layer information and S-frames for supervision. There are four S-frames defined: Receiver Ready (RR), Reject (REJ), Receiver Not Ready (RNR), and Selective Reject (SREJ). All frames formats in Enhanced Retransmission mode shall use the Enhanced Control Field.

8.6.1.1 Receiver Ready (RR)

The RR frame shall be used by an L2CAP entity to

1. Indicate that it is ready to receive I-frames
2. Acknowledge previously received I-frames numbered up to and including ReqSeq - 1.

An RR with P-bit set to 1 (P=1) is used to indicate the clearance of any busy condition that was initiated by an earlier transmission of an RNR frame by the same L2CAP entity.

8.6.1.2 Reject (REJ)

The REJ frame shall be used by an L2CAP entity to request retransmission of I-frames starting with the frame numbered ReqSeq. I-frames numbered ReqSeq - 1 and below shall be considered acknowledged. Additional I-frames awaiting initial transmission may be transmitted following the retransmitted I-frame(s) up to the TxWindow size of the receiver.

At most only one REJ exception from a given L2CAP entity to another L2CAP entity shall be established at any given time. A REJ frame shall not be transmitted until an earlier REJ exception condition or all earlier SREJ exception conditions have been cleared. The REJ exception condition shall be cleared upon the receipt of an I-frame with TxSeq equal to the ReqSeq of the REJ frame.

Two L2CAP entities may be in REJ exception conditions with each other at the same time.

8.6.1.3 Receiver Not Ready (RNR)

The RNR frame shall be used by an L2CAP entity to indicate a busy condition (i.e. temporary inability to receive I-frames). I-frames numbered up to and including ReqSeq - 1 shall be considered acknowledged. The I-frame numbered ReqSeq and any subsequent I-frames sent shall not be considered acknowledged. The acceptance status of these I-frames shall be indicated in subsequent transfers.

8.6.1.4 Selective Reject (SREJ)

The SREJ frame shall be used by an L2CAP entity to request retransmission of one I-frame. The ReqSeq shall indicate the TxSeq of the earliest I-frame to be retransmitted (not yet reported by a SREJ). If the P-bit is set to 1 then I-frames numbered up to and including ReqSeq -1 shall be considered acknowledged. If the P-bit is set to 0 then the ReqSeq field in the SREJ shall not indicate acknowledgment of I-frames.

Each SREJ exception condition shall be cleared upon receipt of an I-frame with TxSeq equal to the ReqSeq sent in the SREJ frame.

An L2CAP entity may transmit one or more SREJ frames with the P=0 before one or more earlier SREJ exception conditions initiated with SREJ(P=0) have been cleared. An L2CAP entity shall not transmit more than one SREJ with P=1 before all earlier SREJ exception conditions have been cleared. A SREJ frame shall not be transmitted if an earlier REJ exception condition has not been cleared. Likewise a REJ frame shall not be transmitted if one or more SREJ exception conditions have not been cleared. Only one I-frame shall be retransmitted in response to receiving a SREJ frame with P=0. Additional I-frames awaiting initial transmission may be transmitted following the retransmission of the specific I-frame requested by SREJ with P=1.

8.6.1.5 Functions of the Poll (P) and Final (F) bits

P-bit set to 1 shall be used to solicit a response frame with the F-bit set to 1 from the remote L2CAP entity at the earliest respond opportunity. At most only one frame with a P=1 shall be outstanding in a given direction at a given time. Before an L2CAP entity issues another frame with P=1, it shall have received a response frame from the remote L2CAP entity with F=1. If no valid frame is received with F=1 within Monitor timeout period, the frame with P=1 may be retransmitted.

The Final bit shall be used to indicate the frame as a response to a soliciting poll (S-frame with P=1). The frame with F=1 shall not be retransmitted. The Monitor-timeout is not used to monitor lost frames with F=1. Additional frames with F=0 may be transmitted following the frame with F=1.

S-frames shall not be transmitted with both the F-bit and the P-bit set to 1 at the same time.

8.6.2 Rules for timers

Timers are started upon transmission of a packet. Timers should be started when the corresponding packet leaves the Controller (transmitted or flushed). If the timer is not started when the packet leaves the Controller then it shall be started when the packet is delivered to the Controller. The specific rules for BR/EDR and BR/EDR/LE Controllers are described in the following sections.

8.6.2.1 Timer rules for ACL-U logical links

If a flush timeout does not exist on the ACL-U logical link for the channel using Enhanced Retransmission mode then the value for the Retransmission timeout shall be at least two seconds and the value for the Monitor timeout shall be at least 12 seconds.

If a flush timeout exists on the link for Enhanced Retransmission mode then the value for the Retransmission timeout shall be three times the value of flush timeout, subject to a minimum of 1 second and maximum of 2 seconds.

If a flush timeout exists on the link for Enhanced Retransmission mode and both sides of the link are configured to the same flush timeout value then the monitor timeout shall be set to a value at least as large as the Retransmission timeout otherwise the value of the Monitor timeout shall be six times the value of flush timeout, subject to a minimum of the retransmission timeout value and a maximum of 12 seconds.

If an L2CAP entity knows that a specific packet has been flushed instead of transmitted then it may execute proper error recovery procedures immediately.

When configuring a channel over an ACL-U logical link the values sent in an L2CAP_CONFIGURATION_REQ packet for Retransmission timeout and Monitor timeout shall be 0.

Note: If the link has a flush timeout and the Non-Flushable Packet Boundary Flag feature is used to mark the Enhanced Retransmission mode packets as non-flushable then the link does not have a flush timeout with regards to Enhanced Retransmission mode.

8.6.2.2 [This section is no longer used]

8.6.2.3 [This section is no longer used]

8.6.3 General rules for the state machine

Enhanced Retransmission mode is specified using a pair of state machines, a Transmitter state machine and a Receiver state machine. The following rules apply to the state machine pair.

1. The state machine pair specifies the behavior of the protocol. Designers and implementers may choose any design / implementation technique they wish, but it shall behave in a manner identical to the external behavior of the specified state machines.
2. There is a single state machine pair for each active L2CAP channel configured to use Enhanced Retransmission mode.

3. Variables are used to limit the number of states by maintaining the state of particular conditions. The variables are defined in Section 8.6.5.2.
4. For some combinations of event and condition, the state tables provide an action that involves alternatives or alternative groups of actions. The alternatives are mutually exclusive; selection of an alternate is done based upon (i) local status, (ii) a layer management action, or (iii) an implementation decision. There is no relationship between the order of the alternatives between events, nor is it implied that the same alternative must be selected every time the event occurs.
5. The state tables use timers. Any Start Timer action restarts the specified timer from its initial value, even if the timer is already running. When the timer reaches 0 the appropriate timer expired event is set and the timer stops. The Stop Timer action stops a timer if it is running.
6. Events not recognized in a particular state are assumed to remain pending until any masking flag is modified or a transition is made to a state where they can be recognized.
7. Some state transitions and actions are triggered by internal events (e.g. requests from the upper layer). It is implementation specific how these internal events are realized. They are used for clarity in specifying the state machine. All events including Internal events are described in Section 8.6.5.3.
8. The state machines specify the exact frames to be sent by transmitters but are relaxed on what receivers are allowed to accept as valid. For example there are cases where the transmitter is required to send a frame with P=1. The correct response is a frame with F=1 but in some cases the receiver is allowed to accept a frame with F=0 in addition to F=1.

8.6.4 State diagram

The state diagram in Figure 8.4 shows the states and the main transitions. Not all events are shown on the state diagram.

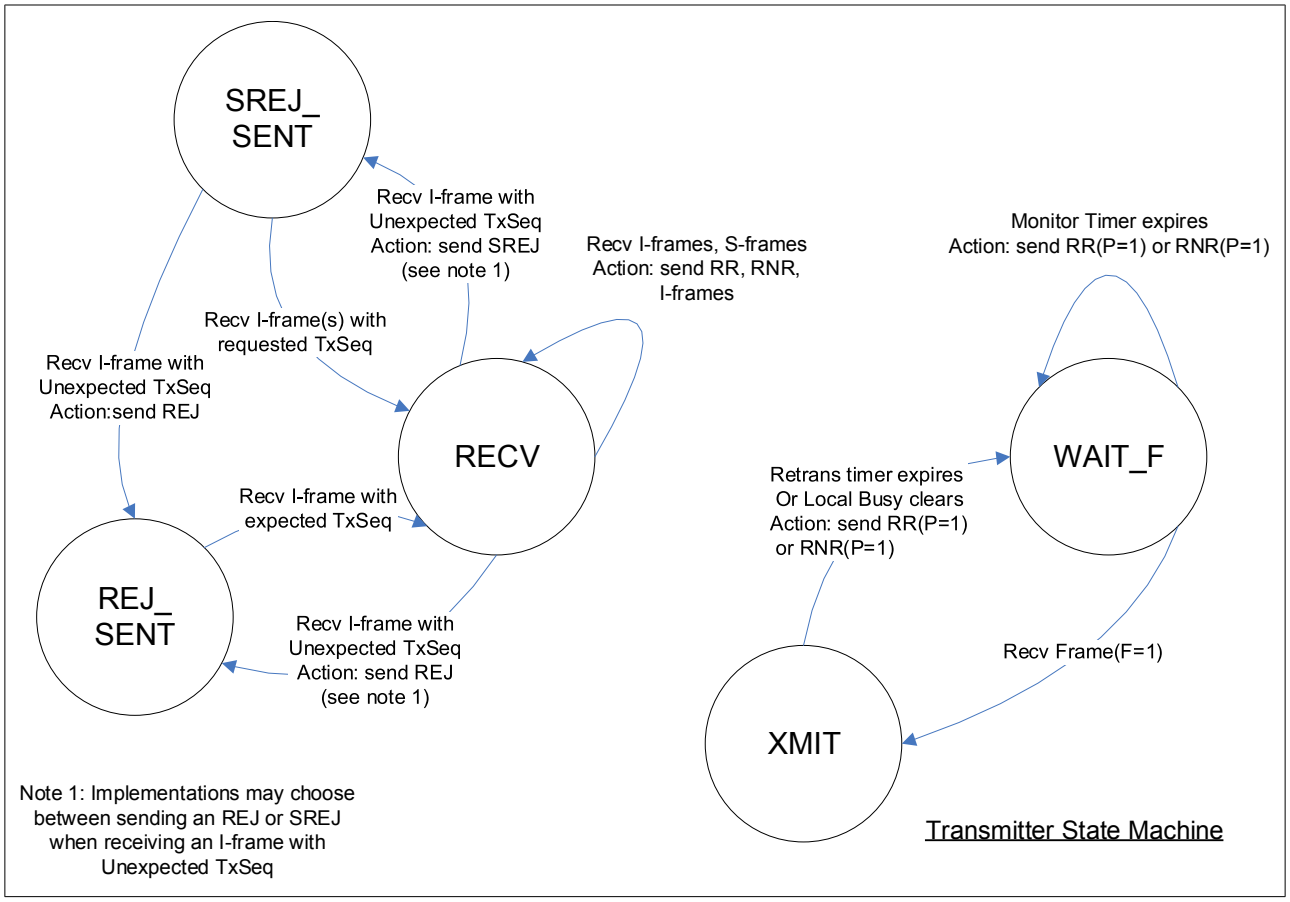

Figure 8.4: Receiver state machine

8.6.5 States tables

8.6.5.1 State machines

Enhanced Retransmission mode is described as a pair of state machine. The Receiver state machine handles all received frames while the Transmitter State machine handles all asynchronous events including requests from the upper layer and the expiration of timers.

The Receiver state machine “calls” the Transmitter state machine using the PassToTx action. This shows up in the Transmitter state machine as an event. When the Transmitter state machine is called it runs to completion before returning to the Receiver state machine. Running to completion means that all actions are executed and the Transmitter state is changed to the new state.

The Receiver and Transmitter state machine share variables and timers.

8.6.5.2 States

The following states have been defined to specify the protocol; the actual number of states and naming in a given implementation is outside the scope of the specification:

RECV—This is the main state of the Receiver state machine.

REJ_SENT—The L2CAP entity has sent a REJ frame to cause the remote L2CAP entity to resend I-frame(s). The L2CAP entity is waiting for the I-frame with a TxSeq that matches the ReqSeq sent in the REJ. Whether to send a REJ versus a SREJ is implementation dependent.

SREJ_SENT—The L2CAP entity has sent one or more SREJ frames to cause the remote L2CAP entity to resend missing I-frame(s). The local L2CAP entity is waiting for all requested I-frames to be received. If additional missing I-frames are detected while in SREJ_SENT then additional SREJ frames or a REJ frame can be sent to request those I-frames. Whether to send a SREJ versus a REJ is implementation dependent.

XMIT—This is the main state of the Transmitter state machine.

WAIT_F—Local busy has been cleared or the Retransmission timer has expired and an S-frame with P=1 has been sent. The local L2CAP entity is waiting for a frame with F=1. New I-frames cannot be sent while in the WAIT_F state to prevent the situation where retransmission of I-frames could result in the channel being disconnected.

8.6.5.3 Variables and timers

Variables are used to limit the number of states and help clarify the state chart tables. Variables can be set to values, evaluated in conditions and compared in conditional statements. They are also used in the action descriptions. Below is a list of the operators, connectives and statements that can be used with variables.

Operator, connective or statement	Description
:=	Assignment operator. Used to set a variable to a value
=	Relational operator "equal"
>	Relational operator "greater than"
<	Relational operator "less than"
≥	Relational operator "greater than or equal"
≤	Relational operator "less than or equal"
+	Arithmetic operator "plus"

Operator, connective or statement	Description
and	logical connective "and." It returns TRUE if both operands are TRUE otherwise it returns FALSE.
or	logical connective "or." It returns TRUE if either of its operands are TRUE otherwise it returns FALSE.
if (expression) **then {** statement **}**	Conditional Statement. If expression is TRUE then the statement is executed otherwise the statement is not executed. The statement is composed of one or more actions. All the actions in the statement are indented under the **if** ... **then** clause and contained within braces “{ }”.
if (expression) **then {** statement1 **}** **else {** statement2 **}**	Conditional Statement. If expression is TRUE then statement1 is executed otherwise statement2 is executed. A statement is composed of one or more actions. All the actions in the statement1 are indented under the **if** ... **then** clause and contained within braces “{ }”. All the actions of statement2 are indented under the else clause and contained within braces “{ }”.

Table 8.2: Operators, connectives, and statements used with variables

Enhanced Retransmission mode uses the following variables and sequence numbers described in Section 8.3:

- TxSeq
- NextTxSeq
- ExpectedAckSeq
- ReqSeq
- ExpectedTxSeq
- BufferSeq

In addition to the variables above the following variables and timers are used:

RemoteBusy—when set to TRUE RemoteBusy indicates that the local L2CAP entity has received an RNR from the remote L2CAP entity and considers the remote L2CAP entity as busy. When the remote device is busy it will likely discard I-frames sent to it. The RemoteBusy flag is set to FALSE when the local L2CAP Entity receives an RR, REJ or SREJ. When set to FALSE the local L2CAP entity considers the remote L2CAP entity able to accept I-frames. When the channel is created RemoteBusy shall be set to FALSE.

LocalBusy—when set to TRUE, LocalBusy indicates the local L2CAP entity is busy and will discard received I-frames. When set to FALSE the local L2CAP entity is not

busy and is able to receive I-frames. When the channel is created LocalBusy shall be set to FALSE.

UnackedFrames—holds the number of unacknowledged I-frames. When the channel is created UnackedFrames shall be set to 0.

UnackedList—holds the unacknowledged I-frames so they can be retransmitted if necessary. I-frames in the list are accessed via their TxSeq number. For example UnackedList[5] accesses the I-frame with TxSeq 5.

PendingFrames—holds the number of pending I-frames. I-frames passed to L2CAP from the upper layer may be unable to be sent immediately because the remote L2CAP entity's TxWindow is full, is in a busy condition or the local L2CAP is in the incorrect state. When I-frames cannot be sent they are stored in a queue until conditions allow them to be sent. When the channel is created PendingFrames shall be set to 0.

SrejList—is a list of TxSeq values for I-frames that are missing and need to be retransmitted using SREJ. A SREJ has already been sent for each TxSeq on the list. When SrejList is empty it equals 0 (i.e. SrejList = 0). If SrejList is not empty it is greater than 0 (i.e. SrejList > 0).

RetryCount—holds the number of times an S-frame operation is retried. If an operation is tried MaxTransmit times without success the channel shall be closed.

RetryIframes[ ]—holds a retry counter for each I-frame that is sent within the receiving device's TxWindow. Each time an I-frame is retransmitted the corresponding counter within RetryIframes is incremented by one. When an attempt to retransmit the I-frame is made and the counter is equal to MaxTransmit then the channel shall be closed.

RNRsent—when set to TRUE it means that the local L2CAP entity has sent an RNR frame. It is used to determine if the L2CAP entity needs to send an RR to the remote L2CAP entity to clear the busy condition. When the channel is created RNRsent shall be set to FALSE.

RejActioned—is used to prohibit a frame with F=1 from causing I-frames already retransmitted in response to a REJ from being retransmitted again. RejActioned is set to TRUE if a received REJ is actioned when a frame sent with P=1 is unanswered. When the channel is created RejActioned shall be set to FALSE.

SrejActioned—is used in conjunction with SrejSaveReqSeq to prohibit a frame with F=1 from causing an I-frame already retransmitted in response to a SREJ from being retransmitted again. SrejActioned is set to TRUE if a received SREJ is actioned when a frame sent with P=1 is unanswered. When the channel is created SrejActioned shall be set to FALSE.

SrejSaveReqSeq—is used to save the ReqSeq of a SREJ frame that causes SrejActioned to be set to TRUE.

SendRej—when set to TRUE it indicates that the local L2CAP entity has determined that a REJ should be sent in the SREJ_SENT state while processing received I-frames. The sending of new SREJ frames is stopped. When the channel is created SendRej shall be set to FALSE.

BufferSeqSrej—is used while in the SREJ_SENT state to keep track of the value to which BufferSeq will be set upon exit of the SREJ_SENT state.

FramesSent—is used to keep track of the number I-frames sent by the Send-Data and Retransmit-I-frames actions.

MaxTxWin—contains the maximum window size plus 1. It is used in TxWindow *mod* operations as the divisor and in state table conditions. This value shall be set to 16384 (0x4000) if the Extended Window Size option is used; otherwise it shall be set to 64.

RetransTimer—The Retransmission Timer is used to detect lost I-frames. When the channel is created the RetransTimer shall be off.

MonitorTimer—The Monitor Timer is used to detect lost S-frames. When the channel is created the MonitorTimer shall be off.

8.6.5.4 Events

Data-Request—The upper layer has requested that an SDU be sent. The SDU may need to be broken into multiple I-frames by L2CAP based on the MPS of the remote device and/or the maximum PDU allowed by the HCI or QoS requirements of the system.

Local-Busy-Detected—A local busy condition occurs when the local L2CAP entity is temporarily unable to receive, or unable to continue to receive, I-frames due to internal constraints. For example, the upper layer has not pulled received I-frames and the local L2CAP entity needs to send an acknowledgment to the remote L2CAP entity. The method for handling the detection of local busy is implementation specific. An implementation may wait to send an RNR to see if the busy condition will clear before the remote L2CAP entity's Retransmission timer expires. If the busy condition clears then frames can be acknowledged with an RR or I-frame. If the busy condition does not clear before the remote L2CAP entity's Retransmission timer expires then an RNR shall be sent in response to the RR or RNR poll sent by the remote L2CAP entity. Optionally an implementation may send an RNR as soon as the local busy condition is detected.

Local-Busy-Clear—The local busy condition clears when L2CAP has buffer space to receive more I-frames (i.e. SDU Reassembly function and/or upper layer has pulled I-frames) and if necessary the upper layer has cleared the busy condition.

Recv ReqSeqAndFbit—This is an event generated by the Receiver state machine. It contains the ReqSeq and F-bit value of a received frame. The value of the F-bit can be checked in a condition.

Recv Fbit—This is an event generated by the Receiver state machine. It contains the F-bit value of a received frame. The value of the F-bit can be checked in a condition.

RetransTimer-Expires—The Retransmission Timer has counted to down to 0 and stopped.

MonitorTimer-Expires—The Monitor Timer has counted down to 0 and stopped.

Recv I-frame—Receive an I-frame with any value for the F-bit.

Recv RR, REJ, RNR, SREJ (P=x) or **(F=x)**—Receive a specific S-frame (RR, REJ, etc.) with a specific value for the P and/or F bit. The F-bit and the P-bit shall not both be set to 1 in a transmitted S-frame so received S-frames with both P and F set to 1 should be ignored. If the P and/or F bit value is not specified in the event then either value is accepted.

Recv RRorRNR—Receive an RR or RNR with any value for the P-bit and F-bit.

Recv REJorSREJ—Receive an REJ or SREJ with any value for the P-bit and F-bit.

Recv frame—This is catch-all for all frames that are not explicitly declared as events in the state table.

8.6.5.5 Conditions

RemoteBusy = TRUE or FALSE—TRUE indicates the remote L2CAP entity is in a busy condition and FALSE indicates the remote L2CAP entity is not busy.

LocalBusy = TRUE or FALSE—TRUE indicates the local L2CAP entity is in a busy condition and FALSE indicates the local L2CAP entity is not busy.

RemWindow-Not-Full—The number of unacknowledged I-frames sent by L2CAP has not yet reached the TxWindow size of the remote L2CAP entity.

RemWindow-Full—The number of unacknowledged I-frames sent by the L2CAP entity has reached the TxWindow size of the remote L2CAP entity. No more I-frames shall be sent until one or more I-frames have been acknowledged.

RNRsent = TRUE or FALSE—**TRUE** indicates an RNR has been sent while a local busy condition exists. It is set to FALSE when the local busy condition clears.

F = 0 or 1—the F-bit of a received frame is checked. The F-bit of the received frame is available as part of the Recv ReqSeqAndFbit and Recv Fbit events.

RetryIframes[i] < or ≥ MaxTransmit—Compare the appropriate counter in RetryIframes after processing the ReqSeq in the receive frame to determine if it has reached MaxTransmit or not.

RetryCount < or ≥ MaxTransmit—Compare RetryCount to determine if it has reached MaxTransmit or not.

With-Expected-TxSeq—The TxSeq of a received I-frame is equal to ExpectedTxSeq.

With-Valid-ReqSeq—The ReqSeq of the received frame is in the range ExpectedAckSeq ≤ ReqSeq < NextTxSeq.

With-Valid-ReqSeq-Retrans—The ReqSeq of the received frame is in the range ExpectedAckSeq ≤ ReqSeq < NextTxSeq.

With-Valid-F-bit —The F-bit of a received frame is valid if it is 0 or if it is 1 and a frame sent with P=1 by the local L2CAP entity is unanswered (i.e. the local L2CAP entity send a frame with P=1 and has not yet received a frame with F=1 until receiving this one). If the Transmitter state machine is in the WAIT_F state then a frame sent with P=1 is unanswered.

With-unexpected-TxSeq—The TxSeq of the received I-frame is within the TxWindow of the L2CAP entity receiving the I-frame but has a TxSeq “greater” than ExpectedTxSeq where “greater” means later in sequence than ExpectedTxSeq.

With-duplicate-TxSeq—The TxSeq of the received I-frame is within the TxWindow of the L2CAP entity receiving the I-frame but has a TxSeq “less” than ExpectedTxSeq where “less” means earlier in the sequence than ExpectedTxSeq. In other words this is a frame that has already been received.

With-Invalid-TxSeq—The TxSeq of the received I-frame is not within the TxWindow of the L2CAP entity receiving the frame.

With-Invalid-ReqSeq—The ReqSeq of the received frame is not in the range ExpectedAckSeq ≤ ReqSeq < NextTxSeq.

With-Invalid-ReqSeq-Retrans—The ReqSeq of the received frame is not in the range ExpectedAckSeq ≤ ReqSeq < NextTxSeq.

Not-With-Expected-TxSeq—The TxSeq of the received I-frame is within the TxWindow of the L2CAP entity receiving the frame but is not equal to ExpectedTxSeq. It is either unexpected or a duplicate.

With-Expected-TxSeq-Srej—The TxSeq of the received I-frame is equal to the TxSeq at the head of SrejList.

SendRej = TRUE or FALSE—**TRUE** indicates that a REJ will be sent after all frames requested using SREJ have been received.

SrejList = or > 1—Determine if the number of items in SrejList is equal to or greater than 1.

With-Unexpected-TxSeq-Srej—The TxSeq of the received I-frame is equal to one of the values stored in SrejList but is not the TxSeq at the head. This indicates that one or more I-frames requested using SREJ are missing either because the SREJ was lost or the requested I-frame(s) were lost. Either way the SREJ frames must be resent to retrieve the missing I-frames.

With-duplicate-TxSeq-Srej—The TxSeq of the received I-frame is equal to a TxSeq of one of the saved I-frames indicating it is a duplicate.

8.6.5.6 Actions

Send-Data—This action is executed as a result of a Data-Request event. The number of I-frames sent without being acknowledged shall not exceed the TxWindow size of the receiving L2CAP entity (UnackedFrames is less than or equal to the remote L2CAP entity's TxWindow). Any I-frames that cannot be sent because they would exceed the TxWindow size are queued for later transmission. For each I-frame the following actions shall be carried out:

```
Send I-frame with TxSeq set to NextTxSeq and ReqSeq set to BufferSeq.
UnackedList[NextTxSeq] := I-frame
UnackedFrames := UnackedFrames + 1
FramesSent := FramesSent + 1
RetryIframes[NextTxSeq] := 1
NextTxSeq := (NextTxSeq + 1) mod MaxTxWin
Start-RetransTimer
```

Pend-Data—This action is executed as a result of a Data-Request when it is not possible to send I-frames because the window is full, the remote L2CAP entity is in a busy condition or the local L2CAP entity is not in a state where I-frames can be sent (e.g. WAIT_F). The I-frame(s) are queued for later transmission.

Process-ReqSeq—the ReqSeq contained in the received frame shall acknowledge previously transmitted I-frames. ExpectedAckSeq shall be set to ReqSeq to indicate that the I-frames with TxSeq up to and including (ReqSeq—1) have been acknowledged. The acknowledged I-frames shall be removed from UnackedList, the retry counters for each acknowledged frame shall be set to 0 and the number of acknowledged frames shall be subtracted from UnackedFrames so that UnackedFrames shall contain the number of the remaining unacknowledged I-frames. Pending I-frames are now available to be transmitted by the Send-Ack action. If UnackedFrames equals 0 then Stop-RetransTimer.

Send RR, RNR (P=x) or (F=x)—Send the specified S-frame with the specified value for the P-bit or F-bit. If a value for the P-bit or F-bit is not specified the value shall be 0. For example Send RR(P=1) means send an RR with the P-bit set to 1 and the F-bit set to 0. The ReqSeq field shall be set to BufferSeq. If an RNR is sent, RNRsent shall be set to TRUE.

Send REJ (P =x) or (F=x)—Send a REJ with the specified value for the P-bit or F-bit. The ReqSeq field shall be set to ExpectedTxSeq. If a value for the P-bit or F-bit is not specified the value shall be 0, which acknowledges previously received I-frames up to ExpectedTxSeq—1 and may allow the remote L2CAP entity to transmit new I-frames. If the local L2CAP entity is not in a position to acknowledge the previously received I-frames it may use SREJ(P=0) or RNR. It may also wait to send the REJ until it is able to acknowledge the I-frames.

Send RRorRNR (P=x) or (F=1)—Send an RR or RNR with the specified value for the P-bit or F-bit based on the value of LocalBusy. If a value for the P-bit or F-bit is not specified the value shall be 0. An RNR shall be sent if LocalBusy equals TRUE. If LocalBusy equals FALSE then an RR shall be sent.

Send IorRRorRNR(F=1)—Send I-frames, an RR or an RNR with the F-bit set to 1. The following algorithm shall be used:

```
FramesSent:=0
if LocalBusy = TRUE then {
    Send RNR(F=1)
}
if RemoteBusy = TRUE and UnackedFrames > 0 then {
    Start-RetransTimer
}
RemoteBusy := FALSE
Send-Pending-I-frames
if LocalBusy = FALSE and FramesSent = 0 then {
    Send RR(F=1)
}
```

The SendIorRRorRNR(F=1) sends frames by invoking other actions. During the execution of SendIorRRorRNR multiple actions may be invoked. The first action invoked shall send the first or only frame with the F-bit set to 1. All other frames sent shall have the F-bit set to 0.

Send SREJ—Send one or more SREJ frames with P=0. For each missing I-frame starting with ExpectedTxSeq up to but not including the TxSeq of the received I-frame, an SREJ frame is sent with ReqSeq set to the TxSeq of the missing frame. The TxSeq is inserted into the tail of SrejList. For example if ExpectedTxSeq is 3 and the received I-frame has a TxSeq of 5 there are two missing I-frames. An SREJ with ReqSeq 3 is sent followed by an SREJ with ReqSeq 4. TxSeq 3 is inserted first into SrejList followed

by TxSeq 4. After all SREJ frames have been sent ExpectedTxSeq shall be set to (the TxSeq of the received I-frame + 1) *mod* MaxTxWin.

Send SREJ(SrejList)—Send one or more SREJ frames with P=0. An I-frame was received that matches one of the TxSeq values in the SrejList but does not match the head of SrejList. This means I-frames requested via SREJ are still missing. For each TxSeq value starting with the head of SrejList and going backwards (i.e., from the head towards the tail) through the SrejList up to but not including the TxSeq of the received frame, an SREJ frame is sent with ReqSeq set to the TxSeq from SrejList. The TxSeq is removed from SrejList and reinserted into the tail of SrejList. Finally, remove the TxSeq of the received frame from the head of the list.

Send SREJ(SrejList-tail)(F=1)—Send a SREJ frame with F=1 and ReqSeq equal to the TxSeq at the tail of SrejList.

Start-RetransTimer—If the Monitor timer is not running then start the Retransmission Timer from its initial value (see Retransmission timeout in Section 5.4). If the Retransmission timer is already running it is restarted from its initial value. If the Monitor timer is running then the Retransmission timer is not started.

Start-MonitorTimer—Start the Monitor Timer from its initial value (see Monitor timeout in Section 5.4). If the timer is already running it is restarted from its initial value.

PassToTx—Pass the ReqSeq and F-bit value of a received frame to the Transmitter state machine. This will show up as a Recv ReqSeqAndFbit event in the Transmitter state machine.

PassToTxFbit—Pass the F-bit value of a received frame to the Transmitter state machine. This will show up as a Recv Fbit event in the Transmitter state machine.

Data-Indication—A received I-frame is passed to the SDU reassembly function. For the purpose of the state machine this operation is completed immediately so the Send_Ack action should be executed as one of the next actions. In some cases the SDU reassembly function cannot accept the I-frame so the I-frame will be stored within the L2CAP Entity consuming a portion of its TxWindow. When the I-frame is pulled by the SDU reassembly function the Send_Ack action should be executed. Before the Send_Ack action is executed BufferSeq is advanced as follows:

```
BufferSeq := (BufferSeq + 1) mod MaxTxWin
```

Increment-ExpectedTxSeq—ExpectedTxSeq is incremented as follows:

```
ExpectedTxSeq := (ExpectedTxSeq + 1) mod MaxTxWin
```

Stop-RetransTimer—the Retransmission timer is stopped.

Stop-MonitorTimer —the Monitor timer is stopped.

Send-Ack (F=x)—an acknowledgment with the specified value for the F-bit may be sent. This action may occur in an action block with other actions that also send frames. If a frame has already been sent then it is not necessary to send additional frames.

If the value for the F-bit is not specified it shall be set to 0. If the value specified is P then the F-bit shall be set equal to the value of the P-bit of the received frame being acknowledged. If more than one frame is sent in the acknowledgment only the first frame shall have an F-bit set to 1. An acknowledgment is an RR, RNR, or pending I-frame(s) (I-frames that have not been transmitted yet). If pending I-frames are available and are allowed to be sent then as many as allowed should be sent as an acknowledgment. Sending an RR or RNR as an acknowledgment for each received I-frame is not required. An implementation may wait to send an RR or RNR until a specific number of I-frames have been received, after a certain period of time has elapsed or some other algorithm. To keep data flowing it is recommended that an acknowledgment be sent before the TxWindow is full. It should also be noted that the maximum size of a remote L2CAP entity's unacknowledged I-frame list may be smaller than the local L2CAP entity's TxWindow. Therefore the local L2CAP entity should not expect the remote L2CAP entity to send enough frames to fill its TxWindow and should acknowledge I-frames accordingly.

The following algorithm shall be used when sending an acknowledgment.

```
if LocalBusy == TRUE then {
    Send_RNR(F=x)
}
else if (RemoteBusy == FALSE) and Pending I-frames Exist and RemWindow-
Not-Full then {
    Send-Pending-I-frames (F=x)
}
else {
    Send_RR (F=x)
}
```

InitSrej—Initialize the variables used for processing SREJ as follows:

```
Clear SrejList - (remove all values)
SendRej := FALSE
BufferSeqSrej := BufferSeq
```

SaveIframeSrej—Save the received I-frame. Missing I-frame(s) will be retransmitted in response to SREJ frames. Implementations may want to save the I-frame in its proper sequence order by leaving room for the missing I-frames.

StoreOrIgnore—If the local L2CAP entity has room to store the received I-frame then it may store it otherwise it shall discard it. If the received I-frame is stored, ExpectedTxSeq is advanced as follows:

```
ExpectedTxSeq := (ExpectedTxSeq + 1) mod MaxTxWin
```

PbitOutstanding—If the Transmitter state machine of the local L2CAP entity is in the WAIT_F state then return TRUE otherwise return FALSE.

Retransmit-I-frames—All the unacknowledged I-frames starting with the I-frame with TxSeq equal to the ReqSeq field of the received S-frame (REJ or RR) is retransmitted. If the P-bit of the received S-frame is 1 then the F-bit of the first I-frame sent shall be 1. If the P-bit of the received S-frame is 0 then the F-bit of the first I-frame sent shall be 0. The F-bit of all other unacknowledged I-frames sent shall be 0. The retry counter in RetryIframes[ ] for each retransmitted I-frame is incremented by 1. If a retry counter in RetryIframes[ ] is equal to MaxTransmit then the channel shall be closed. FramesSent shall be incremented by 1 for each frame sent. If the RetransTimer is not already running then perform the Start-RetransTimer action.

Retransmit-Requested-I-frame—The unacknowledged I-frame with TxSeq equal to the ReqSeq field of the received S-frame (SREJ) is retransmitted. If the P-bit of the received S-frame is 1 then the F-bit of the retransmitted I-frame shall be 1. If the P-bit of the received S-frame is 0 then the F-bit of the retransmitted I-frame shall be 0. The retry counter in RetryIframes[ ] corresponding to the retransmitted I-frame is incremented by 1. If the RetransTimer is not already running then perform the Start-RetransTimer action.

Send-Pending-I-frames (F=x)—If PbitOutstanding equals FALSE then send all pending I-frames that can be sent without exceeding the receiver's TxWindow using the Send-Data action. If a value for the F-bit is specified then the F-bit of the first I-frame sent shall be set to the specified value and the F-bit of all other I-frames sent shall be set to 0. If no value for the F-bit is specified then all I-frames sent shall have the F-bit set to 0. Pending I-frames are I-frames that have been given to the L2CAP entity by the upper layer but have not yet been transmitted. If one or more I-frames are sent and the RetransTimer is not already running then perform the Start-RetransTimer action.

Close Channel—Close the L2CAP channel as described in Section 4.6.

Ignore—Silently discard the event.

CloseChannelOrIgnore—Either close the L2CAP channel as described in Section 4.6 (in which case the next state is ignored) or silently discard the event.

PopSrejList—Remove and discard the TxSeq from the head of SrejList.

Data-IndicationSrej—If the received I-frame fills a gap in a sequence of saved I-frames then all the saved I-frames in the sequence are passed to the SDU reassembly function. For the purpose of the state machine this operation is completed immediately. For example if the TxSeq of saved I-frames before receiving an I-frame is 2, 3, 5, 6, 9 and the received I-frame has a TxSeq of 4 then it fills the gap between 3 and 5 so the sequence 2, 3, 4, 5, 6 can be passed to the SDU reassembly function. When the I-frames are actually removed from the L2CAP entity receive buffers either by being processed immediately or when pulled by the SDU reassembly function, BufferSeqSrej is advanced as follows:

```
BufferSeqSrej := (BufferSeqSrej + 1) mod MaxTxWin
```

Table 8.7: SREJ_SENT state table

8.7 Streaming mode

When a link is configured to work in Streaming mode, the frame format for outgoing data is the same as for Enhanced Retransmission mode but frames are not acknowledged. Therefore

- RR, REJ, RNR and SREJ frames shall not be used in Streaming mode.
- The F-bit shall always be set to zero in the transmitter, and shall be ignored in the receiver.
- the MonitorTimer and RetransmissionTimer shall not be used in Streaming mode.

A channel configured to work in Streaming mode shall be configured with a finite value for the Flush Timeout on the transmitter.

8.7.1 Transmitting I-frames

When transmitting a new I-frame the control field parameter ReqSeq shall be set to 0, TxSeq shall be set to NextTxSeq, and NextTxSeq shall be incremented by one.

8.7.2 Receiving I-frames

Upon receipt of a valid I-frame with TxSeq equal to ExpectedTxSeq, the frame shall be made available to the reassembly function. ExpectedTxSeq shall be incremented by one.

Upon receipt of a valid I-frame with an out-of-sequence TxSeq (see Section 8.7.3.1) all frames with a sequence number less than TxSeq shall be assumed lost and marked as missing. The missing I-frames are in the range from ExpectedTxSeq (the frame that the device was expecting to receive) up to and including TxSeq - 1. ExpectedTxSeq shall be set to TxSeq +1. The received I-frame shall be made available for pulling by the reassembly function. The ReqSeq shall be ignored.

Note: It is possible for a complete window size of I-frames to be missing and thus, no missing I-frames are detected. For example, when a window size of 63 is used this situation occurs when 63 I-frames in a row are missing. If the ability to not detect missing I-frames will cause problems for an application, it is recommended that the Extended Window Size option be used.

If there is no buffer space for the received I-frame an existing I-frame (i.e. the oldest) shall be discarded (flushed) freeing up buffer space for the new I-frame. The discarded I-frame shall be marked as missing.

8.7.3 Exception conditions

Exception conditions may occur as the result of physical layer errors or L2CAP procedural errors. The error recovery procedures which are available following the detection of an exception condition at the L2CAP layer in Streaming mode are defined in this section.

8.7.3.1 TxSeq sequence error

A TxSeq sequence error exception condition occurs in the receiver when a valid I-frame is received which contains a TxSeq value which is not equal to the expected value, thus TxSeq is not equal to ExpectedTxSeq.

The out-of-sequence I-frame is identified by a TxSeq that is greater than ExpectedTxSeq (TxSeq > ExpectedTxSeq). The ReqSeq shall be ignored. The missing I-frame(s) are considered lost and ExpectedTxSeq is set equal to TxSeq+1 as specified in Section 8.7.2. The missing I-frame(s) are reported as lost to the SDU reassembly function.

9 [THIS SECTION IS NO LONGER USED]

10 PROCEDURES FOR CREDIT BASED FLOW CONTROL

There are two credit-based flow control modes: LE Credit Based Flow Control mode and Enhanced Credit Based Flow Control mode.

10.1 LE Credit Based Flow Control mode

LE Credit Based Flow Control mode is used for LE L2CAP connection-oriented channels with flow control using a credit based scheme for L2CAP data (i.e. not signaling packets).

The number of credits (K-frames) that can be received by a device on an L2CAP channel is determined during connection establishment. K-frames shall only be sent on an L2CAP channel if the device has a credit count greater than zero for that L2CAP channel. For each K-frame sent the device decreases the credit count for that L2CAP channel by one. The peer device may return credits for an L2CAP channel at any time by sending an L2CAP_FLOW_CONTROL_CREDIT_IND packet. When a credit packet is received by a device it shall increment the credit count for that L2CAP channel by the value of the Credits field in this packet. The number of credits returned for an L2CAP channel may exceed the initial credits provided in the L2CAP_LE_CREDIT_BASED_CONNECTION_REQ or L2CAP_LE_CREDIT_BASED_CONNECTION_RSP packet. The device sending the L2CAP_FLOW_CONTROL_CREDIT_IND packet shall ensure that the number of credits returned for an L2CAP channel does not cause the credit count to exceed 65535. The device receiving the credit packet shall disconnect the L2CAP channel if the credit count exceeds 65535. The device shall also disconnect the L2CAP channel if it receives a K-frame on an L2CAP channel from the peer device that has a credit count of zero. If a device receives an L2CAP_FLOW_CONTROL_CREDIT_IND packet with credit value set to zero, the packet shall be ignored. A device shall not send credit values of zero in L2CAP_FLOW_CONTROL_CREDIT_IND packets.

If an L2CAP_LE_CREDIT_BASED_CONNECTION_REQ packet is received and there is insufficient authentication between the two devices, the connection shall be rejected with a result value of “Connection refused - insufficient authentication”. If an L2CAP_LE_CREDIT_BASED_CONNECTION_REQ packet is received and there is insufficient authorization between the two devices, the connection shall be rejected with a result value of “Connection refused - insufficient authorization”. If an L2CAP_LE_CREDIT_BASED_CONNECTION_REQ packet is received and the encryption key size is too short, the connection shall be rejected with a result value of “Connection refused – insufficient encryption key size”.

Note: When encryption is not enabled, the result value “Connection refused – insufficient authentication” does not indicate that MITM protection is required.

10.2 Enhanced Credit Based Flow Control Mode

Enhanced Credit Based Flow Control mode is used for L2CAP connection-oriented channels on LE and BR/EDR with flow control using a credit-based scheme for L2CAP data (i.e. not signaling packets). The ACL logical transport shall have an infinite Automatic Flush Timeout.

The number of credits (K-frames) that can be received by a device on an L2CAP channel is determined during connection establishment. K-frames shall only be sent on an L2CAP channel if the device has a credit count greater than zero for that L2CAP channel. For each K-frame sent, the sending device shall decrease the credit count for that L2CAP channel by one. The peer device may return credits for an L2CAP channel at any time by sending an L2CAP_FLOW_CONTROL_CREDIT_IND packet. When a credit packet is received by a device, it shall increment the credit count for that L2CAP channel by the value of the Credits field in this packet. The number of credits returned for an L2CAP channel may exceed the initial credits provided in the L2CAP_CREDIT_BASED_CONNECTION_REQ or L2CAP_CREDIT_BASED_CONNECTION_RSP packet. The device sending the L2CAP_FLOW_CONTROL_CREDIT_IND packet shall ensure that the number of credits returned for an L2CAP channel does not cause the credit count to exceed 65535. The device receiving the credit packet shall disconnect the L2CAP channel if the credit count exceeds 65535. The device shall also disconnect the L2CAP channel if it receives a K-frame on an L2CAP channel from the peer device that has a credit count of zero. If a device receives an L2CAP_FLOW_CONTROL_CREDIT_IND packet with credit value set to zero, the packet shall be ignored. A device shall not send credit values of zero in L2CAP_FLOW_CONTROL_CREDIT_IND packets.

This paragraph applies if an L2CAP_CREDIT_BASED_CONNECTION_REQ packet is received on the LE transport. If there is insufficient authentication between the two devices, the connection shall be rejected with a result value of “All connections refused - insufficient authentication”. If there is insufficient authorization between the two devices, the connection shall be rejected with a result value of “All connections refused - insufficient authorization”. If the encryption key size is too short, the connection shall be rejected with a result value of “All connections refused - insufficient encryption key size”.

Note: When encryption is not enabled, the result value “All connections refused - insufficient authentication” does not indicate that MITM protection is required.

See [Vol 3] Part C, Section 5.2.2 for the requirements for responding to a received L2CAP_CREDIT_BASED_CONNECTION_REQ packet.

Appendix A Configuration MSCs

The examples in this appendix describe a sample of the multiple possible configuration scenarios that might occur.

Figure A.1 illustrates the basic configuration process. In this example, the devices exchange MTU information. All other options are set to their default values.

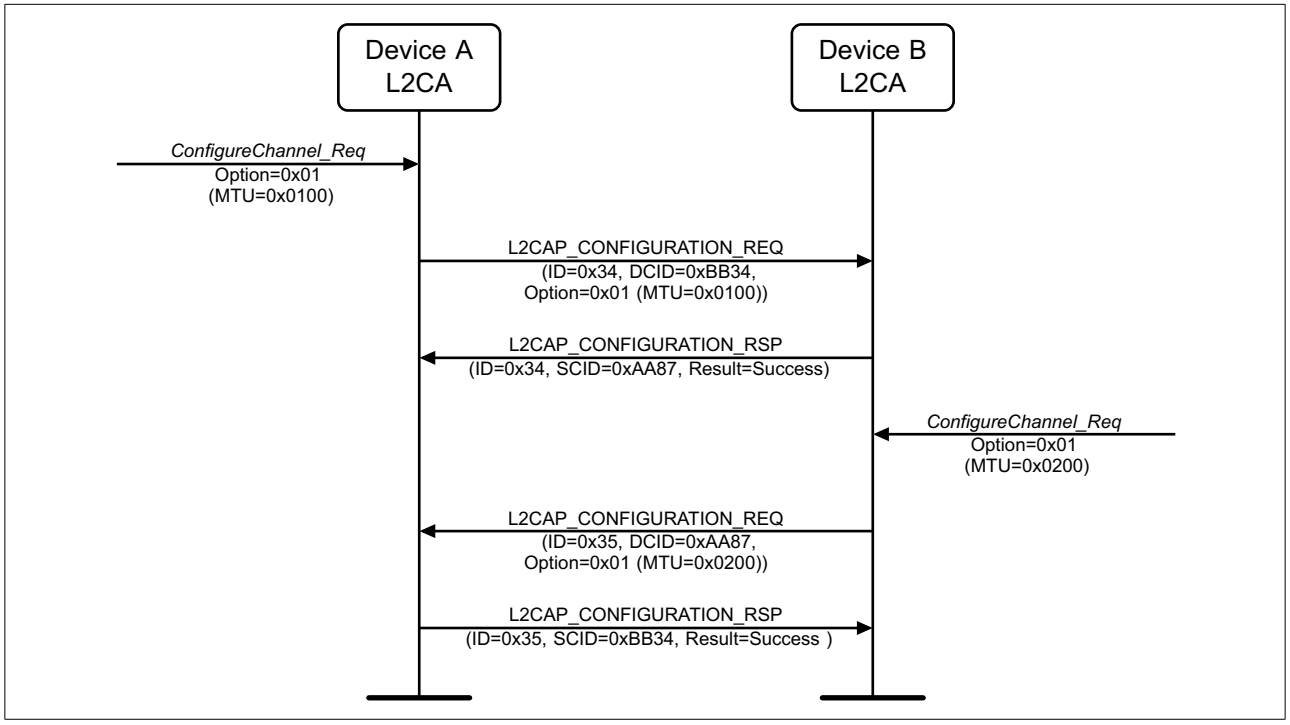

Figure A.1: Basic MTU exchange

Figure A.2 illustrates how two devices interoperate even though one device supports more options than the other does. Device A is an upgraded version. It uses a (hypothetical) option type 0x20. Device B rejects the command using the L2CAP_CONFIGURATION_RSP packet with result ‘unknown parameter’ informing Device A that option 0x20 is not understood. Device A then resends the request omitting option 0x20. As well as accepting this, Device B notices that it does not need such a large MTU and accepts the request but includes in the response the MTU option informing Device A that Device B will not send an L2CAP packet with a payload larger than 0x80 octets over this channel. On receipt of the response, Device A could reduce the buffer allocated to hold incoming traffic.

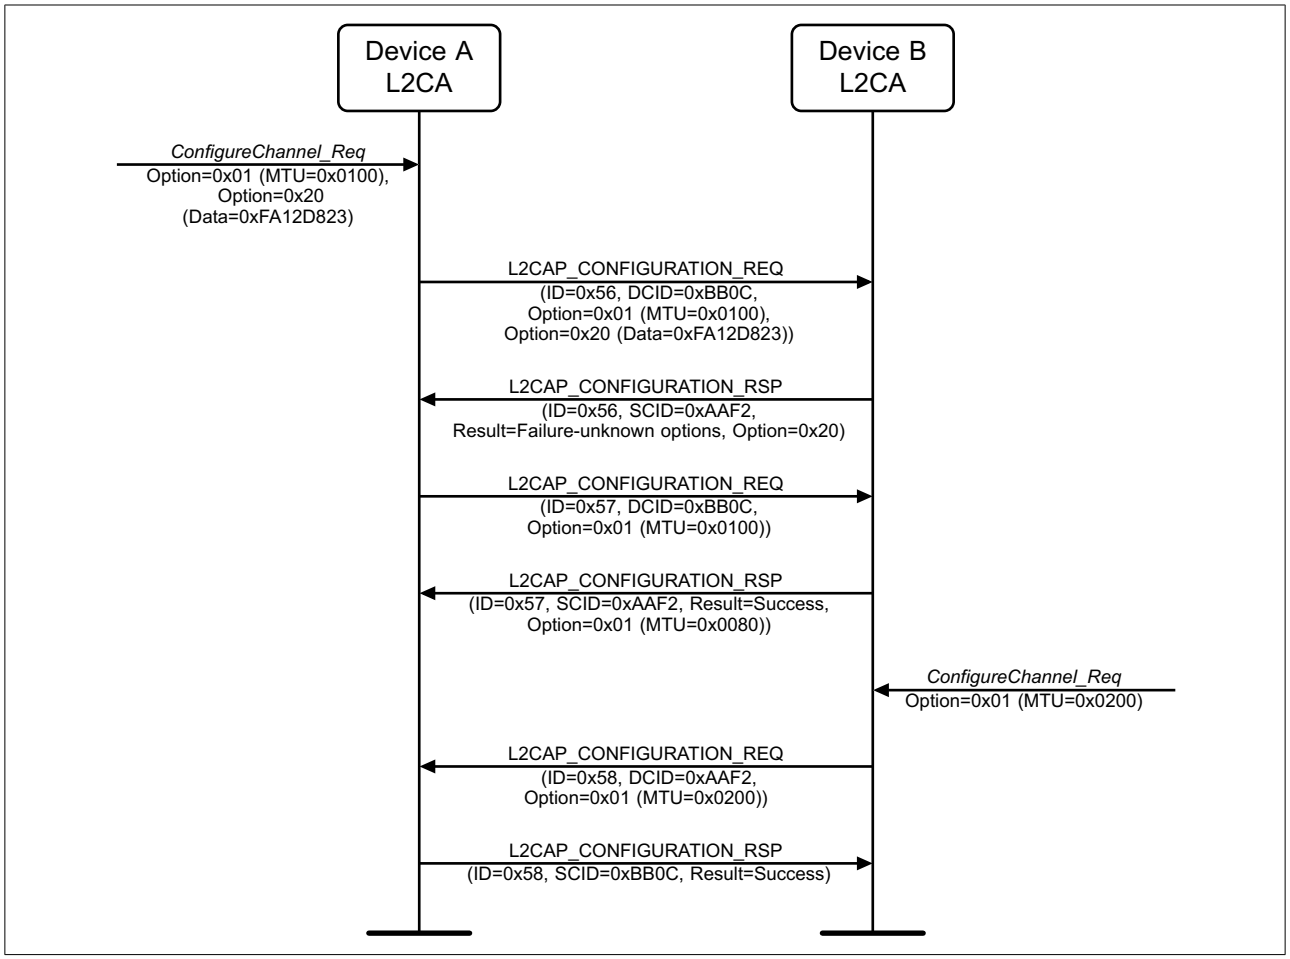

Figure A.2: Dealing with unknown options

Figure A.3 illustrates an unsuccessful configuration request. There are two problems described by this example. The first problem is that Device A has placed the configuration request in an L2CAP packet that is too big to be accepted by Device B. Device B informs Device A of this problem using the L2CAP_COMMAND_REJECT_RSP message. Device A then resends the configuration options using two smaller L2CAP_CONFIGURATION_REQ messages. This exposes the second problem, which is that Device B has no open connection on CID 0x6A67. Again, Device B informs Device A of this problem using the L2CAP_COMMAND_REJECT_RSP message.

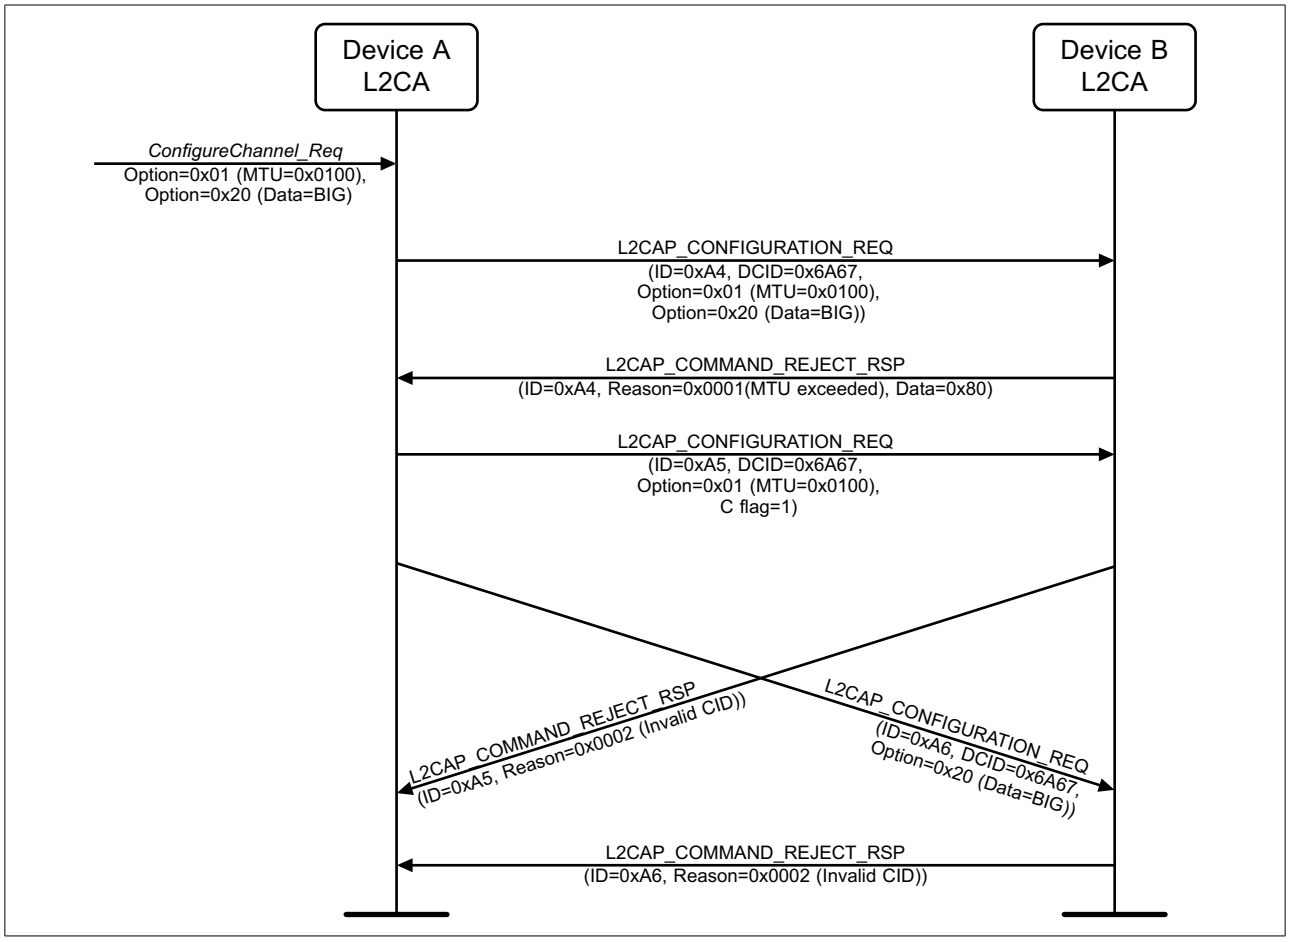

Figure A.3: Unsuccessful configuration request

Appendix B Changes to signaling packet names

Previous versions of this specification used different names for the signalling packets defined in Section 4. Table B.1 shows the previous and current names of these packets.

Previous name	Current name
Command reject	L2CAP_COMMAND_REJECT_RSP
Configuration request	L2CAP_CONFIGURATION_REQ
Configuration response	L2CAP_CONFIGURATION_RSP
Connection Parameter Update request	L2CAP_CONNECTION_PARAMETER_UPDATE_REQ
Connection Parameter Update response	L2CAP_CONNECTION_PARAMETER_UPDATE_RSP
Connection request	L2CAP_CONNECTION_REQ
Connection response	L2CAP_CONNECTION_RSP
Disconnection request	L2CAP_DISCONNECTION_REQ
Disconnection response	L2CAP_DISCONNECTION_RSP
Echo request	L2CAP_ECHO_REQ
Echo response	L2CAP_ECHO_RSP
Information request	L2CAP_INFORMATION_REQ
Information response	L2CAP_INFORMATION_RSP
LE Credit Based Connection request	L2CAP_LE_CREDIT_BASED_CONNECTION_REQ
LE Credit Based Connection response	L2CAP_LE_CREDIT_BASED_CONNECTION_RSP
LE Flow Control Credit	L2CAP_FLOW_CONTROL_CREDIT_IND

Table B.1: Changes to signaling packet names

Host
Part B

SERVICE DISCOVERY PROTOCOL (SDP) SPECIFICATION

This Part defines a protocol for locating services provided by or available through a Bluetooth device.

CONTENTS

1 INTRODUCTION

1.1 General description

The Service Discovery protocol (SDP) provides a means for applications to discover which services are available and to determine the characteristics of those available services.

1.2 [This section is no longer used]

1.3 [This section is no longer used]

1.4 [This section is no longer used]

1.5 Conventions

1.5.1 Bit and byte ordering conventions

When multiple bit fields are contained in a single byte and represented in a drawing in this Part, the more significant (high-order) bits are shown toward the left and less significant (low-order) bits toward the right.

Multiple-byte fields are drawn with the more significant bytes toward the left and the less significant bytes toward the right. Multiple-byte fields are transferred in network byte order. See Section 4.1.

2 OVERVIEW

2.1 SDP Client-Server architecture

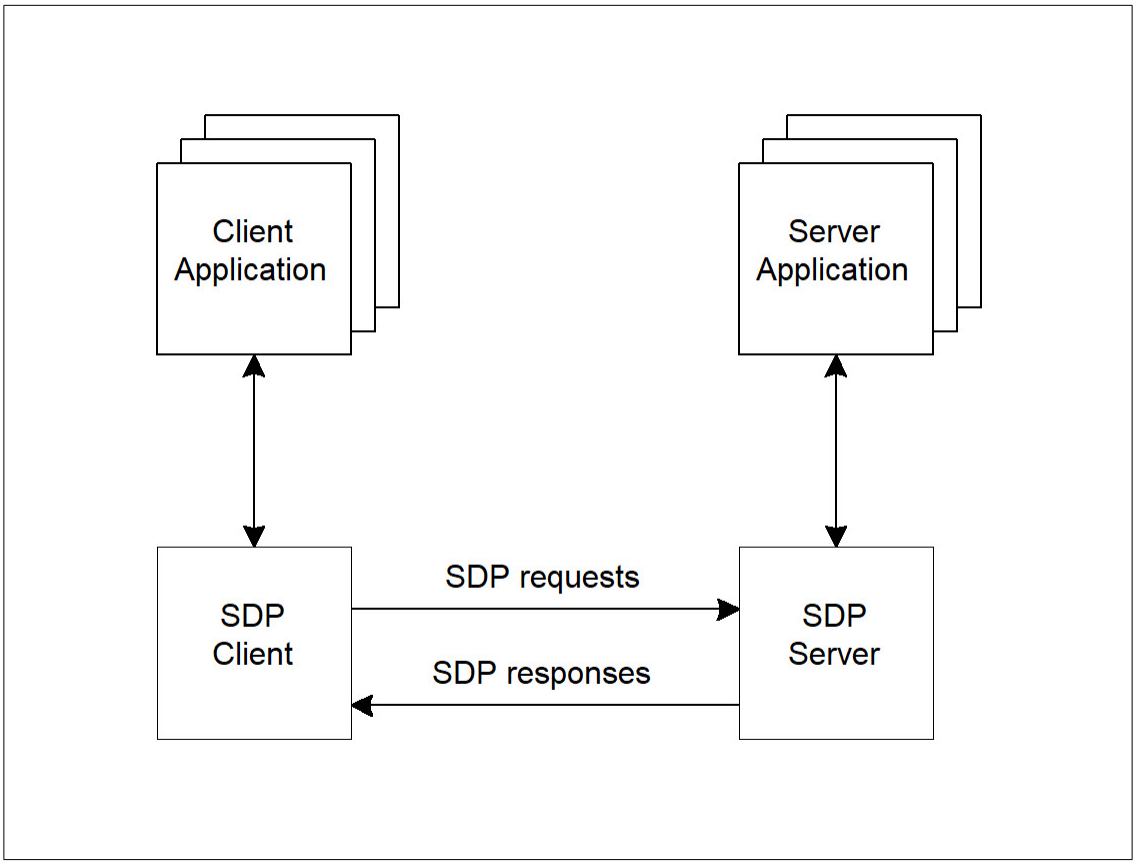

Figure 2.1: SDP Client-Server interaction

The service discovery mechanism provides the means for client applications to discover the existence of services provided by server applications as well as the attributes of those services. The attributes of a service include the type or class of service offered and the mechanism or protocol information needed to utilize the service.

From the perspective of the Service Discovery Protocol (SDP), the configuration shown in Figure 2.1 can be simplified to that shown in Figure 2.2.

Figure 2.2: Simplified SDP Client-Server interaction

SDP involves communication between an SDP Server and an SDP Client. The server maintains an SDP database which consists of a list of service records that describe the characteristics of services associated with the server. Each service record contains information about a single service. A client can retrieve information from a service record maintained by the SDP Server by issuing an SDP request.

If the client, or an application associated with the client, decides to use a service, it opens a separate connection to the service provider in order to utilize the service. SDP provides a mechanism for discovering services and their attributes (including associated service access protocols), but it does not provide a mechanism for utilizing those services (such as delivering the service access protocols).

If multiple applications on a device provide services, an SDP Server can act on behalf of those service providers to handle requests for information about the services that they provide. Similarly, multiple client applications can utilize an SDP Client to query servers on behalf of the client applications.

The set of SDP Servers that are available to an SDP Client will change dynamically based on the RF proximity of the servers to the client. When a server becomes available, a potential client must be notified by a means other than SDP so that the client can use SDP to query the server about its services. Similarly, when a server leaves proximity or becomes unavailable for any reason, there is no explicit notification via the Service Discovery protocol. However, the client can use SDP to poll the server and may infer that the server is not available if it no longer responds to requests.

Additional information regarding application interaction with SDP shall be contained in the Bluetooth Service Discovery Profile document.

2.2 Service record

A service is any entity that can provide information, perform an action, or control a resource on behalf of another entity. A service may be implemented as software, hardware, or a combination of hardware and software.

All of the information about a service that is maintained by an SDP Server is contained within a single service record. The service record shall only be a list of service attributes.

A service record handle is a 32-bit number that shall uniquely identify each service record within an SDP Server. In general, each handle is unique only within each SDP Server. If SDP Server S1 and SDP Server S2 both contain identical service records (representing the same service), the service record handles used to reference these identical service records are completely independent. The handle used to reference the service on S1 will be meaningless if presented to S2.

The Service Discovery protocol does not provide a mechanism for notifying clients when service records are added to or removed from an SDP Server. While an L2CAP (Logical Link Control and Adaptation Protocol) connection is established to a server, a service record handle acquired from the server shall remain valid unless the service record it represents is removed. If a service is removed from the server, further requests to the server (during the L2CAP connection in which the service record handle was acquired) using the service's (now stale) record handle shall result in an error response indicating an invalid service record handle. An SDP Server shall ensure that no service record handle values are re-used while an L2CAP connection remains established. Service record handles shall remain valid across successive L2CAP connections while the ServiceDatabaseState attribute value remains unchanged. Further, service record handles should remain valid until such time that the corresponding service is permanently removed or changes in an incompatible way. See the ServiceRecordState and ServiceDatabaseState attributes in Section 5.

A device may have a service record with a service record handle of 0x00000000 representing the SDP Server itself. This service record contains attributes for the SDP Server and the protocol it supports. For example, one of its attributes is the list of SDP protocol versions supported by the server.

2.3 Service attribute

Each service attribute describes a single characteristic of a service. Some examples of service attributes are given in Table 2.1.

ServiceClassIDList	Identifies the type of service represented by a service record. In other words, the list of classes of which the service is an instance
ServiceID	Uniquely identifies a specific instance of a service
ProtocolDescriptorList	Specifies the protocol stack(s) that may be used to utilize a service
ProviderName	The textual name of the individual or organization that provides a service
IconURL	Specifies a URL that refers to an icon image that may be used to represent a service

ServiceName	A text string containing a human-readable name for the service
ServiceDescription	A text string describing the service

Table 2.1: Example service attributes

See Section 5.1 for attribute definitions that are common to all service records. Service providers can also define their own service attributes.

A service attribute consists of two components: an attribute ID and an attribute value.

2.3.1 Attribute ID

An attribute ID is a 16-bit unsigned integer that distinguishes each service attribute from other service attributes within a service record. The attribute ID also identifies the semantics of the associated attribute value.

A service class definition specifies each of the attribute IDs for a service class and assigns a meaning to the attribute value associated with each attribute ID. Each attribute ID is defined to be unique only within each service class.

All services belonging to a given service class assign the same meaning to each particular attribute ID. See Section 2.4.

In the Service Discovery protocol, an attribute ID is represented as a data element. See Section 3.

2.3.2 Attribute value

The attribute value is a variable length field whose meaning is determined by the attribute ID associated with it and by the service class of the service record in which the attribute is contained. In the Service Discovery protocol, an attribute value is represented as a data element. (See Section 3.) Generally, any type of data element is permitted as an attribute value, subject to the constraints specified in the service class definition that assigns an attribute ID to the attribute and assigns a meaning to the attribute value. See Section 5, for attribute value examples.

2.4 Service class

Each service is an instance of a service class. The service class definition provides the definitions of all attributes contained in service records that represent instances of that class. Each attribute definition specifies the numeric value of the attribute ID, the intended use of the attribute value, and the format of the attribute value. A service record contains attributes that are specific to a service class as well as universal attributes that are common to all services.

Each service class is also assigned a unique identifier. This service class identifier is contained in the attribute value for the ServiceClassIDList attribute, and is represented

as a UUID (see Section 2.5.1). Since the format and meanings of many attributes in a service record are dependent on the service class of the service record, the ServiceClassIDList attribute is very important. Its value shall be examined or verified before any class-specific attributes are used. Since all of the attributes in a service record must conform to all of the service's classes, the service class identifiers contained in the ServiceClassIDList attribute are related. Typically, each service class is a subclass of another class whose identifier is contained in the list. A service subclass definition differs from its superclass in that the subclass contains additional attribute definitions that are specific to the subclass.

When a new service class is defined that is a subclass of an existing service class, the new service class retains all of the attributes defined in its superclass. Additional attributes may be defined that are specific to the new service class. In other words, the mechanism for adding new attributes to some of the instances of an existing service class is to create a new service class that is a subclass of the existing service class.

If a Service Class UUID is exposed in the SDP database of a product, then the product containing the SDP record shall comply with the specification which defines the service corresponding to the UUID.

2.4.1 A printer service class example

A color postscript printer with duplex capability might conform to 4 ServiceClass definitions and have a ServiceClassIDList with UUIDs (See Section 2.5.1.) representing the following ServiceClasses:

DuplexColorPostscriptPrinterServiceClassID,
ColorPostscriptPrinterServiceClassID,
PostscriptPrinterServiceClassID,
PrinterServiceClassID

This example is only illustrative. This is not necessarily a practical printer class hierarchy.

2.5 Searching for services

The Service Search transaction allows a client to retrieve the service record handles for particular service records based on the values of attributes contained within those service records. Once an SDP Client has a service record handle, it can request the values of specific attributes.

The capability search for service records based on the values of arbitrary attributes is not provided. Rather, the capability is provided to search only for attributes whose

values are Universally Unique Identifiers[1] (UUIDs). Important attributes of services that can be used to search for a service are represented as UUIDs.

2.5.1 UUID

A UUID is a universally unique identifier that is expected to be unique across all space and all time (more precisely, the probability of independently-generated UUIDs being the same is negligible). UUIDs can be independently created in a distributed fashion. No central registry of assigned UUIDs is required. A UUID is a 128-bit value.

To reduce the burden of storing and transferring 128-bit UUID values, a range of UUID values has been pre-allocated for assignment to often-used, registered purposes. The first UUID in this pre-allocated range is known as the Bluetooth_Base_UUID and has the value 00000000-0000-1000-8000-00805F9B34FB. UUID values in the pre-allocated range have aliases that are represented as 16-bit or 32-bit values. These aliases are often called 16-bit and 32-bit UUIDs, but each actually represents a 128-bit UUID value.

The full 128-bit value of a 16-bit or 32-bit UUID may be computed by a simple arithmetic operation.

$128\_bit\_value = 16\_bit\_value \times 2^{96} + Bluetooth\_Base\_UUID$

$128\_bit\_value = 32\_bit\_value \times 2^{96} + Bluetooth\_Base\_UUID$

A 16-bit UUID may be converted to 32-bit UUID format by zero-extending the 16-bit value to 32-bits. An equivalent method is to add the 16-bit UUID value to a zero-valued 32-bit UUID.

Note: Two 16-bit UUIDs may be compared directly, as may two 32-bit UUIDs or two 128-bit UUIDs. If two UUIDs of differing sizes are to be compared, the shorter UUID must be converted to the longer UUID format before comparison.

2.5.2 Service search patterns

A service search pattern is a list of UUIDs used to locate matching service records. A service search pattern matches a service record if each and every UUID in the service search pattern is contained within any of the service record's attribute values. The UUIDs need not be contained within any specific attributes or in any particular order within the service record. The service search pattern matches if the UUIDs it contains constitute a subset of the UUIDs in the service record's attribute values. The only time a service search pattern does not match a service record is if the service search pattern contains at least one UUID that is not contained within the service record's attribute values. A valid service search pattern shall contain at least one UUID.

[1]The format of UUIDs is specified in ITU-T Rec. X.667(10/2012), alternatively known as ISO/IEC 9834-8:2014.

2.6 Browsing for services

Normally, a client searches for services based on some desired characteristic(s) (represented by a UUID) of the services. However, there are times when it is desirable to discover which types of services are described by an SDP Server's service records without any a priori information about the services. This process of looking for any offered services is termed browsing. In SDP, the mechanism for browsing for services is based on an attribute shared by all service classes. This attribute is called the BrowseGroupList attribute. The value of this attribute contains a list of UUIDs. Each UUID represents a browse group with which a service may be associated for the purpose of browsing.

When a client desires to browse an SDP Server's services, it creates a service search pattern containing the UUID that represents the root browse group. All services that may be browsed at the top level are made members of the root browse group by having the root browse group's UUID as a value within the BrowseGroupList attribute.

Normally, if an SDP Server has relatively few services, all of its services will be placed in the root browse group. However, the services offered by an SDP Server may be organized in a browse group hierarchy, by defining additional browse groups below the root browse group. Each of these additional browse groups is described by a service record with a service class of BrowseGroupDescriptor.

A browse group descriptor service record defines a new browse group by means of its Group ID attribute. In order for a service contained in one of these newly defined browse groups to be browseable, the browse group descriptor service record that defines the new browse group must in turn be browseable. The hierarchy of browseable services that is provided by the use of browse group descriptor service records allows the services contained in an SDP Server to be incrementally browsed and is particularly useful when the SDP Server contains many service records.

2.6.1 Example service browsing hierarchy

Figure 2.3 illustrates a fictitious service browsing hierarchy that illuminates the manner in which browse group descriptors are used. Browse group descriptor service records are identified with (G); other service records with (S).

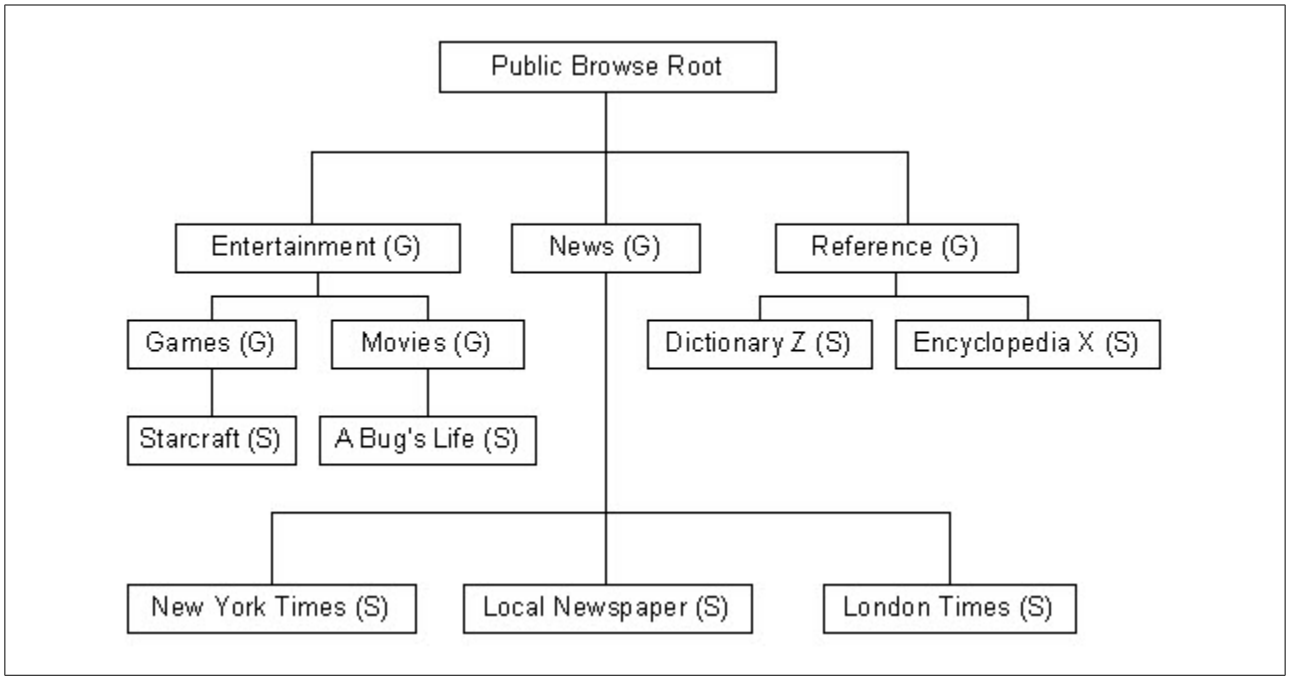

Figure 2.3: Service browsing hierarchy

Table 2.2 shows the services records and service attributes necessary to implement the browse hierarchy.

Service Name	Service Class	Attribute Name	Attribute Value
Entertainment	BrowseGroupDescriptor	BrowseGroupList	PublicBrowseRoot
		GroupID	EntertainmentID
News	BrowseGroupDescriptor	BrowseGroupList	PublicBrowseRoot
		GroupID	NewsID
Reference	BrowseGroupDescriptor	BrowseGroupList	PublicBrowseRoot
		GroupID	ReferenceID
Games	BrowseGroupDescriptor	BrowseGroupList	EntertainmentID
		GroupID	GamesID
Movies	BrowseGroupDescriptor	BrowseGroupList	EntertainmentID
		GroupID	MoviesID
Starcraft	Video Game Class ID	BrowseGroupList	GamesID
A Bug's Life	Movie Class ID	BrowseGroupList	MovieID
Dictionary Z	Dictionary Class ID	BrowseGroupList	ReferenceID
Encyclopedia X	Encyclopedia Class ID	BrowseGroupList	ReferenceID
New York Times	Newspaper ID	BrowseGroupList	NewspaperID

Service Name	Service Class	Attribute Name	Attribute Value
London Times	Newspaper ID	BrowseGroupList	NewspaperID
Local Newspaper	Newspaper ID	BrowseGroupList	NewspaperID

Table 2.2: Service browsing hierarchy

3 DATA REPRESENTATION

Attribute values can contain information of various types with arbitrary complexity; thus enabling an attribute list to be generally useful across a wide variety of service classes and environments.

SDP defines a simple mechanism to describe the data contained within an attribute ID, attribute ID range, and attribute value. The primitive construct used is the data element.

3.1 Data element

A data element is a typed data representation. It consists of two fields: a header field and a data field. The header field, in turn, is composed of two parts: a type descriptor and a size descriptor. The data is a sequence of bytes whose length is specified in the size descriptor (described in Section 3.3) and whose meaning is (partially) specified by the type descriptor.

3.2 Data element type descriptor

A data element type is represented as a 5-bit type descriptor. The type descriptor is contained in the most significant (high-order) 5 bits of the first byte of the data element header. The following types have been defined.

Type Descriptor Value	Valid Size Descriptor Values	Type Description
0	0	Nil, the null type
1	0, 1, 2, 3, 4	Unsigned integer
2	0, 1, 2, 3, 4	Signed integer
3	1, 2, 4	UUID, a universally unique identifier
4	5, 6, 7	Text string
5	0	Boolean (see below)
6	5, 6, 7	Data element sequence, a data element whose data field is a sequence of data elements
7	5, 6, 7	Data element alternative, data element whose data field is a sequence of data elements from which one data element is to be selected.
8	5, 6, 7	URL, a uniform resource locator
Other		Reserved for future use

Table 3.1: Data element

For the boolean type, false shall be represented by the value 0 and true shall be represented by the value 1. Any other value received shall be accepted as representing true.

3.3 Data element size descriptor

The data element size descriptor is represented as a 3-bit size index followed by 0, 8, 16, or 32 bits. The size index is contained in the least significant (low-order) 3 bits of the first byte of the data element header. The size index is encoded as follows.

Size Index	Additional bits	Data Size
0	0	1 byte. Exception: if the data element type is nil, the data size is 0 bytes.
1	0	2 bytes
2	0	4 bytes
3	0	8 bytes
4	0	16 bytes
5	8	The data size is contained in the additional 8 bits, which are interpreted as an unsigned integer.
6	16	The data size is contained in the additional 16 bits, which are interpreted as an unsigned integer.
7	32	The data size is contained in the additional 32 bits, which are interpreted as an unsigned integer.

Table 3.2: Data element size

3.4 Data element examples

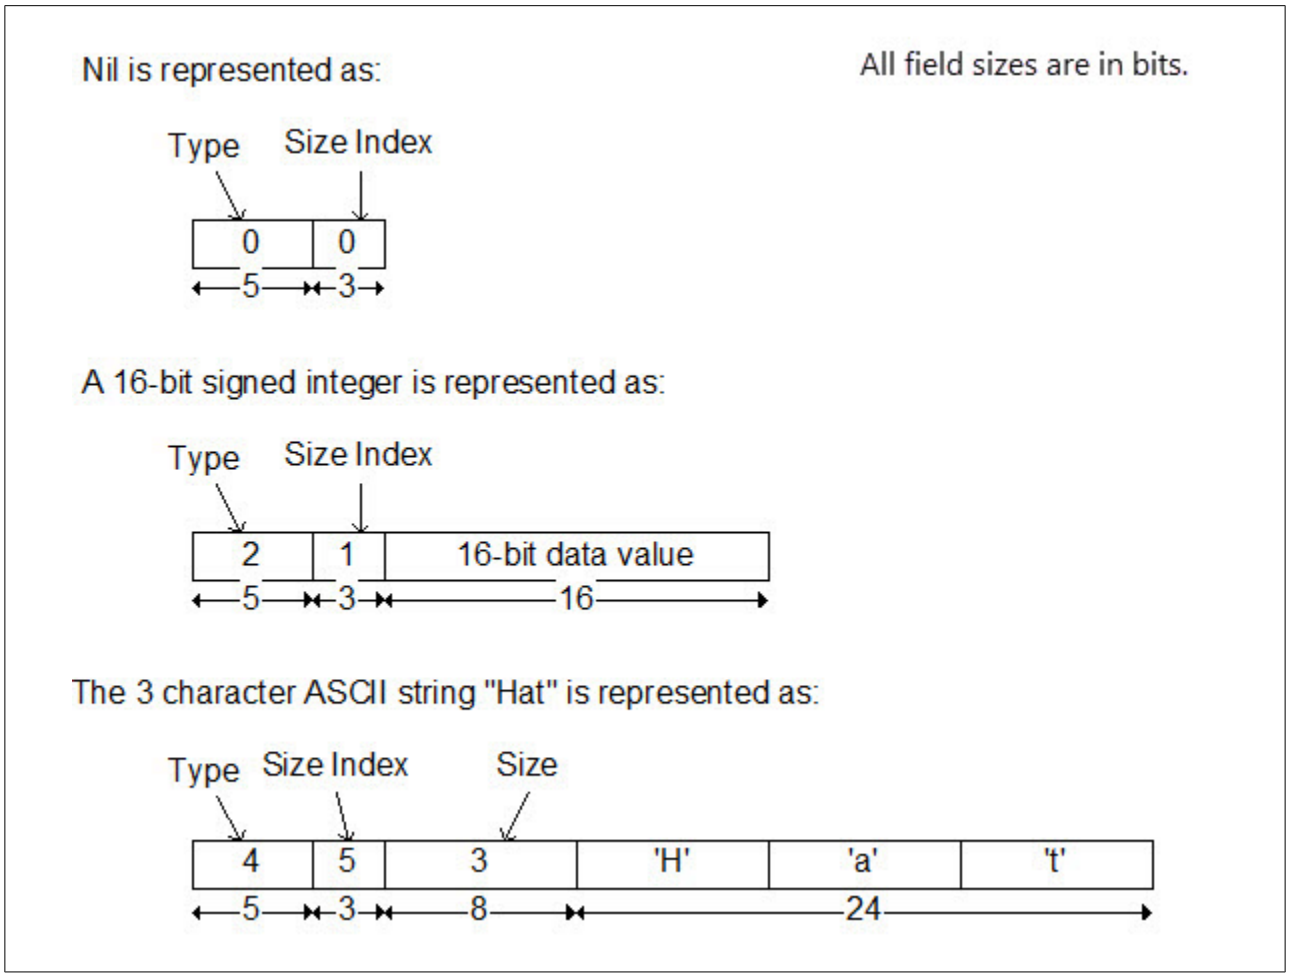

Figure 3.1: Data element

4 PROTOCOL DESCRIPTION

SDP is a simple protocol with minimal requirements on the underlying transport. It can function over a reliable packet transport (or even unreliable, if the client implements timeouts and repeats requests as necessary).

SDP uses a request/response model where each transaction consists of one request protocol data unit (PDU) and one response PDU. In the case where SDP is used with the Bluetooth L2CAP transport protocol, no more than one SDP request PDU per connection to a given SDP Server shall be outstanding at a given instant. In other words, a client shall wait for a response to its current request before issuing another request on the same L2CAP connection. Limiting SDP to sending one unacknowledged request PDU provides a simple form of flow control.

The protocol examples found in Appendix B could be helpful in understanding the protocol transactions.

4.1 Transfer byte order

The Service Discovery protocol shall transfer multiple-byte fields in standard network byte order (big-endian), with more significant (high-order) bytes being transferred before less-significant (low-order) bytes.

4.2 Protocol Data Unit format

Every SDP PDU consists of a PDU header followed by PDU-specific parameters. The header contains three fields: a PDU ID, a Transaction ID, and a ParameterLength. Each of these header fields is described here. Parameters may include a continuation state parameter, described below; PDU-specific parameters for each PDU type are described later in separate PDU descriptions.

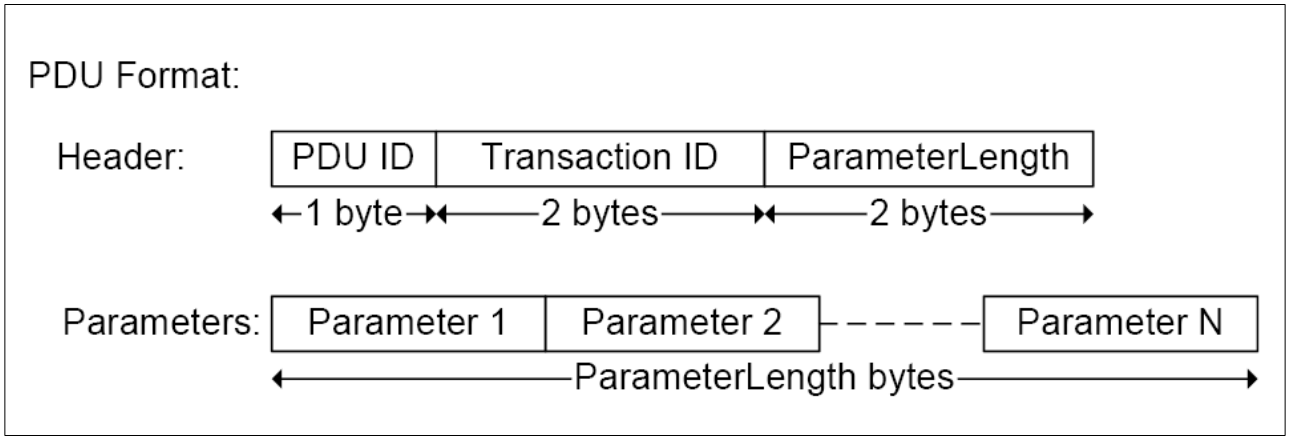

Figure 4.1: Protocol Data Unit format

PDU ID: *Size: 1 Byte*

Value	Parameter Description
N	The PDU ID field identifies the type of PDU. I.e. its meaning and the specific parameters.
0x01	SDP_ERROR_RSP
0x02	SDP_SERVICE_SEARCH_REQ
0x03	SDP_SERVICE_SEARCH_RSP
0x04	SDP_SERVICE_ATTR_REQ
0x05	SDP_SERVICE_ATTR_RSP
0x06	SDP_SERVICE_SEARCH_ATTR_REQ
0x07	SDP_SERVICE_SEARCH_ATTR_RSP
All other values	Reserved for future use

TransactionID: *Size: 2 Bytes*

Value	Parameter Description
N	The TransactionID field uniquely identifies request PDUs and is used to match response PDUs to request PDUs. The SDP Client can choose any value for a request's TransactionID provided that it is different from all outstanding requests. The TransactionID value in response PDUs is required to be the same as the request that is being responded to. Range: 0x0000 to 0xFFFF

ParameterLength: *Size: 2 Bytes*

Value	Parameter Description
N	The ParameterLength field specifies the length (in bytes) of all parameters contained in the PDU. Range: 0x0000 to 0xFFFF

4.3 Partial responses and continuation state

Some SDP requests may require responses that are larger than can fit in a single response PDU. In this case, the SDP Server shall generate a partial response along with a continuation state parameter. The continuation state parameter can be supplied by the client in a subsequent request to retrieve the next portion of the complete response. The continuation state parameter is a variable length field whose first byte contains the number of additional bytes of continuation information in the field (InfoLength).

The format of the continuation information is not standardized among SDP Servers. Each continuation state parameter is meaningful only to the SDP Server that generated

it. The SDP Server should not expose any sensitive information, such as internal data structures, in the continuation state parameter. The SDP Server should validate a continuation state parameter supplied by the client before using it.

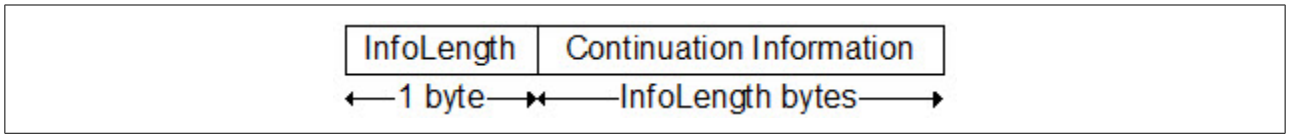

Figure 4.2: Continuation state format

After a client receives a partial response and the accompanying continuation state parameter, it can re-issue the original request (with a new transaction ID) and include the continuation state in the new request indicating to the server that the remainder of the original response is desired. The maximum allowable value of the InfoLength field is 16 (0x10).

Unless otherwise stated in a PDU response specification, an SDP Server may split a response at any arbitrary boundary when it generates a partial response. The SDP Server may select the boundary based on the contents of the reply, but is not required to do so. Therefore, length fields give the lengths as measured in the complete assembled record, not the length of the fields in the partial segment. When a service record is segmented into partial responses all attribute list values are relative to the complete record, not relevant to the partial record.

4.4 Error handling

Each transaction consists of a request and a response PDU. Generally, each type of request PDU has a corresponding type of response PDU. However, if the server determines that a request is improperly formatted or for any reason the server cannot respond with the appropriate PDU type, it shall respond with an SDP_ERROR_RSP PDU.

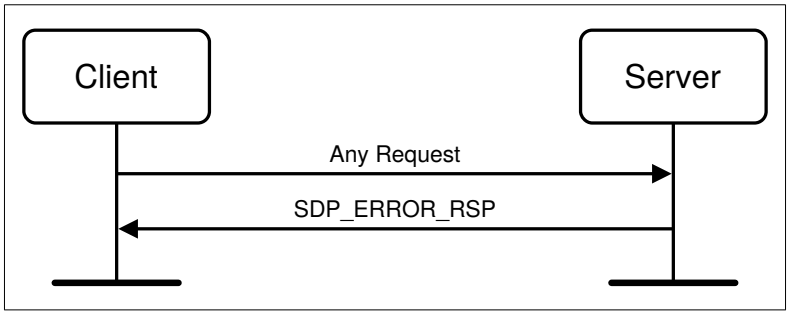

Figure 4.3: Error handling

4.4.1 SDP_ERROR_RSP PDU

PDU Type	PDU ID	Parameters
SDP_ERROR_RSP	0x01	ErrorCode

Description:

The SDP Server generates this PDU type in response to an improperly formatted request PDU or when the SDP Server, for whatever reason, cannot generate an appropriate response PDU.

PDU parameters:

ErrorCode: *Size: 2 Bytes*

Value	Parameter Description
N	The ErrorCode identifies the reason that an SDP_ERROR_RSP PDU was generated.
0x0001	Invalid/unsupported SDP version
0x0002	Invalid Service Record Handle
0x0003	Invalid request syntax
0x0004	Invalid PDU Size
0x0005	Invalid Continuation State
0x0006	Insufficient Resources to satisfy Request
All other values	Reserved for future use

Note: Invalid PDU size should be used, for example, if an incoming request PDU's length is inconsistent with the specification of that request PDU or the length parameter of an incoming request PDU is inconsistent with that request PDU's actual contents.

4.5 Service Search transaction

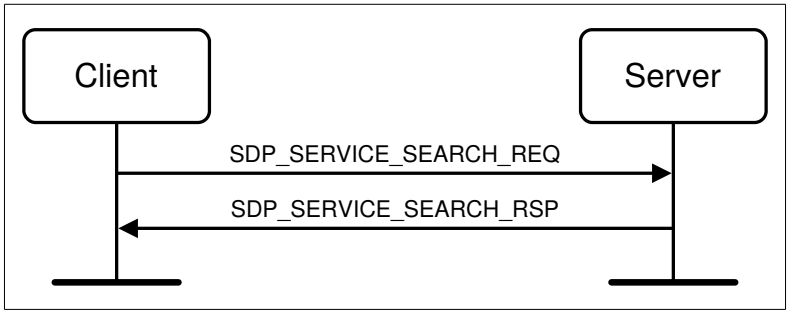

Figure 4.4: Service Search transaction

4.5.1 SDP_SERVICE_SEARCH_REQ PDU

PDU Type	PDU ID	Parameters
SDP_SERVICE_SEARCH_REQ	0x02	ServiceSearchPattern, MaximumServiceRecordCount, ContinuationState

Description:

The SDP Client generates an SDP_SERVICE_SEARCH_REQ to locate service records that match the service search pattern given as the first parameter of the PDU. Upon receipt of this request, the SDP Server shall examine its service record data base and return an SDP_SERVICE_SEARCH_RSP containing the service record handles of service records within its SDP database that match the given service search pattern, or an appropriate error response.

No mechanism is provided to request information for all service records. However, see Section 2.6 for a description of a mechanism that permits browsing for non-specific services without a priori knowledge of the services.

PDU parameters:

ServiceSearchPattern: *Size: Varies*

Value	Parameter Description
Data Element Sequence	The ServiceSearchPattern is a data element sequence where each element in the sequence is a UUID. The sequence shall contain at least one UUID. The maximum number of UUIDs in the sequence is 12[1]. The list of UUIDs constitutes a service search pattern.

[1]The value of 12 has been selected as a compromise between the scope of a service search and the size of a search request PDU. It is not expected that more than 12 UUIDs will be useful in a service search pattern.

MaximumServiceRecordCount: *Size: 2 Bytes*

Value	Parameter Description
N	MaximumServiceRecordCount is a 16-bit count specifying the maximum number of service record handles to be returned in the response(s) to this request. The SDP Server shall not return more handles than this value specifies. If more than N service records match the request, the SDP Server determines which matching service record handles to return in the response(s). Range: 0x0001 to 0xFFFF

ContinuationState: *Size: 1 to 17 Bytes*

Value	Parameter Description
Continuation State	ContinuationState consists of an 8-bit count, N, of the number of bytes of continuation state information, followed by the N bytes of continuation state information that were returned in a previous response from the server. N is required to be less than or equal to 16. If no continuation state is to be provided in the request, N is set to 0.

4.5.2 SDP_SERVICE_SEARCH_RSP PDU

PDU Type	PDU ID	Parameters
SDP_SERVICE_SEARCH_RSP	0x03	TotalServiceRecordCount, CurrentServiceRecordCount, ServiceRecordHandleList, ContinuationState

Description:

The SDP Server generates an SDP_SERVICE_SEARCH_RSP upon receipt of a valid SDP_SERVICE_SEARCH_REQ. The response contains a list of service record handles for service records that match the service search pattern given in the request. If a partial response is generated, it shall only contain complete service record handles; a service record handle value shall not be split across multiple PDUs.

PDU parameters:

TotalServiceRecordCount: *Size: 2 Bytes*

Value	Parameter Description
N	The TotalServiceRecordCount is an integer containing the number of service records that match the requested service search pattern. If no service records match the requested service search pattern, this parameter is set to 0. N should never be larger than the MaximumServiceRecordCount value specified in the SDP_SERVICE_SEARCH_REQ. When multiple partial responses are used, each partial response contains the same value for TotalServiceRecordCount. Range: 0x0000 to 0xFFFF

CurrentServiceRecordCount: *Size: 2 Bytes*

Value	Parameter Description
N	The CurrentServiceRecordCount is an integer indicating the number of service record handles that are contained in the next parameter. If no service records match the requested service search pattern, this parameter is set to 0. N should never be larger than the TotalServiceRecordCount value specified in the current response. Range: 0x0000 to 0xFFFF

ServiceRecordHandleList: *Size: (CurrentServiceRecordCount×4) Bytes*

Value	Parameter Description
List of 32-bit handles	The ServiceRecordHandleList contains a list of service record handles. The number of handles in the list is given in the CurrentServiceRecordCount parameter. Each of the handles in the list refers to a service record that matches the requested service search pattern. This list of service record handles does not have the format of a data element. It contains no header fields, only the 32-bit service record handles.

ContinuationState: *Size: 1 to 17 Bytes*

Value	Parameter Description
Continuation State	ContinuationState consists of an 8-bit count, N, of the number of bytes of continuation state information, followed by the N bytes of continuation information. If the current response is complete, this parameter consists of a single byte with the value 0. If a partial response is contained in the PDU, the ContinuationState parameter may be supplied in a subsequent request to retrieve the remainder of the response.

4.6 Service Attribute transaction

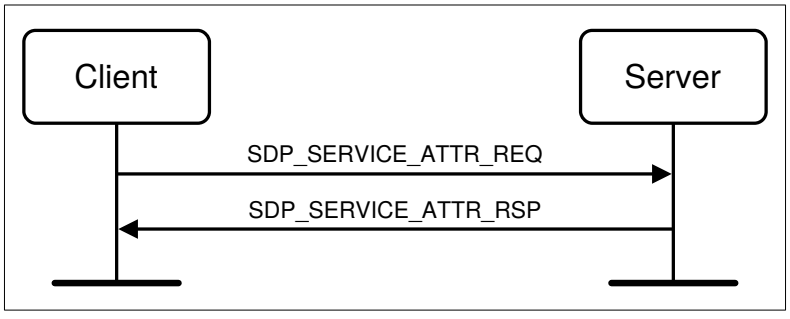

Figure 4.5: Service Attribute transaction

4.6.1 SDP_SERVICE_ATTR_REQ PDU

PDU Type	PDU ID	Parameters
SDP_SERVICE_ATTR_REQ	0x04	ServiceRecordHandle, MaximumAttributeByteCount, AttributeIDList, ContinuationState

Description:

The SDP Client generates an SDP_SERVICE_ATTR_REQ to retrieve specified attribute values from a specific service record. The service record handle of the desired service record and a list of desired attribute IDs to be retrieved from that service record are supplied as parameters.

Command parameters:

ServiceRecordHandle: *Size: 4 Bytes*

Value	Parameter Description
32-bit handle	The ServiceRecordHandle parameter specifies the service record from which attribute values are to be retrieved. The handle is obtained via a previous Service Search transaction.

MaximumAttributeByteCount: *Size: 2 Bytes*

Value	Parameter Description
N	MaximumAttributeByteCount specifies the maximum number of bytes of attribute data to be returned in the response to this request. The SDP Server shall not return more than N bytes of attribute data in the response PDU. If the requested attributes require more than N bytes, the SDP Server determines how to segment the list. In this case the client may request each successive segment by issuing a request containing the continuation state that was returned in the previous response PDU. In the case where multiple response PDUs are needed to return the attribute data, MaximumAttributeByteCount specifies the maximum size of the portion of the attribute data contained in each response PDU. Range: 0x0007 to 0xFFFF

AttributeIDList: *Size: Varies*

Value	Parameter Description
Data Element Sequence	The AttributeIDList is a data element sequence where each element in the list is either an attribute ID or a range of attribute IDs. Each attribute ID is encoded as a 16-bit unsigned integer data element. Each attribute ID range is encoded as a 32-bit unsigned integer data element, where the high order 16 bits are interpreted as the beginning attribute ID of the range and the low order 16 bits are interpreted as the ending attribute ID of the range. The attribute IDs contained in the AttributeIDList shall be listed in ascending order without duplication of any attribute ID values. Note: All attributes can be requested by specifying the range 0x0000 to 0xFFFF.

ContinuationState: *Size: 1 to 17 Bytes*

Value	Parameter Description
Continuation State	ContinuationState consists of an 8-bit count, N, of the number of bytes of continuation state information, followed by the N bytes of continuation state information that were returned in a previous response from the server. N shall be less than or equal to 16. If no continuation state is to be provided in the request, N shall be set to 0.

4.6.2 SDP_SERVICE_ATTR_RSP PDU

PDU Type	PDU ID	Parameters
SDP_SERVICE_ATTR_RSP	0x05	AttributeListByteCount, AttributeList, ContinuationState

Description:

The SDP Server generates an SDP_SERVICE_ATTR_RSP upon receipt of a valid SDP_SERVICE_ATTR_REQ. The response contains a list of attributes (both attribute ID and attribute value) from the requested service record.

PDU parameters:

AttributeListByteCount: *Size: 2 Bytes*

Value	Parameter Description
N	The AttributeListByteCount contains a count of the number of bytes in the AttributeList parameter. N shall never be larger than the MaximumAttributeByteCount value specified in the SDP_SERVICE_ATTR_REQ. Range: 0x0002 to 0xFFFF

AttributeList: *Size: AttributeListByteCount*

Value	Parameter Description
Data Element Sequence	The AttributeList is a data element sequence containing attribute IDs and attribute values. The first element in the sequence contains the attribute ID of the first attribute to be returned. The second element in the sequence contains the corresponding attribute value. Successive pairs of elements in the list contain additional attribute ID and value pairs. Only attributes that have non-null values within the service record and whose attribute IDs were specified in the SDP_SERVICE_ATTR_REQ are contained in the AttributeList. Neither an attribute ID nor an attribute value is placed in the AttributeList for attributes in the service record that have no value. The attributes are listed in ascending order of attribute ID value.

ContinuationState: *Size: 1 to 17 Bytes*

Value	Parameter Description
Continuation State	ContinuationState consists of an 8-bit count, N, of the number of bytes of continuation state information, followed by the N bytes of continuation information. If the current response is complete, this parameter consists of a single byte with the value 0. If a partial response is given, the ContinuationState parameter may be supplied in a subsequent request to retrieve the remainder of the response.

If a partial response is generated, the response may be arbitrarily segmented into multiple PDUs (subject to the constraint imposed by the allowed range of values for the AttributeListByteCount parameter). Attributes in partial responses are not required to be completely within a single PDU.

4.7 Service Search Attribute transaction

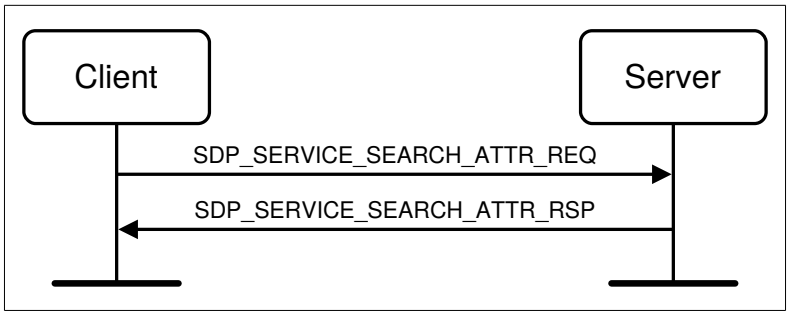

Figure 4.6: Service Search Attribute transaction

4.7.1 SDP_SERVICE_SEARCH_ATTR_REQ PDU

PDU Type	PDU ID	Parameters
SDP_SERVICE_SEARCH_ATTR_REQ	0x06	ServiceSearchPattern, MaximumAttributeByteCount, AttributeIDList, ContinuationState

Description:

The SDP_SERVICE_SEARCH_ATTR_REQ transaction combines the capabilities of the SDP_SERVICE_SEARCH_REQ and the SDP_SERVICE_ATTR_REQ into a single request. As parameters, it contains both a service search pattern and a list of attributes to be retrieved from service records that match the service search pattern. The SDP_SERVICE_SEARCH_ATTR_REQ and its response are more complex and can require more bytes than separate Service Search and Service Attribute transactions. However, using SDP_SERVICE_SEARCH_ATTR_REQ can reduce the total number of SDP transactions, particularly when retrieving multiple service records.

The service record handle for each service record is contained in the ServiceRecordHandle attribute of that service and may be requested along with other attributes.

PDU parameters:

ServiceSearchPattern: *Size: Varies*

Value	Parameter Description
Data Element Sequence	The ServiceSearchPattern is a data element sequence where each element in the sequence is a UUID. The sequence shall contain at least one UUID. The maximum number of UUIDs in the sequence is 12[1]. The list of UUIDs constitutes a service search pattern.

[1]The value of 12 has been selected as a compromise between the scope of a service search and the size of a search request PDU. It is not expected that more than 12 UUIDs will be useful in a service search pattern.

MaximumAttributeByteCount: *Size: 2 Bytes*

Value	Parameter Description
N	MaximumAttributeByteCount specifies the maximum number of bytes of attribute data to be returned in the response to this request. The SDP Server shall not return more than N bytes of attribute data in the response PDU. If the requested attributes require more than N bytes, the SDP Server determines how to segment the list. In this case the client may request each successive segment by issuing a request containing the continuation state that was returned in the previous response PDU. In the case where multiple response PDUs are needed to return the attribute data, MaximumAttributeByteCount specifies the maximum size of the portion of the attribute data contained in each response PDU. Range: 0x0007 to 0xFFFF

AttributeIDList: *Size: Varies*

Value	Parameter Description
Data Element Sequence	The AttributeIDList is a data element sequence where each element in the list is either an attribute ID or a range of attribute IDs. Each attribute ID is encoded as a 16-bit unsigned integer data element. Each attribute ID range is encoded as a 32-bit unsigned integer data element, where the high order 16 bits are interpreted as the beginning attribute ID of the range and the low order 16 bits are interpreted as the ending attribute ID of the range. The attribute IDs contained in the AttributeIDList shall be listed in ascending order without duplication of any attribute ID values. Note: All attributes may be requested by specifying the range 0x0000 to 0xFFFF.

ContinuationState: *Size: 1 to 17 Bytes*

Value	Parameter Description
Continuation State	ContinuationState consists of an 8-bit count, N, of the number of bytes of continuation state information, followed by the N bytes of continuation state information that were returned in a previous response from the server. N shall be less than or equal to 16. If no continuation state is to be provided in the request, N shall set to 0.

4.7.2 SDP_SERVICE_SEARCH_ATTR_RSP PDU

PDU Type	PDU ID	Parameters
SDP_SERVICE_SEARCH_ATTR_RSP	0x07	AttributeListsByteCount, AttributeLists, ContinuationState

Description:

The SDP Server generates an SDP_SERVICE_SEARCH_ATTR_RSP upon receipt of a valid SDP_SERVICE_SEARCH_ATTR_REQ. The response contains a list of attributes (both attribute ID and attribute value) from the service records that match the requested service search pattern.

PDU parameters:

AttributeListsByteCount: *Size: 2 Bytes*

Value	Parameter Description
N	The AttributeListsByteCount contains a count of the number of bytes in the AttributeLists parameter. N shall never be larger than the MaximumAttribute-ByteCount value specified in the SDP_SERVICE_SEARCH_ATTR_REQ. Range: 0x0002 to 0xFFFF

AttributeLists: *Size: Varies*

Value	Parameter Description
Data Element Se-quence	The AttributeLists is a data element sequence where each element in turn is a data element sequence representing an attribute list. Each attribute list contains attribute IDs and attribute values from one service record. The first element in each attribute list contains the attribute ID of the first attribute to be returned for that service record. The second element in each attribute list contains the corresponding attribute value. Successive pairs of elements in each attribute list contain additional attribute ID and value pairs. Only attributes that have non-null values within the service record and whose attribute IDs were specified in the SDP_SERVICE_SEARCH_ATTR_REQ are contained in the AttributeLists. Neither an attribute ID nor attribute value is placed in AttributeLists for attributes in the service record that have no value. Within each attribute list, the attributes are listed in ascending order of attribute ID value.

ContinuationState: *Size: 1 to 17 Bytes*

Value	Parameter Description
Continuation State	ContinuationState consists of an 8-bit count, N, of the number of bytes of continuation state information, followed by the N bytes of continuation information. If the current response is complete, this parameter consists of a single byte with the value 0. If a partial response is given, the Continuation-State parameter may be supplied in a subsequent request to retrieve the remainder of the response.

If a partial response is generated, the response may be arbitrarily segmented into multiple PDUs (subject to the constraint imposed by the allowed range of values for the

AttributeListByteCount parameter). Attributes in partial responses are not required to be completely within a single PDU.

5 SERVICE ATTRIBUTE DEFINITIONS

The service classes and attributes contained in this document are necessarily a partial list of the service classes and attributes supported by SDP. Only service classes that directly support the SDP Server are included in this document. Additional service classes will be defined in other documents and possibly in future revisions of this document. Also, it is expected that additional attributes will be discovered that are applicable to a broad set of services; these may be added to the list of Universal attributes in future revisions of this document.

Where a range of values is specified for a class of attribute IDs, only numbers in that range are assigned numbers for that class and (except for universal attributes) are only assigned numbers for that class.

5.1 Universal attribute definitions

Universal attributes are those service attributes whose definitions are common to all service records. This does not mean that every service record contains values for all of these service attributes. However, if a service record has a service attribute with an attribute ID allocated to a universal attribute, the attribute value shall conform to the universal attribute's definition.

These attributes may be used with any service class.

Universal attributes use attribute IDs 0x0000 to 0x00FF. Specific IDs in this range are defined in Assigned Numbers.

Only two attributes are required to exist in every service record instance. They are the ServiceRecordHandle and the ServiceClassIDList. All other service attributes are optional within a service record.

5.1.1 ServiceRecordHandle attribute

Attribute Name	Attribute Value Type
ServiceRecordHandle	32-bit unsigned integer

Description:

A service record handle is a 32-bit number that uniquely identifies each service record within an SDP Server. In general, each handle is unique only within each SDP Server. If SDP Server S1 and SDP Server S2 both contain identical service records (representing the same service), the service record handles used to reference these identical service records are completely independent. The handle used to reference the service on

S1 will, in general, be meaningless if presented to S2. Service record handle values 0x00000001 to 0x0000FFFF are reserved for future use.

5.1.2 ServiceClassIDList attribute

Attribute Name	Attribute Value Type
ServiceClassIDList	Data Element Sequence

Description:

The ServiceClassIDList attribute consists of a data element sequence in which each data element is a UUID representing the service classes that a given service record conforms to. The UUIDs should be listed in order from the most specific class to the most general class unless otherwise specified by the profile specifications defining the service classes. When profiles are enhanced, any new UUIDs should be added at the end of the ServiceClassIDList (after any existing UUIDs) to minimize interoperability issues with legacy implementations. The ServiceClassIDList shall contain at least one service class UUID.

5.1.3 ServiceRecordState attribute

Attribute Name	Attribute Value Type
ServiceRecordState	32-bit unsigned integer

Description:

The ServiceRecordState is a 32-bit integer that is used to facilitate caching of Service Attributes. If this attribute is contained in a service record, its value shall be changed when any other attribute value is added to, deleted from or changed within the service record. This permits a client to check the value of this single attribute. If its value has not changed since it was last checked, the client knows that no other attribute values within the service record have changed.

5.1.4 ServiceID attribute

Attribute Name	Attribute Value Type
ServiceID	UUID

Description:

The ServiceID is a UUID that universally and uniquely identifies the service instance described by the service record. This service attribute is particularly useful if the same service is described by service records in more than one SDP Server.

5.1.5 ProtocolDescriptorList attribute

Attribute Name	Attribute Value Type
ProtocolDescriptorList	Data Element Sequence or Data Element Alternative

Description:

The ProtocolDescriptorList attribute describes one or more protocol stacks that can be used to gain access to the service described by the service record.

If the ProtocolDescriptorList describes a single stack, it takes the form of a data element sequence in which each element of the sequence is a protocol descriptor. Each protocol descriptor is, in turn, a data element sequence whose first element is a UUID identifying the protocol and whose successive elements are protocol-specific parameters. Potential protocol-specific parameters are a protocol version number and a connection-port number. The protocol descriptors are listed in order from the lowest layer protocol to the highest layer protocol used to gain access to the service.

If it is possible for more than one kind of protocol stack to be used to gain access to the service, the ProtocolDescriptorList takes the form of a data element alternative where each member is a data element sequence as described in the previous paragraph.

Protocol descriptors

A protocol descriptor identifies a communications protocol and provides protocol-specific parameters. A protocol descriptor is represented as a data element sequence. The first data element in the sequence shall be the UUID that identifies the protocol. Additional data elements optionally provide protocol-specific information, such as the L2CAP protocol/service multiplexer (PSM) and the RFCOMM server channel number (CN) shown below.

ProtocolDescriptorList examples

These examples are intended to be illustrative. The parameter formats for each protocol are not defined within the specification.

In the first two examples, it is assumed that a single RFCOMM instance exists on top of the L2CAP layer. In this case, the L2CAP protocol specific information (PSM) points to the single instance of RFCOMM. In the last example, two different and independent RFCOMM instances are available on top of the L2CAP layer. In this case, the L2CAP protocol specific information (PSM) points to a distinct identifier that distinguishes each of the RFCOMM instances. See [Vol 3] Part A, Section 4.2 for the range of allowed PSM values.

IrDA-like printer

((L2CAP, PSM=RFCOMM), (RFCOMM, CN=1), (PostscriptStream))

IP Network Printing

((L2CAP, PSM=RFCOMM), (RFCOMM, CN=2), (PPP), (IP), (TCP), (IPP))

Synchronization Protocol Descriptor Example

((L2CAP, PSM=0x1001), (RFCOMM, CN=1), (Obex), (vCal))

((L2CAP, PSM=0x1003), (RFCOMM, CN=1), (Obex),
(otherSynchronisationApplication))

5.1.6 AdditionalProtocolDescriptorLists attribute

Attribute Name	Attribute Value Type
AdditionalProtocolDescriptorLists	Data Element Sequence

Description:

The AdditionalProtocolDescriptorLists attribute contains a sequence of ProtocolDescriptorList-elements. Each element having the same format as the ProtocolDescriptorList described in section 5.1.5. The ordering of the elements is significant and should be specified and fixed in Profiles that make use of this attribute.

The AdditionalProtocolDescriptorLists attribute supports services that require more channels in addition to the service described in Section 5.1.5. If the AdditionalProtocolDescriptorLists attribute is included in a service record, the ProtocolDescriptorList attribute shall be included.

AdditionalProtocolDescriptorLists examples

The following is just an illustrative example and is not meant to refer a real specified service or protocols.

```
Attribute       Attribute Value type    Attribute Value
ProtocolDescriptorList
        ProtocolDescriptor #0           DataElementSequence
                ProtocolID              UUID        L2CAP
                Param: PSM              PSM         FooDataProtocol
        ProtocolDescriptor #1           DataElementSequence
                ProtocolID              UUID        FooDataProtocol
AdditionalProtocolDescriptorLists
        ProtocolDescriptorList #0       DataElementSequence
        ProtocolDescriptor #0           DataElementSequence
```

```
        ProtocolID              UUID        L2CAP
        Param: PSM              PSM         FooControlProtocol
ProtocolDescriptor #1           DataElementSequence
        ProtocolID              UUID        FooControlProtocol
```

5.1.7 BrowseGroupList attribute

Attribute Name	Attribute Value Type
BrowseGroupList	Data Element Sequence

Description:

The BrowseGroupList attribute consists of a data element sequence in which each element is a UUID that represents a browse group to which the service record belongs. The UUID for the top-level browse group ID, called PublicBrowseRoot and representing the root of the browsing hierarchy, is defined in Assigned Numbers.

5.1.8 LanguageBaseAttributeIDList attribute

Attribute Name	Attribute Value Type
LanguageBaseAttributeIDList	Data Element Sequence

Description:

In order to support human-readable attributes for multiple natural languages in a single service record, a base attribute ID is assigned for each of the natural languages used in a service record. The human-readable universal attributes are then defined with an attribute ID offset from each of these base values, rather than with an absolute attribute ID.

The LanguageBaseAttributeIDList attribute is a list in which each member contains a language identifier, a character encoding identifier, and a base attribute ID for each of the natural languages used in the service record. The LanguageBaseAttributeIDList attribute consists of a data element sequence in which each element is a 16-bit unsigned integer. The elements are grouped as triplets (threes).

The first element of each triplet contains an identifier representing the natural language. The language is encoded according to ISO 639:1988 (E/F): “Code for the representation of names of languages”.

The second element of each triplet contains an identifier that specifies a character encoding used for the language. Values for character encoding can be found in

IANA's database[1], and have the values that are referred to as MIBEnum values. The recommended character encoding is UTF-8.

The third element of each triplet contains an attribute ID that serves as the base attribute ID for the natural language in the service record. Different service records within a server may use different base attribute ID values for the same language.

The base attribute ID value shall be chosen so that all attributes that are specified as being offset from it (e.g. ServiceName, ServiceDescription, and ProviderName) shall have resulting Attribute IDs that are in the range 0x0100 to 0x01FF or a range specified in another specification as being used for this purpose. The range 0x0100 to 0x01FF shall only be used for this purpose.

To facilitate the retrieval of human-readable universal attributes in a principal language, the base attribute ID value for the primary language supported by a service record shall be 0x0100. Also, if a LanguageBaseAttributeIDList attribute is contained in a service record, the base attribute ID value contained in its first element shall be 0x0100. If one or more human readable attributes are contained in a service record, the LanguageBaseAttributeIDList attribute should be included in that service record.

5.1.9 ServiceInfoTimeToLive attribute

Attribute Name	Attribute Value Type
ServiceInfoTimeToLive	32-bit unsigned integer

Description:

The ServiceTimeToLive attribute is a 32-bit integer that contains the number of seconds for which the information in a service record is expected to remain valid and unchanged. This time interval is measured from the time that the attribute value is retrieved from the SDP Server. This value does not imply a guarantee that the service record will remain available or unchanged. It is simply a hint that a client can use to determine a suitable polling interval to re-validate the service record contents.

5.1.10 ServiceAvailability attribute

Attribute Name	Attribute Value Type
ServiceAvailability	8-bit unsigned integer

Description:

The ServiceAvailability attribute is an 8-bit unsigned integer that represents the relative ability of the service to accept additional clients. A value of 0xFF indicates that the

[1]See https://www.iana.org/assignments/character-sets/character-sets.xhtml

service is not currently in use and is thus fully available, while a value of 0x00 means that the service is not accepting new clients. For services that support multiple simultaneous clients, intermediate values indicate the relative availability of the service on a linear scale.

For example, a service that can accept up to 3 clients should provide ServiceAvailability values of 0xFF, 0xAA, 0x55, and 0x00 when 0, 1, 2, and 3 clients, respectively, are utilizing the service. The value 0xAA is approximately $\frac{2}{3}$ × 0xFF and represents $\frac{2}{3}$ availability, while the value 0x55 is approximately $\frac{1}{3}$ × 0xFF and represents $\frac{1}{3}$ availability. The availability value is be approximated as

(1 - (current_number_of_clients ÷ maximum_number_of_clients)) × 0xFF

When the maximum number of clients is large, this formula must be modified to ensure that ServiceAvailability values of 0x00 and 0xFF are reserved for their defined meanings of unavailability and full availability, respectively.

Note: The maximum number of clients a service can support may vary according to the resources utilized by the service's current clients.

A non-zero value for ServiceAvailability does not guarantee that the service will be available for use. It should be treated as a hint or an approximation of availability status.

5.1.11 BluetoothProfileDescriptorList attribute

Attribute Name	Attribute Value Type
BluetoothProfileDescriptorList	Data Element Sequence

Description:

The BluetoothProfileDescriptorList attribute consists of a data element sequence in which each element is a profile descriptor that contains information about a Bluetooth profile to which the service represented by this service record conforms. Each profile descriptor is a data element sequence whose first element is the UUID assigned to the profile and whose second element is a 16-bit profile version number.

Each version of a profile is assigned a 16-bit unsigned integer profile version number, which consists of two 8-bit fields. The higher-order 8 bits contain the major version number field and the lower-order 8 bits contain the minor version number field.

5.1.12 DocumentationURL attribute

Attribute Name	Attribute Value Type
DocumentationURL	URL

Description:

This attribute is a URL which points to documentation on the service described by a service record.

5.1.13 ClientExecutableURL attribute

Attribute Name	Attribute Value Type
ClientExecutableURL	URL

Description:

This attribute contains a URL that refers to the location of an application that can be used to utilize the service described by the service record. Since different operating environments require different executable formats, a mechanism has been defined to allow this single attribute to be used to locate an executable that is appropriate for the client device's operating environment. In the attribute value URL, the first byte with the value 0x2A (ASCII character '*') is to be replaced by the client application with a string representing the desired operating environment before the URL is to be used.

The list of standardized strings representing operating environments is contained in Assigned Numbers.

For example, assume that the value of the ClientExecutableURL attribute is http://my.fake/public/*/client.exe. On a device capable of executing SH3 WindowsCE files, this URL would be changed to http://my.fake/public/sh3-microsoft-wince/client.exe. On a device capable of executing Windows 98 binaries, this URL would be changed to http://my.fake/public/i86-microsoft-win98/client.exe.

5.1.14 IconURL attribute

Attribute Name	Attribute Value Type
IconURL	URL

Description:

This attribute contains a URL that refers to the location of an icon that can be used to represent the service described by the service record. Since different hardware devices require different icon formats, a mechanism has been defined to allow this

single attribute to be used to locate an icon that is appropriate for the client device. In the attribute value URL, the first byte with the value 0x2A (ASCII character '*') is to be replaced by the client application with a string representing the desired icon format before the URL is to be used.

The list of standardized strings representing icon formats is contained in Assigned Numbers.

For example, assume that the value of the IconURL attribute is http://my.fake/public/icons/*. On a device that prefers 24 x 24 icons with 256 colors, this URL would be changed to http://my.fake/public/icons/24x24x8.png. On a device that prefers 10 x 10 monochrome icons, this URL would be changed to http://my.fake/public/icons/10x10x1.png.

5.1.15 ServiceName attribute

Attribute Name	Attribute Value Type
ServiceName	String

Description:

The ServiceName attribute is a string containing the name of the service represented by a service record. It should be brief and suitable for display with an Icon representing the service. An offset specified in Assigned Numbers is added to the attribute ID base (contained in the LanguageBaseAttributeIDList attribute) in order to compute the attribute ID for this attribute.

5.1.16 ServiceDescription attribute

Attribute Name	Attribute Value Type
ServiceDescription	String

Description:

This attribute is a string containing a brief description of the service. It should be less than 200 characters in length. An offset specified in Assigned Numbers is added to the attribute ID base (contained in the LanguageBaseAttributeIDList attribute) in order to compute the attribute ID for this attribute.

5.1.17 ProviderName attribute

Attribute Name	Attribute Value Type
ProviderName	String

Description:

This attribute is a string containing the name of the person or organization providing the service. An offset specified in Assigned Numbers is added to the attribute ID base (contained in the LanguageBaseAttributeIDList attribute) in order to compute the attribute ID for this attribute.

5.1.18 [This section is no longer used]

5.2 ServiceDiscoveryServer service class attribute definitions

This service class describes service record that contains attributes of the service discovery server itself. The attributes listed in this section are only valid if the ServiceClassIDList attribute contains the ServiceDiscoveryServerServiceClassID.

This service class uses attribute IDs 0x0200 to 0x02FF. Specific IDs in this range are defined in Assigned Numbers.

5.2.1 ServiceRecordHandle attribute

Described in the universal attribute definition for ServiceRecordHandle (Section 5.1.1).

Value

A 32-bit integer with the value 0x00000000.

5.2.2 ServiceClassIDList attribute

Described in the universal attribute definition for ServiceClassIDList (Section 5.1.2).

Value

A UUID representing the ServiceDiscoveryServerServiceClassID.

5.2.3 VersionNumberList attribute

Attribute Name	Attribute Value Type
VersionNumberList	Data Element Sequence

Description:

The VersionNumberList is a data element sequence in which each element of the sequence is a version number supported by the SDP Server.

A version number is a 16-bit unsigned integer consisting of two fields. The higher-order 8 bits contain the major version number field and the low-order 8 bits contain the minor version number field. The initial version of SDP has a major version of 1 and a minor version of 0.

5.2.4 ServiceDatabaseState attribute

Attribute Name	Attribute Value Type
ServiceDatabaseState	32-bit unsigned integer

Description:

The ServiceDatabaseState is a 32-bit integer that is used to facilitate caching of service records. If this attribute exists, its value shall be changed when any of the other service records are added to or deleted from the server's SDP database. If this value has not changed since the last time a client queried its value, the client knows that a) none of the other service records maintained by the SDP Server have been added or deleted; and b) any service record handles acquired from the server are still valid. A client shall query this attribute's value when a connection to the server is established, prior to using any service record handles acquired during a previous connection.

The ServiceDatabaseState attribute does not change when existing service records are modified, including the addition, removal, or modification of service attributes. A service record's ServiceRecordState attribute indicates when that service record is modified.

5.2.5 [This section is no longer used]

5.3 BrowseGroupDescriptor service class attribute definitions

This service class describes the ServiceRecord provided for each BrowseGroupDescriptor service offered on a Bluetooth device. The attributes listed in this section are only valid if the ServiceClassIDList attribute contains the BrowseGroupDescriptorServiceClassID.

This service class uses attribute IDs 0x0200 to 0x02FF. Specific IDs in this range are defined in Assigned Numbers.

5.3.1 ServiceClassIDList attribute

Described in the universal attribute definition for ServiceClassIDList (Section 5.1.2).

Value

A UUID representing the BrowseGroupDescriptorServiceClassID.

5.3.2 GroupID attribute

Attribute Name	Attribute Value Type
GroupID	UUID

Description:

This attribute contains a UUID that can be used to locate services that are members of the browse group that this service record describes.

5.3.3 [This section is no longer used]

6 SECURITY

In Security Mode 4, SDP should use no security but may use security (an authenticated or unauthenticated link key with encryption). See [Vol 3] Part C, Section 5.2.2).

Appendix A [This appendix is no longer used]

Appendix B Example SDP Transactions

The following are simple examples of typical SDP transactions. These are meant to be illustrative of SDP flows. The examples do not consider:

- Caching (in a caching system, the SDP Client would make use of the ServiceRecordState and ServiceDatabaseState attributes);
- Service availability (if this is of interest, the SDP Client should use the ServiceAvailability and/or ServiceTimeToLive attributes);
- SDP versions (the VersionNumberList attribute could be used to determine compatible SDP versions);
- SDP Error Responses (an SDP error response is possible for any SDP request that is in error); and
- Communication connection (the examples assume that an L2CAP connection is established).

The examples are meant to be illustrative of the protocol. The format used is `ObjectName[ObjectSizeInBytes] {SubObjectDefinitions}`, but this is not meant to illustrate an interface. The `ObjectSizeInBytes` is the size of the object in decimal. The `SubObjectDefinitions` (inside of {} characters) are components of the immediately enclosing object. Hexadecimal values shown as lower-case letters, such as for transaction IDs and service handles, are variables (the particular value is not important for the illustration, but each such symbol always represents the same value). Comments are included in this manner: `/* comment text */`

B.1 SDP example 1 – ServiceSearchRequest

The first example is that of an SDP Client searching for a generic printing service. The client does not specify a particular type of printing service. In the example, the SDP Server has two available printing services. The transaction illustrates:

1. SDP Client to SDP Server: SDP_SERVICE_SEARCH_REQ, specifying the PrinterServiceClassID (represented as a DataElement with a 32-bit UUID value of `ppp...ppp`) as the only element of the ServiceSearchPattern. The PrinterServiceClassID is assumed to be a 32-bit UUID and the data element type for it is illustrated. The TransactionID is illustrated as `tttt`.
2. SDP Server to SDP Client: SDP_SERVICE_SEARCH_RSP, returning handles to two printing services, represented as `qqqqqqqq` for the first printing service and `rrrrrrrr` for the second printing service. The Transaction ID is the same value as supplied by the SDP Client in the corresponding request (`tttt`).

```
  /* Sent from SDP Client to SDP Server */
SDP_SERVICE_SEARCH_REQ[15] {
  PDUID[1] {
    0x02
  }
  TransactionID[2] {
    0xtttt
  }
  ParameterLength[2] {
    0x000A
  }
  ServiceSearchPattern[7] {
    DataElementSequence[7] {
      0b00110 0b101 0x05
      UUID[5] {
        /* PrinterServiceClassID */
        0b00011 0b010 0xpppppppp
      }
    }
  }
  MaximumServiceRecordCount[2] {
    0x0003
  }
  ContinuationState[1] {
    /* no continuation state */
    0x00
  }
}

/* Sent from SDP Server to SDP Client */
SDP_SERVICE_SEARCH_RSP[18] {
  PDUID[1] {
    0x03
  }
  TransactionID[2] {
    0xtttt
  }
  ParameterLength[2] {
    0x000D
  }
```

```
  TotalServiceRecordCount[2] {
    0x0002
  }
  CurrentServiceRecordCount[2] {
    0x0002
  }
  ServiceRecordHandleList[8] {
    /* print service 1 handle */
    0xqqqqqqqq
    /* print service 2 handle */
    0xrrrrrrrr
  }
  ContinuationState[1] {
    /* no continuation state */
    0x00
  }
}
```

B.2 SDP example 2 – ServiceAttributeTransaction

The second example continues the first example. In Example 1, the SDP Client obtained handles to two printing services. In Example 2, the client uses one of those service handles to obtain the ProtocolDescriptorList attribute for that printing service. The transaction illustrates:

1. SDP Client to SDP Server: SDP_SERVICE_ATTR_REQ, presenting the previously obtained service handle (the one denoted as `qqqqqqqq`) and specifying the ProtocolDescriptorList attribute ID (AttributeID 0x0004) as the only attribute requested (other attributes could be retrieved in the same transaction if desired). The TransactionID is illustrated as `uuuu` to distinguish it from the TransactionID of Example 1.
2. SDP Server to SDP Client: SDP_SERVICE_ATTR_RSP, returning the ProtocolDescriptorList for the specified printing service. This protocol stack is assumed to be ((L2CAP), (RFCOMM, 2), (PostscriptStream)). The ProtocolDescriptorList is a data element sequence in which each element is, in turn, a data element sequence whose first element is a UUID representing the protocol, and whose subsequent elements are protocol-specific parameters. In this example, one such parameter is included for the RFCOMM protocol, an 8-bit value indicating RFCOMM server channel 2. The Transaction ID is the same value as supplied by the SDP Client in the corresponding request (`uuuu`). The Attributes returned are illustrated as a data element sequence where the protocol descriptors

are 32-bit UUIDs and the RFCOMM server channel is a data element with an 8-bit value of 2.

```
/* Sent from SDP Client to SDP Server */
SDP_SERVICE_ATTR_REQ[17] {
  PDUID[1] {
    0x04
  }
  TransactionID[2] {
    0xuuuu
  }
  ParameterLength[2] {
    0x000C
  }
  ServiceRecordHandle[4] {
    0xqqqqqqqq
  }
  MaximumAttributeByteCount[2] {
    0x0080
  }
  AttributeIDList[5] {
    DataElementSequence[5] {
      0b00110 0b101 0x03
      AttributeID[3] {
        0b00001 0b001 0x0004
      }
    }
  }
  ContinuationState[1] {
    /* no continuation state */
    0x00
  }
}

/* Sent from SDP Server to SDP Client */
SDP_SERVICE_ATTR_RSP[38] {
  PDUID[1] {
    0x05
  }
  TransactionID[2] {
```

```
    0xuuuu
  }
  ParameterLength[2] {
    0x0021
  }
  AttributeListByteCount[2] {
    0x001E
  }
  AttributeList[30] {
    DataElementSequence[30] {
      0b00110 0b101 0x1C
      Attribute[28] {
        AttributeID[3] {
          0b00001 0b001 0x0004
        }
        AttributeValue[25] {
          /* ProtocolDescriptorList */
          DataElementSequence[25] {
            0b00110 0b101 0x17
            /* L2CAP protocol descriptor */
            DataElementSequence[7] {
              0b00110 0b101 0x05
              UUID[5] {
                /* L2CAP Protocol UUID */

B.3 SDP example 3 – ServiceSearchAttributeTransaction

The third example is a form of service browsing, although it is not generic browsing in that it does not make use of SDP browse groups. Instead, an SDP Client is searching for available Synchronization services that can be presented to the user for selection. The SDP Client does not specify a particular type of synchronization service. In the example, the SDP Server has three available synchronization services: an address book synchronization service and a calendar synchronization service (both from the same provider), and a second calendar synchronization service from a different provider. The SDP Client is retrieving the same attributes for each of these services; namely, the data formats supported for the synchronization service (vCard, vCal, ICal, etc.) and those attributes that are relevant for presenting information to the user about the services. Also assume that the maximum size of a response is 400 bytes. Since the

result is larger than this, the SDP Client will repeat the request supplying a continuation state parameter to retrieve the remainder of the response. The transaction illustrates:

1. SDP Client to SDP Server: SDP_SERVICE_SEARCH_ATTR_REQ, specifying the generic SynchronisationServiceClassID (represented as a data element whose 32-bit UUID value is `sss...sss`) as the only element of the ServiceSearchPattern. The SynchronisationServiceClassID is assumed to be a 32-bit UUID. The requested attributes are the ServiceRecordHandle (Attribute ID 0x0000), ServiceClassIDList (AttributeID 0x0001), IconURL (AttributeID 0x000C), ServiceName (AttributeID 0x0100), ServiceDescription (AttributeID 0x0101), and ProviderName (AttributeID 0x0102) attributes; as well as the service-specific SupportedDataStores (AttributeID 0x0301). Since the first two attribute IDs (0x0000 and 0x0001) and three other attribute IDs(0x0100, 0x0101, and 0x0102 are consecutive, they are specified as attribute ranges. The TransactionID is illustrated as `vvvv` to distinguish it from the TransactionIDs of the other Examples.

   Values in the service record's primary language are requested for the text attributes (ServiceName, ServiceDescription and ProviderName) so that absolute attribute IDs may be used, rather than adding offsets to a base obtained from the LanguageBaseAttributeIDList attribute.

2. SDP Server to SDP Client: SDP_SERVICE_SEARCH_ATTR_RSP, returning the specified attributes for each of the three synchronization services. In the example, each ServiceClassIDList is assumed to contain a single element, the generic SynchronisationServiceClassID (a 32-bit UUID represented as sss...sss). Each of the other attributes contain illustrative data in the example (the strings have illustrative text; the icon URLs are illustrative, for each of the respective three synchronization services; and the SupportedDataStore attribute is represented as an unsigned 8-bit integer where 0x01 = vCard2.1, 0x02 = vCard3.0, 0x03 = vCal1.0 and 0x04 = iCal). One of the service records (the third for which data is returned) has no ServiceDescription attribute. The attributes are returned as a data element sequence, where each element is in turn a data element sequence representing a list of attributes. Within each attribute list, the ServiceClassIDList is a data element sequence while the remaining attributes are single data elements. The Transaction ID is the same value as supplied by the SDP Client in the corresponding request (0xvvvv). Since the entire result cannot be returned in a single response, a non-null continuation state is returned in this first response.

3. The total length of the initial data element sequence (487 in the example) is indicated in the first response, even though only a portion of this data element sequence (368 bytes in the example, as indicated in the AttributeLists byte count) is returned in the first response. The remainder of this data element sequence is returned in the second response (without an additional data element header).

4. SDP Client to SDP Server: SDP_SERVICE_SEARCH_ATTR_REQ, with the same parameters as in step 1, except that the continuation state received from the server

in step 2 is included as a request parameter. The TransactionID is changed to 0xwww to distinguish it from previous request.

5. SDP Server to SDP Client: SDP_SERVICE_SEARCH_ATTR_RSP, with the remainder of the result computed in step 2 above. Since all of the remaining result fits in this second response, a null continuation state is included.

Appendix C Changes to PDU names

Previous versions of this specification used different names for the PDUs defined in Section 4. Table C.1 shows the previous and current names of these PDUs.

Previous name	Current name
SDP_ErrorResponse	SDP_ERROR_RSP
SDP_ServiceAttributeRequest	SDP_SERVICE_ATTR_REQ
SDP_ServiceAttributeResponse	SDP_SERVICE_ATTR_RSP
SDP_ServiceSearchAttributeRequest	SDP_SERVICE_SEARCH_ATTR_REQ
SDP_ServiceSearchAttributeResponse	SDP_SERVICE_SEARCH_ATTR_RSP
SDP_ServiceSearchRequest	SDP_SERVICE_SEARCH_REQ
SDP_ServiceSearchResponse	SDP_SERVICE_SEARCH_RSP

Table C.1: Changes to PDU names

Host
Part C

GENERIC ACCESS PROFILE

This profile defines the generic procedures related to discovery of Bluetooth devices (idle mode procedures) and link management aspects of connecting to Bluetooth devices (connecting mode procedures). It also defines procedures related to use of different security levels. In addition, this profile includes common format requirements for parameters accessible on the user interface level.

CONTENTS

1 FOREWORD

Interoperability between devices from different manufacturers is provided for a specific service and use case, if the devices conform to a Bluetooth SIG- defined profile specification. A profile defines a selection of messages and procedures (generally termed *capabilities*) from the Bluetooth SIG specifications and gives a description of the air interface for specified service(s) and use case(s).

Whether the provision of a feature is mandatory or optional is stated separately for both sides of the Bluetooth air interface.

1.1 Scope

The purpose of the Generic Access Profile is:

To introduce definitions, recommendations and common requirements related to modes and access procedures that are to be used by transport and application profiles.

To describe how devices are to behave in standby and connecting states in order to avoid situations where links and channels cannot be established between Bluetooth devices or that prevent multi-profile operation. Special focus is put on discovery, link establishment and security procedures.

To state requirements on user interface aspects, mainly coding schemes and names of procedures and parameters, that are needed to provide a satisfactory user experience.

This profile defines three implementation transport types based on the supported Core Configurations as defined in [Vol 0] Part D, Section 2. These implementation transport types are defined in Table 1.1:

Implementation Transport Type	Description
BR/EDR-only	Implementations of a BR/EDR Core Configuration (see [Vol 0] Part D, Section 2.1.1, [Vol 0] Part D, Section 2.2.1, and [Vol 0] Part D, Section 2.3.1)
LE only	Implementations of an LE Core Configuration (see [Vol 0] Part D, Section 2.1.2, [Vol 0] Part D, Section 2.2.2, and [Vol 0] Part D, Section 2.3.2)
BR/EDR/LE	Implementations of a BR/EDR/LE Core Configuration (see [Vol 0] Part D, Section 2.1.3, [Vol 0] Part D, Section 2.2.3, and [Vol 0] Part D, Section 2.3.3)

Table 1.1: Implementation transport types

The terms physical transport, physical link and physical channel as defined in [Vol 1] Part A, Section 3 are used in the specification.

1.2 Symbols and conventions

1.2.1 [This section is no longer used]

1.2.2 Signaling diagram conventions

The arrows shown in Figure 1.1 are used in diagrams describing procedures:

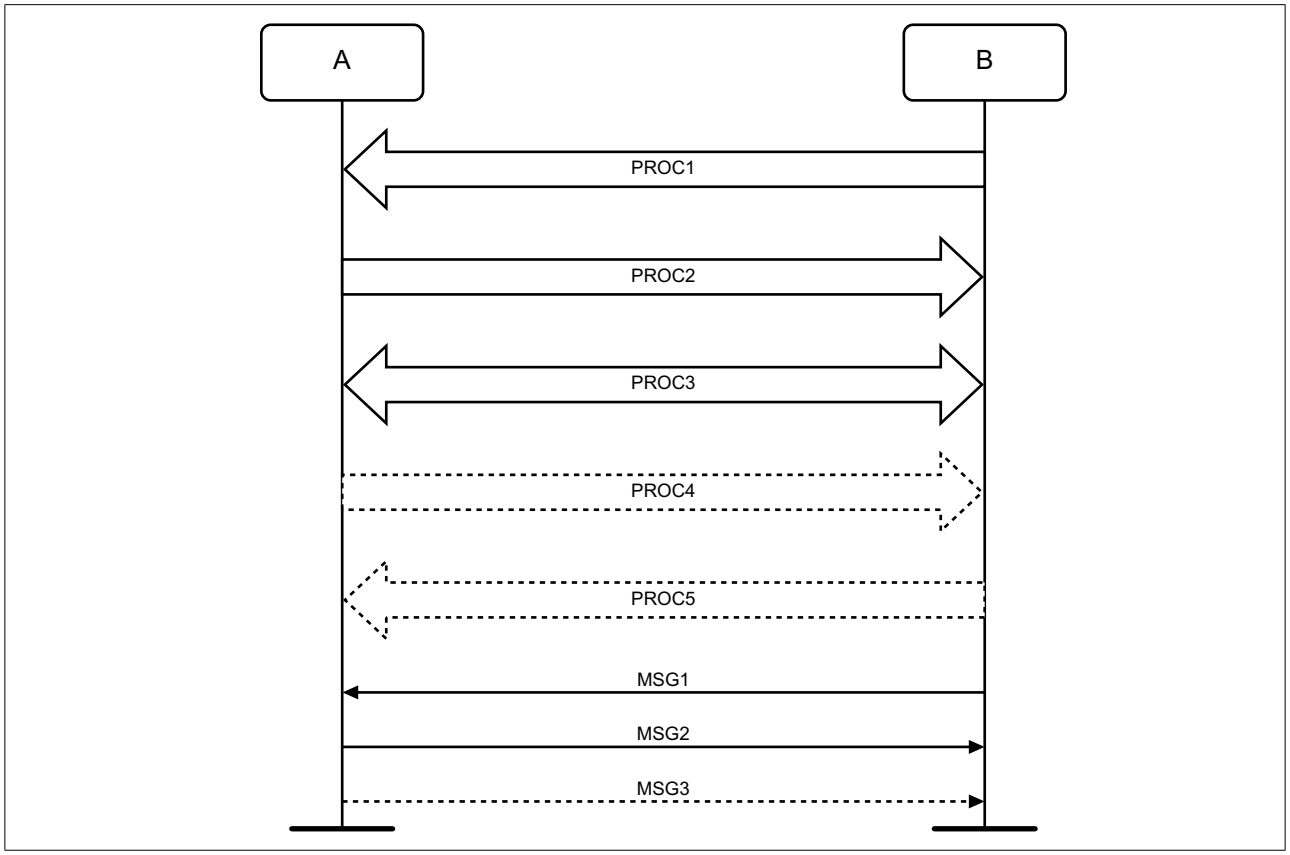

Figure 1.1: Arrows used in signaling diagrams

In Figure 1.1, the following cases are shown: PROC1 is a sub-procedure initiated by B. PROC2 is a sub-procedure initiated by A. PROC3 is a sub-procedure where the initiating side is undefined (may be both A or B). Dashed arrows denote optional steps. PROC4 indicates an optional sub-procedure initiated by A, and PROC5 indicates an optional sub-procedure initiated by B.

MSG1 is a message sent from B to A. MSG2 is a message sent from A to B. MSG3 indicates an optional message from A to B.

1.2.3 Notation for timers and counters

Timers are introduced specific to this profile. To distinguish them from timers used in the Bluetooth protocol specifications and other profiles, these timers are named in the following format: '$T_{GAP}(nnn)$'.

1.2.4 Notation for UUIDs

The use of « » (e.g. «Device Name») indicates a Bluetooth SIG-defined UUID.

1.3 GAP requirements

The sections of GAP that apply to an implementation depend on which Core-Host Configuration or Core-Complete Configuration (see [Vol 0] Part D, Section 2) it implements, as shown in Table 1.2.

Core Configuration	Applicable sections
BR/EDR	1 to 8, 12, 15 to 17, Appendices A and B
LE	1 to 3, 9 to 12, 15 to 17, Appendices A and B
BR/EDR/LE	All

Table 1.2: Required sections for each Core Configuration

2 PROFILE OVERVIEW

2.1 Profile stack

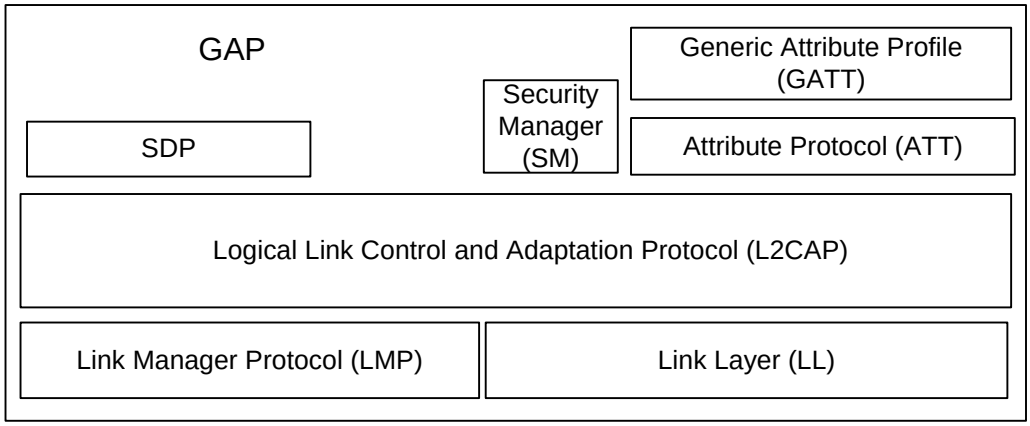

Figure 2.1: Relationship of GAP with lower layers of the Bluetooth architecture

The purpose of this profile is to describe:

- Profile roles
- Discoverability modes and procedures
- Connection modes and procedures
- Security modes and procedures

2.2 Profile roles

2.2.1 Roles when operating over BR/EDR Physical Transport

In GAP, for describing the Bluetooth communication that occurs between two devices in the BR/EDR GAP role, the generic notation of the A-party (the *paging device* in case of link establishment, or *initiator* in case of another procedure on an established link) and the B-party (*paged device* or *acceptor*) is used. The A-party is the one that, for a given procedure, initiates device discovery, initiates the establishment of a physical link or initiates a transaction on an existing link.

This profile handles the procedures between two devices related to discovery and connecting (link and connection establishment) for the case where none of the two devices has any link established as well as the case where (at least) one device has a link established (possibly to a third device) before starting the described procedure.

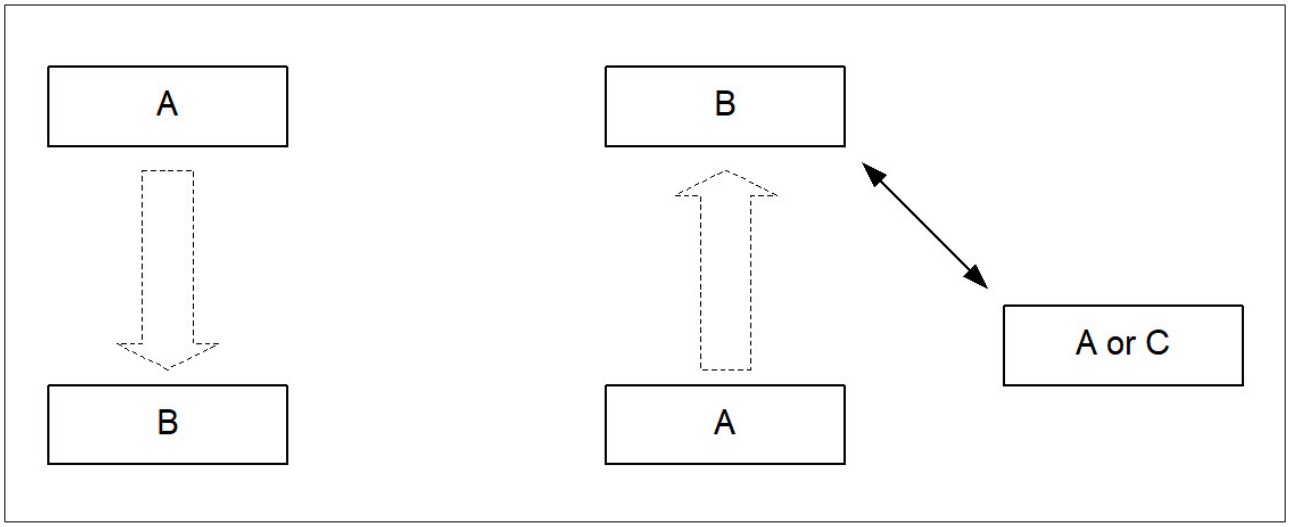

Figure 2.2: This profile covers procedures initiated by one device (A) towards another device (B) whether or not they have an existing Bluetooth link active

The initiator and the acceptor generally operate the generic procedures according to this profile or another profile referring to this profile. If the acceptor operates according to several profiles simultaneously, this profile describes generic mechanisms for how to handle this.

2.2.2 Roles when operating over an LE physical transport

There are four GAP roles defined for devices operating over an LE physical transport:

- Broadcaster
- Observer
- Peripheral
- Central

The GAP roles "Central" and "Peripheral" are related to, but not the same as, the Link Layer roles with the same names and therefore can have different requirements. If a connection is established successfully, the device with one of these GAP roles will also have the corresponding Link Layer role. However, the device can be in the GAP role without a connection being established.

Table 2.1 defines requirements for physical layer and Link Layer functionalities for each GAP role when operating over an LE physical transport.

		GAP Roles When Operating Over an LE Physical Transport			
		Broadcaster	**Observer**	**Peripheral**	**Central**
Physical layer functionality:					
• Transmitter characteristics		M	O	M	M
• Receiver characteristics		O	M	M	M
Link Layer functionality:					
States:					
• Standby state		M	M	M	M
• Advertising state		M	E	M	E
• Scanning state		E	M	E	M
• Initiating state		E	E	E	M
• Synchronization State		E	O	E	E
• Isochronous Broadcasting State		O	E	E	E
• Connection state	Peripheral role	E	E	M	E
	Central role	E	E	E	M
Advertising event types:					
• Connectable and scannable undirected event		E	E	M	E
• Connectable undirected event[1]		E	E	O	E
• Connectable directed event		E	E	O	E
• Non-connectable and non-scannable undirected event		M	E	O	E
• Non-connectable and non-scannable directed event[1]		O	E	O	E
• Scannable undirected event		O	E	O	E
• Scannable directed event[1]		O	E	O	E
Scanning type:					
• Passive scanning		E	M	E	O
• Active scanning		E	O	E	C.1
Link Layer control procedures:					
• Connection Update procedure		E	E	M	M
• Channel Map Update procedure		E	E	M	M
• Encryption procedure		E	E	O	O
• Central-initiated Feature Exchange procedure		E	E	M	M

	GAP Roles When Operating Over an LE Physical Transport			
	Broadcaster	**Observer**	**Peripheral**	**Central**
• Peripheral-initiated Feature Exchange procedure	E	E	C.2	C.2
• Connection Parameters Request procedure	E	E	O	O
• Version Exchange procedure	E	E	M	M
• ACL Termination procedure	E	E	M	M
• LE Ping procedure	E	E	O	O
• Data Length Update procedure	E	E	O	O
• PHY Update procedure	E	E	O	O
• Minimum Number Of Used Channels procedure	E	E	O	O
• Periodic Advertising Sync Transfer procedure	E	E	O	O
• Connected Isochronous Stream Creation procedure	E	E	O	O
• Connected Isochronous Stream Termination procedure	E	E	O	O
Broadcast control procedures:				
• Broadcast Isochronous Channel Map Update procedure	O	O	E	E
• Broadcast Isochronous Termination procedure	O	O	E	E
C.1: Optional if passive scanning is supported, otherwise mandatory.				
C.2: Mandatory if Connection Parameters Request procedure is supported, otherwise optional.				

Table 2.1: GAP requirements for physical layer and Link Layer functionalities for each GAP role when operating over an LE physical transport

[1]These advertising event types are excluded if the device does not support LE Extended Advertising.

2.2.2.1 Broadcaster role

A device operating in the Broadcaster role is a device that sends advertising events or periodic advertising events as described in [Vol 6] Part B, Section 4.4.2, and may also send Broadcast Isochronous Stream (BIS) events as described in [Vol 6] Part B, Section 4.4.6. A device operating in the Broadcaster role is referred to as a Broadcaster and shall have a transmitter and may have a receiver.

2.2.2.2 Observer role

A device operating in the Observer role is a device that receives advertising events or periodic advertising events as described in [Vol 6] Part B, Section 4.4.3, and may also

receive BIS events as described in [Vol 6] Part B, Section 4.4.6. A device operating in the Observer role is referred to as an Observer and shall have a receiver and may have a transmitter.

2.2.2.3 Peripheral role

Any device that accepts the establishment of an LE active physical link using any of the connection establishment procedures as defined in Section 9 is referred to as being in the Peripheral role. A device operating in the Peripheral role will be in the Peripheral role in the Link Layer Connection state as described in [Vol 6] Part B, Section 4.5. A device operating in the Peripheral role is referred to as a Peripheral. A Peripheral shall have both a transmitter and a receiver.

2.2.2.4 Central role

A device that supports the Central role initiates the establishment of an LE active physical link. A device operating in the Central role will be in the Central role in the Link Layer Connection state as described in [Vol 6] Part B, Section 4.5. A device operating in the Central role is referred to as a Central. A Central shall have both a transmitter and a receiver.

2.2.2.5 Concurrent operation in multiple GAP roles

A device may operate in multiple GAP roles concurrently if supported by the Controller. The Host should read the supported Link Layer states and state combinations from the Controller before any procedures or modes are used.

2.3 User requirements and scenarios

The Bluetooth user should, where expected, be able to connect a Bluetooth device to any other Bluetooth device. Even if the two connected devices don’t share any common application, it should be possible for the user to find this out using basic Bluetooth capabilities. When the two devices do share the same application but are from different manufacturers, the ability to connect them should not be blocked just because manufacturers choose to call basic Bluetooth capabilities by different names on the user interface level or implement basic procedures to be executed in different orders.

2.4 Profile fundamentals

This profile states the requirements on names, values and coding schemes used for names of parameters and procedures experienced on the user interface level.

This profile defines modes of operation that are not service- or profile-specific, but that are generic and can be used by profiles referring to this profile, and by devices implementing multiple profiles.

This profile defines the general procedures that can be used for discovering identities, names and basic capabilities of other Bluetooth devices that are in a mode where they can be discovered. Only procedures where no channel or connection establishment is used are specified.

This profile defines the general procedure for how to create bonds (i.e., dedicated exchange of link keys) between Bluetooth devices.

This profile describes the general procedures that can be used for establishing connections to other Bluetooth devices that are in a mode that allows them to accept connections and service requests.

2.5 [This section is no longer used]

3 USER INTERFACE ASPECTS

3.1 The user interface level

In the context of the specification, the user interface level refers to places (such as displays, dialog boxes, manuals, packaging, advertising, etc.) where users of Bluetooth devices encounter names, values, and numeric representations of Bluetooth terminology and parameters.

This profile specifies the generic terms that should be used on the user interface level.

3.2 Representation of Bluetooth parameters

3.2.1 Bluetooth Device Address (BD_ADDR)

3.2.1.1 Definition

A BD_ADDR is the address used by a Bluetooth device as defined in Section 15.1. It is received from a remote device during the device discovery procedure.

3.2.1.2 Term on user interface level

When the Bluetooth address is referred to on the UI level, the term ‘Bluetooth Device Address’ should be used.

3.2.1.3 Representation

On the Baseband level the BD_ADDR is represented as 48 bits (see [Vol 2] Part B, Section 1.2). On the Link Layer the public and random device address are represented as 48-bit addresses.

On the UI level the Bluetooth address shall be represented as 12 hexadecimal characters, possibly divided into sub-parts separated by ‘:’ (e.g., ‘000C3E3A4B69’ or ‘00:0C:3E:3A:4B:69’). On the UI level any number shall have the MSB -> LSB (from left to right) ‘natural’ ordering.

3.2.2 Bluetooth Device Name (the user-friendly name)

3.2.2.1 Definition

The Bluetooth Device Name is the user-friendly name that a Bluetooth device exposes to remote devices. For a BR/EDR-only implementation, the name is a character string returned in the LMP_NAME_RES in response to an LMP_NAME_REQ. For an LE-only implementation, the name is a character string held in the Device Name characteristic as defined in Section 12.1.

3.2.2.1.1 Bluetooth Device Name in a BR/EDR/LE implementation

A BR/EDR/LE implementation shall have a single Bluetooth Device Name which shall be identical irrespective of the physical channel used to perform the name discovery procedure.

For the BR/EDR physical channel the name is received in the LMP_NAME_RES. For the LE physical channel the name can be read from the Device Name characteristic as defined in Section 12.1.

Note: The Device Name Characteristic of the local device can be read by a remote device using ATT over BR/EDR if the local device supports ATT over BR/EDR.

3.2.2.2 Term on user interface level

When the Bluetooth Device Name is referred to on the UI level, the term ‘Bluetooth Device Name’ should be used.

3.2.2.3 Representation

The Bluetooth Device Name can be up to 248 bytes (see [Vol 2] Part C, Section 4.3.5). It shall be encoded according to UTF-8 (therefore the name entered on the UI level may be restricted to as few as 62 characters if codepoints outside the range U+0000 to U+007F are used).

A device cannot expect that a general remote device is able to handle more than the first 40 characters of the Bluetooth Device Name. If a remote device has limited display capabilities, it may use only the first 20 characters.

3.2.3 Bluetooth Passkey (Bluetooth PIN)

3.2.3.1 Definition

The Bluetooth Passkey may be used to authenticate two Bluetooth devices with each other during the creation of a mutual link key via the pairing procedure. The passkey may be used in the pairing procedures to generate the initial link key.

The PIN may be entered on the UI level but may also be stored in the device; e.g., in the case of a device without an interface for entering and displaying digits.

3.2.3.2 Terms at user interface level

When the Bluetooth PIN is referred to on the UI level, the term ‘Bluetooth Passkey’ should be used.

3.2.3.3 Representation

There are a number of different representations of the Bluetooth Passkey. At a high level there are two distinct representations: one used with the Secure Simple Pairing

and Security Manager, and another used with legacy pairing (where it is generally referred to as the Bluetooth PIN).

For Secure Simple Pairing and Security Manager, the Bluetooth Passkey is a 6-digit numeric value. It is represented as integer value in the range 0x00000000 – 0x000F423F (000000 to 999999). The numeric value may be used as the input to the Authentication stage 1 for Secure Simple Pairing Passkey Entry (see [Vol 2] Part H, Section 7.2.3), or as the TK value in the Security Manager for the process defined in [Vol 3] Part H, Section 2.3.5.

For legacy pairing (see Section B.2), the Bluetooth PIN has different representations on different levels. PINBB is used on the Baseband level, and PINUI is used on the user interface level. PINBB is the PIN used in [Vol 2] Part H, Section 3.2.1 for calculating the initialization key during the Pairing procedure.

PINUI is the character representation of the PIN that is entered on the UI level. The transformation from PINUI to PINBB shall be according to UTF-8. PINBB may be 128 bits (16 bytes).

PIN codes may be up to 16 characters. In order to take advantage of the full level of security all PINs should be 16 characters long. Variable PINs should be composed of alphanumeric characters chosen from within the Unicode range U+0000 to U+007F. If the PIN contains any decimal digits these shall be encoded using the Unicode Basic Latin characters (i.e., U+0030 to U+0039) (Note 1).

For compatibility with devices with numeric keypads, fixed PINs shall be composed of only decimal digits, and variable PINs should be composed of only decimal digits.

If a device supports entry of characters outside the Unicode range U+0000 to U+007F, other Unicode code points may be used (Note 2), except the Halfwidth and Fullwidth Forms (i.e., U+FF00 to U+FFEF) shall not be used (Note 3).

Examples:

User-entered code	**Corresponding PIN_{BB}[0..length-1]** **(value as a sequence of octets in hexadecimal notation)**
’0196554200906493’	length = 16, value = 0x30 0x31 0x39 0x36 0x35 0x35 0x34 0x32 0x30 0x30 0x39 0x30 0x36 0x34 0x39 0x33
’Børnelitteratur’	length = 16, value = 0x42 0xC3 0xB8 0x72 0x6E 0x65 0x6C 0x69 0x74 0x74 0x65 0x72 0x61 0x74 0x75 0x72

Note 1: This is to prevent interoperability problems since there are decimal digits at other code points (e.g., the Fullwidth digits at code points U+FF10 to U+FF19).

Note 2: Unicode characters outside the Basic Latin range (U+0000 to U+007F) encode to multiple bytes; therefore, when characters outside the Basic Latin range are used the maximum number of characters in the PINUI will be less than 16. The second example illustrates a case where a 15 character string encodes to 16 bytes because the character ø is outside the Basic Latin range and encodes to two bytes (0xC3 0xB8).

Note 3: This is to prevent interoperability problems since the Halfwidth and Fullwidth forms contain alternative variants of ASCII, Katakana, Hangul, punctuation and symbols. All of the characters in the Halfwidth and Fullwidth forms have other related Unicode characters; for example, U+3150 (Hangul Letter AE) can be used instead of U+FFC3 (Halfwidth Hangul Letter AE).

3.2.4 Class of Device

3.2.4.1 Definition

Class of Device is a parameter received during the device discovery procedure on the BR/EDR physical transport, indicating the type of device. The Class of Device parameter is only used on BR/EDR and BR/EDR/LE devices using the BR/EDR physical transport.

3.2.4.2 Term on user interface level

The information within the Class of Device parameter should be referred to as ‘Bluetooth Device Class’ (i.e., the major and minor device class fields) and ‘Bluetooth Service Type’ (i.e., the service class field). The terms for the defined Bluetooth Device Classes and Bluetooth Service Types are defined in [3].

When using a mix of information found in the Bluetooth Device Class and the Bluetooth Service Type, the term ‘Bluetooth Device Type’ should be used.

3.2.4.3 Representation

The Class of Device is a bit field and is defined in [3]. The UI-level representation of the information in the Class of Device is implementation specific.

3.2.4.4 Usage

Some devices provide more than one service and a given service may be provided by different device types. Therefore, the device type does not have a one-to-one relationship with services supported. The major and minor device class field should not be used to determine whether a device supports any specific service(s). It may be used as an indication of devices that are most likely to support desired services before service discovery requests are made, and it may be used to guide the user when selecting among several devices that support the same service.

3.2.5 Appearance characteristic

3.2.5.1 Definition

The Appearance characteristic contains a 16-bit number that can be mapped to an icon or string that describes the physical representation of the device during the device discovery procedure. It is a characteristic of the GAP Service located on the device's GATT Server. See Section 12.2.

3.2.5.2 Usage at user interface level

The Appearance characteristic value should be mapped to an icon or string or something similar that conveys to the user a visual description of the device. This allows the user to determine which device is being discovered purely by visual appearance. If a string is displayed, this string should be translated into the language selected by the user for the device.

3.2.5.3 Representation

The Appearance characteristic value shall be set to one of the 16-bit numbers assigned by the Bluetooth SIG and defined in Section 1.12 of [4]. The UI-level representation of the Appearance characteristic value is implementation specific.

3.2.6 Broadcast Code

3.2.6.1 Definition

The Broadcast_Code parameter is used to support an encrypted BIG. It is used in the process of encrypting the data in the transmission of an encrypted BIG and in the process of decrypting the data in the reception of a BIS within that BIG.

3.2.6.2 Terms at user interface level

When the Broadcast_Code parameter is referred to on the UI level, the term 'Bluetooth Privacy Code' should be used.

3.2.6.3 Representation

The Broadcast_Code parameter has different representations on different levels.

On the UI level, the Broadcast Code parameter shall be represented as a string of at least 4 octets that meets the requirements in Section 3.2.3.3 for a PINUI (e.g., it is not more than 16 octets when represented in UTF-8). 16 octets should be used for higher level of security.

On all levels other than UI, the Broadcast Code parameter shall be represented as a 128-bit value. The transformation from string to number shall be by representing

the string in UTF-8, placing the resulting bytes in 8-bit fields of the value starting at the least significant bit, and then padding with zeros in the most significant bits if necessary. For example, the string “Børne House” is represented as the value 0x00000000_6573756F_4820656E_72B8C342.

3.3 Pairing

Pairing over a BR/EDR physical link is defined on LMP level (LMP pairing, see Section B.2). Pairing over an LE physical link is defined by the Security Manager specification ([Vol 3] Part H, Section 2.3). Either the user initiates the bonding procedure and enters the passkey with the explicit purpose of creating a bond (and maybe also a secure relationship) between two Bluetooth devices, or the user is requested to enter the passkey during the establishment procedure since the devices did not share a common link key beforehand. In the first case, the user is said to perform “bonding (with entering of passkey)” and in the second case the user is said to “authenticate using the passkey.”

4 MODES – BR/EDR PHYSICAL TRANSPORT

Group	Ref.	Mode	Support
Discoverability modes:	4.1	Non-discoverable	C.1
		Limited discoverable	O
		General discoverable	O
Connectability modes:	4.2	Non-connectable	O
		Connectable	M
Bondable modes:	4.3	Non-bondable	C.4
		Bondable	C.2
Synchronizability modes:	4.4	Non-synchronizable	M
		Synchronizable	C.5
C.1: Mandatory if limited discoverable mode is supported or general discoverable mode is not supported, otherwise optional.			
C.2: Mandatory if the bonding procedure is supported, otherwise optional.			
C.4: Optional if Bondable mode is supported, otherwise mandatory.			
C.5: Optional if the Synchronization Train procedure is supported, otherwise excluded.			

Table 4.1: Conformance requirements related to modes defined in this section

4.1 Discoverability modes

With respect to inquiry, a Bluetooth device shall be either in non-discoverable mode or in a discoverable mode. (The device shall be in one, and only one, discoverability mode at a time.) The two discoverable modes defined here are called limited discoverable mode and general discoverable mode. Inquiry is defined in [Vol 2] Part B, Section 8.4.

When a Bluetooth device is in non-discoverable mode it does not respond to inquiry.

A Bluetooth device is said to be made discoverable, or set into a discoverable mode, when it is in limited discoverable mode or in general discoverable mode. Even when a Bluetooth device is made discoverable, it may be unable to respond to inquiry due to other Baseband activity (for example, reserved synchronous slots should have priority over response packets, so that synchronous links may prevent a response from being returned). A Bluetooth device that does not respond to inquiry is called a silent device.

After being made discoverable, the Bluetooth device shall be discoverable for at least $T_{GAP}(103)$.

The speed of discovery is dependent on the configuration of the inquiry scan interval and inquiry scan type of the Bluetooth device. The Host is able to configure these

parameters based on trade-offs between power consumption, bandwidth and the desired speed of discovery.

4.1.1 Non-discoverable mode

4.1.1.1 Definition

When a Bluetooth device is in non-discoverable mode, it shall never enter the INQUIRY_SCAN state.

4.1.1.2 Term on UI-level

Bluetooth device is ‘non-discoverable’ or in ’non-discoverable mode’.

4.1.2 Limited Discoverable mode

4.1.2.1 Definition

The limited discoverable mode should be used by devices that need to be discoverable only for a limited period of time, during temporary conditions, or for a specific event.

There are two common reasons to use limited discoverable mode:

- Limited discoverable mode can be used to allow remote devices using the general inquiry procedure to prioritize or otherwise identify devices in limited discoverable mode when presenting discovered devices to the end user because, typically, the user is interacting with them.
- Limited discoverable mode can also be used to allow remote devices using the limited inquiry procedure to filter out devices using the general discoverable mode.

A Bluetooth device should not be in limited discoverable mode for more than $T_{GAP}(104)$. The scanning for the limited inquiry access code can be done either in parallel or in sequence with the scanning of the general inquiry access code. When in limited discoverable mode, one of the following options shall be used.

- *Parallel scanning*

  When a Bluetooth device is in limited discoverable mode and when discovery speed is more important than power consumption or bandwidth, it is recommended that the Bluetooth device enter the INQUIRY_SCAN state at least every $T_{GAP}(105)$ and that Interlaced Inquiry scan is used.

  If, however, power consumption or bandwidth is important, but not critical, it is recommended that the Bluetooth device enter the INQUIRY_SCAN state at least every $T_{GAP}(102)$ and Interlaced Inquiry scan is used.

When power consumption or bandwidth is critical it is recommended that the Bluetooth device enter the INQUIRY_SCAN state at least every $T_{GAP}(102)$ and Non-interlaced Inquiry scan is used.

In all cases the Bluetooth device shall enter the INQUIRY_SCAN state at least once in $T_{GAP}(102)$ and scan for the GIAC and the LIAC for at least $T_{GAP}(101)$.

When either a SCO or eSCO link is in operation, it is recommended to use interlaced scan to significantly decrease the discoverability time.

- *Sequential scanning*

  When a Bluetooth device is in limited discoverable mode, it shall enter the INQUIRY_SCAN state at least once in $T_{GAP}(102)$ and scan for the GIAC for at least $T_{GAP}(101)$ and enter the INQUIRY_SCAN state more often than once in $T_{GAP}(102)$ and scan for the LIAC for at least $T_{GAP}(101)$.

  If an inquiry message is received when in limited discoverable mode, the entry into the INQUIRY_RESPONSE state takes precedence over the next entries into INQUIRY_SCAN state until the inquiry response is completed.

4.1.2.2 Conditions

When a device is in limited discoverable mode it shall set bit number 13 in the Major Service Class part of the Class of Device/Service field [3].

4.1.2.3 Term on UI-level

Bluetooth device is ‘discoverable’ or in ‘discoverable mode’.

4.1.3 General Discoverable mode

4.1.3.1 Definition

The general discoverable mode shall be used by devices that need to be

discoverable continuously or for no specific condition.

Devices in the general discoverable mode will not be discovered by devices performing the limited inquiry procedure. General discoverable mode should not be used if it is known that the device performing discovery will be using the limited inquiry procedure (see Section 6.1).

4.1.3.2 Conditions

When a Bluetooth device is in general discoverable mode and when discovery speed is more important than power consumption or bandwidth, it is recommended that the Bluetooth device enter the INQUIRY_SCAN state at least every $T_{GAP}(105)$ and that Interlaced Inquiry scan is used.

If, however, power consumption or bandwidth is important, but not critical, it is recommended that the Bluetooth device enter the INQUIRY_SCAN state at least every $T_{GAP}(102)$ and Interlaced Inquiry scan is used.

When power consumption or bandwidth is critical it is recommended that the Bluetooth device enter the INQUIRY_SCAN state at least every $T_{GAP}(102)$ and Non-interlaced Inquiry scan is used.

In all cases the Bluetooth device shall enter the INQUIRY_SCAN state at least once in $T_{GAP}(102)$ and scan for the GIAC for at least $T_{GAP}(101)$.

When either a SCO or eSCO link is in operation, it is recommended to use interlaced scan to significantly decrease the discoverability time.

A device in general discoverable mode shall not respond to a LIAC inquiry.

4.1.3.3 Term on UI-level

Bluetooth device is ‘discoverable’ or in ‘discoverable mode’.

4.2 Connectability modes

With respect to paging, a Bluetooth device shall be either in non-connectable mode or connectable mode. Paging is defined in [Vol 2] Part B, Section 8.3.

When a Bluetooth device is in non-connectable mode it does not respond to paging. When a Bluetooth device is in connectable mode it responds to paging.

The speed of connections is dependent on the configuration of the page scan interval and page scan type of the Bluetooth device. The Host is able to configure these parameters based on trade-offs between power consumption, bandwidth and the desired speed of connection.

4.2.1 Non-connectable mode

4.2.1.1 Definition

When a Bluetooth device is in non-connectable mode it shall never enter the PAGE_SCAN state.

4.2.1.2 Term on UI-level

Bluetooth device is ‘non-connectable’ or in ‘non-connectable mode’.

4.2.2 Connectable mode

4.2.2.1 Definition

When a Bluetooth device is in connectable mode it shall periodically enter the PAGE_SCAN state. The device performs page scan using the Bluetooth Device Address, BD_ADDR. Connection speed is a trade-off between power consumption / available bandwidth and speed. The Bluetooth Host is able to make these trade-offs using the Page Scan interval, Page Scan window, and Interlaced Scan parameters.

R0 page scanning should be used when connection speeds are critically important and when the paging device has a very good estimate of the Bluetooth clock. Under these conditions it is possible for paging to complete within two times the page scan window. Because the page scan interval is equal to the page scan window it is not possible for any other traffic to go over the Bluetooth link when using R0 page scanning. In R0 page scanning it is not possible to use interlaced scan. R0 page scanning is the highest power consumption mode of operation.

When connection times are critical but the other device either does not have an estimate of the Bluetooth clock or when the estimate is possibly out of date, it is better to use R1 page scanning with a very short page scan interval, $T_{GAP}(106)$, and Interlaced scan. This configuration is also useful to achieve nearly the same connection speeds as R0 page scanning but using less power and leaving bandwidth available for other connections. Under these circumstances it is possible for paging to complete within $T_{GAP}(106)$. In this case the Bluetooth device shall page scan for at least $T_{GAP}(101)$.

When connection times are important but not critical enough to sacrifice significant bandwidth and/or power consumption it is recommended to use either $T_{GAP}(107)$ or $T_{GAP}(108)$ for the scanning interval. Using Interlaced scan will reduce the connection time by half but may use twice the power consumption. Under these circumstances it is possible for paging to complete within one or two times the page scanning interval depending on whether Interlaced Scan is used. In this case the Bluetooth device shall page scan for at least $T_{GAP}(101)$.

In all cases the Bluetooth device shall enter the PAGE_SCAN state at least once in $T_{GAP}(102)$ and scan for at least $T_{GAP}(101)$.

The page scan interval, page scan window size, and scan type for the six scenarios are described in Table 4.2:

Scenario	Page Scan Interval	Page Scan Window	Scan Type
R0 (1.28 s)	$T_{GAP}(107)$	$T_{GAP}(107)$	Normal scan
Fast R1 (100 ms)	$T_{GAP}(106)$	$T_{GAP}(101)$	Interlaced scan

Scenario	Page Scan Interval	Page Scan Window	Scan Type
Medium R1 (1.28 s)	$T_{GAP}(107)$	$T_{GAP}(101)$	Interlaced scan
Slow R1 (1.28 s)	$T_{GAP}(107)$	$T_{GAP}(101)$	Normal scan
Fast R2 (2.56 s)	$T_{GAP}(108)$	$T_{GAP}(101)$	Interlaced scan
Slow R2 (2.56 s)	$T_{GAP}(108)$	$T_{GAP}(101)$	Normal scan

Table 4.2: Page scan parameters for connection speed scenarios

When either a SCO or eSCO link is in operation, it is recommended to use interlaced scan to significantly decrease the connection time.

4.2.2.2 Term on UI-level

Bluetooth device is ‘connectable’ or in ‘connectable mode’.

4.3 Bondable modes

With respect to bonding, a Bluetooth device shall be either in non-bondable mode or in bondable mode. In bondable mode the Bluetooth device accepts bonding initiated by the remote device, and in non-bondable mode it does not.

4.3.1 Non-bondable mode

4.3.1.1 Definition

When a Bluetooth device is in non-bondable mode it shall not accept a pairing request that results in bonding. Devices in non-bondable mode may accept connections that do not request or require bonding.

A device in non-bondable mode shall respond to a received LMP_IN_RAND with LMP_NOT_ACCEPTED with the reason *pairing not allowed*.

When both devices support Secure Simple Pairing and the local device is in non-bondable mode, the local Host shall respond to an IO capability request where the Authentication_Requirements parameter requests dedicated bonding or general bonding with a negative response.

4.3.1.2 Term on UI-level

Bluetooth device is ‘non-bondable’ or in ‘non-bondable mode’ or “does not accept bonding”.

4.3.2 Bondable mode

4.3.2.1 Definition

When a Bluetooth device is in bondable mode, and Secure Simple Pairing is not supported by either the local or remote device, the local device shall respond to a

received LMP_IN_RAND with LMP_ACCEPTED (or with LMP_IN_RAND if it has a fixed PIN).

When both devices support Secure Simple Pairing, the local Host shall respond to a user confirmation request with a positive response.

4.3.2.2 Term on UI-level

Bluetooth device is ‘bondable’ or in ‘bondable mode’ or “accepts bonding”.

4.4 Synchronizability modes

A Bluetooth device shall be either in non-synchronizable mode or synchronizable mode. The synchronization train procedure is defined in [Vol 2] Part B, Section 2.7.2.

When a Bluetooth device is in synchronizable mode, it transmits timing and frequency information for its active Connectionless Peripheral Broadcast packets. When a Bluetooth device is non-synchronizable, timing and frequency information is not transmitted.

The Host is able to configure the Synchronization Train interval based on trade-offs between bandwidth, potential interference to other devices, power consumption, and the desired time for a Peripheral to receive a synchronization train packet.

4.4.1 Non-synchronizable mode

4.4.1.1 Definition

When a Bluetooth device is in non-synchronizable mode it shall never enter the Synchronization Train substate.

4.4.1.2 Term on UI-level

Bluetooth device is ‘non-synchronizable’ or in ‘non-synchronizable mode’.

4.4.2 Synchronizable mode

4.4.2.1 Definition

When a Bluetooth device is in synchronizable mode, it shall enter the Synchronization Train substate using a synchronization train interval of T_{GAP}(Sync_Train_Interval).

After being made synchronizable, the Bluetooth device shall be synchronizable for at least T_{GAP}(Sync_Train_Duration).

4.4.2.2 Term on UI-level

Bluetooth device is 'synchronizable' or in 'synchronizable mode'.

5 SECURITY ASPECTS – BR/EDR PHYSICAL TRANSPORT

Procedure	Ref.	Support
Authentication	5.1	M
Security mode 1	5.2.1.1	E
Security mode 2	5.2.1.2	C.1
Security mode 3	5.2.1.3	E
Security mode 4	5.2.2	M
C.1: Security mode 2 may only be used for backwards compatibility when the remote device does not support Secure Simple Pairing.		

Table 5.1: Conformance requirements related to the generic authentication procedure and the security modes defined in this section

5.1 Authentication

5.1.1 Purpose

The generic authentication procedure describes how the LMP-authentication and LMP-pairing procedures are used when authentication is initiated by one Bluetooth device towards another, depending on if a link key exists or not and if pairing is allowed or not.

5.1.2 Term on UI level

‘Bluetooth authentication’.

5.1.3 Procedure

Figure 5.1 defines the generic authentication procedure.

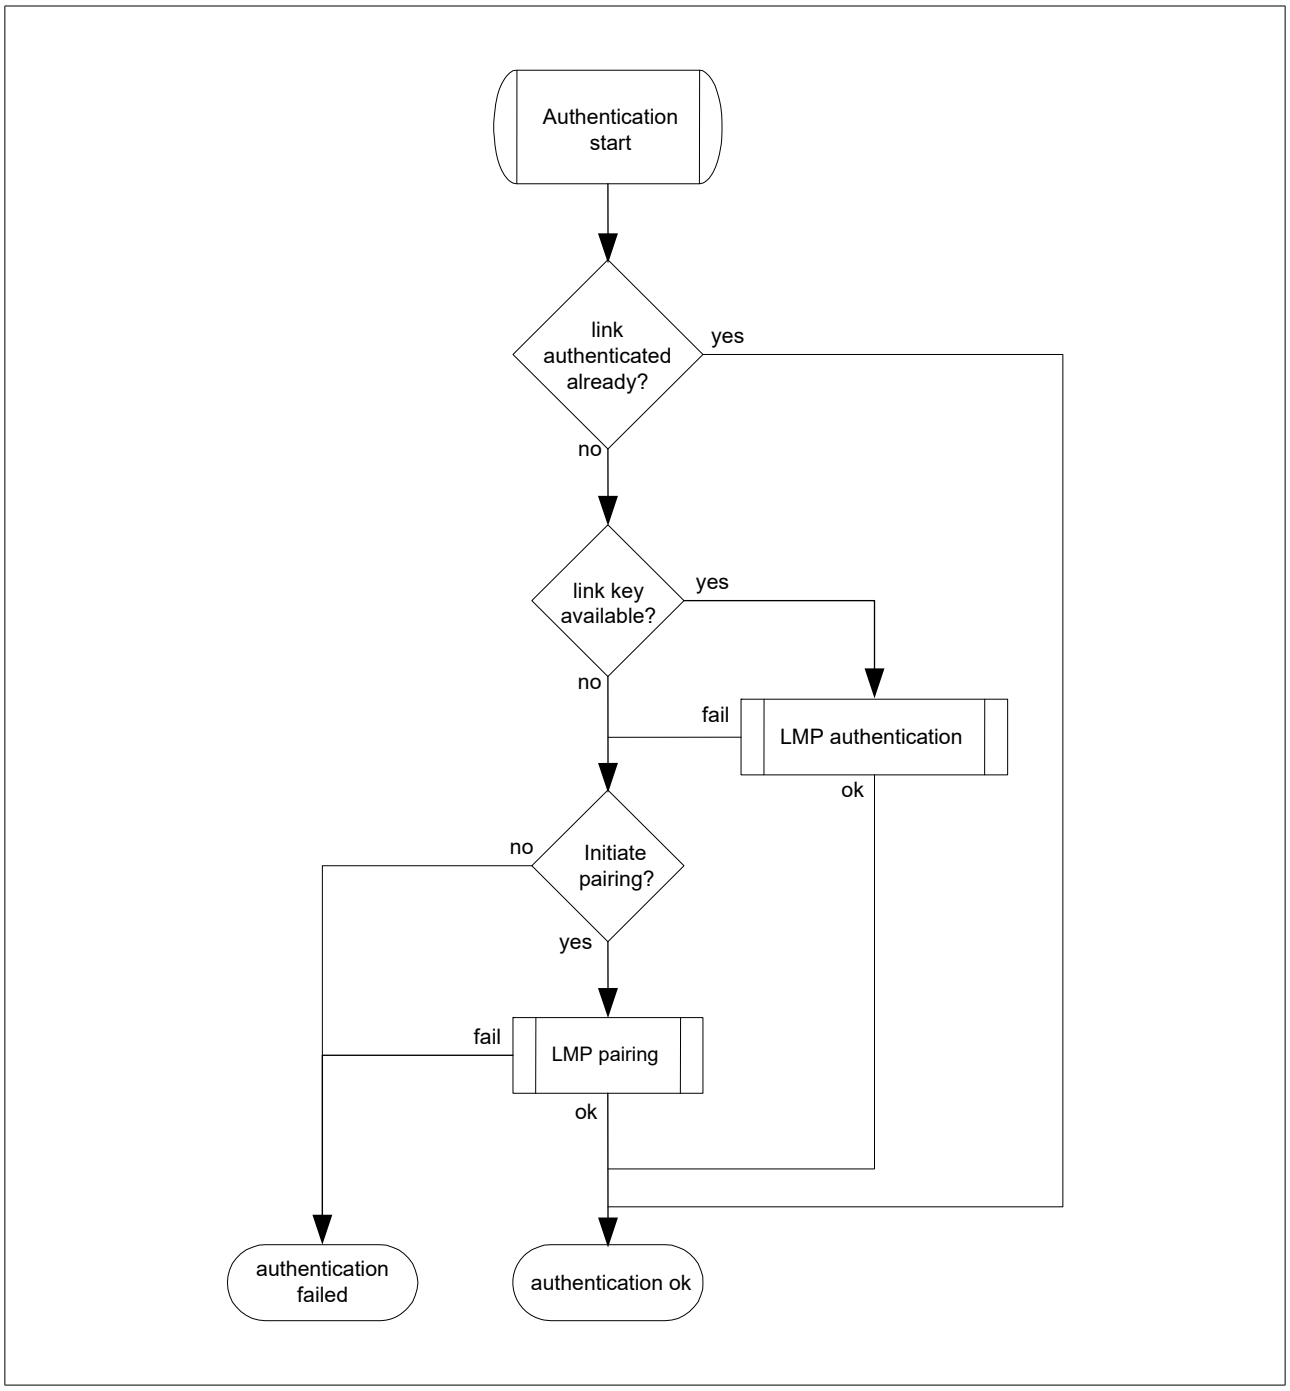

Figure 5.1: Definition of the generic authentication procedure

5.1.4 Conditions

The local device shall initiate authentication after link establishment. The remote device may initiate security during or after link establishment.

5.2 Security modes

The flow chart in Figure 5.2, including the steps in Figure 5.3, Figure 5.4, and Figure 5.5, specifies the overall channel establishment procedures. The following subsections give more details of these procedures.

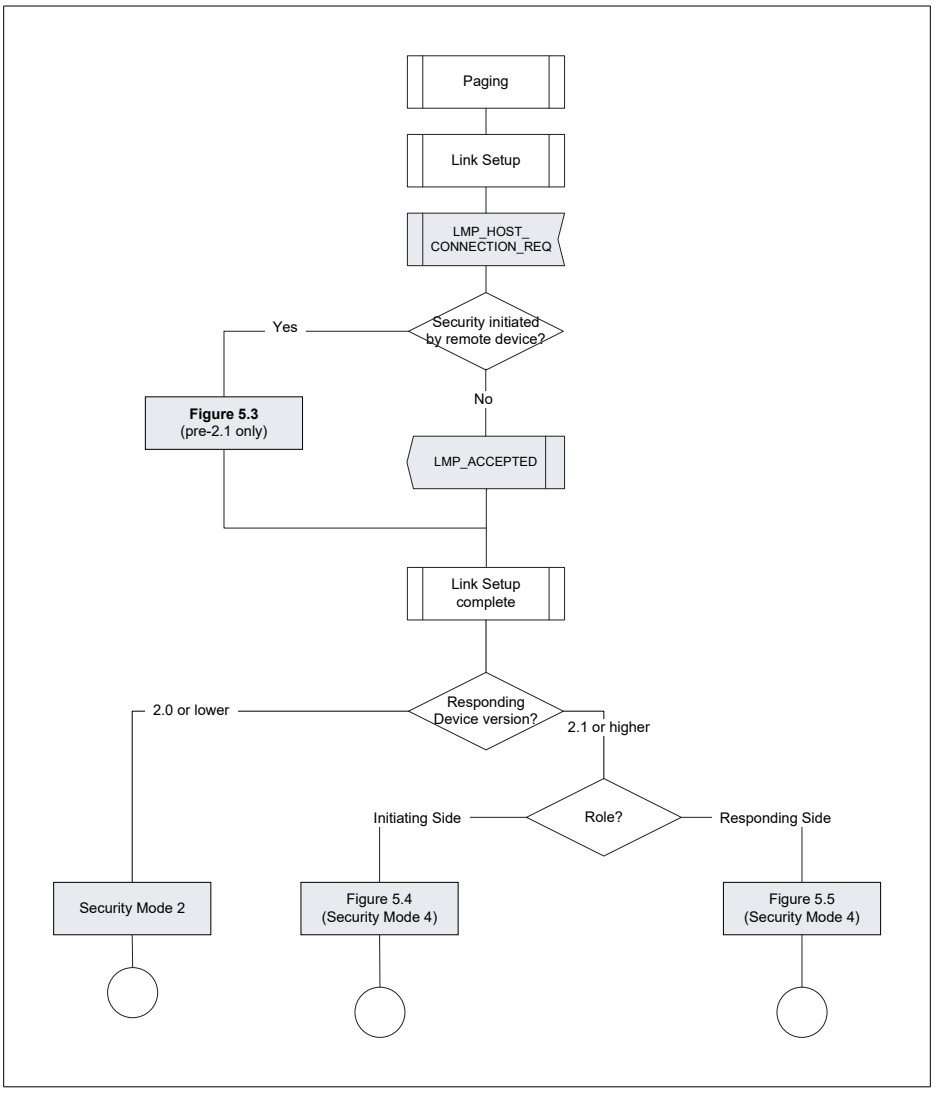

Figure 5.2: Channel establishment with security

A device may support two security modes simultaneously: security mode 2 for backwards compatibility with remote devices that do not support Secure Simple Pairing and security mode 4 for devices that support Secure Simple Pairing.

5.2.1 Legacy security modes

Legacy security modes apply to those devices with a Controller or a Host that does not support SSP.

5.2.1.1 Security mode 1 (non-secure)

When a remote Bluetooth device is in security mode 1 it will never initiate any security procedure (i.e., it will never send LMP_AU_RAND, LMP_IN_RAND or LMP_ENCRYPTION_MODE_REQ).

5.2.1.2 Security mode 2 (service level enforced security)

When a remote Bluetooth device is in security mode 2 it will not initiate any security procedure before a channel establishment request (L2CAP_CONNECTION_REQ) has been received or a channel establishment procedure has been initiated by itself. Whether a security procedure is initiated or not depends on the security requirements of the requested channel or service.

A Bluetooth device in security mode 2 should classify the security requirements of its services using at least the following attributes:

- Authorization required
- Authentication required
- Encryption required

Note: Security mode 1 can be considered (at least from a remote device point of view) as a special case of security mode 2 where no service has registered any security requirements.

5.2.1.3 Security mode 3 (link level enforced security)

When a remote Bluetooth device is in security mode 3 it will initiate security procedures before it sends LMP_SETUP_COMPLETE.

A Bluetooth device in security mode 3 may reject the Host connection request (respond with LMP_NOT_ACCEPTED to the LMP_HOST_CONNECTION_REQ) based on settings in the Host (e.g., only communication with pre-paired devices allowed).

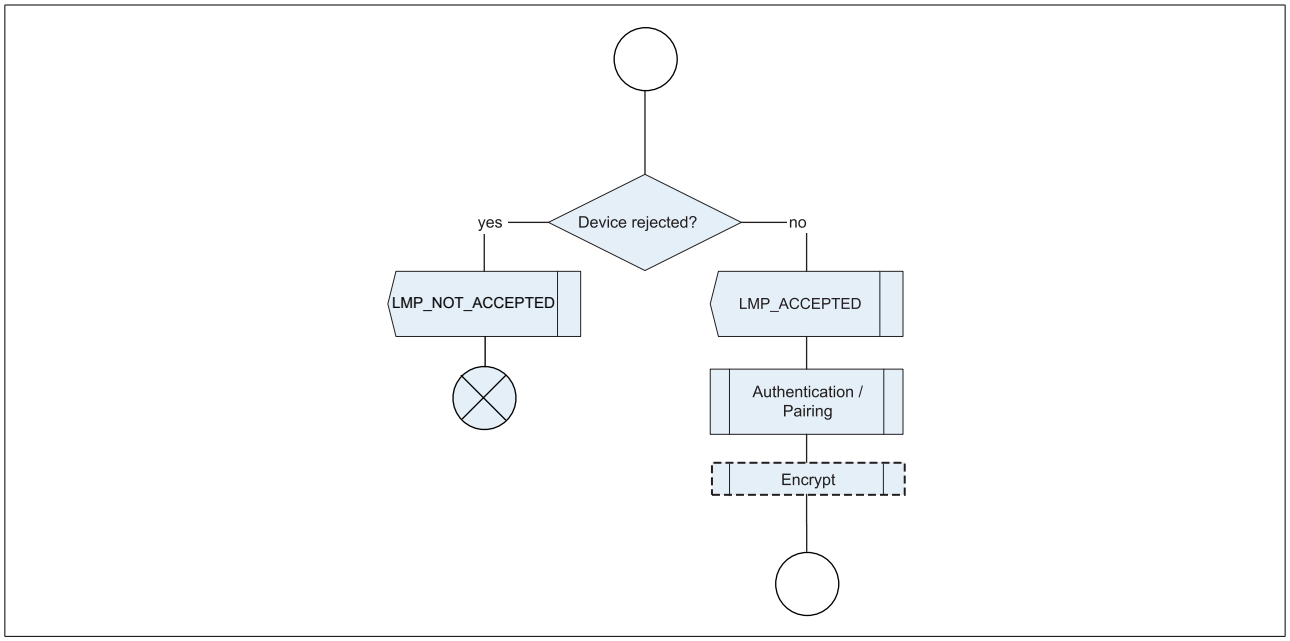

Figure 5.3: Security mode 3 with a legacy remote device

5.2.2 Security mode 4 (service level enforced security)

A Bluetooth device in security mode 4 shall classify the security requirements of its services using at least the following attributes (in order of decreasing security):

- Authenticated link key required
- Unauthenticated link key required
- Security optional; limited to specific services (see Section 5.2.2.8).

When both devices support Secure Simple Pairing, GAP shall require at least an unauthenticated link key and enabling encryption for all connections except those allowed to have security level 0 (see Section 5.2.2.8). A profile or protocol may define services that require more security (e.g., an authenticated link key) or no security (although unencrypted connections are only allowed when connecting to a service allowed to have security level 0). To allow an unauthenticated link key to be created during the Secure Simple Pairing procedure, the Authentication_Requirements parameter may be set to one of the MITM Protection Not Required options.

When the device is in Bondable Mode, it shall enable Secure Simple Pairing mode prior to entering Connectable Mode or establishing a link.

A Bluetooth device in security mode 4 shall respond to authentication requests during link establishment when the remote device is in security mode 3 for backwards compatibility reasons.

A Bluetooth device in security mode 4 enforces its security requirements before it attempts to access services offered by a remote device and before it grants access to services it offers to remote devices. Service access may occur via L2CAP channels or via channels established by protocols above L2CAP such as RFCOMM.

For services transmitting unicast data over the connectionless L2CAP channel, the transmitting device shall enforce its security requirements prior to sending data. There is no mechanism for a device receiving data via the L2CAP connectionless channel to prevent unencrypted data from being received. Hence, Section 5.2.2.1 addresses unicast connectionless data transmission together with devices initiating connection-oriented channels while Section 5.2.2.2 covers only devices responding to requests for connection-oriented channel establishment but does not cover unicast connectionless data reception.

A device may be in a Secure Connections Only mode. When in Secure Connections Only mode, all services (except those allowed to have Security Mode 4, Level 0) available on the BR/EDR physical transport require Security Mode 4, Level 4. The device shall reject both new outgoing and incoming service level connections when the service requires Security Mode 4, Level 4 and either the physical transport does not support Secure Connections or unauthenticated pairing is being requested.

A device operating with a physical transport operating in Secure Connections Only mode may disconnect the ACL connection using error code 0x05 (Authentication Failure) when the physical transport that does not support Secure Connections, tries to access a service that requires Security Mode 4, Level 4.

Note: A device may operate several physical transports simultaneously - in this case all physical transports are required to enable Secure Connections Only Mode simultaneously.

5.2.2.1 Security for access to remote service (initiating side)

When the responding device does not support Secure Simple Pairing, it may disconnect the link while the initiating device is requesting the PIN to be entered by the user. This may occur due to the lack of an L2CAP channel being present for longer than an implementation-specific amount of time (e.g., a few seconds). When this occurs, the initiating device shall allow the user to complete entering the PIN and shall then re-page the remote device and restart the pairing procedure (see [Vol 2] Part C, Section 4.2.2) using the PIN entered.

5.2.2.1.1 Pairing required for access to remote service

When a Bluetooth device in security mode 4 initiates access to a remote service via a connection-oriented L2CAP channel, the service requires security, and a sufficient link-key is not available, the local device shall perform pairing procedures and enable

encryption before sending a channel establishment request (an L2CAP connection request or a higher-layer channel establishment request such as that of RFCOMM).

When a Bluetooth device in security mode 4 transmits data to a remote service via the unicast connectionless L2CAP channel and a sufficient link-key is not available, the local device shall perform pairing procedures and enable encryption before transmitting unicast data on the connectionless L2CAP channel.

See Section 5.2.2.8 for details on determining whether or not a link key is sufficient.

If pairing does not succeed, the local device shall not send a channel establishment request. The local device may re-try pairing up to three (3) times. If pairing fails three consecutive times, the local device shall disconnect the ACL link with error code 0x05 - Authentication Failure.

If the link key generated is not at least as good as the expected or required type, the local device shall fail the establishment and may disconnect the ACL link with error code 0x05 - Authentication Failure.

5.2.2.1.2 Authentication required for access to remote service

When a Bluetooth device in security mode 4 initiates access to a remote service via a connection-oriented L2CAP channel and a sufficient link key is available for the remote device, it shall authenticate the remote device and enable encryption before sending a channel establishment request (an L2CAP connection request or a higher layer-channel establishment request such as that of RFCOMM).

When a Bluetooth device in security mode 4 transmits unicast data to a remote service via the connectionless L2CAP channel and security is required for the application and a sufficient link-key is available then the local device shall authenticate the remote device and enable encryption before transmitting unicast data on the L2CAP connectionless channel.

See Section 5.2.2.8 for details on determining whether or not a link key is sufficient.

If authentication is required by the service but does not succeed, or if a sufficient link-key is not available, then the local device shall not enable encryption. If encryption is not enabled or if enabling encryption does not result in the correct encryption type (i.e. AES-CCM or E0), the local device shall not send a channel establishment request and shall not send any unicast data via the L2CAP connectionless channel for that application. The Host may then notify the user and offer to perform pairing.

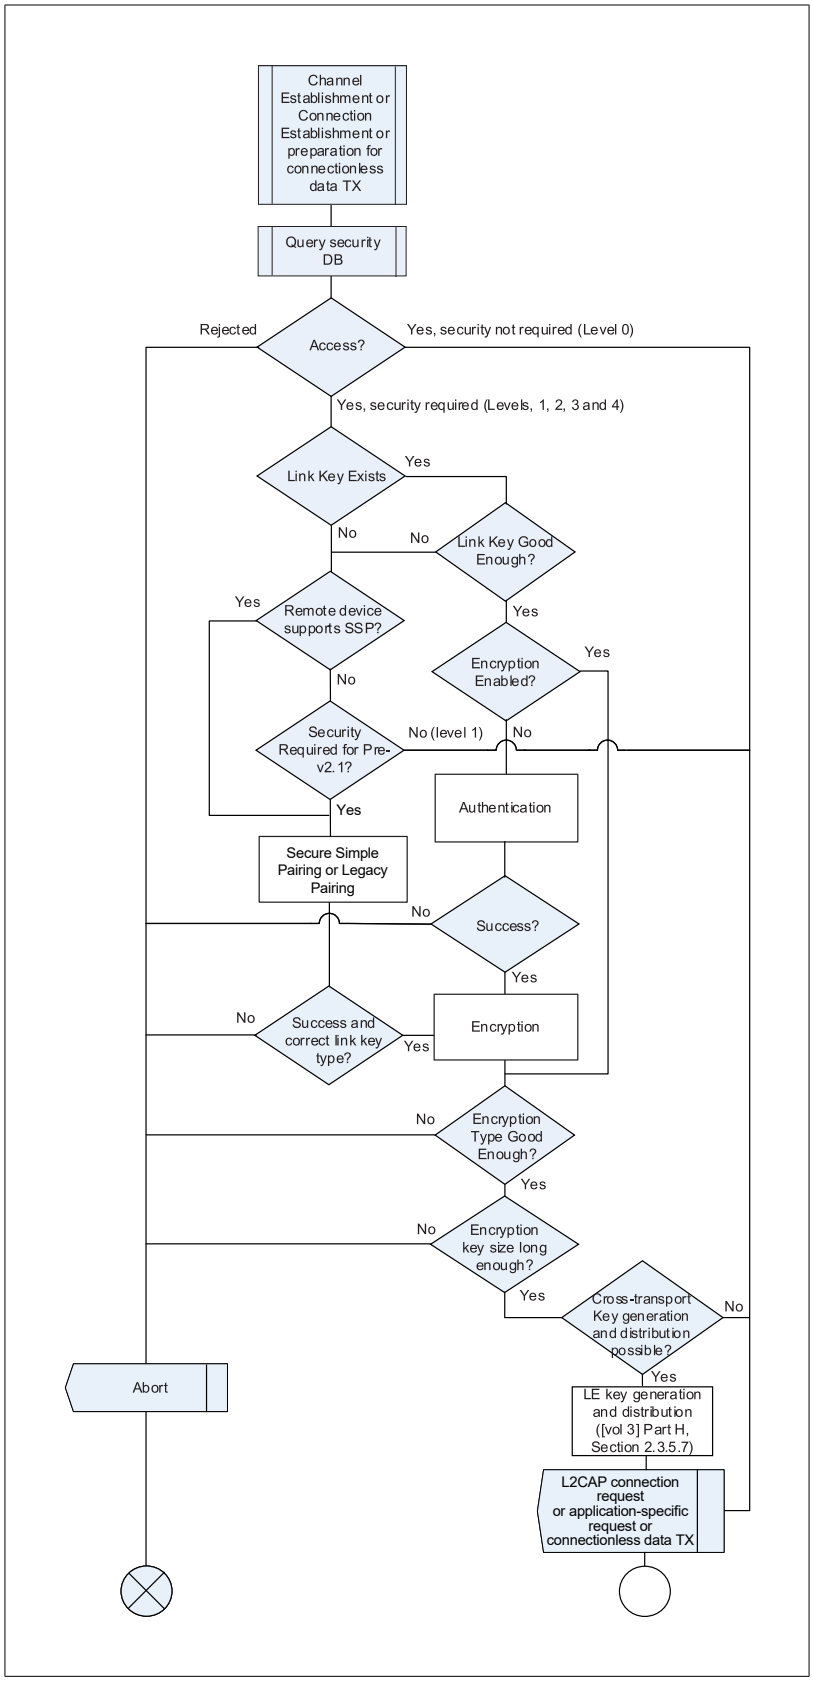

Figure 5.4: Channel establishment using security mode 4 for initiating side

5.2.2.1.3 Cross-transport key generation and distribution

After encryption is enabled and both devices support cross-transport key generation, the Central of the BR/EDR transport may perform LE key generation and distribution ([Vol 3] Part H, Section 2.3.5.7). The Peripheral shall not perform LE key generation and distribution.

If a role switch gets performed after enabling encryption but before the LE keys can be generated and distributed, the new Central may perform LE key generation and distribution once the role switch has completed. The new Peripheral shall not perform LE key generation and distribution once the role switch has completed.

5.2.2.2 Security for access to local service by remote device (responding side)

When a remote device attempts to access a service offered by a Bluetooth device that is in security mode 4 and the service requires security, a sufficient link key exists, and authentication has not been performed, the local device shall authenticate the remote device and enable encryption after the channel establishment request is received but before a channel establishment confirmation (L2CAP connection response with result code of 0x0000 or a higher-level channel establishment confirmation such as that of RFCOMM) is sent.
